Abstract

We propose that the smallness of the light quark masses is related to the smallness of the T (i.e. CP) violation in hadronic weak interactions. Accordingly, for each of the two quark sectors ("upper" and "lower") we construct a 3×3 mass matrix in a bases of unobserved quark states, such that the "upper" and "lower" basis states correspond exactly via the W^\pm transitions in the weak interaction. In the zeroth approximation of our formulation, we assume T conservation by making all matrix elements real. In addition, we impose a "hidden symmetry" (invariance under simultaneous translations of all three basis quark states in each sector), which ensures a zero mass eigenstate in each sector.

Next, we simultaneously break the hidden symmetry and T invariance by introducing a phase factor $e^{i\chi}$ in the interaction for each sector. The Jarlskog invariant J_{CKM} , as well as the light quark masses are evaluated in terms of the parameters of the model. Comparing formulas, we find that most unknown factors drop out, resulting in a simple relation with $J_{CKM} = (m_d m_s / m_b^2)^{1/2} A \lambda^3 \cos \frac{1}{2} \chi$, to leading order in χ and m_s / m_b , with A , λ the Wolfenstein parameters. (Because of the large top quark mass, the contribution from upper quark sector can be neglected.) Setting $J_{CKM} = 3.08 \times 10^{-5}$, $m_b = 4.7 GeV$ ($1s$ mass), $m_s = 95 MeV$, $A = 0.818$ and $\lambda = 0.227$, we find $m_d \cos^2 \frac{1}{2} \chi \simeq 2.4 MeV$, consistent with the accepted value $m_d = 3 - 7 MeV$.

We make a parallel proposal for the lepton sectors. With the hidden symmetry and in the approximation of T invariance, both the masses of e and ν_1 are zero. The neutrino mapping matrix V_ν is shown to be of the same Harrison-Scott form which is in agreement with experiments. We also examine the correction due to T violation, and evaluate the corresponding Jarlskog invariant \mathcal{J}_ν .

Key words: hidden symmetry, CKM matrix, neutrino mapping matrix

1. Introduction

In a recent paper[1], we postulate a new symmetry of the neutrino mass matrix in terms of the field operators ν_e , ν_μ and ν_τ . This symmetry enables us to derive the Harrison-Scott form[2,3] of the neutrino mapping matrix V_ν . However, the formalism has a built-in asymmetry between the charged leptons and the neutral ones. In this paper, we modify the symmetry introduced in [1], as that e , μ , τ and ν_1 , ν_2 , ν_3 are now set on a similar basis. Furthermore, the new symmetry can also be extended to quarks d , s , b and u , c , t . For clarity, we first discuss how the new symmetry, called hidden symmetry, can be realized in the quark sectors leading to the CKM matrix U_{CKM} . Next, we discuss its application to leptons, resulting again in the Harrison-Scott form of the neutrino mapping matrix V_ν .

In the quark sector, let $q_i(\downarrow)$ and $q_i(\uparrow)$ be the quark states "diagonal" in W^\pm transitions:

$$q_i(\downarrow) \Rightarrow q_i(\uparrow) + W^-$$

and (1.1)

$$q_i(\uparrow) \Rightarrow q_i(\downarrow) + W^+$$

with $i = 1, 2, 3$. Their electric charges in units of e are $-\frac{1}{3}$ for $q_i(\downarrow)$, and $+\frac{2}{3}$ for $q_i(\uparrow)$. However, these are not the observed mass eigenstates d , s , b and u , c , t . Likewise, let $l_i(\downarrow)$ and $l_i(\uparrow)$ be the lepton states "diagonal" in the corresponding W^\pm transitions:

$$l_i(\downarrow) \Rightarrow l_i(\uparrow) + W^-$$

and (1.2)

$$l_i(\uparrow) \Rightarrow l_i(\downarrow) + W^+$$

with their electric charge unit -1 for $l_i(\downarrow)$, and 0 for $l_i(\uparrow)$ and $i = 1, 2, 3$. Again, neither $l_i(\downarrow)$ nor $l_i(\uparrow)$ are the mass eigenstates e , μ , τ and ν_1 , ν_2 , ν_3 . Thus, for each of these four triplets

$$\begin{aligned} &\{q_1(\downarrow), q_2(\downarrow), q_3(\downarrow)\}, \{q_1(\uparrow), q_2(\uparrow), q_3(\uparrow)\} \\ &\{l_1(\downarrow), l_2(\downarrow), l_3(\downarrow)\} \text{ and } \{l_1(\uparrow), l_2(\uparrow), l_3(\uparrow)\} \end{aligned} \quad (1.3)$$

there exists a separate 3×3 mass matrix, denoted by

$$M(q_\downarrow), M(q_\uparrow), M(l_\downarrow) \text{ and } M(l_\uparrow) \quad (1.4)$$

respectively. As we shall discuss, these mass matrices satisfy a common set of rules due to hidden symmetry, leading to a unifying formalism of both the CKM matrix U_{CKM} and the neutrino mapping matrix V_ν .

In what follows, we begin our discussion in the approximation assuming time reversal invariance T . Thus, the mass matrix $M(q_\downarrow)$, $M(q_\uparrow)$, $M(l_\downarrow)$ and $M(l_\uparrow)$ are all 3×3 real symmetric matrices. The corresponding mass operators are

$$\mathcal{M}(q_\downarrow) = \left(\bar{q}_1(\downarrow), \bar{q}_2(\downarrow), \bar{q}_3(\downarrow) \right) M(q_\downarrow) \begin{pmatrix} q_1(\downarrow) \\ q_2(\downarrow) \\ q_3(\downarrow) \end{pmatrix}, \quad (1.5)$$

$$\mathcal{M}(q_\uparrow) = \left(\bar{q}_1(\uparrow), \bar{q}_2(\uparrow), \bar{q}_3(\uparrow) \right) M(q_\uparrow) \begin{pmatrix} q_1(\uparrow) \\ q_2(\uparrow) \\ q_3(\uparrow) \end{pmatrix}, \quad (1.6)$$

$$\mathcal{M}(l_\downarrow) = \left(\bar{l}_1(\downarrow), \bar{l}_2(\downarrow), \bar{l}_3(\downarrow) \right) M(l_\downarrow) \begin{pmatrix} l_1(\downarrow) \\ l_2(\downarrow) \\ l_3(\downarrow) \end{pmatrix}, \quad (1.7)$$

and

$$\mathcal{M}(l_\uparrow) = \left(\bar{l}_1(\uparrow), \bar{l}_2(\uparrow), \bar{l}_3(\uparrow) \right) M(l_\uparrow) \begin{pmatrix} l_1(\uparrow) \\ l_2(\uparrow) \\ l_3(\uparrow) \end{pmatrix}. \quad (1.8)$$

In (1.5), $q_i(\downarrow)$ and $\bar{q}_i(\downarrow)$ are related to the corresponding Dirac field operators $\psi(q_i(\downarrow))$ and its Hermitian conjugate $\psi^\dagger(q_i(\downarrow))$ by

$$q_i(\downarrow) = \psi(q_i(\downarrow)) \text{ and } \bar{q}_i(\downarrow) = \psi^\dagger(q_i(\downarrow))\gamma_4. \quad (1.9)$$

Likewise, in (1.6)-(1.8) $q_i(\uparrow)$, $\bar{q}_i(\uparrow)$, $l_i(\downarrow)$, etc. are similarly related to their corresponding Dirac field operators. We assume that each of these four mass operators (1.5)-(1.8) satisfies a hidden symmetry with $\mathcal{M}(q_\downarrow)$ invariant under the transformation

$$q_1(\downarrow) \rightarrow q_1(\downarrow) + z, \quad q_2(\downarrow) \rightarrow q_2(\downarrow) + \eta_\downarrow z \text{ and } q_3(\downarrow) \rightarrow q_3(\downarrow) + \xi_\downarrow \eta_\downarrow z \quad (1.10)$$

where z is a space-time independent constant element of the Grassmann algebra anticommuting with the Dirac field operators, and $\xi_\downarrow, \eta_\downarrow$ are c -numbers. It will be shown in the next section that (1.10) implies a zero down-quark mass in the absence of T violation. Similar symmetries are also assumed for other triplets $\{q_i(\uparrow)\}, \{l_i(\downarrow)\}$ and $\{l_i(\uparrow)\}$. Thus, we correlate the nearly zero masses of d, u, e and ν_1 with T invariance and the new symmetry.

