#### Abstract

We introduce some multiple integrals that are expected to have the same singularities as the singularities of the $n$-particle contributions $\chi^{(n)}$ to the susceptibility of the square lattice Ising model. We find the Fuchsian linear differential equation satisfied by these multiple integrals for $n=1,2,3,4$ and only modulo some primes for $n=5$ and 6 , thus providing a large set of (possible) new singularities of the $\chi^{(n)}$. We discuss the singularity structure for these multiple integrals by solving the Landau conditions. We find that the singularities of the associated ODEs identify (up to $n=6$ ) with the leading pinch Landau singularities. The second remarkable obtained feature is that the singularities of the ODEs associated with the multiple integrals reduce to the singularities of the ODEs associated with a finite number of one dimensional integrals. Among the singularities found, we underline the fact that the quadratic polynomial condition $1+3 w+4 w^{2}=0$, that occurs in the linear differential equation of $\chi^{(3)}$, actually corresponds to a remarkable property of selected elliptic curves, namely the occurrence of complex multiplication. The interpretation of complex multiplication for elliptic curves as complex fixed points of the selected generators of the renormalization group, namely isogenies of elliptic curves, is sketched. Most of the other singularities occurring in our multiple integrals are not related to complex multiplication situations, suggesting an interpretation in terms of (motivic) mathematical structures beyond the theory of elliptic curves.

## 1. Introduction

The susceptibility $\chi$ of the square lattice Ising model has been shown by $\mathrm{Wu}, \mathrm{McCoy}$, Tracy and Barouch [1] to be expressible as an infinite sum of holomorphic functions,
given as multiple integrals, denoted $\chi^{(n)}$, that is $k T \cdot \chi=\sum \chi^{(n)}$. B. Nickel found [2, 3] that each of these $\chi^{(n)}$ 's is actually singular on a set of points located on the unit circle $|s|=|\sinh (2 K)|=1$, where $K=J / k T$ is the usual Ising model temperature variable.

These singularities are located at solution points of the following equations:

$$
\begin{align*}
& 2 \cdot\left(s+\frac{1}{s}\right)=u^{k}+\frac{1}{u^{k}}+u^{m}+\frac{1}{u^{m}} \\
& u^{2 n+1}=1, \quad-n \leq m, k \leq n \tag{1}
\end{align*}
$$

From now on, we will call these singularities of the "Nickelian type", or simply "Nickelian singularities". The accumulation of this infinite set of singularities of the higher-particle components of $\chi(s)$ on the unit circle $|s|=1$, leads, in the absence of mutual cancellation, to some consequences regarding the non holonomic (non Dfinite) character of the susceptibility, possibly building a natural boundary for the total $\chi(s)$. However, it should be noted that new singularities that are not of the "Nickelian type" were discovered as singularities of the Fuchsian linear differential equation associated [4, 5, 6] with $\chi^{(3)}$ and as singularities of $\chi^{(3)}$ itself [7] but seen as a function of $s$. They correspond to the quadratic polynomial $1+3 w+4 w^{2}$ where $2 w=s /\left(1+s^{2}\right)$. In contrast with this situation, the Fuchsian linear differential equation, associated [8] with $\chi^{(4)}$, does not provide any new singularities.

Some remarkable Russian-doll structure as well as direct sum decompositions were found for the corresponding linear differential operators for $\chi^{(3)}$ and $\chi^{(4)}$. In order to understand the "true nature" of the susceptibility of the square lattice Ising model, it is of fundamental importance to have a better understanding of the singularity structure of the $n$-particle contributions $\chi^{(n)}$, and also of the mathematical structures associated with these $\chi^{(n)}$, namely the infinite set of (probably Fuchsian) linear differential equations associated with this infinite set of holonomic functions. Finding more Fuchsian linear differential equations having the $\chi^{(n)}$ 's as solutions, beyond those already found [4, 8 for $\chi^{(3)}$ and $\chi^{(4)}$, probably requires the performance of a large set of analytical, mathematical and computer programming "tours-de-force".

As an alternative, and in order to bypass this "temporary" obstruction, we have developed, in parallel, a new strategy.

We have introduced [7] some single (or multiple) "model" integrals as an "ersatz" for the $\chi^{(n)}$ 's as far as the locus of the singularities is concerned. The $\chi^{(n)}$ 's are defined by $(n-1)$-dimensional integrals [3, 9, 10] (omitting the prefactor $\mathbb{\$ 1}$ )

$$
\begin{equation*}
\tilde{\chi}^{(n)}=\frac{(2 w)^{n}}{n!} \prod_{j=1}^{n-1} \int_{0}^{2 \pi} \frac{d \phi_{j}}{2 \pi}\left(\prod_{j=1}^{n} y_{j}\right) \cdot R^{(n)} \cdot\left(G^{(n)}\right)^{2} \tag{2}
\end{equation*}
$$

where

$$
\begin{equation*}
G^{(n)}=\left(\prod_{j=1}^{n} x_{j}\right)^{(n-1) / 2} \prod_{1 \leq i<j \leq n} \frac{2 \sin \left(\left(\phi_{i}-\phi_{j}\right) / 2\right)}{1-x_{i} x_{j}} \tag{3}
\end{equation*}
$$

and

$$
\begin{equation*}
R^{(n)}=\frac{1+\prod_{i=1}^{n} x_{i}}{1-\prod_{i=1}^{n} x_{i}} \tag{4}
\end{equation*}
$$

$\ddagger$ The prefactor reads $\left(1-s^{4}\right)^{1 / 4} / s$ for $T>T_{c}$ and $\left(1-s^{-4}\right)^{1 / 4}$ for $T<T_{c}$.
with

$$
\begin{align*}
& x_{i}=\frac{2 w}{1-2 w \cos \left(\phi_{i}\right)+\sqrt{\left(1-2 w \cos \left(\phi_{i}\right)\right)^{2}-4 w^{2}}},  \tag{5}\\
& y_{i}=\frac{1}{\sqrt{\left(1-2 w \cos \left(\phi_{i}\right)\right)^{2}-4 w^{2}}}, \quad \sum_{j=1}^{n} \phi_{j}=0 . \tag{6}
\end{align*}
$$

The two families of integrals we have considered in [7] are very rough approximations of the integrals (21). For the first familyt, we considered the $n$-fold integrals corresponding to the product of (the squar $\ddagger$ of the) $y_{i}$ 's, integrated over the whole domain of integration of the $\phi_{i}$ (thus getting rid of the factors $G^{(n)}$ and $R^{(n)}$ ). Here, we found a subset of singularities occurring in the $\chi^{(n)}$ as well as the quadratic polynomial condition $1+3 w+4 w^{2}=0$.

For the second family, we discarded the factor $G^{(n)}$ and the product of $y_{i}$ 's, and we restricted the domain of integration to the principal diagonal of the angles $\phi_{i}\left(\phi_{1}=\phi_{2}=\cdots=\phi_{n-1}\right)$. These simple integrals (over a single variable), were denoted [7] $\Phi_{D}^{(n)}$ :

$$
\begin{equation*}
\Phi_{D}^{(n)}=-\frac{1}{n!}+\frac{2}{n!} \int_{0}^{2 \pi} \frac{d \phi}{2 \pi} \frac{1}{1-x^{n-1}(\phi) \cdot x((n-1) \phi)} \tag{7}
\end{equation*}
$$

where $x(\phi)$ is given by (5).
Remarkably these very simple integrals both reproduce all the singularities, discussed by Nickel [2, 3], as well as the quadratic roots of $1+3 w+4 w^{2}=0$ found [4, 5] for the linear ODE of $\chi^{(3)}$. One should however note that, in contrast with the $\chi^{(n)}$, no Russian-doll or direct sum decomposition structure is found for the linear differential operators corresponding to these $\Phi_{D}^{(n)}$.

Another approach has been introduced as a simplification of the susceptibility of the Ising model by considering a magnetic field restricted to one diagonal of the square lattice [11]. For this "diagonal susceptibility" model [11], we benefited from the form factor decomposition of the diagonal two-point correlations $C(N, N)$, that has been recently presented [12], and subsequently proved by Lyberg and McCoy [13]. The corresponding $n$-fold integrals $\chi_{d}^{(n)}$ were found to exhibit remarkable direct sum structures inherited from the direct sum structures of the form factor [11, 12]. The linear differential operators of the form factor [12] being closely linked to the second order differential operator $L_{E}\left(\right.$ resp. $\left.L_{K}\right)$ of the complete elliptic integrals $E$ (resp. $K$ ), this "diagonal susceptibility" model [11] is closely linked to the elliptic curves of the two-dimensional Ising model. By way of contrast, we note that the singularities of the linear ODE's for these $n$-fold integrals [11] $\chi_{d}^{(n)}$ are quite elementary (consisting of only $n$-th roots of unity) in comparison with the singularities we encounter for the integrals on a single variable (7).

These two approaches corresponding to two different sets of $n$-fold integrals of the Ising class [14] are complementary: (7) is more dedicated to reproduce the nontrivial head polynomials encoding the location of the singularities of the $\chi^{(n)}$, but fails
$\dagger$ Denoted $Y^{(n)}(w)$ in [7].
$\ddagger$ Surprisingly the integrand with $\left(\prod_{j=1}^{n} y_{j}\right)^{2}$ yields second order linear differential equations [7], and consequently, we have been able to totally decipher the corresponding singularity structure. By way of contrast the integrand with the simple product $\left(\prod_{j=1}^{n} y_{j}\right)$ yields linear differential equations of higher order, but with identical singularities [7].
to reproduce some remarkable (Russian-doll, direct sum decomposition) algebraicodifferential structures of the corresponding linear differential operators, while the other one 11 preserves these non-trivial structures of the corresponding linear differential operators but provides a poorer representation of the location of the singularities ( $n$-th roots of unity).

In this paper, we return to the integrals (2) where, this time, the natural next step is to consider the following family of $n$-fold integrals

$$
\begin{equation*}
\Phi_{H}^{(n)}=\frac{1}{n!} \cdot \prod_{j=1}^{n-1} \int_{0}^{2 \pi} \frac{d \phi_{j}}{2 \pi} \cdot\left(\prod_{j=1}^{n} y_{j}\right) \cdot \frac{1+\prod_{i=1}^{n} x_{i}}{1-\prod_{i=1}^{n} x_{i}} \tag{8}
\end{equation*}
$$

which amounts to getting rid of the (fermionic) factor $\left(G^{(n)}\right)^{2}$ in the $n$-fold integral (2). This family is as close as possible to (2), for which we know that finding the corresponding linear differential ODE's is a huge task. The idea here is that the methods and techniques we have developed [4, 5] for series expansions calculations of $\chi^{(3)}$ and $\chi^{(4)}$, seem to indicate that the quite involved fermionic term $\left(G^{(n)}\right)^{2}$ in the integrand of (2) should not impact greatly on the location of singularities of these $n$-fold integrals (2). This is the best simplification of the integrand of (22) for which we can expect to retain much exact information about the location of the singularities of the original Ising problem. However, we certainly do not expect to recover from the $n$-fold integrals (8) the local singular behavior (exponents, amplitudes of singularities, etc ...). Getting rid of the (fermionic) factor $\left(G^{(n)}\right)^{2}$ are we moving away from the elliptic curves of the two-dimensional Ising model ? Could it be possible that we lose the strong (Russian-doll, direct sum decomposition) algebraico-differential structures of the corresponding linear differential operators inherited from the second order differential operator $L_{E}$ (resp. $L_{K}$ ) of the complete elliptic integrals $E$ (resp. K) but keep some characterization of elliptic curves through more "primitive" (universal) features of these $n$-fold integral like the location of their singularities ?

In the sequel, we give the expressions of $\Phi_{H}^{(1)}, \Phi_{H}^{(2)}$ and the Fuchsian linear differential equations for $\Phi_{H}^{(n)}$ for $n=3$ and $n=4$. For $n=5,6$, the computation (linear ODE search of a series) becomes much harder. Consequently we use a modulo prime method to obtain the form of the corresponding linear ODE with totally explicit singularity structure. These results provide a large set of "candidate singularities" for the $\chi^{(n)}$. From the resolution of the Landau conditions [7] for (8), we show that the singularities of (the linear ODEs of) these multiple integrals actually reduce to the concatanation of the singularities of (the linear ODEs of) a set of one-dimensional integrals. We discuss the mathematical, as well as physical, interpretation of these new singularities. In particular we will see that they correspond to pinched Landaulike singularities as previously noticed by Nickel [15]. Among all these polynomial singularities, the quadratic numbers $1+3 w+4 w^{2}=0$ are highly selected. We will show that these selected quadratic numbers are related to complex multiplication for the elliptic curves parameterizing the square Ising model.

The paper is organized as follows. Section (2) presents the multidimensional integrals $\Phi_{H}^{(n)}$ and the singularities of the corresponding linear ODE for $n=3, \cdots, 6$, that we compare with the singularities obtained from the Landau conditions. We show that the set of singularities associated with the ODEs of the multiple integrals $\Phi_{H}^{(n)}$ reduce to the singularities of the ODEs associated with a finite number of onedimensional integrals. Section (3) deals with the complex multiplication for the elliptic
curves related to the singularities given by the zeros of the quadratic polynomial $1+3 w+4 w^{2}=0$. Our conclusions are given in section (4).

## 2. The singularities of the linear ODE for $\Phi_{H}^{(n)}$

For the first two values of $n$, one obtains

$$
\begin{equation*}
\Phi_{H}^{(1)}=\frac{1}{1-4 w} \tag{9}
\end{equation*}
$$

and

$$
\begin{equation*}
\Phi_{H}^{(2)}=\frac{1}{2} \cdot \frac{1}{1-16 w^{2}} \cdot{ }_{2} F_{1}\left(1 / 2,-1 / 2 ; 1 ; 16 w^{2}\right) . \tag{10}
\end{equation*}
$$

For $n \geq 3$, the series coefficients of the multiple integrals $\Phi_{H}^{(n)}$ are obtained by expanding in the variables $x_{i}$ and performing the integration (see Appendix A). One obtains

$$
\begin{equation*}
\Phi_{H}^{(n)}=\frac{1}{n!} \cdot \sum_{k=0}^{\infty} \sum_{p=0}^{\infty}\left(2-\delta_{k, 0}\right) \cdot\left(2-\delta_{p, 0}\right) \cdot w^{n(k+p)} \cdot a^{n}(k, p) \tag{11}
\end{equation*}
$$

where $a(k, p)$ is a ${ }_{4} F_{3}$ hypergeometric series dependent on $w$.
The advantage of using these simplified integrals (8) instead of the original ones (2) is twofold.

Using (11) the series generation is straightforward compared to the complexity related to the $\chi^{(n)}$. As an illustration note that on a desk computer, $\Phi_{H}^{(n)}$ are generated up to $w^{200}$ in less than 10 seconds CPU time for all values of $n$, while the simplest case of the $\chi^{(n)}$, namely $\chi^{(3)}$, tooks three minutes to generate the series up to $w^{200}$. This difference between the $\Phi_{H}^{(n)}$ and $\chi^{(n)}$ increases rapidly with increasing $n$ and increasing number of generated terms. We note that for the $\Phi_{H}^{(n)}$ quantities and for a fixed order, the CPU time is decreasing with increasing $n$. For $\chi^{(n)}$ the opposite is the case.

