#### Abstract

Fractal geom etry of random curves appearing in the scaling lim it of critical tw o-dim ensional statistical system $s$ is characterized by their harm onic $m$ easure and $w$ inding angle. The form er is the $m$ easure of the jaggedness of the curves while the latter quanti es their tendency to form logarithm ic spirals. W e show how these characteristics are related to local operators of conform al eld theory and how they can be com puted using conform alinvariance ofcriticalsystem sw ith central charge c 61.

## 1 Introduction

G eom etric properties of critical tw o-dim ensional system s of statistical mechanics have attracted considerable interest of both physicists and $m$ athe$m$ aticians in recent years. O $n$ the one hand, $m$ ethods of quantum gravity have been successfully applied by D uplantier to obtain the m ultifractalspectrum ofham onicm easure on critical cluster boundaries till, hand, the invention of the Schram m - oew ner evolution (SLE) by Schram m [3] $]$ has $m$ ade it possible to study con form ally-invariant critical curves rigorously (several review s of SLE are available by now ; see, for exam ple, Refs. [4ir 点,

C onform al eld theory (CFT ) has been a natural and traditional language for description of critical statistical system $s$ in two dim ensions. It is im portant to understand how fractal properties of critical curves can be obtained from CFT.A part of the em erging picture is that the stochastic geom etry of critical curves can be studied by traditionalm ethods of C FT.As
any local eld theory, CFT focuses on correlation functions of local operators. It tums out that the stochastic geom etry of critical curves is related to correlators of certain prim ary elds in CFT.This connection, rst discussed
 identi ed the curve-creating prim ary operators and considered their correlators w th other prim aries serving as \probes" of harm on ic m easure. A long this way we have reproduced D uplantier's results form ultifractal exponents associated $w$ ith harm on ic $m$ easure.

In addition to harm onic m easure, com plicated planar dom ains and their boundaries are characterized by winding or rotation. T he notion of rotation spectrum for planar dom ains has been introduced by $B$ inder in $R$ ef. [ $[\overline{1} \bar{Z}]$. $T$ hen the $m$ ixed rotation and harm onic $m$ easure spectrum has been found exactly for critical curves by $D$ uplantier and $B$ inder [1] $]$. In that paper the authors combined an earlier Coulomb gas approach to the distribution of

In this paper we extend our previous analysis [1] , $\left.\left.{ }_{1}^{[1}\right]_{1}^{1}\right]$ to include the winding (rotation) of critical curves. A s it happens, to account for rotation of critical curves, we need to consider CFT prim ary eldsw ith complex weights and charges. The procedure involves an analytic continuation of chiral correlation functions and then gluing the chiralsectors to obtain realbut angu lar dependent correlators. T he paper is organized as follow s. In Section登 we form ulate the problem and give heuristic de nitions of various ob jects of interest inchuding harm onic $m$ easure and rotation of critical curves. In Section ' ${ }_{-1 / 1}^{1}$, we consider a special case of a single probe of harm on ic m easure and rotation near a star con guration of several critical curves. T hen we go on to the general case, where several probes can be placed in the vicin ity of a critical star con guration. W e conclude in Section $\bar{S}_{1}^{1} w$ th a discussion and com parison w th other works.

## 2 D escription of the problem

C onsider a two-dim ensional critical statistical system. Such system s can be form ulated as critical points in an ensemble of curves on a lattice, e.g. the loops of the $O(n) m$ odel or the high- $T$ expansion loops of the $Q$-state P otts m odel. W hen the system is critical, these curves are called critical curves. In the continuum lim it, statistical system $s$ are invariant under conform al transform ations and can be described by a C F T w ith a certain centralcharge c. In this case the critical curves are uctuating fractal curves.

A ny conform al transform ation in two dimensions locally looks like a com bination of rotation and a scale transform ation (dilatation). For a given com position of dilatation and rotation in the plane there exist curves which rem ain invariant. They are logarithm ic spirals $=\ln r$. The quantity characterizes the w inding of a spiral and is called the rate of rotation. For a pure dilatation the spirals degenerate into straight lines (no rotation: $=0$ ) which $m$ ay intersect and form comers $w$ ith arbitrary opening angles.

Since any conform altransform ation is locally a com position ofdilatation and rotation, a conform ally invariant critical curve can be thought of as an assem bly of elem entary comers and logarithm ic spirals at all scales. T he so called m ultifractal analysis aim s at determ ining the fractal dim ensions of the subsets of a critical curve w ith given opening angle and winding. T hese fractal dim ensions form a continuous fam ily ofm ultifractal exponents.

