**Abstract.** A few  $B_{d,s}$  and  $\Lambda_b$  decays induced by  $b \rightarrow s$  transition are studied in the Standard Model and in the framework of the Appelquist, Cheng and Dobrescu (ACD) model, which is a New Physics scenario where a single universal extra dimension is considered. In particular, we investigate the sensitivity of the observables to the radius  $R$  of the compactified extra dimension.

**Keywords:** FCNC decays, Extra Dimensions

**PACS:** 12.60.-i, 13.25.Hw

## INTRODUCTION

Among the ideas proposed to extend the SM, a lot of attention has recently been devoted to models including extra dimensions [1]. An interesting model is that proposed by Appelquist, Cheng and Dobrescu with so-called universal extra dimensions (UED) [2], which means that all the SM fields may propagate in one or more compact extra dimensions. The compactification of the extra dimensions involves the appearance of an infinite discrete set of four dimensional fields which create the so-called KK particles, the masses of which are related to compactification radius according to the relation  $m_n^2 = m_0^2 + \frac{n^2}{R^2}$ , with  $n = 1, 2, \dots$ . The simplest UED scenario is characterized by a single extra dimension. It presents the remarkable feature of having only one new parameter with respect to SM, the radius  $R$  of the compactified extra dimension.

Flavor changing neutral current processes are of particular interest, since they are sensitive to loop contributions involving KK states and therefore can be used to constrain their masses and couplings, i. e. the compactification radius [3]. This observation led Buras and collaborators to compute in the ACD model the effective Hamiltonian of several FCNC processes in particular in the  $b$  sector, namely  $B_{d,s}$  mixing and  $b \rightarrow s$  transitions such as  $b \rightarrow s\gamma$  and  $b \rightarrow sl^+l^-$  [4]. In particular, it was found that  $\mathcal{B}(B \rightarrow X_s\gamma)$  allowed to constrain  $1/R \geq 250$  GeV, a bound updated by a more recent analysis to  $1/R \geq 600$  GeV at 95% CL, or to  $1/R \geq 330$  GeV at 99% CL [5].

In [6] we have analyzed several  $B_{d,s}$  and  $\Lambda_b$  decays induced by  $b \rightarrow s$  transitions, finding that in many cases the hadronic uncertainties do not hide the dependence of the observables on  $R$ , as discussed in the following Sections for the decay modes  $B_d \rightarrow K^*\gamma$ ,  $B_d \rightarrow K^*v\bar{v}$ ,  $B_s \rightarrow \phi\gamma$ ,  $B_s \rightarrow \phi v\bar{v}$ ,  $\Lambda_b \rightarrow \Lambda\gamma$  and  $\Lambda_b \rightarrow \Lambda v\bar{v}$ .

## THE DECAYS $B \rightarrow K^* \gamma, K^* \nu \bar{\nu}$ AND $B_s \rightarrow \phi \gamma, \phi \nu \bar{\nu}$

In the Standard Model the  $b \rightarrow s \gamma$  and  $b \rightarrow s \nu \bar{\nu}$  transitions are described by the effective  $\Delta B = -1, \Delta S = 1$  Hamiltonians

$$H_{b \rightarrow s \gamma} = 4 \frac{G_F}{\sqrt{2}} V_{tb} V_{ts}^* c_7 O_7, \quad H_{b \rightarrow s \nu \bar{\nu}} = \frac{G_F}{\sqrt{2}} \frac{\alpha}{2\pi \sin^2(\theta_W)} V_{tb} V_{ts}^* \eta_X X(x_t) O_L = c_L O_L, \quad (1)$$

involving the operators

$$O_7 = \frac{e}{16\pi^2} [m_b(\bar{s}_L \sigma^{\mu\nu} b_R) + m_s(\bar{s}_R \sigma^{\mu\nu} b_L)] F_{\mu\nu}, \quad O_L = \bar{s} \gamma^\mu (1 - \gamma_5) b \bar{\nu} \gamma_\mu (1 - \gamma_5) \nu.$$

$G_F$  is the Fermi constant and  $V_{ij}$  are elements of the CKM mixing matrix; moreover,

$$b_{R,L} = \frac{1 \pm \gamma_5}{2} b, \quad \alpha = \frac{e^2}{4\pi}$$

is the electromagnetic constant,  $\theta_W$  the Weinberg angle and  $F_{\mu\nu}$  denotes the electromagnetic field strength tensor. The function  $X(x_t)$  ( $x_t = \frac{m_t^2}{M_W^2}$ ,

with  $m_t$  the top quark mass) has been computed in [7, 8]; the QCD factor  $\eta_X$  is close to one, so that we can put it to unity [8, 9].