In Section 3. we derive the form of CKM matrix in the same zeroth approximation of T invariance. The violation of T invariance will be discussed in Section 4. As will be shown, to the first approximation of small T violation, we derive an interesting formula relating T violating Jarlskog invariant J with quark masses:

$$J = \left(\frac{m_d m_s}{m_b^2}\right)^{\frac{1}{2}} A \lambda^3 \cos[\tfrac{1}{2}\chi_T(\downarrow)] + O\left(\frac{m_u m_c}{m_t^2}\right)^{\frac{1}{2}} \quad (1.11)$$

where[4] $A \cong 0.818$, $\lambda \cong 0.2272$ are the Wolfenstein parameters. Using the experimental values[4] $J \cong 3.08 \cdot 10^{-5}$, $m_s \cong 95 MeV$ and $m_b \cong 4.7 GeV$ ($1s$ mass), we find

$$m_d \cos^2[\tfrac{1}{2}\chi_T(\downarrow)] \cong 2.4 MeV, \quad (1.12)$$

where $\chi_T(\downarrow)$ is the T -violating phase in the \downarrow quark sector. Since $\cos \tfrac{1}{2}\chi_T(\downarrow) \leq 1$, we have

$$m_d \geq 2.4 MeV \quad (1.13)$$

consistent with the range $m_d \cong 3$ to $7 MeV$ quoted by the particle data group[4].

In section 5 and 6, we discuss lepton sectors. As in Ref.[1], we show how the new hidden symmetry can also lead to the Harrison-Scott form of the neutrino-mapping matrix V_ν in agreement with experiments. The Jarlskog invariant in the lepton sector is also calculated to the lowest order of the T violating interaction.

2. Hidden Symmetry

Consider first the $\{q_i(\downarrow)\}$ sector. In the approximation of T invariance, the 3×3 matrix in (1.5) becomes a real symmetric matrix $M_0(q_\downarrow)$ characterized by six real parameters: three diagonal and three off-diagonal elements. We propose to represent the corresponding mass operator $\mathcal{M}(q_\downarrow)$ by

$$\mathcal{M}_0(q_\downarrow) = \alpha_\downarrow |q_3(\downarrow) - \xi_\downarrow q_2(\downarrow)|^2 + \beta_\downarrow |q_2(\downarrow) - \eta_\downarrow q_1(\downarrow)|^2 + \gamma_\downarrow |q_1(\downarrow) - \zeta_\downarrow q_3(\downarrow)|^2 \quad (2.1)$$

with also six real parameters α_\downarrow , β_\downarrow , γ_\downarrow , ξ_\downarrow , η_\downarrow and ζ_\downarrow . Their relation with the six diagonal and off-diagonal elements of an arbitrary symmetric matrix $M(q)$ is given in the Appendix. We impose the hidden symmetry requirement that $\mathcal{M}_0(q_\downarrow)$ be invariant under the transformation (1.10). Substituting (1.10) into (2.1) and requiring the symmetry, we see that these three parameters ξ_\downarrow , η_\downarrow and ζ_\downarrow must satisfy

$$\xi_\downarrow \eta_\downarrow \zeta_\downarrow = 1. \quad (2.2)$$

The corresponding mass matrix $M(q_\downarrow)$ defined by (1.5) is

$$M_0(q_\downarrow) = \begin{pmatrix} \gamma + \beta\eta^2 & -\beta\eta & -\gamma\zeta \\ -\beta\eta & \beta + \alpha\xi^2 & -\alpha\xi \\ -\gamma\zeta & -\alpha\xi & \alpha + \gamma\zeta^2 \end{pmatrix}_\downarrow \quad (2.3)$$

where the suffix \downarrow on the right hand side indicates that the parameters α , β , γ , ξ , η , ζ refer to α_\downarrow , β_\downarrow , γ_\downarrow , ξ_\downarrow , η_\downarrow and ζ_\downarrow respectively. From (2.3), we see that the determinant of $M_0(q_\downarrow)$ is given by

$$|M_0(q_\downarrow)| = \left[\alpha\beta\gamma(\xi\eta\zeta - 1)^2 \right]_\downarrow. \quad (2.4)$$

Thus, for

$$(\xi\eta\zeta)_\downarrow \equiv \xi_\downarrow \eta_\downarrow \zeta_\downarrow = 1. \quad (2.5)$$

we have

$$|M_0(q_\downarrow)| = 0. \quad (2.6)$$

Choose α_\downarrow , β_\downarrow and γ_\downarrow to be all positive. The operator $\mathcal{M}_0(q_i)$ is then positive; condition (2.5) implies the smallest eigenvalue of $M(q_\downarrow)$, the down quark mass, to be zero; i.e.,

$$m_d = 0 \quad (2.7)$$

on account of the hidden symmetry requirement (1.10) and the approximation of T invariance.

This result can also be seen directly from the symmetry requirement (1.10). In the three-dimensional space of coordinate axes $q_1(\downarrow)$, $q_2(\downarrow)$ and $q_3(\downarrow)$, the transformation (1.10) represents a translation along the direction parallel to the three dimensional unit vector

$$\epsilon_{\downarrow} \propto \begin{pmatrix} 1 \\ \eta_{\downarrow} \\ \xi_{\downarrow}\eta_{\downarrow} \end{pmatrix}. \quad (2.8)$$

The assumed invariance under (1.10) is identical to the invariance of $\mathcal{M}_0(q_{\downarrow})$ under a translation along the vector ϵ_{\downarrow} ; thus, ϵ_{\downarrow} is an eigenvector of the corresponding mass matrix $M_0(q_{\downarrow})$, with zero eigenvalue (i.e., zero mass).

Likewise, under the transformation $\downarrow \rightarrow \uparrow$,

$$(\alpha_{\downarrow}, \beta_{\downarrow}, \gamma_{\downarrow}) \rightarrow (\alpha_{\uparrow}, \beta_{\uparrow}, \gamma_{\uparrow})$$

$$\text{and} \quad (2.9)$$

$$(\xi_{\downarrow}, \eta_{\downarrow}, \zeta_{\downarrow}) \rightarrow (\xi_{\uparrow}, \eta_{\uparrow}, \zeta_{\uparrow})$$

we have

$$M_0(q_{\downarrow}) \rightarrow M_0(q_{\uparrow}) \quad \text{and} \quad \mathcal{M}_0(q_{\downarrow}) \rightarrow \mathcal{M}_0(q_{\uparrow}). \quad (2.10)$$