H arm onic $m$ easure is anotherw ay of characterizing the com plicated fractal geom etry of a critical curve. In a sim ple electrostatic analogy we can im agine that a critical cluster is charged with a unit charge that all goes to the boundary of the cluster. C harge density (whidh is the density of harm onic m easure) on the boundary is very uneven and hum py, and can be characterized by its $m$ om ents. Therefore, in the ensem ble of critical curves it is natural to characterize their fractal geom etry by the statistics of local $w$ inding and harm onic $m$ easure near som e point on the curve.

Locally, near a charged comer the scaling of the charge density or, equivalently, of the $m$ agnitude of the electric eld $E$ is determ ined by the opening angle at the comer: rE (r) $\quad r^{=}$. W hat $w$ illbe im portant for us in the follow ing is that this pow er-law behavior is the sam e along all straight lines that converge at the apex of the comer. A ll these lines intersect the equipotentials at constant angles, and only one of them is an electric eld line (corresp onding to $==2$ ). In $m$ athem atics such lines are som etim es called \slanted G reen lines", while the electric eld lines are called \G reen lines". In a general situation we w ill denote the slanted $G$ reen line that goes from the origin and form $s$ the angle $w$ ith equipotentials by

Sim ilar statem ents can bem ade for a logarithm ic spiral. T he inform ation about the rate of rotation of a spiral is contained in the $w$ inding of any of the slanted $G$ reen lines that em anate from the spiral's origin. It is easy to see that the line is the rotated logarithm ic spiral $=2+\ln r$ ( $w$ ith
$=\quad=2$ again corresponding to the unique electric eld line going from the origin), and we can follow any of them to \m easure" .
$T$ he inform ation on the scaling of the $m$ agnitude of the electric eld and the winding of a slanted G reen line near a certain point on the critical curve is contained in the value of the derivative of a uniform izing conform al
$m$ ap $w(z)$ that $m$ aps the exterior of the critical chuster onto a standard simple dom ain. In these term $s$, the electrostatic potential of the curve is
$\log j v(z) j$ the $m$ agnitude of the eld near the curve is $E=j{ }^{0}(z) j$ and the direction of the eld is related to $\arg \mathrm{w}^{0}(z)$. (In term $s$ of the complex potential $(z)=\quad \log w(z)$ we have ${ }^{0}(z)=E_{x}+\mathrm{E}_{\mathrm{y}}$. .) Wewilluse this idea extensively in what follow s . It is convenient for our purposes to restrict the statisticalensemble so that a critical curve alw ays passes through a xed point, and work in the vicinity of this point.

In this paper we consider only dihute critical system S , which $m$ eans that critical curves generically do not intersect (see, how ever, the discussion of exceptional star con gurations below). This choice is dictated by the nature of our problem. In the dense phase where critical curves have m ultiple points, the harm onic $m$ easure is only supported on the extemal perim eters of critical clusters (think of electric charge spreading on the surface of a conductor). The extemal perim eters are alw ays sim ple critical curves described by a m odel in the dihute phase, and it is su cient to consider dihute system $s$ in our problem. T he prim e exam ple of this phenom enon is provided by critical percolation : percolation hulls intersect them selves at all scales, while the extemalperim eters ofpercolation clusters are sim ple curves in the universality class of self-avoiding random walks.

In the absence of boundaries in the system critical curves are closed loops. If the system has a boundary and the boundary condition changes at certain boundary points, it gives rise to critical curves which start and end at these points. A hole in the system is a com ponent of the boundary. If the boundary condition changes on 止, we w ill observe critical curves em anating from the hole. On scales m uch larger than the size of the hole the latter becom es a puncture. In this case there are critical curves com ing out of a single point in the bulk of the system. Inserting a puncture at som e point in the bulk we can ensure that in each realization of the statistical ensem ble there is a \star" | a xed num ber k of curves starting from this point.

Generally speaking, a critical system need not contain punctures or be restricted in any way by insertion of curve-creating operators. These are $m$ erely arti cial deviges which we w ill use in our calculations. T he m eaning of $k=2$ stars is obvious: any point on a curve is such a star. In fact, stars $w$ th $k>2$ can also be $m$ eaningfuleven in the absence of punctures. A star w ith an even num ber $k>4$ of legs is a point of self-intersection of a critical curve. Since in the dilute phase the latter are sim ple curves w ith probability one, stars $w$ th $k>4$ can only appear as exceptional con gurations in rare realizations of the statistical ensem ble, all such realizations having the total weight (probability) zero. In fact, we can quantify this discussion by
assigning a negative fractal dim ension $d_{k}$ (see Eq. ( $\left.\overline{5} \overline{0} \overline{1}\right)$ below) to the set of stars $w$ ith $k>4$ legs. The $m$ eaning of a negative fractal dim ension is as follow s. If in a system of size L several curves approach each other w ithin a distance l, then on the scales much larger than l the con guration of the curves will look like a star. H ow ever, in a typical realization of the statistical ensemble, the num ber of points where such approach happens, scales as $(\mathrm{L}=1)^{d_{k}}$, and goes to zero in the therm odynam ic lim it.