The second point is that, for a given $n$, the linear ODE can be found with less terms in the series compared to the linear ODE for the $\chi^{(n)}$. Indeed for $\chi^{(3)}, 360$ terms were needed while 150 terms were enough for $\Phi_{H}^{(3)}$. The same feature holds for $\chi^{(4)}$ and $\Phi_{H}^{(4)}\left(185\right.$ terms for $\chi^{(4)}$ and 56 terma for $\left.\Phi_{H}^{(4)}\right)$.

With the fully integrated sum (11), a sufficient number of terms is generated to obtain the linear differential equations. We succeeded in obtaining the linear differential equations, respectively of minimal order five and six, corresponding to $\Phi_{H}^{(3)}$ and $\Phi_{H}^{(4)}$. These linear ODE's are given in Appendix B.

For $\Phi_{H}^{(n)}(n \geq 5)$, the calculations, in order to get the linear ODEs become really hug $\ddagger$. For this reason, we introduce a modular strategy which amounts to generating large series modulo a prime and then deducing the ODE modulo that prime. Note that the ODE of minimal order is not necessarily the simplest one as far as the required number of terms in the series expansion to find the linear ODE is concerned. We have already encountered such a situation [8, 11]. For $\Phi_{H}^{(5)}\left(\operatorname{resp} . \Phi_{H}^{(6)}\right)$, the linear ODE

[^0]of minimal order is of order 17 (resp. 27) and needs 8471 (resp. 9272) terms in the series expansion to be found.

Actually, for $\Phi_{H}^{(5)}$ (resp. $\Phi_{H}^{(6)}$ ), we have found the corresponding linear ODEs of order 28 (resp. 42) with only 2208 (resp. 1838) terms from which we have deduced the minimal ones.

The form of these two minimal order linear ODEs obtained modulo primes is sketched in Appendix B. In particular, the singularities (given by the roots of the head polynomial in front of the highest order derivative), are given with the corresponding multiplicity in Appendix B. Some details about the ODE search are also given in Appendix B.

We have also obtained very long series ( 20000 coefficients) modulo primes for $\Phi_{H}^{(7)}$, but, unfortunately, this has not been sufficient to identify the linear ODE (mod. prime) up to order 100.

The singularities of the linear ODE for the first $\Phi_{H}^{(n)}$ are respectively zeros of the following polynomials (besides $w=\infty$ ):

$$
\begin{array}{ll}
n=3, & w \cdot\left(1-16 w^{2}\right)(1-w)(1+2 w)\left(1+3 w+4 w^{2}\right), \\
n=4, & w \cdot\left(1-16 w^{2}\right)\left(1-4 w^{2}\right), \\
n=5, & w \cdot\left(1-16 w^{2}\right)\left(1-w^{2}\right)(1+2 w)\left(1+3 w+4 w^{2}\right) \\
& \left(1-3 w+w^{2}\right)\left(1+2 w-4 w^{2}\right)\left(1+4 w+8 w^{2}\right) \\
& \left(1-7 w+5 w^{2}-4 w^{3}\right)\left(1-w-3 w^{2}+4 w^{3}\right) \\
& \left(1+8 w+20 w^{2}+15 w^{3}+4 w^{4}\right), \\
n=6, & w \cdot\left(1-16 w^{2}\right)\left(1-4 w^{2}\right)\left(1-w^{2}\right)\left(1-25 w^{2}\right) \\
& \left(1-9 w^{2}\right)\left(1+3 w+4 w^{2}\right)\left(1-3 w+4 w^{2}\right) \\
& \left(1-10 w^{2}+29 w^{4}\right) . \tag{13}
\end{array}
$$

For $n=7$ and $n=8$, besides modulo primes series calculations described above, we also generated very large series from which we obtained in floating point form, the polynomials given in Appendix C (using generalised differential Padé methods).

If we compare the singularities for $\Phi_{H}^{(n)}$ to those obtained with the "Diagonal mode $\mathbb{H}$ ' presented in [7], i.e. $\Phi_{D}^{(n)}$, one sees that the singularities of the linear ODE for the "Diagonal model" are identical to those of the linear ODE of the $\Phi_{H}^{(n)}$ for $n=3,4$ (and are a proper subset to those of $\Phi_{H}^{(n)}$ for $n=5,6$ ). The additional singularities for $n=5,6$ are zeros of the polynomials:

$$
\begin{aligned}
& n=5, \quad\left(1+3 w+4 w^{2}\right)\left(1+4 w+8 w^{2}\right) \\
& \\
& \quad \times\left(1-7 w+5 w^{2}-4 w^{3}\right) \\
& n=6, \quad\left(1+3 w+4 w^{2}\right)\left(1-3 w+4 w^{2}\right)\left(1-25 w^{2}\right) .
\end{aligned}
$$

For $n=7$, the zeros of the following polynomials (among others) are singularities which are not of Nickel's type (1) and do not occur for $\Phi_{D}^{(n)}$ :

$$
\begin{aligned}
& 1+8 w+15 w^{2}-21 w^{3}-60 w^{4}+16 w^{5}+96 w^{6}+64 w^{7} \\
& 1-4 w-16 w^{2}-48 w^{3}+32 w^{4}-128 w^{5}
\end{aligned}
$$

$\sharp$ Not to be confused with the "diagonal susceptibility" and the corresponding [11 $n$-fold integrals $\chi_{d}^{(n)}$.

The linear ODEs of the multiple integrals $\Phi_{H}^{(n)}$ thus display additional singularities for $n=5,6$ and $n=7(n=8$ see below) compared to the linear ODE of the single integrals $\Phi_{D}^{(n)}$.

We found it remarkable that the linear ODEs for the integrals $\Phi_{D}^{(n)}$ display all the Nickelian singularities, as well as the new quadratic numbers $1+3 w+4 w^{2}=0$ found for $\chi^{(3)}$. It is thus interesting to see how the singularities for $\Phi_{D}^{(n)}$ are included in the singularities for $\Phi_{H}^{(n)}$ and whether the new (with respect to $\Phi_{D}^{(n)}$ ) singularities can be given by one-dimensional integrals similar to $\Phi_{D}^{(n)}$. Let us mention that the singularities of the linear ODE for $\Phi_{H}^{(3)}$ (respectively $\Phi_{H}^{(4)}$ ) are remarkably also singularities of the linear ODE for $\Phi_{H}^{(5)}$ (respectively $\Phi_{H}^{(6)}$ ). In the following, we will show how this comes about and how it generalizes. For this, we solve in the sequel the Landau conditions for the $n$-fold integrals (8).

### 2.1. Landau conditions for the $\Phi_{H}^{(n)}$

We remind the reader that the Landau conditions [7] are necessary conditions for singularities to be the singularities of the integral representation itself. In a previous paper [7], we have shown for particular integral representations belonging to the Ising class integrals [14, that in fact the solutions of Landau conditions identify for specificid configurations (see below) with the singularities of the ODE associated with the quantity under consideration.

The Landau conditions [7] amount to carrying out algebraic calculations [7] on the integrand (8) to get singularities of these $n$-fold integrals or even, as we will see in the sequel, singularities of the corresponding linear ODE [7].

In the sequel we use the following integral representation [1, 2]:

$$
\begin{equation*}
y_{j} x_{j}^{n}=\int_{0}^{2 \pi} \frac{d \psi_{j}}{2 \pi} \cdot \frac{\exp \left(i n \psi_{j}\right)}{1-2 w \cdot\left(\cos \left(\phi_{j}\right)+\cos \left(\psi_{j}\right)\right)} \tag{14}
\end{equation*}
$$

Defining

$$
\begin{equation*}
D\left(\phi_{j}, \psi_{j}\right)=1-2 w \cdot\left(\cos \left(\phi_{j}\right)+\cos \left(\psi_{j}\right)\right) \tag{15}
\end{equation*}
$$

the integral $\Phi_{H}^{(n)}$ (see its expansion (A.1) in Appendix A), becomes

$$
\begin{align*}
\Phi_{H}^{(n)}= & \frac{1}{n!} \cdot \int_{0}^{2 \pi} \prod_{j=1}^{n} \frac{d \phi_{j}}{2 \pi} \frac{d \psi_{j}}{2 \pi}  \tag{16}\\
& \times D^{-1}\left(\phi_{j}, \psi_{j}\right) \cdot \delta\left(\sum_{j=1}^{n} \phi_{j}\right) \delta\left(\sum_{j=1}^{n} \psi_{j}\right)
\end{align*}
$$

where the Dirac delta's are introduced to take care of the conditions

$$
\begin{equation*}
\sum_{j=1}^{n} \phi_{j}=0, \quad \sum_{j=1}^{n} \psi_{j}=0 \quad \bmod .2 \pi \tag{17}
\end{equation*}
$$

on both the angles $\phi_{j}$ and the auxillary angles $\psi_{j}$.
II In that respect one must recall the notion of leading singularities in contrast with the subleading singularities (see page 54 in 16.)

The Landau conditions [16, 17] can easily be written [7]:

$$
\begin{array}{ll}
\alpha_{j} \cdot D\left(\phi_{j}, \psi_{j}\right)=0, & j=1, \cdots, n, \\
\beta_{j} \cdot \phi_{j}=0, & j=1, \cdots, n-1, \\
\alpha_{j} \cdot \sin \left(\phi_{j}\right)-\alpha_{n} \cdot \sin \left(\phi_{n}\right)+\beta_{j}=0, & j=1, \cdots n-1, \\
\alpha_{j} \cdot \sin \left(\psi_{j}\right)-\alpha_{n} \cdot \sin \left(\psi_{n}\right)+\gamma_{j}=0, & j=1, \cdots, n-1 \tag{21}
\end{array}
$$

together with (17). The Landau singularities are obtained by solving these equations in all the unknowns, where the parameters $\alpha_{j}, \beta_{j}, \gamma_{j}$ should not be all equal to zero.

In this paper, our aim is not to find all the solutions of the above equations but to show that the singularities of the linear ODE for the $\Phi_{H}^{(n)}$ are solutions of the Landau conditions. Furthermore, in working out various Ising class integrals [14] and the two models of [7] (see Appendix D), we remarked that the singularities of the linear ODE are, in fact, included in a particular "configuration". What we mean by "configuration" is the set of values (equal to zero or not) of the parameters $\alpha_{j}, \beta_{j}, \gamma_{j}$.

The "configuration" we consider

$$
\begin{equation*}
\alpha_{j} \neq 0, \quad \beta_{j}=\gamma_{j}=0 \tag{22}
\end{equation*}
$$

corresponds to pinch singularities on the manifolds $D\left(\phi_{j}, \psi_{j}\right)=0$. One may also be convinced to take $\beta_{j}=\gamma_{j}=0$, since the integrand is periodidt in $\phi_{j}$ and $\psi_{j}$.

Let us stress that the the configuration considered where all the Lagrange multipliers of the singularity manifolds $D(\phi, \psi)$ are different from zero ( $\alpha_{j} \neq 0$, for any $j$ ) leads to the so-called leading Landau singularities following the terminology of page 54 of 16.

The Landau conditions become:

$$
\begin{array}{lc}
1-2 w \cdot\left(\cos \left(\phi_{j}\right)+\cos \left(\psi_{j}\right)\right)=0, & j=1, \cdots, n, \\
\alpha_{j} \sin \left(\phi_{j}\right)-\alpha_{n} \sin \left(\phi_{n}\right)=0, & j=1, \cdots, n-1, \\
\alpha_{j} \sin \left(\psi_{j}\right)-\alpha_{n} \sin \left(\psi_{n}\right)=0, & j=1, \cdots, n-1 \tag{25}
\end{array}
$$

and:

$$
\begin{equation*}
\sum_{j=1}^{n} \phi_{j}=0, \quad \sum_{j=1}^{n} \psi_{j}=0 \quad \bmod .2 \pi \tag{26}
\end{equation*}
$$

The Landau singularities are solutions of these conditions (see Appendix E for details). Note that the first three conditions (23), (24), (25) are invariant by the transformation:

$$
\begin{equation*}
w \longrightarrow-w, \quad \phi_{j} \longrightarrow \phi_{j}+\pi, \quad \psi_{j} \longrightarrow \psi_{j}+\pi . \tag{27}
\end{equation*}
$$

but the Landau conditions (23), (24), (25) together with (26) are invariant by transformation (27) if and only if $n$ is even. This distinction between even and odd integer $n$ (corresponding to the symmetry breaking of $w \leftrightarrow-w$ ) is reminiscent of the distinction between even and odd integer $n$ for the $\chi^{(n)}$ associated with the distinction between low and high temperature regimes.

The Landau conditions yield two families of singularities expressed in terms of Chebyshev polynomials of the first and second kind. The first family reads:

$$
\begin{array}{lr}
T_{2 p_{1}}(1 / 2 w+1)= & T_{n-2 p_{1}-2 p_{2}}(1 / 2 w-1)  \tag{28}\\
0 \leq p_{1} \leq[n / 2], & 0 \leq p_{2} \leq[n / 2]-p_{1}
\end{array}
$$

$\sharp$ Note that conditions (19), $\beta_{j} \cdot \phi_{j}=0, \gamma_{j} \cdot \psi_{j}=0, j=1, \cdots, n-1$ have to be considered in the general Landau conditions. They do not occur if one restricts oneself to pinch singularities.
$\dagger$ B. Nickel, private communication.

The second family is given by the elimination of $z$ from:

$$
\begin{align*}
& T_{n_{1}}(z)-T_{n_{2}}\left(\frac{4 w-z}{1-4 w z}\right)=0  \tag{29}\\
& T_{n_{1}}\left(\frac{1}{2 w}-z\right)-T_{n_{2}}\left(\frac{1}{2 w}-\frac{4 w-z}{1-4 w z}\right)=0 \\
& U_{n_{2}-1}(z) \cdot U_{n_{1}-1}\left(\frac{1}{2 w}-\frac{4 w-z}{1-4 w z}\right) \\
& \quad-U_{n_{2}-1}\left(\frac{1}{2 w}-z\right) \cdot U_{n_{1}-1}\left(\frac{4 w-z}{1-4 w z}\right)=0
\end{align*}
$$

with

$$
\begin{array}{lr}
n_{1}=p_{1}, & n_{2}=n-p_{1}-2 p_{2} \\
0 \leq p_{1} \leq n, & 0 \leq p_{2} \leq\left[\left(n-p_{1}\right) / 2\right] \tag{31}
\end{array}
$$

One recognizes in the first set of equations (28), a generalization of the singularities given by Nickel [15] for the pinch singularities coming from the product of the $y_{j}$ 's, and also derived for our multiple integral denoted $Y^{(n)}$ in [7]. These have been written as [7, 15]:

$$
\begin{equation*}
T_{k}(1 / 2 w+1)=T_{n-k}(1 / 2 w-1) \tag{32}
\end{equation*}
$$

Note that, comparatively to (28), the integer $k$ should be event.
The second set of equations (29) is a generalization of the singularities we derived for $\Phi_{D}^{(n)}$ in [7]. In both formulae, one notes the occurrence of a second varying integer $p_{2}$, leading to a better understanding of the singularities of these integrals. Indeed with $p_{2}$ running, the linear ODE for $\Phi_{H}^{(n)}$ will automatically contain all the singularities of the linear ODEs for $\Phi_{H}^{(n-2)}, \Phi_{H}^{(n-4)}, \cdots, \Phi_{H}^{(n-2 q)}$.