As in (1.10), the hidden symmetry

$$q_1(\uparrow) \rightarrow q_1(\uparrow) + z, \quad q_2(\uparrow) \rightarrow q_2(\uparrow) + \eta_{\uparrow}z \quad \text{and} \quad q_3(\uparrow) \rightarrow q_3(\uparrow) + \xi_{\uparrow}\eta_{\uparrow}z \quad (2.11)$$

implies the corresponding invariance of the mass operator $\mathcal{M}_0(q_{\uparrow})$, in the approximation of T invariance. Thus, (2.11) implies

$$\xi_{\uparrow}\eta_{\uparrow}\zeta_{\uparrow} = 1 \quad (2.12)$$

and the up quark u to be of zero mass; i.e., with hidden symmetry and T invariance,

$$m_u = 0. \quad (2.13)$$

3. CKM Matrix (neglecting T violation)

In this section, we discuss the CKM matrix in the same zeroth approximation by neglecting T violation. Let $(U_\downarrow)_0$ and $(U_\uparrow)_0$ be the unitary matrices that diagonalize $M_0(q_\downarrow)$ and $M_0(q_\uparrow)$:

$$(U_\downarrow)_0^\dagger M_0(q_\downarrow) (U_\downarrow)_0 = \begin{pmatrix} m_0(d) & 0 & 0 \\ 0 & m_0(s) & 0 \\ 0 & 0 & m_0(b) \end{pmatrix} \quad (3.1)$$

and

$$(U_\uparrow)_0^\dagger M_0(q_\uparrow) (U_\uparrow)_0 = \begin{pmatrix} m_0(u) & 0 & 0 \\ 0 & m_0(c) & 0 \\ 0 & 0 & m_0(t) \end{pmatrix}. \quad (3.2)$$

The corresponding CKM matrix is given by

$$(U_{CKM})_0 = (U_\uparrow)_0^\dagger (U_\downarrow)_0. \quad (3.3)$$

In accordance with (2.7) and (2.13), we have in the notation of (3.1) and (3.2)

$$m_0(d) = m_0(u) = 0. \quad (3.4)$$

Without T violation, $(U_\downarrow)_0$, $(U_\uparrow)_0$ and $(U_{CKM})_0$ are each a 3×3 real orthogonal matrix characterized by three real parameters.

In (2.3), the mass matrix $M_0(q_\downarrow)$ has six parameters α_\downarrow , β_\downarrow , γ_\downarrow , ξ_\downarrow , η_\downarrow and ζ_\downarrow . With the constraint $\xi_\downarrow \eta_\downarrow \zeta_\downarrow = 1$ in accordance with (2.5), there are still five independent parameters in $M_0(q_\downarrow)$. Together with $M_0(q_\uparrow)$, we have $5 + 5 = 10$ parameters. Assuming that the only observables are the quark masses and the CKM matrix. Since $m_0(d) = m_0(u) = 0$ in this approximation, there are only four nonzero masses $m_0(s)$, $m_0(b)$, $m_0(c)$ and $m_0(t)$. In addition, the CKM matrix with T invariance is characterized by three real parameters; together, there are

$$4 + 3 = 7$$

observables in this approximation. That means among the 10 parameters, there are

$$10 - 7 = 3 \quad (3.5)$$

parameters which are "unphysical". The elimination of these three unphysical parameters is analogous to the gauge condition in a vector field theory. As we shall see, a convenient choice is to eliminate two of these three by requiring

$$\frac{\beta_{\downarrow}}{\gamma_{\downarrow}} = \zeta_{\downarrow}^2 \quad \text{and} \quad \frac{\beta_{\uparrow}}{\gamma_{\uparrow}} = \zeta_{\uparrow}^2. \quad (3.6)$$

Define four real angular variables θ_{\downarrow} , ϕ_{\downarrow} and θ_{\uparrow} , ϕ_{\uparrow} by

$$\xi_{\downarrow} = \tan \phi_{\downarrow}, \quad \xi_{\uparrow} = \tan \phi_{\uparrow}$$

$$\eta_{\downarrow} = \tan \theta_{\downarrow} \cos \phi_{\downarrow} \quad \text{and} \quad \eta_{\uparrow} = \tan \theta_{\uparrow} \cos \phi_{\uparrow}. \quad (3.7)$$

It can be readily verified that with (3.6) the eigenstates of $M_0(q_{\downarrow})$ become quite simple, given by

$$\epsilon_{\downarrow} = \begin{pmatrix} \cos \theta_{\downarrow} \\ \sin \theta_{\downarrow} \cos \phi_{\downarrow} \\ \sin \theta_{\downarrow} \sin \phi_{\downarrow} \end{pmatrix} \quad \text{with eigenvalue } \lambda(\epsilon_{\downarrow}), \quad (3.8)$$

$$p_{\downarrow} = \begin{pmatrix} -\sin \theta_{\downarrow} \\ \cos \theta_{\downarrow} \cos \phi_{\downarrow} \\ \cos \theta_{\downarrow} \sin \phi_{\downarrow} \end{pmatrix} \quad \text{with eigenvalue } \lambda(p_{\downarrow}), \quad (3.9)$$

and

$$P_{\downarrow} = \begin{pmatrix} 0 \\ -\sin \phi_{\downarrow} \\ \cos \phi_{\downarrow} \end{pmatrix} \quad \text{with eigenvalue } \lambda(P_{\downarrow}). \quad (3.10)$$

Here $\lambda(\epsilon_{\downarrow})$, $\lambda(p_{\downarrow})$ and $\lambda(P_{\downarrow})$ are the same 0th order approximation $m_0(d)$, $m_0(s)$ and $m_0(b)$ in (3.1), with

$$m_0(d) = \lambda(\epsilon_{\downarrow}) = 0, \quad (3.11)$$

$$m_0(s) = \lambda(p_{\downarrow}) = \beta_{\downarrow}[1 + \eta_{\downarrow}^2(1 + \xi_{\downarrow}^2)] \quad (3.12)$$

and

$$m_0(b) = \lambda(P_{\downarrow}) = \alpha_{\downarrow}(1 + \xi_{\downarrow}^2) + \beta_{\downarrow}. \quad (3.13)$$

In terms of ξ_{\downarrow} and η_{\downarrow} , the statevector ϵ_{\downarrow} satisfies (2.8).

Likewise, the eigenstates of $M_0(q_\uparrow)$ are

$$\epsilon_\uparrow = \begin{pmatrix} \cos \theta_\uparrow \\ \sin \theta_\uparrow \cos \phi_\uparrow \\ \sin \theta_\uparrow \sin \phi_\uparrow \end{pmatrix} \text{ with eigenvalue } \lambda(\epsilon_\uparrow), \quad (3.14)$$

$$p_\uparrow = \begin{pmatrix} -\sin \theta_\uparrow \\ \cos \theta_\uparrow \cos \phi_\uparrow \\ \cos \theta_\uparrow \sin \phi_\uparrow \end{pmatrix} \text{ with eigenvalue } \lambda(p_\uparrow), \quad (3.15)$$

and

$$P_\uparrow = \begin{pmatrix} 0 \\ -\sin \phi_\uparrow \\ \cos \phi_\uparrow \end{pmatrix} \text{ with eigenvalue } \lambda(P_\uparrow) \quad (3.16)$$

where

$$m_0(u) = \lambda(\epsilon_\uparrow) = 0, \quad (3.17)$$

$$m_0(c) = \lambda(p_\uparrow) = \beta_\uparrow[1 + \eta_\uparrow^2(1 + \xi_\uparrow^2)] \quad (3.18)$$

and

$$m_0(t) = \lambda(P_\uparrow) = \alpha_\uparrow(1 + \xi_\uparrow^2) + \beta_\uparrow. \quad (3.19)$$