In the rest of the paper we apply $m$ ethods of CF T to the problem of the $m$ ixed $m$ ultifractal spectrum of harm onic $m$ easure and $w$ inding of critical curves. In this approach a k-legged star of critical curves is created by an
 can be realized as a vertex operator in the C oulom b gas form ulation of C FT, and has known holom onphic charge $0 ; \mathrm{k}=2$ and weight $h_{0 ; k=2}$, see Eqs. 依, 畐, (G) below. O ther prim ary operators inserted close to the curve-creating one can then serve as probes for the harm onicm easure. T his has been explained and used in our previous works $\left[\begin{array}{ll}101 \\ 1 & 1 \\ 1 & 1 \\ 1\end{array}\right]$. In the present paper we w ill see that to account for $w$ inding of critical curves, the probes m ust have com plex charges and conform al weights.

W e want to point out here that while harm onic m easure can behave nontrivially and be probed both in the bulk and on a boundary of a critical system, the $m$ ixed spectrum that takes into account $w$ inding is only de ned in the bulk. Indeed, there is no way a critical curve can rotate around a point on a boundary. Therefore, our present analysis only deals $w$ th the bulk curve creating operators.

## 3 The case of a single point

For sim plicity we start w ith the case of the electric eld (both the m agnitude and the direction) $m$ easured at a single point and then generalize the $m$ ethod to m ultiple points.

### 3.1 De nition of multifractal exponents

C onsider a $k$-legged star $\mid \mathrm{k}$ critical curves em anating from the origin in the bulk of the system. W e are interested in the properties of the star $m$ uch closer to the origin than the system boundaries. T he shape of the legs of the star far from the origin is unim portant, which allow s us to trace each leg only up to a certain distance from the origin. Let us describe the shape of such a truncated star by an analytic function $w(z)$ which $m$ aps the exterior $S$ of the star onto the exterior of the unit disk $C n D$. T he statisticalensem ble

Figure 1: T he conform altransform ation blow s up the star into the shape of a disk, like a pu er sh. The origin of the star is m apped to severalpoints $u_{i}$. The point $z$ is chosen to lie on the dotted circle of a xed radius and so that $w(z)$ lies on the sam e radial line as $u_{1}$.
of the shapes of the star de nes the statisticalensem ble ofw (z). C lose to the origin the $k$ curves of the star divide the plane into $k$ sectors. A pproached from di erent sectors, the origin is $m$ apped onto $k$ points $u_{i}$ on the unit circle: $\lim _{z}$ ! $0 w(z)=u_{i}$ for $z$ in the $i$-th sector. To $m$ ake $w(z)$ unique we specify $w(1)=1$ and $\mathrm{w}^{0}(1)=1>0$, where is the conform al radius of the star. Its uctuations are unim portant. For each realization of the star we can choose the truncation radius so that $=1$.

As we have explained above, the $m$ agnitude and the direction of the electric eld at a point $z$ are determ ined by jw ${ }^{0}(z) j$ and $\arg w^{0}(z)$ respectively. B oth these quantities are random. C onform al invariance suggests that locally $j^{0}(z) j$ scales as a power of $\dot{\xi} j$ and $\arg w^{0}(z)$ behaves as $\ln \dot{k} j$. $T$ herefore, we can study the joint $m$ om ents of $j{ }^{0}(z)$ jand $e^{\arg w^{0}(z)}$ expecting them to scale as

$$
\begin{equation*}
\mathrm{E} \quad \mathrm{j}^{0}(\mathrm{z}) \mathrm{j}^{\mathrm{n}} \mathrm{e}^{\mathrm{parg} \mathrm{w}^{0}(\mathrm{z})} \quad \dot{\mathrm{z}} \mathrm{j}^{\mathrm{k}(\mathrm{n} ; \mathrm{p})} ; \tag{1}
\end{equation*}
$$

where $E$ denotes average over the uctuating geom etry of the star. This equation de nes the multifractal exponents $k(n ; p)$, and our goalbelow is to obtain them using $m$ ethods of CFT.

Let us now discuss a subtle point about Eq. (11) . W e can treat the average over the star shapes in two ways. The rst way is to specify the position of point $z$ in such $a$ way that for any star $S$ this point is on the slanted G reen line in, say, the rst sector (the choide of the sector is arbitrary and im $m$ aterial). Let us denote this choice by $z$ (im plicitly keeping in $m$ ind
that the choice depends on the star shape). T hen the average in the left hand side of Eq. (II-1) should be understood as
(only the argum ent of $z \quad$ uctuates here, while $\dot{k} j$ is xed). The simplest such choice is to place $z$ on the electric eld line $=2$. Then in the w plane the im age $w(z)$ lies on a radial straight line:

$$
\begin{equation*}
\operatorname{argw}\left(z_{=2}\right)=\arg u_{1} ; \tag{3}
\end{equation*}
$$

see F ig. ${ }_{1}^{111}$ for illuistration.
On the other hand, as we have argued in the previous section, the scaling of $j^{0}(z) j$ and $e^{\arg w^{0}(z)}$ should be the sam e along any line. Therefore, we can average (integrate) over (and sum over the di erent sectors) in Eq. (Zָ) while keeping ju jconstant. This procedure produces a m anifestly rotationally invariant average. In this average we can distribute the contributions that com e from star shapes w hich di er by a global rotation around the origin into sets, and then sum up all such sets. D ue to isotropy of our critical system, all term s in a given set have the sam e statistical w eight. T herefore, to calculate the average, we can choose any single term from each set and sum these up. W e can choose these term sothat arg $z$ is the sam efor all of them, which gives the left hand side in Eq. (프) w ith a xed point z. This is the second way to interpret the average over the star shapes. A s we see, the two w ays are equivalent and produce the sam e scaling behavior w th the $m$ ultifractal exponents $k(n ; p)$.

### 3.2 CFT calculation of m ultifractal exponents

A criticalsystem is characterized by the centralcharge cw hich we param etrize, as is usual in CFT, by the so called background charge 0 :

$$
\begin{equation*}
c=1 \quad 24{ }_{0}^{2}: \tag{4}
\end{equation*}
$$

A s we have show $n$ in $R$ ef. $[1] 1 \overline{1}]$, in the $C$ oulom $b$ gas description of the dihute phase we have to im pose the D irichlet conditions on the system boundaries. A consistent way of doing it also im plies that the background charge 0 in Eq. (4) is non-positive: 060 .
 $m$ atical apparatus of C F T used below ) a k-legged star centered at the origin
is created by inserting the curve-creating operator $0 ; \mathrm{k}=2$ ( 0 ) $[\overline{1} \overline{\underline{0}}, \bar{i} \overline{1} \overline{1}]$. This operator has holom orphic charge

$$
\begin{equation*}
0 ; k=2=0 \frac{k}{4} \quad 0 \quad \mathrm{p} \overline{0_{0}^{2}+1} ; \tag{5}
\end{equation*}
$$

and its antiholom orphic charge is $0 ; k=2=0 ; k=2$. It is spinless $w$ ith real conform al w eights:

$$
\mathrm{h}=\mathrm{h}=\mathrm{h}_{0 ; \mathrm{k}=2}=0 ; \mathrm{k}=2\left(\begin{array}{lll}
0 ; \mathrm{k}=2 & 2 \tag{6}
\end{array}\right):
$$

To calculate them ixed multifractalexponents $k(n ; p)$ by $m$ eans of C F T we consider a prim ary operator $\mathrm{O}_{\mathrm{h} ; \mathrm{h}}$ whose holom onphic and antiholom orphic weights h;h are com plex and con jugate to each other:

$$
\begin{equation*}
h=h: \tag{7}
\end{equation*}
$$

( $N$ otice that we use asterisk to denote com plex conjugation, while the bar over a weight or charge sim ply indicates the antiholom orphic sector.) Its holom orphic and antiholom orphic charges are related to the weights by the equations [1] $]_{1}^{1}$ ]

$$
h=\left(\begin{array}{lll}
2 & 0 \tag{8}
\end{array}\right) ; \quad h=(+20):
$$

(T he introduction of the charges is convenient because they $m$ ake fiusion of prim ary operators look sim ple: the charges of the fused elds sim ply add up.) N ote the sign di erence in the formula for $h$ com pared to that in $R$ ef. [1] $\overline{1}]$ ]. The di erence is necessitated by our convention ( 060 ) for the dilute phase. The solutions (h), (h) are chosen so that $(0)=(0)=0$ :

$$
\begin{equation*}
=0+\sqrt{{ }_{0}^{2}+h} ; \quad=\quad 0 \sqrt{0_{0}^{2}+h}: \tag{9}
\end{equation*}
$$

The tw o charges are related by $=$. Ifw e denote the realand im aginary parts of the holom orphic charge as ${ }^{0}$ and ${ }^{\omega}$, the real and im aginary parts of the holom orphic w eight h can be w rilten as

$$
\operatorname{Reh}=\quad \propto \quad 2_{0} \quad 0^{0} \quad \quad \operatorname{lm} h=2^{\infty}\left(\begin{array}{ll}
0 & 0 \tag{10}
\end{array}\right):
$$