For $n=7$, we have checked that the singularities specific to $n=7\left(p_{2}=0\right.$ in (28), (291) also appear as singularities of the linear ODE in floating point form (see Appendix D for details). For $p_{2}=1$, part of the singularities appear in floating point form, while for $p_{2}=2$ (i.e. singularities of $\left.\Phi_{H}^{(3)}\right)$, no singularities appear in floating point form. Similarly, for $n=8$, we have checked that the singularities specific to $n=8\left(p_{2}=0\right.$ in (28), (29)) also appear as singularities of the linear ODE in floating point form (see Appendix D for details). For $p_{2} \geq 1$, no singularities appear in floating point form.

Let us remark that the non observation of some singularities in floating point form is not really significant. Indeed, we have used 1250 (resp. 1200 terms) for $\Phi_{H}^{(7)}$ (resp. $\Phi_{H}^{(8)}$ ) while the $\Phi_{H}^{(7)}$ and $\Phi_{H}^{(8)}$ linear ODEs need more than 20000 terms.

Figure 1 shows the first family of singularities (28) displayed in the complex $s$ plane close enough to the unit $s$-circle. This figure clearly shows a quite rich structure for these set of points. This figure looks like a network of nodal points linked together by (cardioid-like) curves that can, at first sight, hardly be distinguished from arcs of circles. In particular the selected points $1+3 w+4 w^{2}=0$ as well as the singularities for $\Phi^{(5)}$, like $1+8 w+20 w^{2}+15 w^{3}+4 w^{4}=0$ can be seen to occur quite clearly as some of these nodal points.

[^1]

Figure 1. First family of singularities (28) in the complex $s$ plane $(n \leq 51)$.

Figure 2. First family of singularities (28) in the complex $s$ plane far from the unit circle $(n \leq 51)$.

Figure 3. First and second family of singularities (28), (29) in the complex $s$ plane ( $n \leq 16$ ).

Figure 4. First and second family of singularities (28), (29) in the complex $s$ plane far from the unit circle $(n \leq 16)$.

Figure 2 shows the first family of singularities (28) far from the unit circle. Figure 3 shows all the singularities altogether (first and second family) close to the unit $s$ circle. Finally figure 4 shows all the singularities together $(\sqrt{28}),(\sqrt{29})$ ) that are not so close to the unit $s$-circle.

The accumulation of singularities one can see on figure near $s=i$ and $s=-i$ seem to confirm the statement made in Orrick et al [18] that these two points are two quite unpleasant points for the susceptibility of the Ising model for which the series expansions are not even asymptotically convergent.

Besides reproducing exactly the singularities of the linear ODE for $\Phi_{H}^{(n)}$, it is remarkable to see from the formula (28), (29), how to track where each singularitypolynomial comes from. This allows one to understand how the singularities of the Ising like integrals $Y^{(n)}$ and $\Phi_{D}^{(n)}$ (see [7]) and even the Nickelian singularities (1) emerge in these multiple integrals (8). This comes simply from the partition (30) and the equivalent one in (28).

### 2.2. Singularities: from $n$-fold integrals to one dimensional integrals

Consider for instance the singularities $1-7 w+5 w^{2}-4 w^{3}=0$ occurring in $\Phi_{H}^{(5)}$, which are given by (28) for $n=5, p_{1}=1$ and $p_{2}=0$. As far as conditions on the integration angles (see (33) below), this arises from a situation where two angles are equal and the three others are equal. Recall that the $\Phi_{D}^{(n)}$ integrals are constructed with the following restrictions on the angles:

$$
\begin{equation*}
\phi_{1}=\phi_{2}=\cdots=\phi, \quad \phi_{n}=-(n-1) \phi \tag{33}
\end{equation*}
$$

One sees that a generalization of this model (33) is simply:

$$
\begin{align*}
& \phi_{1}=\phi_{2}=\cdots=\phi_{k}, \\
& \phi_{k+1}=\phi_{k+2}=\cdots=\phi_{n}, \quad k=0,1, \cdots,[n / 2] \tag{34}
\end{align*}
$$

By the condition on the angles, this case is indeed one dimensional, with:

$$
\begin{equation*}
\phi_{n}=-\frac{(n-k)}{k} \cdot \phi+\frac{2 j \pi}{k}, \quad j \text { integer } \tag{35}
\end{equation*}
$$

The model (33) is obviously given by (34) for $k=1$. The Nickelian singularities are also given by (34) for $k=0$, but this time, the underlying model is "zerodimensional". The model constructed along the same lines as in [7 corresponds to an integrand:

$$
\begin{equation*}
\sum_{j=0}^{n-1} \frac{1}{1-x^{n}\left(\frac{2 \pi j}{n}\right)} \tag{36}
\end{equation*}
$$

The Nickelian singularities arise as poles.
For $k \geq 2$, the singularities given by the model (34), which appear in (8), are thus given neither by (11) nor by $\Phi_{D}^{(n)}$. Consider one variable of integration such as (7), where the integrand is:

$$
\begin{equation*}
\frac{1}{1-x^{n-1}(\phi) \cdot x((n-1) \phi)} \quad \longrightarrow \quad \frac{1}{1-x^{n-k}(\phi) \cdot x^{k}\left(\phi_{n}\right)} . \tag{37}
\end{equation*}
$$

and denote by $\Phi_{k}^{(n)}$ such integrals (one then has $\Phi_{1}^{(n)}=\Phi_{D}^{(n)}$ ).

Fix $n=5$ and $k=2$. The constraint (35) on the angles reads:

$$
\begin{equation*}
\phi_{5}=-\frac{3}{2} \phi_{1}+j \pi, \quad j \text { integer } \tag{38}
\end{equation*}
$$

with one integration variable. The series of coefficients of $\Phi_{2}^{(5)}$ is generated along the same lines as for $\Phi_{D}^{(n)}$ (see Appendix A). The Fuchsian linear differential equation is of order six and this order is independent of the value of $j$ in (38). The singularities of the linear ODE are zeros of the following polynomials:

$$
\begin{gather*}
w \cdot\left(1-16 w^{2}\right)(1+w)\left(1-3 w+w^{2}\right)\left(1+2 w-4 w^{2}\right) \\
\times\left(1+4 w+8 w^{2}\right)\left(1-7 w+5 w^{2}-4 w^{3}\right) \tag{39}
\end{gather*}
$$

We obtain singularities (from the last two polynomials) appearing for $\Phi_{H}^{(5)}$ and not occurring for $\Phi_{D}^{(5)}$.

The occurrence of the singularities $1+3 w+4 w^{2}=0$ for (the linear ODE of) $\Phi_{H}^{(5)}$ but not for (the linear ODE of) $\Phi_{D}^{(5)}$ is explained along similar lines. Note that these singularities are common to (the linear ODE of) $\Phi_{H}^{(3)}, \Phi_{H}^{(5)}$ and $\Phi_{H}^{(6)}$. The polynomial $1+3 w+4 w^{2}$ appears for (the linear ODE of) $\Phi_{H}^{(5)}$ from (28), namely:

$$
\begin{equation*}
T_{2 p_{1}}(1 / 2 w+1)=T_{n-2 p_{2}-2 p_{1}}(1 / 2 w-1) \tag{40}
\end{equation*}
$$

One sees that the polynomial $1+3 w+4 w^{2}$ will appear for all combinations of $n, p_{1}$ and $p_{2}$ such that:

$$
\begin{equation*}
2 p_{1}=2, \quad n-2 p_{2}-2 p_{1}=1 \tag{41}
\end{equation*}
$$

In other words, the polynomial that arises for given $n$ and $p_{1}$, will also appear for the same value of $p_{1}$ and for $n-2 p_{2}$. The singularities corresponding to $1+3 w+4 w^{2}=0$ occur for $\Phi_{H}^{(5)}$ with $n=5, p_{1}=1$ and $p_{2}=1$, but (41) is also satisfied for $n=3$, $p_{1}=1$ and $p_{2}=0$ which shows a situation with three angles, with two of them equal. This is precisely the integrand in (7), i.e. in $\Phi_{D}^{(3)}$.

Consider now the case $n=6$ and $k=2$. This amounts to considering the $n$-fold integral $\Phi_{2}^{(6)}$ with:

$$
\begin{equation*}
\phi_{6}=-2 \phi_{1}+j \pi, \quad j \text { integer. } \tag{42}
\end{equation*}
$$

The results are dependent on the integer $j$. For instance, the series around $w=0$ reads:

$$
\begin{align*}
& \Phi_{2}^{(6)}=1+w^{6}+32 w^{8} \pm w^{9}+659 w^{10}  \tag{43}\\
& \pm 1296 w^{11}+11691 w^{12}+\cdots
\end{align*}
$$

With the + sign in the series (43), the linear differential equation is of order five and the singularities are given by the zeros of the polynomials:

$$
\begin{align*}
w \cdot\left(1-16 w^{2}\right) & (1-w)(1+2 w)\left(1-9 w^{2}\right) \\
& \times\left(1-25 w^{2}\right)\left(1+3 w+4 w^{2}\right) \tag{44}
\end{align*}
$$

The results corresponding to the choice of a minus sign in the series (43) are obviously obtained by $w \rightarrow-w$. We obtain the singularities $1-25 w^{2}$ and $1 \pm 3 w+4 w^{2}=0$ occurring for (the linear ODE of) $\Phi_{H}^{(6)}$ but not for (the linear ODE of) $\Phi_{D}^{(6)}$.

Similarly, for $n=7$, ( $k$ goes to 3 ), one obtains for $k=2$, the singularities as zeros of the following polynomial $1+8 w+15 w^{2}-21 w^{3}-60 w^{4}+16 w^{5}+96 w^{6}+64 w^{7}$, $\S$ The last case for $n=6$, i.e. $k=3$ does not provide singularities other than Nickel's.
which has indeed been found numerically in the linear ODE search on a large series corresponding to $\Phi_{H}^{(7)}$ (see Appendix C).

We have the remarkable fact that the singularities of the linear ODE for the multiple integral $\Phi_{H}^{(n)}$ are given by a finite set of singularities of linear ODEs of a set of one-dimensional integrals, namely, $N(N+1) / 2$ one-dimensional integrals, with $N=[n / 2]$. For instance, the singularities of the four-dimensional integral $\Phi_{H}^{(5)}$ identify with those of, at most, three one-dimensional integrals. This appears, simply, from the couple of integers in (28) which read $\left(2 p_{1}, n-2 p_{2}-2 p_{1}\right)$. For fixed $n$, when $p_{2}$ varies, one sees that we are in fact considering all the lower integer values $n-2 p_{2}$. The same situation holds for (29). This identification leads, obviously, to particular structures in the singularities for different $n$. This is what we show in the sequel.

### 2.3. Singularity structures of $n$-fold integrals and particular sets of one-dimensional integrals

The Landau singularities given in Appendix E are checked against the singularities of the linear ODE for $\Phi_{H}^{(n)}(n=3, \cdots, 6)$, and are found to be identical. Assume that these formulae do indeed reproduce all the singularities of the linear ODE for $\Phi_{H}^{(n)}$, for any $n$. In this case, we can check whether the singularities appearing at $n=m$ also occur for $n=m+1, n=m+2, \cdots$

We have found that the singularities at order $2 n$ will also be singularities at order $2 n+2 p$, where $p$ is a positive integer. Similarly, the singularities at order $2 n+1$ will also be present at the following odd orders.

What is remarkable is the fact that the singularities at odd order also appear at even orders. The rule is: all the singularities at odd order $n$ also appear in the higher orders (odd and even) except for the first $(n-1) / 2$ even orders. For instance, the singularities appearing at $n=3$ will occur for all $n$, except the first even order, i.e. 4. The singularities appearing at $n=5$ will occur for all $n$, except the first two even orders, i.e. 6 and 8 .

The consequence of this embedding of the singularities is the occurrence of some singularities at predefined orders. The singularity $1+2 w=0$ is present at any order $n$. The singularity $1-2 w=0$ is present for any even order $2 n$. The singularity $1+w=0$ occurs at any order $n \geq 5$. The singularity $1-w=0$ occurs at any order $n$, except for $n=4$. All these singularities are Nickelian. The first non Nickelian singularity $1+3 w+4 w^{2}=0$ appears at all orders $n$, except for $n=4$.

Moreover, we have given in [7] the Landau singularities for the (linear ODEs of the) integrals $\Phi_{D}^{(n)}$. These singularities have been found to be identical with the singularities of the linear ODE for $\Phi_{D}^{(n)}$ obtained exactly up to $n=8$ and modulo a prime up to $n=14$. We have seen that all the singularities of the linear ODE of $\Phi_{D}^{(n)}$ in the variable $s$ lie in the annulus defined by two concentric circles of radius $\sqrt{2}$ and $1 / \sqrt{2}$. The radii of the two concentric circles are the roots, in the variable $s$, of the polynomial $1+3 w+4 w^{2}=0$, that is $s^{2}+s+2=0$ and $1+s+2 s^{2}=0$. With the multiple integrals $\Phi_{H}^{(n)}$, one sees that some of the singularities are not confined to this annulus anymore.

Thanks to the Landau conditions, one can now understand this structure from the reduction of the multiple integrals $\Phi_{H}^{(n)}$ to a set of one-dimensional integrals $\Phi_{k}^{(n)}$ as far as the location of singularities is concerned. For $k=0$, which corresponds to the

Nickelian singularities, the "annulus" is the unit circle. For $k=1$ corresponding to the integrals $\Phi_{D}^{(n)}$, one has the annulus of radii $\sqrt{2}$ and its inverse. For each $k$, one expects the singularities to lie in an annulus with a concentric structure. For these annuli the larger radius increases (smaller radius decreases) as $k$ increases. From the reduction of the singularities of $\Phi_{H}^{(n)}$ to these $\Phi_{k}^{(n)}$, all the singularities for fixed $p_{1}=k$ in (28) and for fixed $p_{1}=k$ in (29) will be confined to one annulus. For instance for $k=2$, all the singularities occurring in the linear $\operatorname{ODE}$ for $\Phi_{k}^{(n)}$, (i.e. for all $n$ ), or, equivalently, all the singularities obtained by (28) for $p_{1}=1$ and by (29) for $p_{1}=2$ will be confined to the annulus of radii $2.79 \cdots$ and its inverse. This value is the root, in the variable $s$, of $1-7 w+5 w^{2}-4 w^{3}=0$ occurring for $\Phi_{H}^{(5)}$. For $k=3$, one remarks that the annulus will not be obtained from (28) which is restricted by $2 p_{1}$, an even integer. In fact this is general. The radii of the annuli are given by (28) for $k$ even and by (29) for $k$ odd. The root in the variable $s$ that will define the annulus occurs at odd order $n$ given by $2 k+1$.