Correspondingly, the 3×3 unitary matrices $(U_\downarrow)_0$ and $(U_\uparrow)_0$ of (3.1) and (3.2) are given by

$$(U_\downarrow)_0 = (\epsilon_\downarrow, p_\downarrow, P_\downarrow) \quad (3.20)$$

and

$$(U_\uparrow)_0 = (\epsilon_\uparrow, p_\uparrow, P_\uparrow). \quad (3.21)$$

Thus, in accordance with (3.3), the corresponding CKM matrix in the same approximation is given by

$$(U_{CKM})_0 = \begin{pmatrix} \cos \theta_\downarrow \cos \theta_\uparrow & -\sin \theta_\downarrow \cos \theta_\uparrow & \sin \theta_\uparrow \sin \phi \\ + \sin \theta_\downarrow \sin \theta_\uparrow \cos \phi & + \cos \theta_\downarrow \sin \theta_\uparrow \cos \phi & \\ -\cos \theta_\downarrow \sin \theta_\uparrow & \sin \theta_\downarrow \sin \theta_\uparrow & \cos \theta_\uparrow \sin \phi \\ + \sin \theta_\downarrow \cos \theta_\uparrow \cos \phi & + \cos \theta_\downarrow \cos \theta_\uparrow \cos \phi & \\ -\sin \theta_\downarrow \sin \phi & -\cos \theta_\downarrow \sin \phi & \cos \phi \end{pmatrix}, \quad (3.22)$$

in which

$$\phi = \phi_{\uparrow} - \phi_{\downarrow}. \quad (3.23)$$

Equations (3.6) and (3.23) eliminate the three unphysical variables, as we shall see. Upon comparison with experimental values, we find from (3.22)

$$\theta_{\uparrow} - \theta_{\downarrow} = \text{Cabibbo angle} \quad (3.24)$$

with

$$\sin(\theta_{\uparrow} - \theta_{\downarrow}) \cong \lambda = 0.227. \quad (3.25)$$

By taking the ratio of (1,3) and (2,3) matrix elements of $(U_{CKM})_0$, we estimate $\theta_{\uparrow} = O(\lambda)$; likewise, from the corresponding (3,1) and (3,2) matrix elements, $\theta_{\downarrow} = O(\lambda)$. Using the (2,3) matrix element, we derive

$$\sin \phi \cong A\lambda^2 \quad (3.26)$$

with $A = 0.818$.

We observe that the dependence of $(U_{CKM})_0$ on ϕ_{\downarrow} and ϕ_{\uparrow} is only through $\phi = \phi_{\uparrow} - \phi_{\downarrow}$. Thus, $(U_{CKM})_0$ is independent of $\phi_{\uparrow} + \phi_{\downarrow}$, which together with the two conditions given by (3.6) eliminate the 3 unphysical parameters mentioned in (3.5).

4. T -Violation

In the approximation of T invariance, by using (2.1) and constraints

$$\xi_{\downarrow}\eta_{\downarrow}\zeta_{\downarrow} = 1 \quad \text{and} \quad \frac{\beta_{\downarrow}}{\gamma_{\downarrow}} = \zeta_{\downarrow}^2 \quad (4.1)$$

in accordance with (2.5) and (3.6), we find that the mass operator (2.1) can also be written as

$$\mathcal{M}_0(q_{\downarrow}) = \alpha_{\downarrow}|q_3(\downarrow) - \xi_{\downarrow}q_2(\downarrow)|^2 + \beta_{\downarrow}|q_2(\downarrow) - \eta_{\downarrow}q_1(\downarrow)|^2 + \beta_{\downarrow}|q_3(\downarrow) - \xi_{\downarrow}\eta_{\downarrow}q_1(\downarrow)|^2 \quad (4.2)$$

With T violation, we replace $\mathcal{M}_0(q_{\downarrow})$ by

$$\mathcal{M}(q_{\downarrow}) = \alpha_{\downarrow}|q_3(\downarrow) - \xi_{\downarrow}e^{i\chi_T}q_2(\downarrow)|^2 + \beta_{\downarrow}|q_2(\downarrow) - \eta_{\downarrow}q_1(\downarrow)|^2 + \beta_{\downarrow}|q_3(\downarrow) - \xi_{\downarrow}\eta_{\downarrow}q_1(\downarrow)|^2 \quad (4.3)$$

in which

$$\chi_T = \chi_T(\downarrow) \quad (4.4)$$

is the T -violating phase factor for the \downarrow quark sector. The corresponding mass matrix defined by (1.5) is given by

$$M(q_{\downarrow}) = M_0(q_{\downarrow}) + M_1(q_{\downarrow}) \quad (4.5)$$

with $M_0(q_{\downarrow})$ given by (2.3). Because of (2.5) and the first equation in (3.6), $M_0(q_{\downarrow})$ can also be written as

$$M_0(q_{\downarrow}) = \begin{pmatrix} \beta\eta^2(1 + \xi^2) & -\beta\eta & -\beta\xi\eta \\ -\beta\eta & \beta + \alpha\xi^2 & -\alpha\xi \\ -\beta\xi\eta & -\alpha\xi & \alpha + \beta \end{pmatrix}_{\downarrow}. \quad (4.6)$$

The T violating term in (4.5) is

$$M_1(q_{\downarrow}) = \alpha_{\downarrow}\xi_{\downarrow} \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 - e^{-i\chi_T(\downarrow)} \\ 0 & 1 - e^{i\chi_T(\downarrow)} & 0 \end{pmatrix}. \quad (4.7)$$

Because of T violation, the mass of d quark is not zero and the CKM matrix is unitary but not real.

4.1 d quark mass

In accordance with (3.11)-(3.13), the eigenvalues of $M_0(q_\downarrow)$ are $\lambda(\epsilon_\downarrow) = 0$, $\lambda(p_\downarrow)$ and $\lambda(P_\downarrow)$, whereas those of $M(q_\downarrow)$ are the observed quark masses $m = m_d$, m_s and m_b determined by

$$|M(q_\downarrow) - m| = 0. \quad (4.8)$$

By using (3.11)-(3.13) and (4.5)-(4.7), we find (4.8) to be the cubic equation,

$$m(m - \lambda(p_\downarrow))(m - \lambda(P_\downarrow)) = |M(q_\downarrow)| \quad (4.9)$$

with

$$|M(q_\downarrow)| = 2\alpha_\downarrow\beta_\downarrow^2\xi_\downarrow^2\eta_\downarrow^2(1 - \cos\chi_T(\downarrow)). \quad (4.10)$$

Since in accordance with (3.12)-(3.13), $\lambda(p_\downarrow) = m_0(s)$ and $\lambda(P_\downarrow) = m_0(b)$ are the zeroth order values of m_s and m_b , both are $\gg m_d$. From (3.7) and (3.12)-(3.13),

$$\begin{aligned} m_0(s) &= \lambda(p_\downarrow) = \beta_\downarrow \sec^2 \theta_\downarrow \\ \text{and} \\ m_0(b) &= \lambda(P_\downarrow) = \alpha_\downarrow \sec^2 \phi_\downarrow + \beta_\downarrow. \end{aligned} \quad (4.11)$$

By setting $m = m_d$, m_s and m_b respectively in (4.9), we have

$$m_d = [(m_0(s) - m_d)(m_0(b) - m_d)]^{-1} |M(q_\downarrow)|, \quad (4.12)$$

$$m_s - m_0(s) = -[m_s(m_0(b) - m_s)]^{-1} |M(q_\downarrow)| \quad (4.13)$$

and

$$m_b - m_0(b) = [m_b(m_b - m_0(s))]^{-1} |M(q_\downarrow)|. \quad (4.14)$$

Thus, neglecting corrections $O(m_d/m_s)$ and $O(m_d/m_b)$, we find from (4.12)-(4.14)

$$m_d \cong [m_s m_b]^{-1} |M(q_\downarrow)|, \quad (4.15)$$

$$m_s - m_0(s) \cong -[m_s(m_b - m_s)]^{-1} |M(q_\downarrow)| \quad (4.16)$$

and

$$m_b - m_0(b) \cong [m_b(m_b - m_s)]^{-1} |M(q_\downarrow)|. \quad (4.17)$$

Likewise, (4.11) leads to

$$\beta_\downarrow \cong m_s \cos^2 \theta_\downarrow, \quad (4.18)$$

$$\alpha_{\downarrow} \cong (m_b - m_s \cos^2 \theta_{\downarrow}) \cos^2 \phi_{\downarrow} \quad (4.19)$$

and

$$m_d \cong 2m_s \left(1 - \frac{m_s}{m_b} \cos^2 \theta_{\downarrow}\right) \sin^2 \theta_{\downarrow} \cos^2 \theta_{\downarrow} \sin^2 \phi_{\downarrow} \cos^2 \phi_{\downarrow} (1 - \cos \chi_T(\downarrow)). \quad (4.20)$$

In (4.20), we may further neglect m_s/m_b as compared to 1; this yields

$$m_d \cong 2m_s \sin^2 \theta_{\downarrow} \cos^2 \theta_{\downarrow} \sin^2 \phi_{\downarrow} \cos^2 \phi_{\downarrow} (1 - \cos \chi_T(\downarrow)). \quad (4.21)$$

When $\chi_T(\downarrow) = 0$, we have $m_d = 0$.