The effect of the Kaluza-Klein states only consists in a modification of the Wilson coefficients  $c_7$  and  $c_L$  in (1), which acquire a dependence on the compactification radius  $R$ . In particular, the coefficients can be expressed in terms of functions  $F(x_t, 1/R)$ , which generalize their SM analogues  $F_0(x_t)$  according to:  $F(x_t, 1/R) = F_0(x_t) + \sum_{n=1}^{\infty} F_n(x_t, x_n)$ , with  $x_n = \frac{m_n^2}{M_W^2}$ ,  $m_n = \frac{n}{R}$ .

The description of the decay modes  $B \rightarrow K^* \gamma$  and  $B \rightarrow K^* \nu \bar{\nu}$  involves the hadronic matrix elements of the operators appearing in the effective Hamiltonians (1), which can be parameterized in the following way:

$$\begin{aligned} \langle K^*(p', \varepsilon) | \bar{s} \sigma_{\mu\nu} q^\nu \frac{(1 + \gamma_5)}{2} b | B(p) \rangle &= i \varepsilon_{\mu\nu\alpha\beta} \varepsilon^{*\nu} p^\alpha p'^\beta 2 T_1(q^2) + \\ &+ \left[ \varepsilon_\mu^* (M_B^2 - M_{K^*}^2) - \varepsilon^* \cdot q (p + p')_\mu \right] T_2(q^2) + \varepsilon^* \cdot q \left[ q_\mu - \frac{q^2}{M_B^2 - M_{K^*}^2} (p + p')_\mu \right] T_3(q^2), \\ \langle K^*(p', \varepsilon) | \bar{s} \gamma_\mu (1 - \gamma_5) b | B(p) \rangle &= \varepsilon_{\mu\nu\alpha\beta} \varepsilon^{*\nu} p^\alpha p'^\beta \frac{2V(q^2)}{M_B + M_{K^*}} - i \left[ \varepsilon_\mu^* (M_B + M_{K^*}) A_1(q^2) \right. \\ &\quad \left. - (\varepsilon^* \cdot q) (p + p')_\mu \frac{A_2(q^2)}{M_B + M_{K^*}} - (\varepsilon^* \cdot q) \frac{2M_{K^*}}{q^2} (A_3(q^2) - A_0(q^2)) q_\mu \right], \end{aligned}$$

where  $q = p - p'$ , and  $\varepsilon$  is the  $K^*$  meson polarization vector. At zero value of  $q^2$  the condition  $T_1(0) = T_2(0)$  holds, so that the  $B \rightarrow K^* \gamma$  decay amplitude involves a single hadronic parameter,  $T_1(0)$ . Furthermore, a relation holds the form factors  $A_1, A_2$  and  $A_3$ :  $A_3(q^2) = \frac{M_B + M_{K^*}}{2M_{K^*}} A_1(q^2) - \frac{M_B - M_{K^*}}{2M_{K^*}} A_2(q^2)$  together with  $A_3(0) = A_0(0)$ .

We use for the form factors two sets of results: the first one, denoted as set A, obtained by three-point QCD sum rules based on the short-distance expansion [10]; the second one, denoted as set B, obtained by QCD sum rules based on the light-cone expansion [11].

