#### Abstract

W e analyze the e ect of local spin operators in the $K$ itaev m odel on the honeycom b lattice. W e show, in perturbation around the isolated-dim er lim it, that they create Abelian anyons together w ith ferm ionic excitations which are likely to play a role in experim ents. W e derive the explicit form of the operators creating and $m$ oving A belian anyons w ithout creating ferm ions and show that it involves $m$ ulti-spin operations. Finally, the im portant experim ental constraints stem $m$ ing from our results are discussed.

PACS num bers: 75.10 Jm, 05.30. Pr

A nyons are particlesw hich obey quantum statistics different from bosons and ferm ions [1]. In condensed $m$ atter physics, such weird ob jects are expected to arise, for instance, in fractional quantum H all system s [2], p -w ave superconductors [3], or Josephson junctions arrays [4], but have never been directly observed yet. W ithin the last few years, anyons have also been shown to be of prim er interest for topologicalquantum com putation [5]. Follow ing $K$ itaev's sem inalw ork related to this problem atics [6], severalspin system $s$ w ith em erging A belian and non-A belians anyons have been proposed [7, 8], together w ith experim ental proposals susceptible to capture their fascinating braiding properties $[9,10,11]$. In this perspective, K itaev's honeycom b m odel [7] which only involves tw o-spin interactions seem s easier to realize than the toric code $m$ odel [6] based on four-spin interactions.

As shown by $K$ itaev using 4th order perturbation theory, the honeycom b $m$ odel can be $m$ apped onto the toric code, thus proving the existence of anyons in the $m$ odel [7]. H ow ever, orders lower than 4 also bring their physical contributions and deserve a careful treatm ent, especially when considering correlation functions and, m ore im portantly, the action of spin operators. The aim of this Letter is to shed light on these issues and to bring som e insights for experim ents. $W$ e show that the original spin operators applied onto the ground state create both anyons and ferm ions and we give the explicit form of an operator creating anyons w ithout ferm ions. At lowest nontrivial order, this operator involves a supenposition of states involving one-spin and three-spin operations on the ground state. To conclude, we discuss the constraints raised by our results for experim ents in optical lattices.

Them odel | K itaev's honeycom b (orbrickw all) model is a two-dim ensional spin-1=2 system described by the H am iltonian

$$
H=\begin{array}{cc}
\mathrm{X} & \mathrm{X}  \tag{1}\\
=x ; y ; \mathrm{z} & \mathrm{links}
\end{array} \begin{gathered}
\text { i }
\end{gathered}
$$

where the $i$ 's are the usual Pauli m atrices at site i. W thout loss of generality [7], in the follow ing, we assum e
$J \quad 0$ for all and $J_{z} \quad J_{x} ; J_{y}$.
For our punpose, it is convenient to $m$ ap the spin $m$ odel (1) on the honeycom b lattice onto an e ective spin hardcore boson problem on a square lattice. This $m$ apping is achieved via the follow ing rules

$$
\begin{align*}
& \underset{i}{\mathrm{x}}=\underset{i}{\mathrm{x}}\left(\mathrm{~b}_{\mathrm{i}}^{\mathrm{y}}+\mathrm{b}_{\mathrm{i}}\right) \quad \text {; } \underset{\mathrm{i} ;}{\mathrm{x}}=\mathrm{b}_{\mathrm{i}}^{\mathrm{y}}+\mathrm{b}_{\mathrm{i}} \text {; } \\
& { }_{i}^{y}{ }_{i}^{1 ;}={ }_{i}^{y}\left(b_{i}^{y}+b_{i}\right) ;{ }_{i}^{y}=i_{i}^{z}\left(b_{i}^{y} \quad(\underline{y}) ;\right. \tag{2}
\end{align*}
$$

where $b_{i}^{y}\left(b_{i}\right)$ is the creation (annihilation) operator of a hardcore boson at site $i$ of the square lattice depicted in Fig. 1 and $i_{i}$ the Paulim atrices of the e ective spin at the sam e site. H ere, we have attached each site of the honeycomblattioe ( or ) to the z-dim er it belongs to.