The operator $O_{h ; h}$ plays the role of $a$ \probe" of harm onic $m$ easure and rotation of critical curves when we place it at a point $z$ near the origin of a k -star. T he star is created by inserting the curve-creating operator $0 ; \mathrm{k}=2(0)$. Thus we propose to consider the follow ing correlation function:

$$
\begin{equation*}
0 ; k=2(0) O_{h ; h}(z)(1)^{E} / z^{2} 0_{0 ; k=2}^{2}=\dot{k} \mathcal{J}^{4} 0 ; k=2 e^{4} \quad 0 ; k=2{ }^{\infty} \arg z: \tag{D}
\end{equation*}
$$

H ere and in what follow s these angular brackets denote a CFT average and
stands for all operators far from the origin and is necessary to $m$ ake the correlation function non-zero. T he right hand side in Eq. (111) w as obtained in a standard way by fusion of prim ary operators (expressed as vertex operators in the C oulom b gas form ulation of CFT). N otice that the presence of com plex w eights and charges leads to an expression that is explicitly angular dependent and multivalued. T hus, this correlator does not correspond to any physical quantity, and we need to consider

$$
\begin{equation*}
C=e^{D} e_{0 ; k=2}^{\infty}{ }^{\infty} \operatorname{argz}{ }_{0 ; k=2}(0) O_{h ; h}(z)(1)^{E} / \dot{\bar{z}} \jmath^{4} 0 ; k=2^{0}: \tag{12}
\end{equation*}
$$

In this form ulation the position of the point $z$ is $x e d$, and the extra exponential factor is a constant that can be pulled out of the average h: : :i.
$T$ he sam e correlation function $C$, being an average over all degrees of freedom in the system, can be evaluated in another way, using the so-called tw o-step averaging procedure $\left[\bar{T}_{1}, 1 \overline{1}, 1,1\right.$ the star and sum over the rest of the degrees of freedom. T hen we average over all possible shapes of the star:

$$
\begin{equation*}
C=E e^{h}{ }_{0 ; k=2}^{\infty} \operatorname{argz} O_{h ; h}(z)(1)_{s}: \tag{13}
\end{equation*}
$$

The subscript of a correlation function refers to the dom ain in which it is com puted, in this case the exterior of the star $S$.

The point $z$ is still xed in Eq. (13 ${ }^{1}$ ), therefore, for each shape $S$ this point lies on a di erent slanted G reen line. H ow ever, as in Section $\overline{3}$ we can argue that the scaling w ith $\dot{\xi} j \dot{j}$ is the sam e (independent of ) for all the term $s w$ th di erent values of . Then to nd the exponents $k(n ; p)$ it is su cient to retain only term $s$ w ith a $x e d$ (in each star con guration) value of and consider a di erent quantity

$$
\begin{equation*}
C=E e^{h}{ }_{0 ; k=2}^{\infty}{ }^{\infty} \operatorname{argz} O_{h ; h}(z)(1)_{S}^{i}: \tag{14}
\end{equation*}
$$

There is a parallelbetw een the correlator $C$ and the expression in Eq. (1్11), and the correlator $C$ and the expression in $E q$. ( $\overline{1}_{2}^{2}$ ): though $C$ and $C$ are form ally very di erent objects, they scale with jkj in the same way. $T$ he crucial di erence between $C$ and $C$ is that in the latter ob ject the argum ent of $z$ is uctuating (止 depends on the star con guration) and the factor $e^{4} \quad 0 ; k=2^{\infty} \arg z \mathrm{~m}$ ust be kept under the average $\mathrm{E}[::::]$.
$T$ he next step in transform ing the expression (1) is to $m$ ap the exterior of the star $S$ onto the exterior of the unit disk by $w(z)$. Under this $m$ ap
the operator $\mathrm{O}_{\mathrm{h} ; \mathrm{h}}$ transform s according to the de nition of a CFT prim ary eld, and operators at in nity do not transform due to the norm alization of $w(z)$. Then conform al covariance of correlators of CFT im plies

$$
\begin{equation*}
C=E e^{h}{ }_{0 ; k=2}^{\infty} \arg w^{0}(z)^{h} w^{0}(z)^{h} O_{h ; h}(w(z))(1)_{C n D}: \tag{15}
\end{equation*}
$$

In this correlator the value of the angle is im $m$ aterial. For simplicity of notation let us choose it to be $==2$, which m eans that the point $\mathrm{z}=2$ is chosen according to Eq. $(\bar{i})$ ) and lies on the unique electric eld line connected to the origin of the star. W e will drop the subscript $=2$ in the subsequent equations.