4.2 Eigenstates of $M(q_{\downarrow}) = M_0(q_{\downarrow}) + M_1(q_{\downarrow})$

Let d , s , b be the normalized eigenstates of $M(q_{\downarrow})$, with

$$\begin{aligned} M(q_{\downarrow})|d\rangle &= m_d|d\rangle \\ M(q_{\downarrow})|s\rangle &= m_s|s\rangle \\ M(q_{\downarrow})|b\rangle &= m_b|b\rangle. \end{aligned} \quad (4.22)$$

Throughout the paper, the 3×1 normalized state vectors $|d\rangle$, $|s\rangle$, $|b\rangle$ may be denoted simply by d , s , b as well. Likewise, the states ϵ_{\downarrow} , p_{\downarrow} and P_{\downarrow} of (3.8)-(3.10) may also be denoted by $|\epsilon_{\downarrow}\rangle$, $|p_{\downarrow}\rangle$ and $|P_{\downarrow}\rangle$. Introduce the perturbation matrix

$$g_{\downarrow} \cong (U_{\downarrow})_0^{\dagger} M_1(q_{\downarrow}) (U_{\downarrow})_0 \quad (4.23)$$

by using ϵ_{\downarrow} , p_{\downarrow} and P_{\downarrow} as base vectors, with $(U_{\downarrow})_0$ given by (3.20). To the lowest order in $\sin \chi_T(\downarrow)$,

$$g \equiv g_{\downarrow} = i\alpha_{\downarrow}\xi_{\downarrow} \sin \chi_T(\downarrow) \begin{pmatrix} 0 & 0 & \sin \theta_{\downarrow} \\ 0 & 0 & \cos \theta_{\downarrow} \\ -\sin \theta_{\downarrow} & \cos \theta_{\downarrow} & 0 \end{pmatrix} + O(\chi_T^2). \quad (4.24)$$

The corresponding eigenstates d , s , b to the first order in $\sin \chi_T(\downarrow)$ are given by

$$\begin{aligned} |d\rangle &= |\epsilon_{\downarrow}\rangle - \frac{1}{\lambda(P_{\downarrow})} g_{P\epsilon} |P_{\downarrow}\rangle \\ |s\rangle &= |p_{\downarrow}\rangle + \frac{1}{m_s - \lambda(P_{\downarrow})} g_{Pp} |P_{\downarrow}\rangle \end{aligned} \quad (4.25)$$

and

$$|b\rangle = |P_\downarrow\rangle + \frac{1}{m_b} g_{\epsilon P} |\epsilon_\downarrow\rangle + \frac{1}{m_b - \lambda(p_\downarrow)} g_{pP} |p_\downarrow\rangle$$

where

$$g_{\epsilon P} = g_{P\epsilon}^* = i\alpha_\downarrow \xi_\downarrow \sin \theta_\downarrow \sin \chi_T(\downarrow)$$

and

$$g_{pP} = g_{Pp}^* = i\alpha_\downarrow \xi_\downarrow \cos \theta_\downarrow \sin \chi_T(\downarrow)$$

(4.26)

are the first order nonzero matrix elements of g_\downarrow in accordance with (4.24).

4.3 CKM Matrix and Jarlskog Invariant

Anticipating that the Jarlskog Invariant J in this model is dominated by the \downarrow quark sector because of

$$\frac{m_u m_c}{m_t^2} \ll \frac{m_d m_s}{m_b^2}$$

in accordance with (1.11), our discussions can be much simplified by setting the T -violating phase

$$\chi_T(\uparrow) = 0 \quad (4.27)$$

as an approximation. In this case,

$$|u\rangle \cong |\epsilon_\uparrow\rangle, \quad |c\rangle \cong |p_\uparrow\rangle \quad \text{and} \quad |t\rangle \cong |P_\uparrow\rangle \quad (4.28)$$

and

$$U_\uparrow \cong (U_\uparrow)_0 = (\epsilon_\uparrow, p_\uparrow, P_\uparrow). \quad (4.29)$$

The corresponding CKM matrix is given by

$$U_{CKM} = U_\uparrow^\dagger U_\downarrow, \quad (4.30)$$

with its matrix elements in this approximation given by

$$\begin{aligned} U_{ud} &= u^\dagger d = \epsilon_\uparrow^\dagger \epsilon_\downarrow + i(\alpha \xi \sin \theta \sin \chi_T)_\downarrow \frac{\epsilon_\uparrow^\dagger P_\downarrow}{m_b}, \\ U_{cd} &= c^\dagger d = p_\uparrow^\dagger \epsilon_\downarrow + i(\alpha \xi \sin \theta \sin \chi_T)_\downarrow \frac{p_\uparrow^\dagger P_\downarrow}{m_b}, \\ U_{td} &= t^\dagger d = P_\uparrow^\dagger \epsilon_\downarrow + i(\alpha \xi \sin \theta \sin \chi_T)_\downarrow \frac{P_\uparrow^\dagger P_\downarrow}{m_b}, \\ U_{us} &= u^\dagger s = \epsilon_\uparrow^\dagger p_\downarrow + i(\alpha \xi \cos \theta \sin \chi_T)_\downarrow \frac{\epsilon_\uparrow^\dagger P_\downarrow}{m_b - m_s}, \\ U_{cs} &= c^\dagger s = p_\uparrow^\dagger p_\downarrow + i(\alpha \xi \cos \theta \sin \chi_T)_\downarrow \frac{p_\uparrow^\dagger P_\downarrow}{m_b - m_s}, \\ U_{ts} &= t^\dagger s = P_\uparrow^\dagger p_\downarrow + i(\alpha \xi \cos \theta \sin \chi_T)_\downarrow \frac{P_\uparrow^\dagger P_\downarrow}{m_b - m_s}, \end{aligned} \quad (4.31)$$

etc., in which $\epsilon_{\uparrow}^{\dagger}\epsilon_{\downarrow}$, $p_{\uparrow}^{\dagger}\epsilon_{\downarrow}$, etc. are given by the approximate matrix elements in $(U_{CKM})_0$ of (3.22).

Define

$$\begin{aligned}\mathcal{S}_1 &\equiv U_{ud}^* U_{us} \\ \mathcal{S}_2 &\equiv U_{cd}^* U_{cs}\end{aligned}\tag{4.32}$$

and

$$\mathcal{S}_3 \equiv U_{td}^* U_{ts}.$$

We have

$$\mathcal{S}_1 + \mathcal{S}_2 + \mathcal{S}_3 = 0\tag{4.33}$$

and the Jarlskog Invariant

$$J = \text{Im}\mathcal{S}_1^* \mathcal{S}_2 = \text{Im}\mathcal{S}_2^* \mathcal{S}_3 = \text{Im}\mathcal{S}_3^* \mathcal{S}_1.\tag{4.34}$$

Assume θ_{\uparrow} and θ_{\downarrow} are all small and $O(\lambda)$, with λ given by (3.25). To the lowest order in powers of $\lambda = 0.227$ and of m_s/m_b , we find

$$J \cong \frac{m_s}{m_b} \sin(\theta_{\uparrow} - \theta_{\downarrow}) \sin \theta_{\downarrow} \cos \theta_{\downarrow} \sin \phi_{\downarrow} \cos \phi_{\downarrow} \sin \phi \sin \chi_T\tag{4.35}$$

where

$$\phi = \phi_{\uparrow} - \phi_{\downarrow}.\tag{4.36}$$

Combining the square root of (4.21) with (4.35), we derive, to the accuracy of the calculated order,

$$J = \left(\frac{m_d m_s}{m_b^2} \right)^{1/2} \sin(\theta_{\uparrow} - \theta_{\downarrow}) \sin \phi \cos[\tfrac{1}{2}\chi_T(\downarrow)].\tag{4.37}$$

By using (3.25)-(3.26), we derive (1.11) for J , which is consistent with all available data. As the time reversal violating phase $\chi_T(\downarrow) \rightarrow 0$, both J and $(m_d m_s/m_b^2)^{1/2}$ approach zero; their ratio remains fixed by the T -conserving elements of the CKM matrix:

$$\sin(\theta_{\uparrow} - \theta_{\downarrow}) \cdot \sin \phi = A\lambda^2 \cdot \lambda.\tag{4.38}$$

It is satisfying that this limiting value is consistent with available experimental data, as shown by (1.11)-(1.13).