In the follow ing, we set $J_{z}=1=2$ so that the H am iltonian reads

$$
\begin{equation*}
H=\frac{N}{2}+Q+T_{0}+T_{+2}+T_{2} ; \tag{3}
\end{equation*}
$$

$w$ here $N$ is the num ber of $z$-dim ers,

$$
\begin{align*}
Q & ={ }^{X}{ }^{i} b_{i}^{y} b_{i} ;  \tag{4}\\
T_{0} & ={ }^{X} J_{x} t_{i}^{i+n_{1}}+J_{y} t_{i}^{i+n_{2}}+h: c: ;  \tag{5}\\
T_{+2} & =X^{i} J_{x} V_{i}^{i+n_{1}}+J_{y} v_{i}^{i+n_{2}}=T_{2}^{y} ;
\end{align*}
$$

w ith hopping and pair creation operators $t$ and $v$

$$
\begin{aligned}
& t_{i}^{i+n_{1}}=b_{i+n_{1}}^{y} b_{i} \underset{i+n_{1}}{x} ; \quad t_{i}^{i+n_{2}}=\quad i \underline{q}_{+n_{2}}^{y} b_{i} \underset{i+n_{2}}{y} \underset{i}{z} ;(7) \\
& v_{i}^{i+n_{1}}=b_{i+n_{1}}^{y} b_{i}^{y} \underset{i+n_{1}}{x} ; v_{i}^{i+n_{2}}=i b_{i+n_{2}}^{y} b_{i}^{y} \underset{i+n_{2}}{y} \underset{i}{z}:(8)
\end{aligned}
$$

We em phasize that this $m$ apping is exact and sim ply relies on an altemative interpretation of the four possible spin states of a dim er (see [12, 13] for details). A key feature of this $m$ odel is that $H$ com $m$ utes $w$ ith
 notations given in F ig. 1 , so that it describes a $\mathrm{Z}_{2}$ gauge

FIG. 1: (color online). M apping of the honeycom b (brickwall) lattice (a) onto an e ective square lattice (b) with unit basis vectors $n_{1}$ and $n_{2}$. The num bering of the sites of $a$ plaquette $p$ is show $n$ in both cases.
theory. Further and $m$ ore interestingly, it is exactly solvable via several ferm ionization m ethods $[7,14,15]$. Its phase diagram consists in a gaplessphase for $J_{x}+J_{y}>J_{z}$ and a gapped phase otherw ise. T he latter contains highenergy ferm ions and low-energy A belian anyons which are the focus of the present work.

Perturbation theory | H ere, we focus on the isolateddim er lim it ( $J_{z} \quad J_{x} ; J_{y}$ ) and, follow ing $K$ itaev, we perform a perturbative analysis of the gapped phase. A reliable tool to investigate this problem is the continuous unitary transform ations (CUTs) m ethod [16], used in its perturbative version $[12,17,18]$. W ith in this approach, the Ham iltonian (3) is transform ed into an effective $H$ am iltonian $H e$ which conserves the num ber of bosons ( $\left.H_{e} ; Q\right]=0$ ). The comerstone of the $m$ ethod is that $\mathrm{H}_{\mathrm{e}}$ is unitarily equivalent to H , i. e., there exists a unitary transform ation $U$ such that $H_{e}=U^{Y} H U$. This implies that $H$ and $H_{e}$ have the sam e spectrum but not the sam e eigenstates. At order 1, the fill e ective $H$ am iltonian reads $H_{e}=N=2+Q+T_{0}$, and leads to high-energy ferm ionic excitations $m$ ade of a hardcore boson and a spin-string [12,13]. At order 4, the e ective H am iltonian in the low-energy (no ferm ion) subspace is the toric code H am iltonian [7]

$$
\begin{equation*}
\frac{\mathrm{He}_{\mathrm{e}} \dot{\mathrm{~b}}}{\mathrm{~N}}=\frac{1}{2}+\frac{\mathrm{J}_{\mathrm{x}}^{2}+\mathrm{J}_{\mathrm{y}}^{2}}{2}+\frac{\mathrm{J}_{\mathrm{x}}^{4}+\mathrm{J}_{\mathrm{y}}^{4}}{8} \frac{\mathrm{~J}_{\mathrm{x}}^{2} \mathrm{~J}_{\mathrm{y}}^{2}}{2 N} \mathrm{X}_{\mathrm{p}}: \tag{9}
\end{equation*}
$$

A simple way to obtain this result is to study the action of $H$, in perturbation, on the low -energy eigenstates of the unperturbed Ham iltonian ( $\mathrm{J}_{\mathrm{x}}=\mathrm{J}_{\mathrm{y}}=0$ ) which are ferrom agnetic con gurations of $z$ dim ers. H ow ever, we em phasize that the low-energy eigenstates of H are not solely built from these states, but involve high-energy (antiferrom agnetic) con gurations, even at order 1 [19]. This point is the source of the discrepancy betw een the correlation functions com puted in [20] and exact results $[12,21]$. T he perturbative expansion of the exact ground state spin-spin correlation functions at order 2 read

$$
\begin{gather*}
h_{i ;}^{x} \underset{i+n_{1} ; i=}{x} J_{x} ; h h_{i ;}^{y} \underset{i+n_{2} ;}{y} i=J_{y} ;  \tag{10}\\
h_{i ;}^{z} \underset{i}{z} i=1 \quad\left(J_{x}^{2}+J_{y}^{2}\right): \tag{11}
\end{gather*}
$$

These results clearly show that sticking to ferrom agnetic dim er con gurations fails to capture the form of the low energy states [19, 20].