Let us consider the radiative mode  $B \rightarrow K^* \gamma$ . Its decay rate is given by:

$$\Gamma(B \rightarrow K^* \gamma) = \frac{\alpha G_F^2}{8\pi^4} |V_{tb} V_{ts}^*|^2 m_b^2 |c_7|^2 [T_1(0)]^2 M_B^3 \left(1 - \frac{M_{K^*}^2}{M_B^2}\right)^3. \quad (2)$$

One can appreciate the consequences of the existence of a single universal extra dimension considering Fig. 1, where the branching fraction is plotted as a function of  $1/R$ . The hadronic uncertainty is evaluated comparing the two set of form factors and taking into account their errors. A comparison between experimental data [12] (represented by the horizontal band in the Fig. 1) and theoretical predictions allows to put a lower bound of  $1/R \geq 250$  GeV adopting set A, and a stronger bound of  $1/R \geq 400$  GeV for set B.

**FIGURE 1.**  $\mathcal{B}_{B \rightarrow K^* \gamma}$  versus  $1/R$  using set A (left) and B (right) of form factors. The horizontal band corresponds to the experimental result.

For the mode  $B \rightarrow K^* \nu \bar{\nu}$  it is interesting to consider the missing energy distribution. We define  $E_{miss}$  the energy of the neutrino pair in the  $B$  rest frame and consider the dimensionless variable  $x = E_{miss}/M_B$ , which varies in the range  $\frac{1-r}{2} \leq x \leq 1 - \sqrt{r}$  with  $r = M_{K^*}^2/M_B^2$ . One can separately consider the missing energy distributions for longitudinally and transversely polarized  $K^*$ :

$$\frac{d\Gamma_L}{dx} = 3 \frac{|c_L|^2}{24\pi^3} \frac{|\vec{p}'|}{M_{K^*}^2} \left[ (M_B + M_{K^*})(M_B E' - M_{K^*}^2) A_1(q^2) - \frac{2M_B^2}{M_B + M_{K^*}} |\vec{p}'|^2 A_2(q^2) \right]^2, \quad (3)$$

and

$$\frac{d\Gamma_{\pm}}{dx} = 3 \frac{|\vec{p}'| q^2}{24\pi^3} |c_L|^2 \left| \frac{2M_B |\vec{p}'|}{M_B + M_{K^*}} V(q^2) \mp (M_B + M_{K^*}) A_1(q^2) \right|^2 \quad (4)$$

where  $\vec{p}'$  and  $E'$  are the  $K^*$  three-momentum and energy in the  $B$  meson rest frame and the sum over the three neutrino species is understood. The missing energy distributions for polarized  $K^*$  are shown, for different values of the compactification radius, in the left part of Fig. 2, whereas in the right part of it, the branching fraction is plotted as a function of the compactification radius.

Also the decay modes  $B_s \rightarrow \phi \gamma$  and  $B_s \rightarrow \phi \nu \bar{\nu}$  are described through the effective Hamiltonians (1). It is useful to relate the branching fraction  $\mathcal{B}_{B_s \rightarrow \phi \gamma}$  to the measured

**FIGURE 2.** Left: missing energy distribution in  $B \rightarrow K^* \nu \bar{\nu}$  for a longitudinally polarized  $K^*$  (lower curves) and a transversally polarized  $K^*$  (upper curves) for set A. The dark region corresponds to SM, the intermediate one to  $1/R = 500$  GeV and the light one to  $1/R = 200$  GeV. Right:  $\mathcal{B}_{B \rightarrow K^* \nu \bar{\nu}}$  versus  $1/R$ , with set A of form factors.

value of  $\mathcal{B}_{B_d \rightarrow K^{*0} \gamma}$ :

$$\mathcal{B}_{B_s \rightarrow \phi \gamma} = \left( \frac{T_1^{B_s \rightarrow \phi}(0)}{T_1^{B_d \rightarrow K^{*0}}(0)} \right)^2 \left( \frac{M_{B_d}}{M_{B_s}} \right)^3 \left( \frac{M_{B_s}^2 - M_\phi^2}{M_{B_d}^2 - M_{K^{*0}}^2} \right)^3 \frac{\tau_{B_s}}{\tau_{B_d}} \mathcal{B}_{B_d \rightarrow K^{*0} \gamma}. \quad (5)$$