5. Lepton Sectors (neglecting T violations)

The application of hidden symmetry to the lepton sectors will be examined in this and the following sections.

5.1 General Discussion

The lepton mass operators are given by (1.7)-(1.8). In the zeroth approximation of T invariance, these operators can be written as

$$\mathcal{M}_0(l_\downarrow) = a_\downarrow |l_3(\downarrow) - \kappa_\downarrow l_2(\downarrow)|^2 + b_\downarrow |l_2(\downarrow) - \rho_\downarrow l_1(\downarrow)|^2 + c_\downarrow |l_1(\downarrow) - \sigma_\downarrow l_3(\downarrow)|^2 \quad (5.1)$$

and

$$\mathcal{M}_0(l_\uparrow) = a_\uparrow |l_3(\uparrow) - \kappa_\uparrow l_2(\uparrow)|^2 + b_\uparrow |l_2(\uparrow) - \rho_\uparrow l_1(\uparrow)|^2 + c_\uparrow |l_1(\uparrow) - \sigma_\uparrow l_3(\uparrow)|^2 \quad (5.2)$$

where the twelve parameters $a_\uparrow, a_\downarrow, \kappa_\uparrow, \kappa_\downarrow, b_\uparrow, b_\downarrow, \dots$ are all real, with at least six of them $a_\uparrow, a_\downarrow, b_\uparrow, b_\downarrow, c_\uparrow, c_\downarrow$ positive. As in (2.2) and (3.6), we impose

$$\kappa_\downarrow \rho_\downarrow \sigma_\downarrow = \kappa_\uparrow \rho_\uparrow \sigma_\uparrow = 1, \quad (5.3)$$

$$\frac{b_\downarrow}{c_\downarrow} = \sigma_\downarrow^2 \quad \text{and} \quad \frac{b_\uparrow}{c_\uparrow} = \sigma_\uparrow^2. \quad (5.4)$$

Hence, as in (4.2) these mass operators become

$$\mathcal{M}_0(l_\downarrow) = a_\downarrow |l_3(\downarrow) - \kappa_\downarrow l_2(\downarrow)|^2 + b_\downarrow |l_2(\downarrow) - \rho_\downarrow l_1(\downarrow)|^2 + b_\downarrow |l_3(\downarrow) - \kappa_\downarrow \rho_\downarrow l_1(\downarrow)|^2 \quad (5.5)$$

and

$$\mathcal{M}_0(l_\uparrow) = a_\uparrow |l_3(\uparrow) - \kappa_\uparrow l_2(\uparrow)|^2 + b_\uparrow |l_2(\uparrow) - \rho_\uparrow l_1(\uparrow)|^2 + b_\uparrow |l_3(\uparrow) - \kappa_\uparrow \rho_\uparrow l_1(\uparrow)|^2. \quad (5.6)$$

Correspondingly, the mass matrices $M(l_\downarrow)$ and $M(l_\uparrow)$ defined by (1.7)-(1.8) are, similar to (4.6),

$$[M_0(l)]_{\downarrow \text{ or } \uparrow} = \begin{pmatrix} b\rho^2(1 + \kappa^2) & -b\rho & -b\kappa\rho \\ -b\rho & b + a\kappa^2 & -a\kappa \\ -b\kappa\rho & -a\kappa & a + b \end{pmatrix}_{\downarrow \text{ or } \uparrow}. \quad (5.7)$$

Since their determinants satisfy

$$|M_0(l_\downarrow)| = |M_0(l_\uparrow)| = 0, \quad (5.8)$$

each matrix has an eigenvector of zero eigenvalue:

$$M_0(l_\downarrow)\delta_\downarrow = 0 \quad (5.9)$$

and

$$M_0(l_\uparrow)\delta_\uparrow = 0. \quad (5.10)$$

As in (3.1)-(3.2), let $(V_\downarrow)_0$ and $(V_\uparrow)_0$ be the real unitary matrices that diagonalize $M_0(l_\downarrow)$ and $M_0(l_\uparrow)$:

$$(V_\downarrow)_0^\dagger M_0(l_\downarrow) (V_\downarrow)_0 = \begin{pmatrix} m_0(e) & 0 & 0 \\ 0 & m_0(\mu) & 0 \\ 0 & 0 & m_0(\tau) \end{pmatrix} \quad (5.11)$$

and

$$(V_\uparrow)_0^\dagger M_0(l_\uparrow) (V_\uparrow)_0 = \begin{pmatrix} m_0(\nu_1) & 0 & 0 \\ 0 & m_0(\nu_2) & 0 \\ 0 & 0 & m_0(\nu_3) \end{pmatrix}. \quad (5.12)$$

The corresponding zeroth order neutrino mapping matrix is

$$(V_\nu)_0 = (V_\downarrow)_0^\dagger (V_\uparrow)_0. \quad (5.13)$$

Note that the roles of \uparrow and \downarrow in (5.13) are switched in comparison between those in (3.3) because of our accustomed definitions of V_ν and U_{CKM} .

We will further simplify the lepton mass operators by assuming

$$\kappa_\downarrow = -1, \rho_\downarrow = y, \sigma_\downarrow = -\frac{1}{y} \quad (5.14)$$

$$\kappa_\uparrow = x, \rho_\uparrow = -\frac{1}{\sqrt{2}} \text{ and } \sigma_\uparrow = -\frac{\sqrt{2}}{x}$$

with x, y two small real parameters; i.e.,

$$|x| \ll 1 \text{ and } |y| \ll 1. \quad (5.15)$$

Thus, (5.1) and (5.2) become

$$\mathcal{M}_0(l_\downarrow) = a_\downarrow |l_3(\downarrow) + l_2(\downarrow)|^2 + b_\downarrow |l_2(\downarrow) - y l_1(\downarrow)|^2 + b_\downarrow |l_3(\downarrow) + y l_1(\downarrow)|^2 \quad (5.16)$$

and

$$\mathcal{M}_0(l_\uparrow) = a_\uparrow |l_3(\uparrow) - x l_2(\uparrow)|^2 + b_\uparrow |l_2(\uparrow) + \sqrt{\frac{1}{2}} l_1(\uparrow)|^2 + b_\uparrow |l_3(\uparrow) + \sqrt{\frac{1}{2}} x l_1(\uparrow)|^2. \quad (5.17)$$

Correspondingly (5.7) can be written as

$$M_0(l_\downarrow) = \begin{pmatrix} 2b_\downarrow y^2 & -b_\downarrow y & b_\downarrow y \\ -b_\downarrow y & a_\downarrow + b_\downarrow & a_\downarrow \\ b_\downarrow y & a_\downarrow & a_\downarrow + b_\downarrow \end{pmatrix} \quad (5.18)$$

and

$$M_0(l_\uparrow) = \begin{pmatrix} \frac{1}{2} b_\uparrow (1 + x^2) & \sqrt{\frac{1}{2}} b_\uparrow & \sqrt{\frac{1}{2}} b_\uparrow x \\ \sqrt{\frac{1}{2}} b_\uparrow & b_\uparrow + a_\uparrow x^2 & -a_\uparrow x \\ \sqrt{\frac{1}{2}} b_\uparrow x & -a_\uparrow x & a_\uparrow + b_\uparrow \end{pmatrix}. \quad (5.19)$$