In the $w$ plane, $\arg w(z)$ is a xed number no greater than 2 . At the sam e tim $e, w$ hen $w(z)$ approaches $u_{1}$, itspre-im age $z m$ oves along the electric eld line and exhibits a lot of $w$ inding. Since $\arg w(z) \quad \operatorname{argw}{ }^{0}(z)+\arg z$, we can w rite

$$
\begin{equation*}
\arg z \quad \arg w^{0}(z) ; \tag{16}
\end{equation*}
$$

because both angles here are large. Thus, we can replace arg $z$ by $\arg ^{0}{ }^{0}(z)$ in Eq. ( $\left.\overline{1} \underline{I}_{1}^{\prime}\right)$. U sing Eq. (

$$
\begin{align*}
& w^{0}(z)^{h} w^{0}(z)^{h}=w^{0}(z)^{h}{ }^{2}=j w^{0}(z) \rho^{\text {Reh }} e^{2 \text { Im harg }}{ }^{0}(z) \tag{17}
\end{align*}
$$

The rem aining CFT correlation function in the exterior of the disk is com puted by fusion of the prim ary eld with the boundary (which m eans the fusion of the holom onphic part $\mathrm{O}_{\mathrm{h}}(\mathrm{w}(\mathrm{z}))$ w ith its im age across the boundary of the unit disk). A ccording to Eq. (ī) , both $w(z)$ and its im age in the unit circle $1=\mathrm{w}$ ( $z$ ) have the sam e (constant) argum ent arg $u_{1}$. Then we nd the follow ing scaling behavior:

$$
\begin{align*}
& \dot{z}^{\left.f^{\left(\varrho^{( }\right.}+{ }^{\infty}\right)}{ }_{j}{ }^{0}(z) f^{\left({ }^{( }+{ }^{\infty}\right)} \text { : } \tag{18}
\end{align*}
$$

At this stage the correlator C evaluated in two steps becom es

Since, as we have argued, both C and C should scale in the sam e way w ith

$$
\begin{equation*}
E j v^{0}(z) j^{4}{ }^{0}\left(0^{0} e^{4}{ }^{\infty}\left(0^{0} \quad 0_{0 ; k=2}\right) \arg w^{0}(z) \quad \dot{k} j^{2\left(\infty^{2}\right.} \infty^{\infty}\right)+4_{0 ; k=2}^{0} \text { : } \tag{20}
\end{equation*}
$$

T he last equation is identical to the de nition (1ָ1) provided we denote

$$
\begin{align*}
& \mathrm{n}=4^{0}\left(\begin{array}{ll}
0 & 0
\end{array}\right) ; \quad \mathrm{p}=4^{\infty}\left(\begin{array}{c}
0 \\
0
\end{array} 0^{0 ; k=2}\right) \text {; }  \tag{21}\\
& k(n ; p)=2\left(^{\infty}+\omega^{\infty}\right)+4_{0 ; k=2}^{0}: \tag{22}
\end{align*}
$$

A s usual, we need to choose the solutions of Eqs. [2]1) that vanish for $\mathrm{n}=0 ; \mathrm{p}=0$ :

$$
\begin{equation*}
2^{0}=0_{0}+\frac{p}{2_{0}^{2}+n} ; \quad \quad \infty=\frac{p}{4\left(00^{+} 0 ; k=2\right)}: \tag{23}
\end{equation*}
$$

Substituting these values into Eq. (2̄2̄) we nd the m ixed multifractal exponents $k(n ; p) . W$ th the shorthand

$$
\begin{equation*}
n=0+p \frac{}{{ }_{0}^{2}+n} \tag{24}
\end{equation*}
$$

the answ er can be w ritten as

$$
\begin{equation*}
\mathrm{k}(\mathrm{n} ; \mathrm{p})=2_{0 ; \mathrm{k}=2 \mathrm{n}} \quad \frac{1}{2}{\underset{\mathrm{n}}{ }}_{2}^{\frac{1}{8}} \frac{\mathrm{p}^{2}}{\frac{1}{2} \mathrm{n} \quad 0^{+} 0_{0 ; \mathrm{k}=2}^{2}}: \tag{25}
\end{equation*}
$$

W e can also rew rite this result as

$$
\begin{equation*}
\left.k(n ; p)=k(n) \quad \frac{1}{4} \frac{p^{2}}{k(n)+n+2(0 ; k=2} 0\right)^{2} ; \tag{26}
\end{equation*}
$$

where

$$
\begin{equation*}
k(n)=k(n ; 0)=20 ; k=2 n \quad \frac{1}{2}{ }_{n}^{2}: \tag{27}
\end{equation*}
$$

## 4 The general case

To de ne a m ulti-point generalization of them ixed spectrum (ī1) we consider the follow ing average:

$$
\begin{equation*}
E e^{\mathrm{pargw}}{ }^{0}\left(z_{1}\right)^{Y^{k}} \dot{j}^{0}\left(z_{i}\right)^{n_{i}} \quad r^{k\left(f_{i} g ; p\right)}: \tag{28}
\end{equation*}
$$

$H$ ere all the points $z_{i}$ have the sam e distance to the star origin : $\dot{\mathcal{z}}_{i} j=r$, and no tw o of them lie in the sam e sector. B ecause the curves do not intersect, all the $w$ inding angles $\arg w^{0}\left(z_{i}\right)$ di er by no $m$ ore than 2 , and since they are all very large, they m ust all scale in the sam eway: $\operatorname{argw}^{0}\left(z_{i}\right) \quad \arg w^{0}\left(z_{1}\right)$.