This equation shows that a crucial quantity to predict  $\mathcal{B}_{B_s \rightarrow \phi \gamma}$  is the  $SU(3)_F$  breaking parameter  $\hat{r}$  defined by  $\frac{T_1^{B_s \rightarrow \phi}(0)}{T_1^{B_d \rightarrow K^{*0}}(0)} = 1 + \hat{r}$ . Detailed analyses of the range of values within which  $\hat{r}$  can vary are not available, yet. Using  $\hat{r} = 0.048 \pm 0.006$  estimated by Light Cone Sum Rules (LCSR) [11] we predict:  $\mathcal{B}_{B_s \rightarrow \phi \gamma} = (4.2 \pm 0.3) \times 10^{-5}$ . This prediction is compatible with the recent measurement performed by Belle Collaboration [13]:  $\mathcal{B}_{B_s \rightarrow \phi \gamma}^{exp} = (5.7_{-1.5}^{+1.8}(stat)_{-1.1}^{+1.2}(syst)) \times 10^{-5}$ .

In the single extra dimension scenario the modification of the Wilson coefficient  $c_7$  changes the prediction for  $\mathcal{B}_{B_s \rightarrow \phi \gamma}$ , as shown in Fig. 3 where we plot the branching ratio versus  $1/R$ .

Let us consider the mode  $B_s \rightarrow \phi \nu \bar{\nu}$ . The missing energy distributions for polarized  $\phi$  mesons have expressions completely analogous to the case  $B \rightarrow K^* \nu \bar{\nu}$ , eqs. (3),(4). For computing their values, we have used  $B_s \rightarrow \phi$  form factors determined by LCSR [11]. The distributions result to be sensitive to the extra dimension, in particular the maximum of the distributions is always higher than in the SM.

**FIGURE 3.** Left:  $\mathcal{B}(B_s \rightarrow \phi \gamma)$  vs the compactification parameter  $1/R$ . The present experimental upper bound is  $\mathcal{B}_{B_s \rightarrow \phi \gamma} < 12 \times 10^{-5}$  (at 90% CL). Right:  $\mathcal{B}_{B_s \rightarrow \phi \nu \bar{\nu}}$  versus  $1/R$ .

The SM prediction for the branching ratio is  $\mathcal{B}_{B_s \rightarrow \phi \nu \bar{\nu}} = (1.3 \pm 0.3) \times 10^{-5}$ . It suggests that this mode is within the reach of future experiments, although the observation of a final state involving a neutrino-antineutrino pair is a challenging task. The dependence of  $\mathcal{B}_{B_s \rightarrow \phi \nu \bar{\nu}}$  on  $1/R$  is depicted in the right part of Fig. 3.

## THE DECAYS $\Lambda_b \rightarrow \Lambda \gamma$ AND $\Lambda_b \rightarrow \Lambda \nu \bar{\nu}$

In the case of  $\Lambda_b \rightarrow \Lambda$  transitions the hadronic matrix elements of the operators  $O_7$  and  $O_L$  in eq. (1) involve a larger number of form factors. At present, a determination of such form factors is not available. However, it is possible to invoke heavy quark symmetries for the hadronic matrix elements involving an initial spin= $\frac{1}{2}$  heavy baryon comprising a single heavy quark  $Q$  and a final  $\frac{1}{2}$  light baryon; the heavy quark symmetries reduce to two the number of independent form factors. As a matter of fact, in the infinite heavy quark limit  $m_Q \rightarrow \infty$  and for a generic Dirac matrix  $\Gamma$  one can write [15]:

$$\langle \Lambda(p', s') | \bar{s} \Gamma b | \Lambda_b(p, s) \rangle = \bar{u}_\Lambda(p', s') \{ F_1(p' \cdot v) + \not{v} F_2(p' \cdot v) \} \Gamma u_{\Lambda_b}(p, s) \quad (6)$$

where  $u_\Lambda$  and  $u_{\Lambda_b}$  are the  $\Lambda$  and  $\Lambda_b$  spinors, and  $v = \frac{p}{M_{\Lambda_b}}$  is the  $\Lambda_b$  four-velocity. The form factors  $F_{1,2}$  depend on  $p' \cdot v = \frac{M_{\Lambda_b}^2 + M_\Lambda^2 - q^2}{2M_{\Lambda_b}}$  (for convenience we instead consider them as functions of  $q^2$  through this relation).