Since the matrices (5.18) and (5.19) are special cases of the matrix (2.3) with the constraints (2.5) and (3.6), their eigenvectors and eigenvalues can be readily obtained. Arrange the three eigenvalues λ_e , λ_m and λ_t of $M_0(l_\downarrow)$ in the same order as those in (3.11)-(3.13) and (5.11); we have

$$m_0(e) = \lambda_e = 0, \quad (5.20)$$

$$m_0(\mu) = \lambda_m = b_\downarrow (1 + 2y^2) \quad (5.21)$$

and

$$m_0(\tau) = \lambda_t = 2a_\downarrow + b_\downarrow. \quad (5.22)$$

Likewise, the eigenvalues of $M_0(l_\uparrow)$, in the same ascending order as (3.17)-(3.19) and (5.12), are

$$m_0(\nu_1) = \lambda_n = 0, \quad (5.23)$$

$$m_0(\nu_2) = \lambda_l = \frac{1}{2} b_\uparrow (3 + x^2) \quad (5.24)$$

and

$$m_0(\nu_3) = \lambda_L = a_\uparrow (1 + x^2) + b_\uparrow. \quad (5.25)$$

Similarly, by using (3.8)-(3.10) and (3.14)-(3.16) the corresponding eigenvectors of $M_0(l_\downarrow)$ and $M_0(l_\uparrow)$ can be readily written down.

5.2 A limiting Case

In the limit

$$x \rightarrow 0 \quad \text{and} \quad y \rightarrow 0, \quad (5.26)$$

the mass matrices (5.18) and (5.19) become

$$[M_0(l)]_\downarrow \rightarrow \begin{pmatrix} 0 & 0 & 0 \\ 0 & a_\downarrow + b_\downarrow & a_\downarrow \\ 0 & a_\downarrow & a_\downarrow + b_\downarrow \end{pmatrix} \quad (5.27)$$

and

$$[M_0(l)]_\uparrow \rightarrow \begin{pmatrix} \frac{1}{2} b_\uparrow & \sqrt{\frac{1}{2}} b_\uparrow & 0 \\ \sqrt{\frac{1}{2}} b_\uparrow & b_\uparrow & 0 \\ 0 & 0 & a_\uparrow + b_\uparrow \end{pmatrix}. \quad (5.28)$$

In accordance with (5.11)-(5.12), the matrices $(V_\downarrow)_0$ and $(V_\uparrow)_0$ becomes

$$(V_\downarrow)_0 \rightarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & \sqrt{\frac{1}{2}} & \sqrt{\frac{1}{2}} \\ 0 & -\sqrt{\frac{1}{2}} & \sqrt{\frac{1}{2}} \end{pmatrix} \quad (5.29)$$

and

$$(V_\uparrow)_0 \rightarrow \begin{pmatrix} -\sqrt{\frac{2}{3}} & \sqrt{\frac{1}{3}} & 0 \\ \sqrt{\frac{1}{3}} & \sqrt{\frac{2}{3}} & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad (5.30)$$

with the corresponding neutrino-mapping matrix $(V_\nu)_0$ given by the Harrison-Scott form

$$(V_\nu)_0 \equiv (V_\downarrow)_0^\dagger (V_\uparrow)_0 \rightarrow \begin{pmatrix} -\sqrt{\frac{2}{3}} & \sqrt{\frac{1}{3}} & 0 \\ \sqrt{\frac{1}{6}} & \sqrt{\frac{1}{3}} & -\sqrt{\frac{1}{2}} \\ \sqrt{\frac{1}{6}} & \sqrt{\frac{1}{3}} & \sqrt{\frac{1}{2}} \end{pmatrix}. \quad (5.31)$$

Thus, the matrices (5.18) and (5.19) agree with all existing experimental data provided x and y are small.

6. Lepton Sectors (with T violation)

With T violations, we generalize (5.16)-(5.17) and write in accordance with (1.7)-(1.8):

$$\begin{aligned}\mathcal{M}(l_\downarrow) &= \left(\bar{l}_1(\downarrow), \bar{l}_2(\downarrow), \bar{l}_3(\downarrow) \right) M(l_\downarrow) \begin{pmatrix} l_1(\downarrow) \\ l_2(\downarrow) \\ l_3(\downarrow) \end{pmatrix} \\ &= a_\downarrow |l_3(\downarrow) + e^{i\phi_\downarrow} l_2(\downarrow)|^2 + b_\downarrow |l_2(\downarrow) - y l_1(\downarrow)|^2 + b_\downarrow |l_3(\downarrow) + y l_1(\downarrow)|^2, \quad (6.1)\end{aligned}$$

and

$$\begin{aligned}\mathcal{M}(l_\uparrow) &= \left(\bar{l}_1(\uparrow), \bar{l}_2(\uparrow), \bar{l}_3(\uparrow) \right) M(l_\uparrow) \begin{pmatrix} l_1(\uparrow) \\ l_2(\uparrow) \\ l_3(\uparrow) \end{pmatrix} \\ &= a_\uparrow |l_3(\uparrow) - x l_2(\uparrow)|^2 + b_\uparrow |l_2(\uparrow) + \sqrt{\frac{T}{2}} e^{i\phi_\uparrow} l_1(\uparrow)|^2 + b_\uparrow |l_3(\uparrow) + \sqrt{\frac{T}{2}} x l_1(\uparrow)|^2. \quad (6.2)\end{aligned}$$

The matrices $M(l_\downarrow)$ and $M(l_\uparrow)$ can also be written as

$$M(l_\downarrow) = M_0(l_\downarrow) + M_1(l_\downarrow) \quad (6.3)$$

and

$$M(l_\uparrow) = M_0(l_\uparrow) + M_1(l_\uparrow) \quad (6.4)$$

with $M_0(l_\downarrow)$ and $M_0(l_\uparrow)$ given by (5.18) and (5.19),

$$M_1(l_\downarrow) = a_\downarrow \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & e^{-i\phi_\downarrow} - 1 \\ 0 & e^{i\phi_\downarrow} - 1 & 0 \end{pmatrix} \quad (6.5)$$

and

$$M_1(l_\uparrow) = \frac{1}{\sqrt{2}} b_\uparrow \begin{pmatrix} 0 & e^{-i\phi_\uparrow} - 1 & 0 \\ e^{i\phi_\uparrow} - 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad (6.6)$$

in which ϕ_\downarrow and ϕ_\uparrow are the T -violating phases.

The determinants of $M(l_\downarrow)$ and $M(l_\uparrow)$ are

$$|M(l_\downarrow)| = 2a_\downarrow b_\downarrow^2 y^2 (1 - \cos \phi_\downarrow) \quad (6.7)$$

and

$$|M(l_\uparrow)| = a_\uparrow b_\uparrow^2 x^2 (1 - \cos \phi_\uparrow). \quad (6.8)$$

The three eigenvalues of $M(l_\downarrow)$ are the physical masses of charged leptons e , μ and τ :

$$m = m_e, \ m_\mu, \ m_\tau, \quad (6.9)$$

determined by the cubic equation

$$m(m - \lambda_m)(m - \lambda_t) = |M(l_\downarrow)| \quad (6.10)$$

with λ_m , λ_t given by (5.21) and (5.22). Likewise, the eigenvalues of $M(l_\uparrow)$ are the three neutrino masses

$$m = m_1, \ m_2, \ m_3, \quad (6.11)$$

determined by

$$m(m - \lambda_l)(m - \lambda_L) = |M(l_\uparrow)| \quad (6.12)$$

with λ_l , λ_L given by (5.24)-(5.25). As in (4.9), Eqs. (6.10) and (6.12), together with (5.20)-(5.25) give a simple way to derive the physical masses of leptons with the inclusion of T violation effects.