The picture now, is as follows. The singularities of the linear ODE for the integrals $\Phi_{H}^{(n)}$ are partionned into "families" indexed by the integer $k$. The singularities for $k=0$ are Nickelian and lie on the unit circle, say, $r_{0}=1$. The singularities for $k=1$ lie in the annulus $r_{1}=\sqrt{2}, 1 / \sqrt{2}$ (we discard from now on, the smaller radius). The singularities for $k=2$ will be confined in the annulus $r_{2}$. The singularities for $k=N$ will be in the annulus $r_{N}$. These concentric annuli are such that $r_{0}<r_{2}<\cdots<r_{2 N}$ and $r_{1}<r_{3}<\cdots<r_{2 N+1}$, (with $r_{2 k}<r_{2 k+1}$ ). As $k$ grows, the radii of two neighboring circles behave as $r_{2 k+2}-r_{2 k} \rightarrow 0$ and $r_{2 k+3}-r_{2 k+1} \rightarrow 0$. This decrease is not enough to create an accumulation of circles. We checked with $k=300$ circles that the decrease goes as $k^{-\alpha}$ with $\alpha<1$ preventing any convergence. For $n$ large these radii diverge: $r_{N} \rightarrow \infty$ when $N \rightarrow \infty$.

Note that these families, (i.e. the index $k$ ) come from the resolution of the Landau conditions and from the reduction of the singularities for $\Phi_{H}^{(n)}$ to the ones of $\Phi_{k}^{(n)}$, ( $k=0,1, \cdots[n / 2]$ ). We have no idea as to how these families can be seen directly from the mutiple integrals $\Phi_{H}^{(n)}$. If the singularities for $\Phi_{H}^{(n)}$ happen to be identical with those occurring in the linear ODE for $\chi^{(n)}$, it may become important to see whether this picture persists and whether this picture is showing another partition of the susceptibility $\chi$ instead of the known sum on $\chi^{(n)}$.

Figure 5, 6 and 7 show how the first family of singularities (28) in the $s$ complex plane is decomposed according to the integer $k$ in (34). Figure 5 shows singularities (28) for a given odd value of $k$, namely $k=5$ for any odd values of $n$ up to 91. Figure 6 shows singularities (28) for a given even value of $k$, namely $k=2$ for any odd values of $n$ up to 71. Figure 7 shows singularities (28) for a given even value of $k$, namely $k=6$ for any even values of $n$ up to 80 . The figures corresponding to the filtration of the singularities of the first family (28) in terms of the integer $k$ (previously displayed altogether with figures 1 and 2) deserve some comments. First, one sees that the various "crescent" corresponding to different values of $k$ are very similar. Secondly one sees from figure 5 that the odd $n$, odd $k$ "crescent" break the $s \leftrightarrow-s$ symmetry (for even $n$, even $k$, the equations for the set of singularities are functions of $s^{2}$, see figure (7) in a quite dramatic way: the singularities in the "crescent" of figure 5 all lie only in the left half $s$-complex plane. Similarly the singularities in the "crescent" of figure 6 all lie in the right half $s$-complex plane.

Along this $s \leftrightarrow-s$ symmetry line it is worth recalling that the low-temperature

Figure 5. Crescent in the complex $s$ plane given by (28): $k=5, n \leq 91, n$ odd.

Figure 6. Crescent in the complex $s$ plane given by (28): $k=2, n \leq 71, n$ odd.

Figure 7. Crescent in the complex $s$ plane given by (28): $k=6, n \leq 80, n$ even.
susceptibility of the Ising model has this $s \leftrightarrow-s$ symmetry (the low-temperature susceptibility is a function of $s^{2}$ or $w^{2}$ ) but the high-temperature susceptibility breaks that $s \leftrightarrow-s$ symmetry, and this is also the case for the $n$-fold integral $\chi^{(n)}$ with $n$ odd. Our $n$-fold integrals (8) are introduced to provide an educated guess as to the location of the singularities of the $\chi^{(n)}$. As far as location of singularities of the $\chi^{(n)}$ are concerned, it is not totally clear for $n$ odd if the $s \leftrightarrow-s$ (resp. $w \leftrightarrow-w$ ) symmetry will not be partially restored on the global set of singularities with the occurence for a singularity $P_{n}(w)=0$ for a given value of $n$, of the opposite value for, perhaps, a different value of $n: P_{m}(-w)=0$.

Remark: Quite often, in this paper, we use (by abuse of language) the words "singularities of an $n$-fold integral" to describe a larger set of singularities, namely the singularities of the linear ODEs that the $n$-fold integral satisfies. A rigorous study would require, for any "singularity", to perform the (differential Galois group and connection matrix) analysis we have performed in 6]. It amounts to getting extremely large series, deduced from the obtained linear ODE, that coincide with the series expansion of the $n$-fold integral we are interested in, and find out if these series actually exhibit these singularities. With this tedious, but straightforward, procedure we can extract the singularities of a specific $n$-fold integral among the larger set of singularities of the corresponding linear differential equation. In view of the large number of singularities we display in this paper, we have not performed such a systematic analysis, that would have been quite huge. Furthermore it is important to note that this "connection matrix" approach [6] requires to have the linear ODE of the $n$-fold integral. A knowledge of the linear ODE modulo a prime is not sufficient. We could have performed this analysis for $\Phi_{H}^{(3)}$ and $\Phi_{H}^{(4)}$, but, in that case, we already
have a deeper result [6] namely the connection matrix analysis for $\chi^{(3)}$ and $\chi^{(4)}$, providing an understanding of the singularities of these $n$-fold integrals themselves (in $w$ and also in $s$ ).

Right now, the only singularities found for the $\chi^{(n)}$, other than Nickelian, are the quadratic roots of $1+3 w+4 w^{2}=0$, (i.e. the first annulus) which appear at all orders (except $n=4$ for $\Phi_{H}^{(n)}$ ). Let us show, in the sequel, how this polynomial can be "special".

## 3. Towards a mathematical interpretation of the singularities

In a set of papers [19, 20, we have underlined the central role played by the elliptic parametrization of the Ising model, in particular the role played by the second order linear differential operators corresponding to the complete elliptic integral $E$ (or $K$ ), and the occurrence of an infinite number of modular curves [12], canonically associated with elliptic curves. The deep link between the theory of elliptic curves and the theory of modular forms is now well established [21].

Consequently, it may be interesting to seek "special values" of the modulus $k$, (singularities of the $\chi^{(n)}$ ) that might have a "physical meaning", as well as a "mathematical interpretation".

For that purpose, recall that the modular group requires one to introduce the elliptic nome, defined in terms of the periods of the elliptic functions,

$$
\begin{equation*}
q=\exp \left(-\pi \frac{K\left(1-k^{2}\right)}{K\left(k^{2}\right)}\right)=\exp (i \pi \tau) \tag{45}
\end{equation*}
$$

and the half period ratid $\tau$. We write the complete elliptic integral $K$ as

$$
\begin{equation*}
K(k)={ }_{2} F_{1}(1 / 2,1 / 2 ; 1 ; k) \tag{46}
\end{equation*}
$$

Relations between $K(k)$ evaluated at two different moduli can be found in, e.g. 22.

### 3.1. Some isogenies of elliptic curves seen as generators of the renormalization group

The arguments in $K$ in these identities are related by the so-called, respectively, descending Landen and ascending Landen (or Gauss) transformations:

$$
\begin{align*}
& k \quad \longrightarrow \quad k_{-1}=\frac{1-\sqrt{1-k^{2}}}{1+\sqrt{1-k^{2}}}  \tag{47}\\
& k \quad \longrightarrow \quad k_{1}=\frac{2 \sqrt{k}}{1+k} \tag{48}
\end{align*}
$$

These transformations (or correspondences [23, 24]), decrease or increase the modulus respectively. Iterating (47) or (48), one converges to $k=0$ or $k=1$ respectively. The half period ratio transforms through (47), (48), as

$$
\begin{equation*}
\tau \rightarrow 2 \tau, \quad \quad \tau \rightarrow \frac{1}{2} \tau \tag{49}
\end{equation*}
$$

respectively. The real fixed points of the transformations (47) and (48) are $k=0$ (the trivial infinite or zero temperature points) and $k=1$ (the ferromagnetic and

ब In the theory of modular forms $q^{2}$ is also sometimes used instead of $q$. In number theory literature the half-period ratio is taken as $-i \tau$.
antiferromagnetic critical point of the square Ising model). In terms of the half period ratio, this reads $\tau=\infty$ and $\tau=0$ respectively, which correspond to a degeneration of the elliptic parametrization into a rational parametrization. In view of these fixed points, it is natural to identify the transformations (47) or (48), and more generally any transformation $\tau \rightarrow n \cdot \tau$ or $\tau \rightarrow \tau / n$ ( $n$ integer), as exact generators of the renormalization group of the two-dimensional Ising mode $\ddagger$.

One does not need to restrict the analysis to the real fixed points of the transformations. If one considers the Landen transformation (48) as an algebraic transformation of the complex variable $k$ and if one solves $k_{1}^{2}-k^{2}=0$, one obtains:

$$
\begin{equation*}
k \cdot(1-k) \cdot\left(k^{2}+3 k+4\right)=0 \tag{50}
\end{equation*}
$$

The quadratic roots

$$
\begin{equation*}
k^{2}+3 k+4=0 \tag{51}
\end{equation*}
$$

are (up to a sign) fixed points of (48). We thus see the occurrence of additional non-trivial complex selected values of the modulus $k$, beyond the well-known values $k=1,0, \infty$ (corresponding to degeneration of the elliptic curve into a rational curve). Physically, these well-known values $k=1,0, \infty$ correspond to the critical Ising model $(k=1)$ and to (high-low temperature) trivializations of the model $(k=0, \infty)$.

### 3.2. Complex multiplication for elliptic curves as (complex) fixed points of the renormalization group

We come now to our point. The first "unexpected" singularities $1+3 w+4 w^{2}=0$ found [4, 5] for the Fuchsian linear differential equation of $\chi^{(3)}$, and also in other $n$-fold integrals of the Ising class [7], reads in the variable $k=s^{2}$ as

$$
\begin{equation*}
\left(k^{2}+3 k+4\right)\left(4 k^{2}+3 k+1\right)=0 . \tag{52}
\end{equation*}
$$

The first polynomia $\ddagger$ corresponds to fixed points of the Landen transformation (see (50)). In other words we see that the selected quadratic values $1+3 w+4 w^{2}=0$, occurring in the (high-temperature) susceptibility of the Ising model as singularities of the three-particle term $\chi^{(3)}$, can be seen as fixed points of the renormalization group when extended to complex values of the modulus $k$.

For elliptic curves in fields of characteristic zero, the only well-known selected set of values for $k$ corresponds to the values for which the elliptic curve has complex multiplication [26]. Complex multiplication for elliptic curves corresponds to algebraic integer values (integers in the case of the Heegner numbers, see Appendix F) of the modular $j$-function, which corresponds to Klein's absolute invariant multiplied by $(12)^{3}=1728$ :

$$
\begin{equation*}
j(k)=256 \cdot \frac{\left(1-k^{2}+k^{4}\right)^{3}}{k^{4} \cdot\left(1-k^{2}\right)^{2}} \tag{53}
\end{equation*}
$$

A straightforward calculation of the elliptic nome (45) gives, for the polynomials (52), respectively, an exact value for $\tau$, the half period ratio, as very simple quadratic numbers:

$$
\begin{equation*}
\tau_{1}=\frac{ \pm 3+i \sqrt{7}}{4}, \quad \tau_{2}=\frac{ \pm 1+i \sqrt{7}}{2} \tag{54}
\end{equation*}
$$

§ See relation (1.3) in 25.
$\ddagger$ A similar identification of these isogenies $\tau \rightarrow n \cdot \tau$ with exact generators of the renormalization group can be introduced for any lattice model with an elliptic parametrization (Baxter model, ...). $\ddagger$ Note that the two polynomials in (52) are related by the Kramers-Wannier duality $k \rightarrow 1 / k$.

These quadratic numbers actually correspond to complex multiplication of the elliptic curve and for both one has $j=(-15)^{3}$. These two quadratic numbers are such that $2 \tau_{1} \mp 1=\tau_{2}$. Let us focus on $\tau_{2}$ for which we can write:

$$
\begin{equation*}
\tau=1-\frac{2}{\tau} \tag{55}
\end{equation*}
$$

Taking into account the two modular group involutions $\tau \rightarrow 1-\tau$ and $\tau \rightarrow 1 / \tau$, we find that $1-2 / \tau$ is, up to the modular group, equivalent to $\tau / 2$. The quadratic relation $\tau^{2}-\tau+2=0$ thus amounts to looking at the fixed points of the Landen transformation $\tau \rightarrow 2 \tau$ up to the modular group. This is, in fact a quite general statement. The complex multiplication values can all be seen as fixed points, up to the modular group, of the generalizations of Landen transformation, namely $\tau \rightarrow n \tau$ for $n$ integer, $\tau^{2}-\tau+n=0$ or $\tau=1-\frac{n}{\tau} \simeq n \cdot \tau$, where $\simeq$ denotes the equivalence up to the modular group.

Appendix G presents an alternative view by considering the solutions as fixed points under Landen transformations of the modular $j$-function.

In view of the remarkable mathematical (and physical) interpretation of the quadratic values $1+3 w+4 w^{2}=0$ in terms of complex multiplication for elliptic curves, or fixed points of the renormalization group, it is natural to see if such a "complex multiplication of elliptic curves" interpretation also exists for other singularities of $\chi^{(n)}$, and as a first step, for the singularities of the linear differential equations of our $n$-fold integrals (8), that we expect to be identical, or at least have some overlap, with the singularities of the $\chi^{(n)}$.

Noting that the modular $j$-function is a function of $s^{2}$ or $w^{2}$ (see (F.2) in Appendix F) the occurence of $1+3 w+4 w^{2}=0$ as a selected quadratic polynomial condition means, at the same time, the occurence of the other quadratic polynomial condition $1-3 w+4 w^{2}=0$ (see Appendix F and Appendix G.2).

Besides $1-3 w+4 w^{2}=0$, we have found two other polynomial conditions which correspond to remarkable integer values of the modular $j$-function. The singularities $1-8 w^{2}=0$ correspond to $j=(12)^{3}$ and $\tau= \pm 1+i$ (see Appendix F). They correspond to "Nickelian singularities" for $\chi^{(8)}$ (and thus $\Phi_{H}^{(8)}$ ) and to "non-Nickelian singularities" for $\Phi_{H}^{(10)}$. Another polynomial condition is $1-32 w^{2}=0$, which gives "non-Nickelian singularities" that begin to appear at $n=10$ for $\Phi_{H}^{(10)}$. These singularities correspond to the integer value of the modular $j$-function, $j=(66)^{3}$ and to $\tau=2 i$ or $\tau=-4 / 5+2 i / 5$.