The H am iltonian (9), known as the toric code [6], has its ground state in the vortex-free sector ( $W_{p}=+1 ; 8 p$ ) and contains A belian anyons de ned as plaquette excitations $\left(\mathbb{W}_{p}=1\right)$. The real challenge is obviously to observe these anyons experim entally. In this perspective ultracold atom $s$ in optical lattices are good candidates [9] although devices using polarm olecules have also been proposed [10]. Recently, severaldetection protocols in optical lattices based on the possibility to perform sequences of single-spin operations have been proposed [11,22]. U nfortunately, although such operations create and $m$ ove anyons, they also create ferm ionic excitations which are susceptible to spoil the detection process. O ur aim is to show that this crucial fact, alw ays neglected in previous studies, is ofm a jor im portance for experim ents.

Single-spin operations | Let us rst discuss the action of single-spin operations on the ground state and focus on ${ }_{i}^{z}={\underset{i}{z}}_{z}$. This operator is used, in Refs. [11, 23], as the basic tile to create two anyons on left and right plaquettes of the site i [see inset in Fig. 2 (left)]. A s $m$ entionned above the $m$ ain problem is that it does not sim ply transform the ground state j0i (belonging to the vortex-free sector) into the low est-energy state of the tw ovortex con guration one seeks to obtain. To make this statem ent quantitative, we consider the spectral w eights

$$
\begin{equation*}
I_{n}={ }_{k}^{x} \quad h f p_{1} ; p_{2} g ; n ; k j_{i} j 0 i j^{2} ; \tag{12}
\end{equation*}
$$

which obey the sum nule ${ }^{P}{ }_{n} I_{n}=1$. Here, fipg; $n$;kidenotes the eigenstate of $H$ in a sector given by an anyon con guration $\mathrm{W}_{\mathrm{p}}=1$, and n high-energy quasiparticles w th quantum numbers $k$. $P$ laquettes $p_{1}$ and $p_{2}$ are neighbors of $i$ and depend on $=y ; z$ (see insets of Fig . 2). W ith these notations, the eigenstates of H e are given by $U^{y}$ fipg; $n$;ki. To com pute $I_{n}^{z}$, one is thus led to determ ine how the observable $i_{i}^{z}$ is renorm alized under the unitary transform ation $U$. W thin the CUT form alism, this can be achieved e ciently order by order in perturbation [13,24]. At order 1, one gets

$$
\begin{equation*}
U^{y}{\underset{i}{z} U={ }_{i}^{z} 1+J_{x} v_{i}^{i} n_{1}+J_{y} v_{i}^{i} n_{2}+h . c . ; ~ ; ~}_{\text {in }} \tag{13}
\end{equation*}
$$

which clearly show s that pairs of quasiparticles are created or anninilated. In addition, one can see that the action of ${ }_{i}^{z}$ on the ground state yields a supenposition of statesw ith the appropriate tw o-vortex con guration, but w ith di erent num ber of quasiparticles. W e com puted the renorm alization of ${ }_{i}^{z}$ up to order 6 but we em phasize that quasiparticles arise at order $1 \mathrm{which} m$ akes this phenom enon strongly relevant. T he pertunbative expansion of $U{ }^{Y}{ }_{i}^{z} U$ allow s a straigh forw ard calculation of the overlap probability which reads at order 6: $I_{0}^{z}=1 \quad \frac{z_{2}^{z}}{2}$

F IG . 2: (color online). Behavior of the spectral weights $I_{n}^{z}$ (left) and $I_{n}^{Y}$ (right) for ferm ion num bers $n=0 ; 2 ; 4$, as a function of the coupling $J=J_{x}=J_{y}$ for $J_{z}=1=2$. Grey plaquettes in the insets $p_{1}^{z(y)}$ and $p_{2}^{z(y)}$ show where anyons are created under the action of $\underset{i}{z}$ (left) and $\underset{i}{y}$ (right).
w ith

$$
\begin{align*}
I_{2}^{z}= & J_{x}^{2}+J_{y}^{2}+\frac{3}{2} J_{x}^{4}+J_{y}^{4}+4 J_{x}^{2} J_{y}^{2}+ \\
& \frac{7}{2} J_{x}^{6}+J_{y}^{6}+\frac{43}{2} J_{x}^{2} J_{y}^{4}+J_{x}^{4} J_{y}^{2}: \tag{14}
\end{align*}
$$

$N$ ote that only even $n$ contributions are nonvanishing. In addition, we found that $I_{n}^{z}{ }_{4}=0$ at order 6 , show ing the sum rule is ful lled.