On the other hand, for evaluation of eigenvectors it is more convenient to transform

$$l_1(\downarrow) = l'_1(\downarrow), \quad l_2(\downarrow) = e^{-i\phi_\downarrow/2} l'_2(\downarrow) \quad \text{and} \quad l_3(\downarrow) = e^{i\phi_\downarrow/2} l'_3(\downarrow). \quad (6.13)$$

Thus,

$$\mathcal{M}(l_\downarrow) = (\bar{l}'_1(\downarrow), \bar{l}'_2(\downarrow), \bar{l}'_3(\downarrow)) (H_0(l_\downarrow) + H_1(l_\downarrow)) \begin{pmatrix} l'_1(\downarrow) \\ l'_2(\downarrow) \\ l'_3(\downarrow) \end{pmatrix} \quad (6.14)$$

with

$$H_0(l_\downarrow) = \begin{pmatrix} 2b_\downarrow y^2 & 0 & 0 \\ 0 & a_\downarrow + b_\downarrow & a_\downarrow \\ 0 & a_\downarrow & a_\downarrow + b_\downarrow \end{pmatrix} \quad (6.15)$$

and

$$H_1(l_\downarrow) = b_\downarrow y \begin{pmatrix} 0 & -z_\downarrow^* & z_\downarrow \\ -z_\downarrow & 0 & 0 \\ z_\downarrow^* & 0 & 0 \end{pmatrix}, \quad (6.16)$$

with

$$z_{\downarrow} = e^{i\frac{1}{2}\phi_{\downarrow}}. \quad (6.17)$$

Likewise, introduce $l'_1(\uparrow)$ and $l'_2(\uparrow)$ through

$$l_1(\uparrow) = e^{-i\phi_{\uparrow}} l'_1(\uparrow), \quad l_2(\uparrow) = e^{i\phi_{\uparrow}} l'_2(\uparrow) \quad \text{and} \quad l_3(\uparrow) = l'_3(\uparrow). \quad (6.18)$$

Correspondingly,

$$\mathcal{M}(l_{\uparrow}) = \left(\bar{l}'_1(\uparrow), \bar{l}'_2(\uparrow), \bar{l}'_3(\uparrow) \right) \left(H_0(l_{\uparrow}) + H_1(l_{\uparrow}) \right) \begin{pmatrix} l'_1(\uparrow) \\ l'_2(\uparrow) \\ l'_3(\uparrow) \end{pmatrix} \quad (6.19)$$

with

$$H_0(l_{\uparrow}) = \begin{pmatrix} \frac{b_{\uparrow}}{2}(1+x^2) & \sqrt{\frac{\mathbb{T}}{2}} b_{\uparrow} & 0 \\ \sqrt{\frac{\mathbb{T}}{2}} b_{\uparrow} & b_{\uparrow} + a_{\uparrow}x^2 & 0 \\ 0 & 0 & a_{\uparrow} + b_{\uparrow} \end{pmatrix} \quad (6.20)$$

and

$$H_1(l_{\uparrow}) = x \begin{pmatrix} 0 & 0 & \sqrt{\frac{\mathbb{T}}{2}} b_{\uparrow} z_{\uparrow} \\ 0 & 0 & -a_{\uparrow} z_{\uparrow}^* \\ \sqrt{\frac{\mathbb{T}}{2}} b_{\uparrow} z_{\uparrow}^* & -a_{\uparrow} z_{\uparrow} & 0 \end{pmatrix}, \quad (6.21)$$

with

$$z_{\uparrow} = e^{i\frac{1}{2}\phi_{\uparrow}}. \quad (6.22)$$

The smallness of x and y makes it possible to use $H_1(\downarrow)$ and $H_1(\uparrow)$ as perturbations.

Let V_{\downarrow} and V_{\uparrow} be the unitary matrices that diagonalize $M(l_{\downarrow})$ and $M(l_{\uparrow})$ of (6.1) and (6.2). The corresponding neutrino mapping matrix is

$$V_{\nu} = V_{\downarrow}^{\dagger} V_{\uparrow}. \quad (6.23)$$

Define

$$\begin{aligned} T_1 &= (V_{\nu})_{21}^* (V_{\nu})_{31}, \\ T_2 &= (V_{\nu})_{22}^* (V_{\nu})_{32} \end{aligned} \quad (6.24)$$

and

$$T_3 = (V_{\nu})_{23}^* (V_{\nu})_{33}.$$

Their sum satisfies

$$T_1 + T_2 + T_3 = 0. \quad (6.25)$$

The corresponding Jarlskog invariant for leptons is

$$\mathcal{J}_\nu = \text{Im} T_1^* T_2 = \text{Im} T_2^* T_3 = \text{Im} T_3^* T_1. \quad (6.26)$$

To first order in x and y , we find

$$\begin{aligned} \mathcal{J}_\nu = & -\frac{y}{3\sqrt{2}} \left[\cos \frac{\phi_\downarrow}{2} \sin\left(\frac{\phi_\downarrow}{2} + \phi_\uparrow\right) + \frac{b_\downarrow}{2a_\downarrow + b_\downarrow} \sin \phi_\downarrow \cos\left(\frac{\phi_\downarrow}{2} + \phi_\uparrow\right) \right] \\ & + \frac{x}{3} \frac{a_\uparrow b_\uparrow}{(a_\uparrow + b_\uparrow)(2a_\uparrow - b_\uparrow)} \left[-\sin \phi_\downarrow + \sin(\phi_\downarrow + \phi_\uparrow) \right]. \end{aligned} \quad (6.27)$$

As in(4.37), there is an interesting relation between \mathcal{J}_ν and lepton masses, which will be discussed in a separate paper.

Appendix

In (2.3), the 3×3 symmetric matrix is written in the form

$$M = \begin{pmatrix} \gamma + \beta\eta^2 & -\beta\eta & -\gamma\zeta \\ -\beta\eta & \beta + \alpha\xi^2 & -\alpha\xi \\ -\gamma\zeta & -\alpha\xi & \alpha + \gamma\zeta^2 \end{pmatrix} \quad (A.1)$$

with six parameters α , β , γ , ξ , η and ζ . On the other hand, any such symmetric M can also be expressed by

$$M = \begin{pmatrix} c & -e & -f \\ -e & b & -d \\ -f & -d & a \end{pmatrix} \quad (A.2)$$

with

$$a = \alpha + \gamma\zeta^2, \quad (A.3)$$

$$b = \beta + \alpha\xi^2, \quad (A.4)$$

$$c = \gamma + \beta\eta^2, \quad (A.5)$$

$$d = \alpha\xi, \quad (A.6)$$

$$e = \beta\eta \quad (A.7)$$

and

$$f = \gamma\zeta. \quad (A.8)$$

In this Appendix, we give the answer to the inverse problem: Given a , b , \dots , f what are the corresponding α , β , \dots , ζ ?

Introduce

$$A = bc - e^2 \quad (A.9)$$

$$B = ae^2 + bf^2 - cd^2 - abc \quad (A.10)$$

and

$$C = (ac - f^2)d^2. \quad (A.11)$$

One can readily verify that α satisfies

$$A\alpha^2 + B\alpha + C = 0. \quad (A.12)$$

Knowing α , (A.6) gives ξ . From $\alpha\xi^2$, β can be determined. Thus, η is known from (A.7). Likewise, γ can be deduced from (A.5) and ζ from (A.3).

For α , β , γ , ξ , η , ζ real, so are a , b , c , d , e , f . However, the converse is not always true, as can be readily studied by examining the solutions of the quadratic equation (A.12).