### 3.3. Beyond elliptic curves

Among the singularities of the linear ODE for $\Phi_{H}^{(n)}$ given in (12), (13) or obtained from the formula given in Appendix E up to $n=15$, we have found no other singularity identified with selected algebraic values of the modular $j$-function corresponding to complex multiplication for elliptic curves. Could it be that the (non-Nickelian) singularities (12), (13), which do not match with complex multiplication for elliptic curves, are actually remarkable selected situations for mathematical structures more complex than elliptic curves? With these new singularities, are we possibly exploring some remarkable "selected situations" of some moduli space of curves corresponding to pointed (marked) curves [27, instead of simple elliptic curves [28]? In practice this just corresponds to considering a product of $n$ times a rational, or elliptic, curve
minus some sets of remarkable codimension-one algebraic varieties [11], $x_{i} x_{j}=1$, $x_{i} x_{j} x_{k}=1$, hyperplanes $x_{i}=x_{j}, \cdots$

We try to fully understand the singularities of the $n$-fold integrals corresponding to the $\chi^{(n)}$, that is to say particular $n$-fold integrals linked to the theory of elliptic curves. These $n$-fold integrals are more involved than the (simpler) $n$-fold integrals introduced by Beukers, Vasilyev [29, 30] and Sorokin [31, 32], or the Goncharov-Manin integrals [33] which occur in some moduli space of curves [34, 35] simply corresponding to a product of rational curves $\left(C P_{1} \times C P_{1} \cdots \times C P_{1}\right)$. An example of such integrals, linked to $\zeta(3)$, is displayed in Appendix H.

Let us close this section by noting that Heegner numbers and, more generally, complex multiplication have already occurred in other contexts, even if the statement was not explicit. In the framework of the construction of Liouville field theory, Gervais and Neveu have suggested 41] new classes of critical statistical models, where, besides the well-known $N$-th root of unity situation, they found the following selected values of the multiplicative crossing $t$ [42]:

$$
\begin{align*}
& t=e^{i \pi(1+i \sqrt{3}) / 2}=i \cdot e^{-\pi \sqrt{3} / 2}  \tag{56}\\
& t=e^{i \pi(1+i)}=-e^{-\pi} \tag{57}
\end{align*}
$$

If one wants to see this multiplicative crossing as a modular nome, the two previous situations actually correspond to selected values of the modular $j$-function namely $j((1+i \sqrt{3}) / 2)=(0)^{3}$ for (56), and $j(1+i)=(12)^{3}$ for (57), which actually correspond to Heegner numbers and, more generally, complex multiplication [26]. It is however important not to feed the confusion already too prevalant in the literature, between a "temperature-like" nome such as (45) and a multiplicative crossing modular nome. In the Baxter model [43, 44, the first is denoted by $q$ and the second one by $x$. In fact one probably has, not one, but two modular groups taking place, one acting on the "temperature-like" nome $q$ and the other acting on the multiplicative crossing $x$. We will not go further along this quite speculative line which amounts to introducing elliptic quantum groups [45] and elliptic gamma functiond (generalization of theta functionstil).

## 4. Conclusion

The ultimate goal of our "Ising class" integrals is to get some insight into the $\chi^{(n)}$ and, hopefully, into the susceptibility of the Ising model. For that purpose we have introduced $n$-fold integrals (8) such that we expect the singularities of the corresponding linear ODE to overlap, as much as possible, with the singularities of the linear ODE for the $\chi^{(n)}$. We have obtained the linear differential equations for

[^2]these $n$-fold integrals $\Phi_{H}^{(n)}$, up to $n=4$ and up to $n=6$ modulo a prime. From these exact results together with an exhaustive Landau singularity analysis, we provided a quite complete description of the singularities of these linear ODEs.

From the Landau conditions, the singularity structures are explained. The singularities corresponding to $\Phi_{H}^{(n)}$ are found to also occur at a higher predefined order $p>n$. With these multiple integrals and the associated Landau conditions, we have been able to understand why the simple integrals $\Phi_{D}^{(n)}$ have succeeded reproducing the Nickelian singularities and the new quadratic $1+3 w+4 w^{2}=0$. These simple integrals appear to be "a first approximation" to $\Phi_{H}^{(n)}$. Other one-dimensional integrals pop up to account for the additional singularities not occurring for $\Phi_{D}^{(n)}$.

We have then a remarkable finding that, the singularities for the multiple integrals can be associated with the singularities for a finite number of one dimensional integrals. If the singularities, associated with these $n$-fold integrals (8), happen to be identical with (or to overlap) the singularities associated with the $\chi^{(n)}$, it becomes important to understand this mechanism for the $\chi^{(n)}$ themselves. If this mechanism of singularity embedding occurs for $\chi^{(n)}$, it might be explained by a Russian doll structure for the same linear differential operators. We know that the linear differential operator for $\chi^{(1)}$ (respectively $\chi^{(2)}$ ) is "contained" in (rightdivides) the linear differential operator for $\chi^{(3)}$ (respectively $\chi^{(4)}$ ), and furthermore we even have direct sum decomposition properties. For the $\Phi_{H}^{(n)}$, it is not these mechanisms which are at work.

Our primary goal in this study is to identify as many singularities as possible for the $\chi^{(n)}$. The singularities of the ODEs associated with the $\Phi_{H}^{(n)}$ quantities correspond, in the Landau equations framework, to leading pinch singularities (relatively to the singularities manifolds $D(\phi, \psi)=0$ ). For the other quantities previously studied [7] which belong to the Ising class integrals, the same feature holds.

At this step, the natural questions arising are: whether the scheme, from the Landau singularities point of view, which holds for $\Phi_{H}^{(n)}$, still holds for $\chi^{(n)}$ and whether the singularities of $\Phi_{H}^{(n)}$ can be considered as singularities of the $\chi^{(n)}$ ?

From the Landau singularities viewpoint, the Fermionic determinant $G(n)^{2}$ is going to introduce new manifolds of singularities. When the Lagrange multipliers relative to the singularities manifolds introduced by the Fermionic determinant are all set equal to zero, one deals with the Landau equations of the $\Phi_{H}^{(n)}$ quantities. Thus the singularities obtained for the $\Phi_{H}^{(n)}$ quantities are also solutions of the Landau equations of the $\chi^{(n)}$. However this feature does not mean that the singularities of the $\Phi_{H}^{(n)}$ quantities will necessarly appear as singularities of the $\chi^{(n)}$ ODEs. Indeed some selection rules may take place and may reject some of them. For instance, one expects singularities linked to the $\prod y_{i}$ to occur for the Landau singularities of the $\Phi_{H}^{(n)}$. One finds that some selection rules exclude them. Our "educated guess" is that all the Landau singularities of the $\Phi_{H}^{(n)}$ will be in the Landau singularities of the $\chi^{(n)}$, however we do not exclude the possibility that the $\chi^{(n)}$ will have more Landau singularities than the $\Phi_{H}^{(n)}$. Another "educated guess" is that the Landau singularities of the $\chi^{(n)}$ will exhibit a similar embedding that the one we found for the $\Phi_{H}^{(n)}$. This naturally raises the question already considered in [8], of a "strong" Russian doll structure for the linear differential operators of the $\chi^{(n)}$, namely that the linear differential operator of $\chi^{(3)}$ (resp. $\chi^{(4)}$ ) could right-divide the linear differential operator of $\chi^{(5)}$ (resp. $\chi^{(6)}$ ), and so on.

This knowledge of the singularities will help in the search for the corresponding linear ODE. For instance, we have 24 head polynomial "candidates" for $\chi^{(5)}$ and 19 "candidates" for $\chi^{(6)}$ that can, from the outset, be put in front of the higher order derivative of the unknown linear ODE. From the knowledge we have gained from all these $n$-fold integrals of the "Ising class", one can guess the order of magnitude of the multiplicity of some singularities. Furthermore, as shown for the linear ODE for $\Phi_{H}^{(5)}$ and $\Phi_{H}^{(6)}$ (and also from previous ODEs), we know that the "cost" (in terms of the number of series coefficients) will be much less for a non minimal order linear ODE than for the minimal order one.

Concerning the non Nickelian singularities that the multiple integrals $\Phi_{H}^{(n)}$ have given, we focussed on $1+3 w+4 w^{2}=0$ which actually occurs for the linear ODE of $\chi^{(3)}$, or for $\chi^{(3)}$ seen as a function of $s$. As far as a mathematical interpretation is concerned, we have shown that this quadratic polynomial condition corresponds to a selected situation for elliptic curves namely the occurrence of complex multiplication. The other non-Nickelian (candidate) singularities, (12), (13) do not correspond to complex multiplication of elliptic curves.

Assuming that the non Nickelian singularities obtained in the linear ODE for the integrals (8), will be, at least, included in those for the $\chi^{(n)}$, various lines of thought are possible.

One may imagine that the decomposition of the susceptibility of the Ising model in terms of an infinite sum of $\chi^{(n)}$ is quite an artificial one with no deep mathematical meaning, i.e. $\chi^{(n)}$ are quite arbitrary $n$-fold integrals. In this case, no interpretation within the theory of elliptic curves has to be looked for and the occurrence for $1+3 w+4 w^{2}=0$ of complex multiplication for elliptic curves would be just a coincidence.

Another option amounts to saying that one needs to introduce (motivic) mathematical structures [36, 37, 38, 39, 40] beyond the theory of elliptic curves (moduli spaces, marked curves, ...), and beyond the elliptic curves of the Ising (or Baxter) model, to get a mathematical interpretation of these singularities. We tend to favour the latter option.

Acknowledgments: We have derived great benefit from discussions on various aspects of this work with F. Chyzak, S. Fischler, P. Flajolet, A. J. Guttmann, L. Merel, B. Nickel, I. Jensen, B. Salvy and J-A. Weil. We thank A. Bostan for a search of linear ODE mod. prime with one of his Magma programs. We acknowledge CNRS/PICS financial support. One of us (NZ) would like to acknowledge the kind hospitality at the LPTMC where part of this work has been completed. One of us (JMM) thanks MASCOS (Melbourne) where part of this work was performed.

## Appendix A. Series expansions of $\Phi_{H}^{(n)}$ and of single integrals $\Phi_{k}^{(n)}$

We give in this Appendix, the series expansion that has been used for $\Phi_{H}^{(n)}$. Expanding the integrand of (8) in the variables $x_{j}$, one obtains

$$
\begin{equation*}
\Phi_{H}^{(n)}=\frac{1}{n!} \cdot \prod_{j=1}^{n-1} \int_{0}^{2 \pi} \frac{d \phi_{j}}{2 \pi} \cdot \sum_{p=0}^{\infty}\left(2-\delta_{p, 0}\right) \cdot \prod_{j=1}^{n} y_{j} x_{j}^{p} . \tag{A.1}
\end{equation*}
$$

We make use of the $y_{j} x_{j}^{p}$ Fourier expansion [4, 5, 8]

$$
\begin{equation*}
y_{j} x_{j}^{p}=w^{p} \cdot \sum_{k=-\infty}^{\infty} w^{|k|} \cdot a(p,|k|) \cdot Z_{j}^{k}, \quad Z_{j}=\exp \left(i \phi_{j}\right) \tag{A.2}
\end{equation*}
$$

where $a(k, p)$ is a non-terminating hypergeometric function that reads (with $m=$ $k+p)$ :

$$
\begin{align*}
& a(k, p)=\binom{m}{k} \times  \tag{A.3}\\
& \quad{ }_{4} F_{3}\left(\frac{1+m}{2}, \frac{1+m}{2}, \frac{2+m}{2}, \frac{2+m}{2} ; 1+k, 1+p, 1+m ; 16 w^{2}\right) .
\end{align*}
$$

We define $\langle\rho\rangle$ by

$$
\begin{equation*}
\langle\rho\rangle=\left(\prod_{j=1}^{n} \int_{0}^{2 \pi} \frac{d \phi_{j}}{2 \pi}\right) \cdot 2 \pi \delta\left(\sum_{j=1}^{n} \phi_{j}\right) \cdot \rho \tag{A.4}
\end{equation*}
$$

where the angular constraint is introduced through the delta function that has the Fourier expansion:

$$
\begin{equation*}
2 \pi \delta\left(\sum_{j=1}^{n} \phi_{j}\right)=\sum_{k=-\infty}^{\infty}\left(Z_{1} Z_{2} \cdots Z_{n}\right)^{k} \tag{A.5}
\end{equation*}
$$

The integrals (A.1) become

$$
\begin{equation*}
\Phi_{H}^{(n)}=\frac{1}{n!} \cdot \sum_{k=-\infty}^{\infty} \sum_{p=0}^{\infty}\left(2-\delta_{p, 0}\right) \cdot\left\langle\prod_{j=1}^{n} y_{j} x_{j}^{p} Z_{j}^{k}\right\rangle \tag{A.6}
\end{equation*}
$$

where the integration is over independent angles.
Using the Fourier expansion (A.2), one obtains the integration rule

$$
\begin{equation*}
\left\langle y_{j} x_{j}^{p} Z_{j}^{k}\right\rangle=w^{p+|k|} \cdot a(p,|k|) \tag{A.7}
\end{equation*}
$$

and finally:

$$
\begin{equation*}
\Phi_{H}^{(n)}=\frac{1}{n!} \cdot \sum_{k=0}^{\infty} \sum_{p=0}^{\infty}\left(2-\delta_{k, 0}\right) \cdot\left(2-\delta_{p, 0}\right) \cdot w^{n(k+p)} \cdot a^{n}(k, p) . \tag{A.8}
\end{equation*}
$$

The derivation of the series expansions for the one dimensional integrals (37) proceeds along similar lines. The integrand of the integrals (37) is expanded in $x$

$$
\begin{equation*}
\frac{1}{1-x^{n-k}(\phi) \cdot x^{k}\left(\phi_{n}\right)}=\sum_{p=0}^{\infty} x^{p(n-k)}(\phi) x^{p k}\left(\phi_{n}\right) \tag{A.9}
\end{equation*}
$$

with

$$
\begin{equation*}
\phi_{n}=-\frac{n-k}{k} \cdot \phi+\frac{2 \pi j}{k} . \tag{A.10}
\end{equation*}
$$

Here, we use the Fourier expansion

$$
\begin{equation*}
x^{m}=w^{m} \cdot \sum_{p=0}^{\infty}\left(2-\delta_{p, 0}\right) \cdot w^{p} \cdot b(p, m) \cdot \cos (p \phi) \tag{A.11}
\end{equation*}
$$

where $b(k, p)$ is a non-terminating hypergeometric function that reads (with $m=$ $k+p)$ :

$$
\begin{align*}
b(k, p) & =\binom{m-1}{k} \times  \tag{A.12}\\
& { }_{4} F_{3}\left(\frac{1+m}{2}, \frac{1+m}{2}, \frac{2+m}{2}, \frac{m}{2} ; 1+k, 1+p, 1+m ; 16 w^{2}\right) .
\end{align*}
$$