M ultiple-spin operations | T he sam e approach can be used to analyze the action of $\underset{i}{y}=\stackrel{y}{i} \underset{i}{i} \underset{i}{x}$, on the ground state, which creates tw o anyons on the up and down plaquettes of the site $i$ [see inset in Fig .2 (right)] as well as quasiparticles. A s previously, we com puted the spectral weights up to order 6 and obtained: $I_{0}^{Y}=1 \quad{\underset{F}{Y}}_{Y}^{\frac{Y}{4}}$ w ith

$$
\begin{align*}
I_{2}^{Y}= & J_{\mathrm{x}}^{2}+J_{\mathrm{y}}^{2}+\frac{3}{2} J_{\mathrm{x}}^{4}+J_{\mathrm{y}}^{4}+ \\
& \frac{7}{2} J_{\mathrm{x}}^{6}+J_{\mathrm{y}}^{6}+3 J_{\mathrm{x}}^{2} J_{\mathrm{y}}^{4}+J_{\mathrm{x}}^{4} \mathrm{~J}_{\mathrm{y}}^{2} ;  \tag{15}\\
I_{4}^{\mathrm{y}=} & J_{\mathrm{x}}^{2} J_{\mathrm{y}}^{4}+J_{\mathrm{x}}^{4} J_{\mathrm{y}}^{2}: \tag{16}
\end{align*}
$$

The behavior of $I_{n}^{z}$ and $I_{n}^{y}$ are plotted in $F$ ig. 2 as a function of the param eter $J_{x}=J_{y}=J$. O ne can directly observe the grow ing weight (for increasing $J$ ) of the excited states after the operations $z$ or $y$ have been applied on the ground state.

O ther im portant quantities are string operators w hich are crucial in experim ents to perform braiding of anyons. To investigate the e ect ofsych $m$ ultiple-spin operations, let us consider a string $S={ }_{a=1, m} \quad \begin{aligned} & z \\ & i_{a}\end{aligned} ;$ along a horizontal line of the original brickw all-lattice (see Fig. 3 w ith $m=3$ for notations). W hen such a sequence is applied on the ground state j0i, the probability to nd the nal state in the low est-energy state w ith anyons at plaquettes

FIG. 3: (color online). A ction, in the vortex-free sector, of the string operator $S=\underset{i_{3}}{z} ;{\underset{i}{2}}_{z}^{z} \underset{i_{1}}{z} ;$. Each operator ips the two plaquettes adjacent to the $z$-dim er it is attached to but also creates ferm ionic excitations (not shown).

1 and $(m+1)$ is given, at order 2 , by

$$
\begin{equation*}
\mathfrak{h f} 1 ; m+1 g ; 0 j \mathfrak{j} i \jmath^{2}=1 \quad m\left(\mathrm{~J}_{\mathrm{x}}^{2}+\mathrm{J}_{\mathrm{y}}^{2}\right) ; \tag{17}
\end{equation*}
$$

which obviously coincides $w$ ith $I_{0}^{z}$ for $m=1$. $N$ ote that w e dropped the $k$ index which is useless for states $w$ ithout ferm ions. This result show $s$ that, at this order, the role played by the excited states is directly proportional to the length of the string.

A nyons without ferm ions | At this stage, we have shown that the action of the original spins $i$ on the ground state does generate unw anted excited states as can be seen at low est nontrivial order in the perturbation theory. O ne m ay w onder how to create anyons w thout ferm ions. In other words, we w ish to determ ine the operators that only ip two W p's and nothing else.