A determination of  $F_1$  and  $F_2$  has been obtained by three-point QCD sum rules in the  $m_Q \rightarrow \infty$  limit [16]. In the following we use the expressions for the functions  $F_1, F_2$  obtained by updating some of the parameters used in [16]:

$$F_{1,2}(q^2) = \frac{F_{1,2}(0)}{1 + a_{1,2} q^2 + b_{1,2} q^4} \quad (7)$$

with  $F_1(0) = 0.322 \pm 0.015$ ,  $a_1 = -0.0187 \text{ GeV}^{-2}$ ,  $b_1 = -1.6 \times 10^{-4} \text{ GeV}^{-4}$ , and  $F_2(0) = -0.054 \pm 0.020$ ,  $a_2 = -0.069 \text{ GeV}^{-2}$ ,  $b_2 = 1.5 \times 10^{-3} \text{ GeV}^{-4}$ .

The knowledge of  $\Lambda_b$  form factors deserves a substantial improvement; in the meanwhile, we use in our analysis the form factors in (7) stressing that the uncertainties attached to the various predictions only take into account the errors of the parameters of the model chosen for  $F_1$  and  $F_2$ .

The  $\Lambda_b \rightarrow \Lambda \gamma$  branching ratio can be related to that of  $B_d \rightarrow K^{*0} \gamma$  through the expression:

$$\mathcal{B}_{\Lambda_b \rightarrow \Lambda \gamma} = \left( \frac{F_1(0)}{T_1^{B_d \rightarrow K^{*0}}(0)} \right)^2 \left( 1 + \frac{M_\Lambda}{M_{\Lambda_b}} \frac{F_2(0)}{F_1(0)} \right)^2 \left( \frac{M_{B_d}}{M_{\Lambda_b}} \frac{M_{\Lambda_b}^2 - M_\Lambda^2}{M_{B_d}^2 - M_{K^{*0}}^2} \right)^3 \frac{\tau_{\Lambda_b}}{4\tau_{B_d}} \mathcal{B}_{B_d \rightarrow K^{*0} \gamma}$$

Using the ratio of form factors obtained from (7) and the form factor  $T_1$  in [11], we predict:  $\mathcal{B}_{\Lambda_b \rightarrow \Lambda \gamma} = (3.4 \pm 0.7) \times 10^{-5}$ . As for the effect of the extra dimension in modifying the decay rate, in Fig. 4 we show how  $\mathcal{B}_{\Lambda_b \rightarrow \Lambda \gamma}$  depends on  $1/R$ .

For the mode  $\Lambda_b \rightarrow \Lambda \nu \bar{\nu}$ , in Fig. 4 (right part) we plot the dependence of the branching ratio on  $1/R$ . The SM value is expected to be  $\mathcal{B}_{\Lambda_b \rightarrow \Lambda \nu \bar{\nu}} = (6.5 \pm 0.9) \times 10^{-6}$ .

These results suggest that these processes are within the reach of LHC experiments.

**FIGURE 4.**  $\mathcal{B}_{\Lambda_b \rightarrow \Lambda\gamma}$  (left) and  $\mathcal{B}_{\Lambda_b \rightarrow \Lambda V\gamma}$  (right) plotted as function of  $1/R$ . The uncertainty shown by the dark band is mainly due to the errors on the form factors of the model (7).

## CONCLUSIONS

We have studied how a single universal extra dimension could have an impact on several loop induced  $B_{d,s}$  and  $\Lambda_b$  decays. For the  $B \rightarrow K^*\gamma$  mode, the uncertainty related to the form factors does not obscure the sensitivity to the compactification radius. From the comparison between predictions and experimental data we obtain a lower bound of  $1/R \geq 300 - 400$  GeV. Then, we have found that hadronic uncertainties are not large in case of  $B_s$  decays, whereas for  $\Lambda_b$  the situation is more uncertain. These results can be useful for the Physics programs at the hadron colliders.