The integration of the one-dimensional integrals (A.9) gives

$$
\begin{align*}
\Phi_{k}^{(n)}= & \left\langle\frac{1}{1-x^{n-k}(\phi) \cdot x^{k}\left(\phi_{n}\right)}\right\rangle=\sum_{p=0}^{\infty} \sum_{p_{1}=0}^{\infty} \sum_{p_{2}=0}^{\infty}\left(2-\delta_{p_{1}, 0}\right) \cdot\left(2-\delta_{p_{2}, 0}\right) \\
& \times w^{p n+p_{1}+p_{2}} \cdot b\left(p_{1}, p(n-k)\right) \cdot b\left(p_{2}, p k\right) I\left(p_{1}, p_{2}\right) \tag{A.13}
\end{align*}
$$

with

$$
I\left(p_{1}, p_{2}\right)=\frac{1}{2} \cdot\left(1+\delta_{p_{1}, 0}\right) \cdot \cos (c), \quad \text { for } p_{2} \cdot(n-k)=k \cdot p_{1}
$$

and

$$
I\left(p_{1}, p_{2}\right)=\frac{1}{\pi} \frac{b^{2}}{b^{2}-p_{1}^{2}} \cdot \sin (b \pi) \cdot \cos (b \pi-c), \quad \text { for } \quad p_{2} \cdot(n-k) \neq k \cdot p_{1}
$$

where

$$
\begin{equation*}
b=\frac{n-k}{k} \cdot p_{2}, \quad c=\frac{2 \pi j}{k} \cdot p_{2} \tag{A.14}
\end{equation*}
$$

## Appendix B. Linear differential equations of some $\Phi_{H}^{(n)}$

Appendix B.1. Linear $O D E$ for $\Phi_{H}^{(3)}$
The minimal order linear differential equation satisfied by $\Phi_{H}^{(3)}$ reads

$$
\begin{equation*}
\sum_{n=0}^{5} a_{n}(w) \cdot \frac{d^{n}}{d w^{n}} F(w)=0 \tag{B.1}
\end{equation*}
$$

where

$$
\begin{align*}
& a_{5}(w)=(1-w)(1-4 w)^{4}(1+4 w)^{2}(1+2 w) \\
& \quad \times\left(1+3 w+4 w^{2}\right) \cdot w^{3} \cdot P_{5}(w)  \tag{B.2}\\
& a_{4}(w)=(1-4 w)^{3}(1+4 w) \cdot w^{2} \cdot P_{4}(w), \\
& a_{3}(w)=-2(1-4 w)^{2} \cdot w P_{3}(w), \quad a_{2}(w)=2(1-4 w) \cdot P_{2}(w), \\
& a_{1}(w)=-8 P_{1}(w), \quad a_{0}(w)=-96 P_{0}(w),
\end{align*}
$$

with

$$
\begin{aligned}
& P_{5}(w)=-5+21 w+428 w^{2}+5364 w^{3}-82416 w^{4}-299504 w^{5} \\

\end{align*}
$$

Appendix B.2. Linear $O D E$ for $\Phi_{H}^{(4)}$
The minimal order linear differential equation satisfied by $\Phi_{H}^{(4)}$ reads (with $x=16 w^{2}$ )

$$
\begin{equation*}
\sum_{n=0}^{6} a_{n}(x) \cdot \frac{d^{n}}{d x^{n}} F(x)=0 \tag{B.4}
\end{equation*}
$$

where

$$
\begin{aligned}
& a_{6}(x)=64(x-4)(1-x)^{4} x^{4} \cdot P_{6}(x), \quad a_{5}(x)=-128(1-x)^{3} x^{3} \cdot P_{5}(x), \\
& a_{4}(x)=16(1-x)^{2} x^{2} \cdot P_{4}(x), \quad a_{3}(x)=-64(1-x) x \cdot P_{3}(x) \\
& a_{2}(x)=-4 \cdot P_{2}(x), \quad a_{1}(x)=-8 \cdot P_{1}(x), \quad a_{0}(x)=-3(1-x) \cdot P_{0}(x),
\end{aligned}
$$

with:

$$
\begin{aligned}

$$

Appendix B.3. Linear ODE modulo a prime for $\Phi_{H}^{(5)}$
The linear differential equation of minimal order seventeen satisfied by $\Phi_{H}^{(5)}$ is of the form

$$
\begin{equation*}
\sum_{n=0}^{17} a_{n}(w) \cdot \frac{d^{n}}{d w^{n}} F(w)=0 \tag{B.5}
\end{equation*}
$$

with

$$
\begin{aligned}
& a_{17}(w)=(1-4 w)^{12}(1+4 w)^{9}(1-w)^{2}(w+1)(1+2 w) \\
& \times\left(1+3 w+4 w^{2}\right)^{2}\left(1-3 w+w^{2}\right)\left(1+2 w-4 w^{2}\right) \\
& \times\left(1+4 w+8 w^{2}\right)\left(1-7 w+5 w^{2}-4 w^{3}\right) \\
& \times\left(1-w-3 w^{2}+4 w^{3}\right)\left(1+8 w+20 w^{2}+15 w^{3}+4 w^{4}\right) \cdot w^{12} \cdot P_{17}(w)
\end{aligned}
$$

$$
\begin{aligned}
& a_{16}(w)=w^{11}(1-4 w)^{11}(1+4 w)^{8}(1-w)\left(1+3 w+4 w^{2}\right) \cdot P_{16}(w) \\
& a_{15}(w)=w^{10}(1-4 w)^{10}(1+4 w)^{7} \cdot P_{15}(w) \\
& a_{14}(w)=w^{9}(1-4 w)^{9}(1+4 w)^{6} \cdot P_{14}(w) \\
& \ldots
\end{aligned}
$$

where the 430 roots of $P_{17}(w)$ are apparent singularities. The degrees of these polynomials $P_{n}(w)$ are such that the degrees of $a_{i}(w)$ are decreasing as: $\operatorname{deg}\left(a_{i+1}(w)\right)=\operatorname{deg}\left(a_{i}(w)\right)+1$. In fact, with 2208 terms we have found the ODE of $\Phi_{H}^{((5)}$ at order $q=28$ using the following ansatz for the linear ODE search ( $D w$ denotes $d / d w)$

$$
\begin{equation*}
\sum_{i=0}^{q} s(i) \cdot p(i) \cdot D w^{i} \tag{B.6}
\end{equation*}
$$

with:

$$
\begin{equation*}
s(i)=w^{\alpha(-1+i)} \cdot\left(1-16 w^{2}\right)^{\alpha(-1+i)} \cdot s_{0}^{\alpha(1+i-q)} \tag{B.7}
\end{equation*}
$$

where $\alpha(n)=\operatorname{Min}(0, n)$ and

$$
\begin{aligned}
& s_{0}=(1+w) \cdot(1-w) \cdot(1+2 w) \cdot\left(1-3 w+w^{2}\right)\left(1+2 w-4 w^{2}\right) \\
& \times\left(1+3 w+4 w^{2}\right) \cdot\left(1+4 w+8 w^{2}\right) \cdot\left(1-7 w+5 w^{2}-4 w^{3}\right) \\
& \times\left(1-w-3 w^{2}+4 w^{3}\right) \cdot\left(1+8 w+20 w^{2}+15 w^{3}+4 w^{4}\right)
\end{aligned}
$$

the $p(i)$ being the unknown polynomials.
The minimal order ODE is deduced from the set of linear independant ODEs found at order 28.

## Appendix B.4. Linear ODE modulo a prime for $\Phi_{H}^{(6)}$

The linear differential equation of minimal order twenty-seven satisfied by $\Phi_{H}^{(6)}$ reads (with $x=w^{2}$ )

$$
\begin{equation*}
\sum_{n=0}^{27} a_{n}(x) \cdot \frac{d^{n}}{d x^{n}} F(x)=0 \tag{B.8}
\end{equation*}
$$

with

$$
\begin{align*}
& a_{27}(x)=(1-16 x)^{16}(1-4 x)^{3}(1-x)(1-25 x)(1-9 x) x^{21} \\
& \quad \times\left(1-x+16 x^{2}\right)\left(1-10 x+29 x^{2}\right) \cdot P_{27}(x), \\
& a_{26}(x)=(1-16 x)^{15}(1-4 x)^{2} x^{20} \cdot P_{26}(x), \\
& a_{25}(x)=(1-16 x)^{14}(1-4 x) x^{19} \cdot P_{25}(x), \\
& a_{24}(x)=(1-16 x)^{13} x^{18} \cdot P_{24}(x), \\
& \ldots \tag{B.9}
\end{align*}
$$

where the 307 roots of $P_{27}(x)$ are apparent singularities. The degrees of the $P_{n}(w)$ polynomials are such that the degrees of $a_{i}(w)$ are decreasing as: $\operatorname{deg}\left(a_{i+1}(w)\right)=$ $\operatorname{deg}\left(a_{i}(w)\right)+1$

In fact, with 1838 terms we have found the linear ODE of $\Phi_{H}^{(6)}$ at order $q=42$ using the following ansatz for the linear ODE search ( $D x$ denotes $d / d x$ )

$$
\begin{equation*}
\sum_{i=0}^{q} s(i) \cdot p(i) \cdot D x^{i} \tag{B.10}
\end{equation*}
$$

with:

$$
\begin{equation*}
s(i)=x^{\alpha(-1+i)} \cdot(1-16 x)^{\alpha(-1+i)} \cdot s_{0}^{\alpha(1+i-q)} \tag{B.11}
\end{equation*}
$$

where $\alpha(n)=\operatorname{Min}(0, n)$ and

$$
\begin{align*}
s_{0}= & (1-25 x) \cdot(1-9 x) \cdot(1-4 x) \cdot(1-x) \\
& \times\left(1-x+16 x^{2}\right) \cdot\left(1-10 x+29 x^{2}\right) \tag{B.12}
\end{align*}
$$

the $p(i)$ being the unknown polynomials.
The minimal order ODE is deduced from the set of linear independant ODEs found at order 42.

## Appendix C. Singularities in the linear ODE for $\Phi_{H}^{(7)}$ and $\Phi_{H}^{(8)}$

For $\Phi_{H}^{(7)}$, we generated large series, ( 1250 coefficients and 20000 coefficients modulo primes), unfortunately, insufficient to obtain the corresponding linear ODE. However, by steadily increasing the order $q$ of the ODE (and consequently decreasing the degrees $n$ of the polynomials in front of the derivatives), one may recognize, in floating point form, the singularities of the ODE as the roots of the polynomial in front of the higher derivative. A root is considered as singularity of the still unknown linear ODE, when as $q$ increase (and consequently decreasing $n$ ), it persists with more stabilized digits.

Using 1250 terms in the series for $\Phi_{H}^{(7)}$, the following singularities are recognized

$$
\begin{aligned}
& (1-4 w)\left(1-5 w+6 w^{2}-w^{3}\right)\left(1+2 w-8 w^{2}-8 w^{3}\right)(1+4 w) \cdot w \\
& \left(1+2 w-w^{2}-w^{3}\right)\left(1-3 w+w^{2}\right)\left(1+2 w-4 w^{2}\right)(1+w) \\
& \left(16 w^{8}-32 w^{7}-17 w^{6}+62 w^{5}-5 w^{4}-35 w^{3}+10 w^{2}+3 w-1\right) \\
& \left(64 w^{7}+96 w^{6}+16 w^{5}-60 w^{4}-21 w^{3}+15 w^{2}+8 w+1\right) \\
& \left(128 w^{5}-32 w^{4}+48 w^{3}+16 w^{2}+4 w-1\right) \\
& \left(4 w^{5}+51 w^{3}-21 w^{4}-1+10 w-35 w^{2}\right) \\
& \left(4 w^{3}+7 w-5 w^{2}-1\right)\left(4 w^{4}+1+7 w+26 w^{2}+7 w^{3}\right) \\
& \left(4 w^{4}+1+8 w+20 w^{2}+15 w^{3}\right) \\
& \left(1+12 w+54 w^{2}+112 w^{3}+105 w^{4}+35 w^{5}+4 w^{6}\right)=0 .
\end{aligned}
$$

We will see in the next section Appendix E. 3 that we missed the polynomials:

$$
\begin{align*}
&\left(1+3 w+4 w^{2}\right)\left(1+4 w+8 w^{2}\right)(1-w)  \tag{C.1}\\
&(1+2 w)\left(1-w-3 w^{2}+4 w^{3}\right)
\end{align*}
$$

Note that we have not seen with the precision of these calculations the occurence of the singularities of the $\Phi_{H}^{(3)}$.

With similar calculations using 1200 terms for $\Phi_{H}^{(8)}$, the following singularities are recognized:

$$
\begin{aligned}
& (1-2 w)(1+2 w)\left(1-2 w^{2}\right)(1-4 w)\left(1-4 w+2 w^{2}\right)(1+4 w) \\
& \left(1+4 w+2 w^{2}\right)\left(8 w^{2}-1\right)(3 w-1)(1-w)(1+w)(3 w+1) w \\
& \left(1138 w^{10}-1685 w^{8}+960 w^{6}-242 w^{4}+26 w^{2}-1\right) \\
& \left(32 w^{4}-10 w^{2}+1\right)\left(1312 w^{6}-56 w^{4}+30 w^{2}-1\right) \\
& \left(10 w^{2}-6 w+1\right)\left(4 w^{3}-8 w^{2}+6 w-1\right)
\end{aligned}
$$

$$
\begin{aligned}
& (5 w-1)\left(1+2 w^{2}\right)(5 w+1) \\
& \left(10 w^{2}+6 w+1\right)\left(4 w^{3}+8 w^{2}+6 w+1\right)=0
\end{aligned}
$$

We will see in the next section Appendix E. 3 that we missed the polynomials:

$$
\left(1-3 w+4 w^{2}\right)\left(1+3 w+4 w^{2}\right)\left(1-10 w^{2}+29 w^{4}\right)
$$

Note that the stabilized digits in these singularities can be as low as two digits.
Appendix D. Landau conditions and pinch singularities for $\Phi_{D}^{(n)}$ and integrals of $\prod y_{j}$.