A s an exam ple, we focus on the operator creating two vortices at the left and right plaquettes of a given site i [see inset Fig. 2 (left)]. Let us denote this operator i, and show how to com pute its perturbative expansion, $i={ }_{\mathrm{k} 2 \mathrm{~N}}^{\mathrm{i}} \mathrm{i}^{(\mathrm{k})}$, where ${ }_{i}^{(\mathrm{k})}$ contains all operators of order $k$ and thus associated to $J_{x}^{l} J_{y}^{m} \quad(w$ ith $1+m=k$ ). The
 to $I_{0}^{z}=1$. At order 0 , operators are not renom alized so that one obviously has ${ }_{i}^{(0)}=i_{i}^{z}$. The renom alization of $i$ under the unitary transform ation $U$ reads
where $i_{e}^{(k) ;[1]}$ is of order $(k+1)$. O rder 0 being already ful lled, let us w rite this constraint at order 1, using Eq. (13) and $i_{i}^{(k) ;[0]}={ }_{i}^{(k)}$
$0=i_{e}^{(0) ;[1]}+i_{e}^{(1) ;[0]}=J_{x} V_{i}^{i} n_{1}+J_{y} v_{i}^{i} n_{2}+h . C .+{ }_{i}^{(1)}:$
This equation yields ${ }_{i}^{(1)}$, so that using the inverse m apping of Eq. (2) one nally gets, in the original spin language and at order 1

$$
\begin{align*}
& i={\underset{i}{i}}_{z}^{i}+\frac{1}{2} \tag{20}
\end{align*}
$$

$$
\begin{aligned}
& + \\
& \text { i }
\end{aligned}
$$

This expression show s that to create anyons w thout ferm ions, one $m$ ust be able to build a delicate supenposition of single spin-ip and three spin- ip states. Furtherm ore, the weights of the latter have to be ne-tuned since they depend on the precise values of the couplings $w$ hich $m$ ay be experim entally challenging. $N$ ote also that higher order corrections w ould even involve m ore spins.

Experim entaldiscussion | Let us now put our results in an experim ental perspective, setting, for sim plicity, $J_{\mathrm{x}}=J_{\mathrm{y}}=J$ and $=J=J_{z}$. Equation (17) show $s$ that the repeated action of $m$ spin- ips decreases the weight of the (pure) two-anyon state in the low-energy subspace. O ne should thus work with sm all enough values of . For a reasonable num berm ' 25 of operations needed to perform a braiding of anyons, and assum ing that $m{ }^{2}=2^{\prime} \quad 1=2$ [25] leads to conclusive experim ents, one is led to choose . 0:2.

From a practicalpoint ofview, we also $w$ ish to $m$ ention that detecting anyons using ground-state tw o-spin correlation functions after an anyonic braiding is rather di cult. Indeed, contrary to what is m entioned in [11], these functions do not change sign in the presence of anyons. The latter are only responsible for 4th order corrections
 for 3rd order changes in $h \underset{i}{x} \underset{i+n_{1}}{x} ; i$ and $h \underset{i}{y} \underset{i+n_{2}}{y} ; i$ whose leading tem s are of order 1 [13]. In this respect, the $m$ ore e cient and sophisticated set-up recently proposed in [22] is an interesting altemative.

We end this section with some rem arks about tem perature issues in experim ents, based on the orders of m agnitude $\mathrm{J}_{\mathrm{z}}=\mathrm{h}=5 \mathrm{kHz}$ and $\mathrm{J}=\mathrm{h}=1 \mathrm{kHz}$ [26] ( $=0.2$ ). To perform anyonic interferom etry experim ents [11, 22], the tem perature of the system should be sm all enough to prevent them al excitations of unw anted anyons. A ssum ing therm alequilibrium, the typical low -energy scale $J_{e}=J_{z}{ }^{4}=16$ appearing in front of the plaquette term in Eq. (9) leads to the constraint $T \quad J_{e}=k_{B}$ ' 20pK. Such a tem perature is lower than recently reached tem peratures [27], but th is problem $m$ ay be circum vented by working out of equilibrium .

To sum up, we have shown that unless experim entalists m anage to apply the operators given in Eq. (20), they w ill have to m ake sure the constraint $=J=J_{z} .0 .2$ is ful-
lled. This constraint, arising from the renorm alization ofspin operators at order 1 in perturbation, could lead to a problem atic upper bound on the tem perature. T he latter indeed scales as ${ }^{4}$ since the toric code H am iltonian arises as an e ective $H$ am iltonian of $K$ itaev's honeycom b m odel only at order 4 in perturbation. Finally, let us $m$ ention that the tim e evolution of the system betw een spin operations $m$ ay also lead to an unwanted dynam ics
of the ferm ions but this di culty can be circum vented by freezing the system via an increase of the optical lattice barriers.

W e are indebted to Liang Jiang for fruitful discussions and for his help conceming experim ents. KPS acknowledges ESF and EuroH orcs for funding through his EU RYI.