Similarly to the integral representation (16) of $\Phi_{H}^{(n)}$, one has:

$$
\begin{align*}
\Phi_{D}^{(n)}=\int_{0}^{2 \pi} & \frac{d \phi}{2 \pi} \int_{0}^{2 \pi} \cdot \frac{d \psi}{2 \pi} \frac{\sqrt{(1-2 w \cos \phi)^{2}-4 w^{2}}}{D(\phi, \psi)}  \tag{D.1}\\
& \times \frac{\sqrt{(1-2 w \cos ((n-1) \phi))^{2}-4 w^{2}}}{D((n-1) \phi,(n-1) \psi)}
\end{align*}
$$

and

$$
\begin{equation*}
\prod_{i=1}^{n} y_{i}=\int_{0}^{2 \pi} \prod_{i=1}^{n} \frac{d \phi_{i}}{2 \pi} \cdot \frac{d \psi_{i}}{2 \pi} \cdot \frac{1}{D\left(\phi_{i}, \psi_{i}\right)} \cdot \delta\left(\sum_{i=1}^{n} \phi_{i}\right) \tag{D.2}
\end{equation*}
$$

For $\Phi_{D}^{(n)}$ the singularities of the associated ODEs are given as solutions of:

$$
\begin{align*}
& D(\phi, \psi)=0 \\
& D((n-1) \phi,(n-1) \psi)=0, \\
& \alpha_{1} \cdot \sin (\phi)+\alpha_{2} \cdot \sin ((n-1) \phi)=0, \quad \text { with } \quad \alpha_{1}, \alpha_{2} \neq 0 \\
& \alpha_{1} \cdot \sin (\psi)+\alpha_{2} \cdot \sin ((n-1) \psi)=0 \tag{D.3}
\end{align*}
$$

which are nothing less than the Landau conditions restricted to pinch singularities of the singularity manifolds $D\left(\phi_{i}, \psi_{i}\right)=0$. For $\prod_{i=1}^{n} y_{i}$ the singularities of the associated ODEs can be written as the solutions of:

$$
\begin{align*}
& D\left(\phi_{i}, \psi_{i}\right)=0, \\
& \alpha_{i} \cdot \sin \left(\phi_{i}\right)-\alpha_{n} \cdot \sin \left(\phi_{n}\right)=0, \quad i=1, \cdots, n-1, \quad \text { with } \quad \alpha_{i} \neq 0 \\
& \alpha_{i} \cdot \sin \left(\psi_{i}\right)=0, \quad i=1, \cdots, N \tag{D.4}
\end{align*}
$$

which are also Landau conditions restricted to pinch singularities of the singularity manifolds $D\left(\phi_{i}, \psi_{i}\right)=0$.

## Appendix E. The singularities from Landau conditions

In this Appendix, we give further details corresponding to (28), (29) obtained from the Landau conditions:

$$
\begin{array}{ll}
1-2 w \cdot\left(\cos \left(\phi_{j}\right)+\cos \left(\psi_{j}\right)\right)=0, & j=1, \cdots, n \\
\alpha_{j} \cdot \sin \left(\phi_{j}\right)-\alpha_{n} \cdot \sin \left(\phi_{n}\right)=0, & j=1, \cdots, n-1 \\
\alpha_{j} \cdot \sin \left(\psi_{j}\right)-\alpha_{n} \cdot \sin \left(\psi_{n}\right)=0, & j=1, \cdots, n-1 . \tag{E.3}
\end{array}
$$

$\# \prod y_{i}$ or $\prod y_{i}^{2}$ integrand are similar as far as location of singularities of the corresponding ODE is concerned.
and:

$$
\begin{equation*}
\sum_{j=1}^{n} \phi_{j}=0, \quad \sum_{j=1}^{n} \psi_{j}=0 \quad \bmod .2 \pi \tag{E.4}
\end{equation*}
$$

We solve these equations for the values (zero or not) of $\sin \left(\phi_{n}\right)$ and $\sin \left(\psi_{n}\right)$. For $\sin \left(\phi_{n}\right)=\sin \left(\psi_{n}\right)=0$, the case is simple and gives $w= \pm 1 / 4$.

Appendix E.1. The case $\sin \left(\phi_{n}\right) \neq 0, \sin \left(\psi_{n}\right)=0$
In this case, there are $k$ angles $\psi_{j}=\pi$ and the remaining ones are $\psi_{j}=0$. By (17), the integer $k$ should be even, $k=2 p$. From (E.1), we obtain and defing $\ddagger$

$$
\begin{equation*}
\cos \left(\phi^{+}\right)=\frac{1}{2 w}+1, \quad \cos \left(\phi^{-}\right)=\frac{1}{2 w}-1 \tag{E.5}
\end{equation*}
$$

One obtains $2 p$ angles $\phi_{j}= \pm \phi^{+}$and $n-2 p$ angles $\phi_{j}= \pm \phi^{-}$. The angles $\phi_{j}$ are then partitioned in sets of $p_{1}$ angles $+\phi^{+},\left(2 p-p_{1}\right)$ angles $-\phi^{+},\left(n-2 p-p_{2}\right)$ angles $+\phi^{-}$ and $p_{2}$ angles $-\phi^{-}$. By ( $\left.\overline{\mathrm{E} .4}\right)$, one gets $\left(2 p-2 p_{1}\right) \cdot \phi^{+}=\left(n-2 p-2 p_{2}\right) \cdot \phi^{-}$. Note that some manipulations on the indices lead to $\cos \left(|2 p| \cdot \phi^{+}\right)=\cos \left(|n-2 p-2 k| \cdot \phi^{-}\right)$and thus $|2 p| \cdot \phi^{+}= \pm|n-2 p-2 k| \cdot \phi^{-}$, allowing us to write

$$
\begin{array}{lc}
T_{2 p}(1 / 2 w+1)= & T_{n-2 p-2 k}(1 / 2 w-1)  \tag{E.6}\\
0 \leq p \leq[n / 2], & 0 \leq k \leq[n / 2]-p
\end{array}
$$

where $T_{n}(x)$ is the Chebyshev polynomial of the first kind.
One obtains the same results for the case $\sin \left(\phi_{n}\right)=0$ and $\sin \left(\psi_{n}\right) \neq 0$.
Appendix E.2. The case $\sin \left(\phi_{n}\right) \neq 0, \sin \left(\psi_{n}\right) \neq 0$
In this case, by (E.2), (E.3), we have $\sin \left(\phi_{j}\right) \neq 0$ and $\sin \left(\psi_{j}\right) \neq 0$. The equations (E.1), (E.3) become:

$$
\begin{align*}
\cos \left(\psi_{j}\right)=1-2 w \cdot \cos \left(\phi_{j}\right), & j=1, \cdots, n  \tag{E.7}\\
\sin \left(\psi_{j}\right)=\sin \left(\phi_{j}\right) \cdot \frac{\sin \left(\psi_{n}\right)}{\sin \left(\phi_{n}\right)}, & j=1, \cdots, n \tag{E.8}
\end{align*}
$$

Squaring both sides of both equations and summing, one obtains

$$
\begin{equation*}
\left(\cos \left(\phi_{j}\right)-\cos \left(\phi_{n}\right)\right) \cdot\left(\cos \left(\phi_{j}\right)-\cos \left(\phi_{0}\right)\right)=0 \tag{E.9}
\end{equation*}
$$

where we have defined

$$
\begin{equation*}
\cos \left(\phi_{0}\right)=\frac{4 w-\cos \left(\phi_{n}\right)}{1-4 w \cos \left(\phi_{n}\right)} \tag{E.10}
\end{equation*}
$$

The angles $\phi_{j}$ are then partitioned into four sets $\pm \phi_{0}$ and $\pm \phi_{n}$. Note that a similar condition ( (E.9) occurs for the angles $\psi_{j}$ which are partitioned likewise. Writing (E.7), (E.8) for $j=0$ and $j=n$ and with the conditions (17), the equations become in terms of Chebyshev polynomialstt:

$$
\begin{equation*}
T_{n_{1}}(z)-T_{n_{2}}\left(\frac{4 w-z}{1-4 w z}\right)=0 \tag{E.11}
\end{equation*}
$$

$\ddagger$ Note that $\phi^{+}$and $\phi^{-}$(which correspond to $\psi_{j}=\pi$ and $\psi_{j}=0$ respectively) are not on the same footing: indeed, the number of $\phi^{+}$angles must be even, while the number of $\phi^{-}$angles depends on the parity of $n$.
$\dagger \dagger$ Note that in equation (E.11) one must realise that one takes the numerator of these rational expressions.

$$
\begin{aligned}
& T_{n_{1}}\left(\frac{1}{2 w}-z\right)-T_{n_{2}}\left(\frac{1}{2 w}-\frac{4 w-z}{1-4 w z}\right)=0 \\
& U_{n_{2}-1}(z) \cdot U_{n_{1}-1}\left(\frac{1}{2 w}-\frac{4 w-z}{1-4 w z}\right) \\
& \quad-\quad U_{n_{2}-1}\left(\frac{1}{2 w}-z\right) \cdot U_{n_{1}-1}\left(\frac{4 w-z}{1-4 w z}\right)=0
\end{aligned}
$$

with

$$
\begin{array}{ll}
n_{1}=p, & n_{2}=n-p-2 k \\
0 \leq p \leq n, & 0 \leq k \leq[(n-p) / 2] \tag{E.13}
\end{array}
$$

At this step, some computational remarks are in order. In the course of deriving (E.11), some manipulations such as dividing by a term have been done. Rigorously, the solutions that come from (E.11) have to be checked against this point. We have found, that as they are written, the formulas are "safe" from this perspective, except of the following. For $n=p / 2$ (fixing $k=0$ for convenience), thus for $n$ even, the formulas (E.11) give a common curve which reads:

$$
\begin{equation*}
w=\frac{1}{2} \frac{z}{1+z^{2}} \tag{E.14}
\end{equation*}
$$

This relation comes from the condition $\cos \left(\phi_{0}\right)=\cos \left(\phi_{n}\right)$ in (E.10) which makes (E.9) a perfect square. We have checked that considering this condition at the outset, i.e. (E.7), (E.8) yields no solution.

## Appendix E.3. Landau singularities

We can write the singularities obtained from (E.6) as:

$$
\begin{aligned}
n=3, & (1-4 w)(1-w)\left(1+3 w+4 w^{2}\right)=0 \\
n=4, & \left(1-16 w^{2}\right)\left(1-4 w^{2}\right)=0, \\
n=5, & (1-4 w)(1-w)\left(1+3 w+4 w^{2}\right)\left(1-3 w+w^{2}\right) \\
& \times\left(1-7 w+5 w^{2}-4 w^{3}\right)\left(1+8 w+20 w^{2}+15 w^{3}+4 w^{4}\right)=0, \\
n= & 6, \quad\left(1-16 w^{2}\right)\left(1-4 w^{2}\right)\left(1-w^{2}\right)\left(1-25 w^{2}\right)\left(1-9 w^{2}\right) \\
& \times\left(1+3 w+4 w^{2}\right)\left(1-3 w+4 w^{2}\right)=0
\end{aligned}
$$

The solutions of (E.11) include some of the solutions of (E.6). We give in the following only those not occurring in (E.6):

$$
\begin{array}{ll}
n=3, & w \cdot(1+4 w)(1+2 w)=0 \\
n=4, & w=0, \\
n=5, & w \cdot(1+4 w)(1+w)(1+2 w)\left(1+2 w-4 w^{2}\right) \\
& \times\left(1+4 w+8 w^{2}\right)\left(1-w-3 w^{2}+4 w^{3}\right)=0 \\
n=6, & w \cdot\left(1-10 w^{2}+29 w^{4}\right)=0
\end{array}
$$

All these singularities can be identified with the singularities occurring in the linear ODE for $\Phi_{H}^{(n)},(n=3, \cdots, 6)$.

For $n=7$ and $n=8$, the solutions of ( (E.6) and (E.11) can be identified with the singularities given in Appendix C and obtained in floating point form. They also give:

$$
n=7, \quad\left(1+3 w+4 w^{2}\right)\left(1+4 w+8 w^{2}\right)(1-w)(1+2 w)
$$

$$
\begin{aligned}
& \quad \times\left(1-w-3 w^{2}+4 w^{3}\right)=0 \\
& n=8, \quad\left(1-3 w+4 w^{2}\right)\left(1+3 w+4 w^{2}\right)\left(1-10 w^{2}+29 w^{4}\right)=0
\end{aligned}
$$

which have not been found in the series with the currently available number of terms.

## Appendix F. Heegner numbers and other selected values of the modular $j$-function

The nine Heegner numbers 51] and their associated modular $j$-function $j(\tau)$, yield the following conditions in the variable $w$ :

$$
\begin{aligned}
& j(1+i)=(12)^{3}, \quad\left(1-8 w^{2}\right)\left(1-16 w^{2}-8 w^{4}\right)=0 \\
& j(1+i \sqrt{2})=\begin{array}{l}
(20)^{3}, \quad\left(64 w^{4}+16 w^{2}-1\right) \\
\times\left(64 w^{8}+1792 w^{6}-368 w^{4}+32 w^{2}-1\right)=0 \\
j\left(\frac{1+i \sqrt{3}}{2}\right)=(0)^{3}, \quad 1-16 w^{2}+16 w^{4}=0, \\
j\left(\frac{1+i \sqrt{7}}{2}\right)=(-15)^{3}, \quad\left(1-31 w^{2}+256 w^{4}\right)\left(1-16 w^{2}+w^{4}\right) \\
\\
\times\left(1+3 w+4 w^{2}\right)\left(1-3 w+4 w^{2}\right)=0
\end{array} \\
& \begin{array}{r}
j\left(\frac{1+i \sqrt{11}}{2}\right)=(-32)^{3}, \quad P_{3}=1-48 w^{2}+816 w^{4}-5632 w^{6} \\
\quad+45824 w^{8}-536576 w^{10}+4096 w^{12}=0
\end{array}
\end{aligned}
$$

and

$$
\begin{aligned}
j\left(\frac{1+i \sqrt{d}}{2}\right) & =(-m)^{3}, \quad P_{d}=0 \quad \text { with: } \\
P_{d} & =P_{3}+N \cdot\left(1-16 w^{2}\right) \cdot w^{8}
\end{aligned}
$$

with the following values for the triplet $(d, m, N)$ :

$$
\begin{aligned}
& (19,96,851968), \quad(43,960,884703232), \\
& (67,5280,147197919232), \quad(163,640320,262537412640735232)
\end{aligned}
$$

Beyond Heegner numbers there are many other selected quadratic values [52, 53] of $j$, for instance:

$$
\begin{equation*}
j=-4096 \cdot(15+7 \sqrt{5})^{3}=j\left(\frac{1+i \sqrt{35}}{2}\right) \tag{F.1}
\end{equation*}
$$

Which is known [51] to be one of the eighteen numbers having class number $h(-d)=2$, and which corresponds to the quadratic relation $-134217728000+117964800 j+j^{2}=$ 0 . Recalling the expression of the modular $j$-function in term of the variable $w$

$$
\begin{equation*}
j=\frac{\left(1-16 w^{2}+16 w^{4}\right)^{3}}{\left(1-16 w^{2}\right) w^{8}} \tag{F.2}
\end{equation*}
$$

this quadratic relation in $j$ becomes a quite involved polynomial expression that we have not seen emerging as singularities of (the linear ODE's of) our $n$-fold integrals.

## Appendix G. Landen transformations and the modular $j$-function

In this Appendix the modular $j$-function (53) will be seen, alternatively, as a function of the modulus $k$, and thus denoted $j[k]$, or as a function of the half period ratio $\tau$, and thus denoted $j(\tau)$. The modular function called the $j$-function when seen as a function of the modulus $k$ reads:

$$
\begin{equation*}
j[k]=256 \cdot \frac{\left(1-k^{2}+k^{4}\right)^{3}}{k^{4} \cdot\left(1-k^{2}\right)^{2}} \tag{G.1}
\end{equation*}
$$

Increasing the modulus by (48), the modular function $j(k)$ becomes:

$$
\begin{equation*}
j\left[k_{1}\right]=j_{1}[k]=16 \cdot \frac{\left(1+14 k^{2}+k^{4}\right)^{3}}{k^{2} \cdot\left(1-k^{2}\right)^{4}} \tag{G.2}
\end{equation*}
$$

Iterating this procedure once more one obtains:

$$
\begin{equation*}
j_{1}\left[k_{1}\right]=j_{2}[k]=4 \cdot \frac{\left(k^{4}+60 k^{3}+134 k^{2}+60 k+1\right)^{3}}{k \cdot(1+k)^{2}(1-k)^{8}} \tag{G.3}
\end{equation*}
$$

The decrease of the modulus by (47) gives:

$$
\begin{equation*}
j\left[k_{-1}\right]=j_{-1}[k]=16 \cdot \frac{\left(k^{4}-16 k^{2}+16\right)^{3}}{k^{8}\left(1-k^{2}\right)} \tag{G.4}
\end{equation*}
$$

The next iterations (the cube of (48) and the square of (47)) gives algebraic expressions for $j[k]$.

It is easy to get a representation of the Landen transformation on the modular $j$-functions by elimination of the modulus $k$ between (53) and (G.2). One obtains the well-known fundamental modular curve [49, 50]:

$$
\begin{align*}
\Gamma_{1}\left(j, j_{1}\right)= & j^{2} \cdot j_{1}^{2}-\left(j+j_{1}\right) \cdot\left(j^{2}+1487 j j_{1}+j_{1}^{2}\right) \\
+ & 3 \cdot 15^{3} \cdot\left(16 j^{2}-4027 j j_{1}+16 j_{1}^{2}\right)  \tag{G.5}\\
& -12 \cdot 30^{6} \cdot\left(j+j_{1}\right)+8 \cdot 30^{9}=0 .
\end{align*}
$$

This algebraic curve is symmetric in $j$ and $j_{1}$. We will obtain the same modular curve (G.5) by elimination of the modulus $k$ between (G.2) and (G.3), or between (G.1) and (G.4). The two modular functions $j$ and $j_{1}$ are invariant by the $S L(2, Z)$ modular group, and, in particular, transformation $\tau \rightarrow 1 / \tau$. As a consequence, the transformation $\tau \rightarrow 2 \cdot \tau$, and its inverse $\tau \rightarrow \tau / 2$, have to be on the same footing in the modular curve representation (G.5) for the Landen and Gauss transformations.

Similarly, one can easily find the (genus zero) modular curve $\Gamma_{2}$ obtained by the elimination of the modulus $k$ between (G.1) and (G.3), (or between (G.4) and (G.4)), which corresponds to the transformation $\tau \rightarrow 4 \cdot \tau$ and, at the same time, to its inverse $\tau \rightarrow \tau / 4$. This last algebraic curve is, of course, also a modular curve.

## Appendix G.1. Fixed points of these modular representations in terms of $j$-function

Transformations like $j \rightarrow j_{1}$, or $j \rightarrow j_{2}$, corresponding to the previous modular curves, are not (one-to-one) mappings, they are called "correspondence" by Veselov [23, 24]. In order to look at the fixed points of the Landen, Gauss transformations (or their iterates) seen as transformations on complex variables, within the framework of (modular) representations on the modular $j$-functions, we write, respectively, $\Gamma_{1}\left(j, j_{1}=j\right)=0$ and $\Gamma_{2}\left(j, j_{2}=j\right)=0$

The "fixed points" $\Gamma_{1}\left(j, j_{1}=j\right)=0$ of the (modular) "correspondence" (G.5), are $j=j_{1}=(12)^{3}$ or $(20)^{3}$ or $(-15)^{3}$.

The "fixed points" $\Gamma_{2}\left(j, j_{2}=j\right)=0$ of modular curve corresponding to the square of the Landen transformation, are $j=j_{2}=(66)^{3}$, or $2 \cdot(30)^{3}$, or $(-15)^{3}$ or the solutions of $j^{2}+191025 \cdot j-121287375=0$, namely:

$$
\begin{equation*}
j=-3^{3} \cdot\left(\frac{1+\sqrt{5}}{2}\right)^{2} \cdot(5+4 \cdot \sqrt{5})^{3}=j\left(\tau=\frac{1+i \sqrt{15}}{2}\right) \tag{G.6}
\end{equation*}
$$

and its Galois conjugate (change $\sqrt{5}$ into $-\sqrt{5}$ ).
Appendix G.2. Alternative approach to fixed points of the Landen transformation and its iterates

In order to get the "fixed points" of the Landen transformation, let us impose that (G.1) and (G.2) are actually equal, thus $j[k]=j\left[k_{1}\right]$. This yields the condition (already seen to correspond to the $\chi^{(3)}$-singularities $1+3 w+4 w^{2}=0$ ):

$$
\begin{equation*}
\left(4 k^{2}+3 k+1\right)\left(k^{2}+3 k+4\right)=0 \tag{G.7}
\end{equation*}
$$

together with:

$$
\begin{align*}
& \left(4 k^{2}-3 k+1\right)\left(k^{2}-3 k+4\right) \\
& \left(k^{2}+2 k-1\right)\left(k^{2}-2 k-1\right)\left(1+k^{2}\right)=0 \tag{G.8}
\end{align*}
$$

The first two polynomial conditions in (G.8), $\left(4 k^{2}-3 k+1\right)\left(k^{2}-3 k+4\right)=0$, correspond to the Heegner number associated with the integer value $j=(-15)^{3}$. The next two polynomial conditions in (G.8), $k^{2} \pm 2 k-1=0$, correspond to the Heegner number associated with the integer value $j=(20)^{3}$. The last polynomial condition in (G.8), $1+k^{2}=0$, corresponds to the Heegner number associated with the integer value $j=(12)^{3}$.

Similarly, in order to get the "fixed points" of the square of the Landen transformation, let us require that (G.1) and (G.3) are actually equal: $j[k]=j\left[k_{2}\right]$. This yields the conditions (G.7) (fixed points of the Landen transformation) together with:

$$
\begin{align*}
& \left(k^{2}-6 k+1\right)\left(1+14 k^{2}+k^{4}\right)=0  \tag{G.9}\\
& \left(k^{4}-6 k^{3}+17 k^{2}+36 k+16\right)  \tag{G.10}\\
& \quad \times\left(16 k^{4}+36 k^{3}+17 k^{2}-6 k+1\right)=0
\end{align*}
$$

In (G.9) the condition $1+14 k^{2}+k^{4}=0$ (or $1-16 w^{2}+256 w^{4}=0$ ) corresponds to $j=2(30)^{3}$ which is not a Heegner number but actually corresponds to complex multiplication. The condition $k^{2}-6 k+1=0$ in (G.9) (or $1-32 w^{2}=0$ ) corresponds to $j=(66)^{3}$ which is not a Heegner number either but actually corresponds to complex multiplication. Note that both polynomials under the Landen transformation (48) give respectively $j=(0)^{3}$ and $j=(12)^{3}$, i.e. Heegner numbers. The last two (self-dual) conditions in (G.10), read in $w$

$$
\begin{align*}
& 1-9 w+17 w^{2}+24 w^{3}+6 w^{4}=0  \tag{G.11}\\
& 1+9 w+17 w^{2}-24 w^{3}+6 w^{4}=0
\end{align*}
$$

and yield as selected value [52, 53] of $j$, the quadratic roots $-121287375+191025 j+$ $j^{2}=0$, already given in (G.6).
$\ddagger$ This corresponds to a value of $j$ of class number $h(-d)=2$, see (58) in [51].

One more step can be performed writing the condition $j\left[k_{-1}\right]=j\left[k_{2}\right]$. One gets the conditions:

$$
\left(k^{2}+3 k+4\right)^{2}\left(4 k^{2}-3 k+1\right)\left(k^{2}+2 k-1\right)\left(k^{2}+1\right)=0
$$

previously obtained and corresponding to $j=(-15)^{3}, 20^{3}, 12^{3}$, together with:

$$
\begin{align*}
& k^{6}-27 k^{5}+363 k^{4}+423 k^{3}-168 k^{2}-144 k+64=0 \\
& k^{6}+17 k^{5}+143 k^{4}+203 k^{3}+52 k^{2}+32 k+64=0 \tag{G.12}
\end{align*}
$$

corresponding, respectively, to the two cubic relations on $j$ :

$$
\begin{align*}
& 1566028350940383-58682638134 j+39491307 j^{2}+j^{3}=0 \\
& 12771880859375-5151296875 j+3491750 j^{2}+j^{3}=0 \tag{G.13}
\end{align*}
$$

These conditions (G.13) yield quite involved polynomial expressions in the variable $w$ that we have not seen emerging as singularities of (the linear ODE's of) our $n$-fold integrals (or the $Y^{(n)}$ or $\Phi^{(n)}$ either).

## Appendix H. Linear differential operators for the Sorokin integrals

Recall the occurrence of zeta functions evaluated at integer values in many $n$-fold integrals corresponding to particle physics, field theory, ... For instance, the following integral [33, 36] is associated with $\zeta(3)$ :

$$
\begin{equation*}
I_{n}(z)=\int_{0}^{1} d u d v d w \cdot \frac{(1-u)^{n} u^{n} \cdot(1-v)^{n} v^{n} \cdot(1-w)^{n} w^{n}}{(1-u v)^{n+1} \cdot(z-u v w)^{n+1}} \tag{H.1}
\end{equation*}
$$

From the series expansion of this holonomic $n$-fold integral, we have obtained the corresponding order four Fuchsian linear differential equation. On these linear differential operators the "logarithmic" nature of these integrals becomes clear.

The fully integrated series expansion of the triple integral (H.1) is given by (where $x$ denotes $1 / z)$ :

$$
\begin{aligned}
I_{n}(x)= & \sum_{i=0}^{\infty} x^{n+i+1} \cdot \frac{\Gamma^{2}(n+1) \cdot \Gamma^{4}(n+i+1)}{\Gamma(i+1) \cdot \Gamma^{3}(2+2 n+i)} \times \\
& { }_{3} F_{2}(n+1, n+i+1, n+i+1 ; 2 n+i+2,2 n+i+2 ; 1)
\end{aligned}
$$

The triple integral $I_{n}(x)$ is solution of the order four Fuchsian linear differential operator ( $D x$ denotes $d / d x$ )

$$
\begin{aligned}
L_{n}= & D x^{4}+\frac{2(3 x-1)}{(x-1) x} \cdot D x^{3} \\
& +\frac{\left(7 x^{2}+\left(n^{2}+n-5\right) x-2 n(n+1)\right)}{(x-1)^{2} x^{2}} \cdot D x^{2} \\
& +\frac{\left(x^{2}+2 n(n+1)\right)}{(x-1)^{2} x^{3}} \cdot D x \\
& +\frac{n(n+1) \cdot\left(\left(n^{2}+n+1\right) x+(n-1)(n+2)\right)}{(x-1)^{2} x^{4}}
\end{aligned}
$$

which has the following factorization

$$
\begin{align*}
L_{n}=(D x & \left.+\frac{d \ln \left(A_{1}\right)}{d x}\right) \cdot\left(D x+\frac{d \ln \left(A_{2}\right)}{d x}\right)  \tag{H.2}\\
& \times\left(D x+\frac{d \ln \left(A_{3}\right)}{d x}\right) \cdot\left(D x+\frac{d \ln \left(A_{4}\right)}{d x}\right)
\end{align*}
$$

where:

$$
\begin{aligned}
& A_{1}=-(n-1) \cdot \ln (x)+2 \cdot \ln (x-1)+\ln \left(P_{n}\right) \\
& A_{2}=(n+1) \cdot \ln (x)-(n-1) \cdot \ln (x-1)-\ln \left(P_{n}\right)+\ln \left(Q_{n}\right) \\
& A_{3}=-n \cdot \ln (x)+(n+1) \cdot \ln (x-1)+\ln \left(P_{n}\right)-\ln \left(Q_{n}\right) \\
& A_{4}=n \cdot \ln (x)-\ln \left(P_{n}\right)
\end{aligned}
$$

and where $P_{n}$ and $Q_{n}$ are polynomials in $x$ of degree $n$. They are the polynomial solutions behaving as $\cdots+x^{n}$ for a system of coupled differential equations $\left(P_{n}^{(m)}\right.$ (resp. $Q_{n}^{(m)}$ ) denotes the $m$-th derivative of $P_{n}(x)$ (resp. $P_{n}(x)$ ) with respect to $x$ ):

$$
\begin{aligned}
& (x-1)^{2} \cdot x^{2} \cdot P_{n}^{(4)} \\
& -2 \cdot(2(x-1) \cdot n-3 x+1) \cdot(x-1) \cdot x \cdot P_{n}^{(3)} \\
& +\left((2 x-1)(3 x-4) \cdot n^{2}-\left(12 x^{2}-13 x+2\right) \cdot n+(7 x-5) x\right) \cdot P_{n}^{(2)} \\
& -\left(2(2 x-3) \cdot n^{3}-2(3 x-1) \cdot n^{2}+2(2 x-1) \cdot n-x\right) \cdot P_{n}^{(1)} \\
& +n^{4} \cdot P_{n}=0, \\
& -(x-1) \cdot x \cdot P_{n} \cdot Q_{n}^{(2)} \\
& +\left(2(x-1) \cdot x \cdot P_{n}^{(1)}+(1-x+2 n) \cdot P_{n}\right) \cdot Q_{n}^{(1)} \\
& -\left(2(x-1) \cdot x \cdot P_{n}^{(2)}-2((x-2) n-x) \cdot P_{n}^{(1)}+n^{2} P_{n}\right) \cdot Q_{n}=0 .
\end{aligned}
$$

[^0]:    $\sharp$ This can be seen from the series expansion (11). Denoting $R_{0}$ the fixed order, one has $n \cdot(p+k) \leq$ $R_{0}$, while the CPU time for the series generation of $a^{n}(k, p)$ is not strongly dependent on $n$.
    I From now on, for even $n$, the number of terms stands for the number of terms in the variable $x=w^{2}$.
    $\ddagger$ Except the generation of large series which remains reasonable.

[^1]:    $\dagger$ This is a consequence of (23), (24), (25), (26) yielding $k \cdot \pi=0 \bmod .2 \pi$ (see Appendix E. 1 .

[^2]:    - Note that $\zeta$ (or the polyzeta) function evaluated at integer values $(\zeta(3), \zeta(5), \ldots$ ) do occur in our more involved $n$-fold integrals, in particular in the representation of the connection matrices [6] of the differential Galois group of the Fuchsian linear ODEs of $\chi^{(n)}$.
    $\#$ These $n$-fold integrals [36, 37, 38, 39, 40 look almost the same as the ones we have introduced and analyzed in the study of the diagonal susceptibility of the Ising model 11 for which $n$-th root of unity singularities occur.
    $\dagger$ Which can be seen 46 as "automorphic forms of degree 1 " when the Jacobi modular forms are "automorphic forms of degree 0 " and are associated (up to simple semi-direct products) with $S L(3, Z)$ instead of $S L(2, Z)$
    $\dagger \dagger$ The partition function of the Baxter model can be seen as a ratio and product of elliptic gamma functions and theta functions. It is thus naturally expressed as a double infinite product. Similar double, and even triple, products appear in correlation functions of the eight vertex model 47, 48.