Thus, the topology of the star leads to only one param eter p describing the rotation, while we have $k$ param eters $n_{i}$ for harm onic $m$ easure in each of the sectors betw een the star's legs.

Sim ilar to the discussion in Section or can be chosen to lie on speci c slanted G reen lines. T hese choices do not a ect the scaling w th $r$ in $E q$. ( $\left.\overline{2} \underline{B}_{\bar{\prime}}^{\prime}\right)$. For exam $p l e$, we can choose arg $z_{i}$ by the requirem ent

$$
\begin{equation*}
\operatorname{argw}\left(z_{i}\right)=\arg u_{i}: \tag{29}
\end{equation*}
$$

Then in all realizations of the star each $z_{i}$ lies on the unique $G$ reen line in the i-th sector that starts at the star's origin .

The calculation of $k$ ( $f n_{i} g ; p$ ) is a straightforw ard generalization of the calculation of the previous section. W e introduce $k$ prim ary operators $\mathrm{O}_{\mathrm{h}_{\mathrm{i}} ; \mathrm{h}_{\mathrm{i}}}\left(\mathrm{z}_{\mathrm{i}}\right)$ each w th com plex con jugate weights: $\mathrm{h}_{\mathrm{i}}=\mathrm{h}_{\mathrm{i}}$ and holom orphic charges $i={ }_{i}^{0}+i \underset{i}{\infty}$. In close parallel to Eq. (1]íl) we consider a CFT correlation function:

$$
\begin{align*}
& C_{k}=e^{4} \quad 0 ; k=2 \sum_{i}{ }_{i}^{\infty} \arg z_{i}+4 \sum_{i<j}\left(\begin{array}{c}
0 \\
i \\
j
\end{array}+\underset{i}{\infty} \underset{j}{0}\right) \arg \left(z_{i} z_{j}\right) \\
& \mathrm{Y}^{\mathrm{k}} \mathrm{O}_{\mathrm{h}_{\mathrm{i}} ; \mathrm{h}_{\mathrm{i}}}\left(\mathrm{z}_{\mathrm{i}}\right)(1)^{\mathrm{E}} \text { : } \\
& 0 ; \mathrm{k}=2(0) \underset{\mathrm{i}=1}{ } \mathrm{O}_{\mathrm{h}_{\mathrm{i}} ; \mathrm{h}_{\mathrm{i}}}\left(\mathrm{z}_{\mathrm{i}}\right)(1) \quad: \tag{30}
\end{align*}
$$

This correlation function can be com puted by fusion of prim ary elds:

$$
\begin{align*}
& i=1 \quad i \quad i<j \\
& =\dot{k}_{i} J^{4} 0 ; k=2{\underset{i}{i}}_{0}^{4} \quad 0 ; k=2{\underset{i}{i}}_{\infty}^{\arg } z_{i} \\
& { }^{i}{ }_{Y} \tag{31}
\end{align*}
$$

$$
\begin{aligned}
& \text { i< j }
\end{aligned}
$$

The exponential factors in the de nition of $C_{k}$ are chosen to cancel the angular dependence in the last equation. Since in our setup $\dot{Z}_{i} j=r$ and $\dot{z}_{i} \quad z_{j} j \quad r$ for all $i$ and $j$, the correlation function $C_{k}$ scales as

$$
C_{k} \quad r^{4} \quad 0 ; k=2 \sum_{i}{ }_{i}^{0}+4 \sum_{i<j}\left(\begin{array}{cccc}
0 & 0  \tag{32}\\
i & j & \infty \\
i
\end{array}\right):
$$

On the other hand, we can consider the sim ilar correlator $C_{k ;}$ w here the points $z_{i}$ are chosen according to Eq. $\left[\overline{2}_{2} \overline{9}_{1}\right)$ and, therefore, uctuate form con guration to con guration. The correlatons $C_{k}$ and $C_{k}$; should scale as
the sam e pow ens of $r$. $W$ e can evaluate the correlation fiunction $C_{k}$; in two steps: rst we $x$ the shape of the star and sum over the rest of the degrees of freedom. N ear a xed star all the argum ents arg $z_{i}$ and $\arg \left(z_{i} \quad z_{j}\right)$ are large and di er by no $m$ ore than 2 . Therefore we can replace them all by one of them, say $\arg z_{1}$. T hen we average over allpossible shapes of the star:

N ow wem ap the exterior of the star $S$ onto the exterior of the disc $C n D$ and note that $\arg z_{1} \quad \arg w^{0}\left(z_{1}\right)$ (com pare w th Eqs. (1] $\left.\left.\bar{T}_{1}, 1 \overline{1} \bar{G}\right)\right)$ :

$$
\begin{align*}
& { }_{i}^{Y} \quad W^{0}\left(z_{i}\right)^{h_{i}} 2^{D Y} O_{h_{i} ; h_{i}}\left(w\left(z_{i}\right)\right)(1)^{E n D} \quad i \tag{34}
\end{align*}
$$

T he rem aining correlator in CnD is com puted by fusion of prim ary elds w ith the boundary (com pare w ith Eq. (1] $\overline{1}$ )) :

There are other factors in this correlator that are com ing from the fusion of di erent bulk elds $O_{h_{i} ; h_{i}}\left(w\left(z_{i}\right)\right)$ w ith each other. These crossterm s look like $\left(\mathrm{w}\left(\mathrm{z}_{\mathrm{i}}\right) \mathrm{w}\left(\mathrm{z}_{\mathrm{j}}\right)\right)^{2} \mathrm{i}_{\mathrm{j}}{ }^{2}$, and do not contribute to the short-distance behavior, since all $z_{i}$ lie in di erent sectors of the star, and the di erence $\mathrm{w}\left(\mathrm{z}_{\mathrm{i}}\right) \quad \mathrm{w}\left(\mathrm{z}_{\mathrm{j}}\right)$ stays nite in the $\lim$ 达 $\mathrm{z}_{\mathrm{i}}$ ! 0. A s a result,

$$
\begin{equation*}
\left.C_{k} ; \quad r^{2 \sum_{i}\left({ }_{i}^{\infty}+{ }_{i}^{\infty}\right)} E e^{\operatorname{pargw}^{0}\left(z_{1}\right)} Y_{j{ }^{0}}\left(z_{i}\right)\right)^{n_{i}} ; \tag{36}
\end{equation*}
$$

where

W e solve these equations for ${ }_{i}^{0}$ and $P$ in $\quad \underset{i}{\infty}$ and choose the solutions which

$$
\begin{align*}
& \frac{1}{8} \frac{\mathrm{p}^{2}}{\frac{1}{2}^{\mathrm{P}} \quad \mathrm{i}_{\mathrm{i}} \quad 0+0 ; \mathrm{k}=2}{ }^{2} \text {; } \tag{38}
\end{align*}
$$

where $n_{i}=0+P \overline{{ }_{0}^{2}+n_{i}}$. Sim ilarly to Eq. (2, $\left.\underline{Q}_{\mathbf{Q}}\right)$, this result can be rew ritten as

## 5 D iscussion

The exponents $k(n ; p)$ and $k$ (fng;p) that we have obtained in Eqs. [2 $\overline{2}=1$, , ofprim ary operators. They are easily related to otherm ultifractalexponents de ned directly in term s of harm onic m easure and $w$ inding. To exhibit th is relation we start w ith a special case.

C onsider a closed critical curve. Let us cover it by circles of radius r $w$ ith centers at $i$. Let us denote the harm on ic $m$ easure $w$ ith in each circle by H ( $i ; r$ ), and the $w$ inding angle of the $G$ reen line ending at $i$ at distance $r$ aw ay from $i$ by ( $i ; r$ ). Then we can de ne a sort of $\backslash g l 0 b a l " m$ ixed spectrum ( $n ; p$ ) by (see Eq. (2) in Ref. [1] [1]

$$
\begin{equation*}
E^{h_{X}} H^{n}(i ; r) e^{p(i ; r)^{i}} / r^{(n ; p)}: \tag{41}
\end{equation*}
$$

If we set $n=p=0$ in the above equation, we sim ply get the num ber of circles of radius r needed to cover the curve. This number should scale as $r^{d_{f}}$, where $d_{f}$ is the fractal dim ension of the critical curve. Therefore, $(0 ; 0)=d_{f}$.

It is natural to assum e som e sort of ergodicity, so that the average of the sum in Eq. (4̄1피) can be replaced by the local average E $\mathbb{H}^{n} e^{p}$ ] m ultiolied by the num ber of term $s$ in the sum. If the local average scales as $r^{\sim}(n ; p)$, then the global and the local exponents are related by

$$
\begin{equation*}
(n ; p)=\sim(n ; p) \quad c: \tag{42}
\end{equation*}
$$

The harm onic m easure $H$ ( $i ; r$ ) by electrostatic analogy should locally scale as $r j j^{0}\left(z_{i}\right) j$ where $z_{i}$ is a point that lies not on the curve at distance $r$ aw ay from ir compare w ith Fig . ${ }_{1} \overline{11}$. In the situation we describe here each point on the curve can be viewed as the origin of a 2-legged star. T hen
we can relate our exponent $2(n ; p)$ to the local and the global exponents $\sim(n ; p), \quad(n ; p)$ :

$$
\begin{equation*}
\sim(n ; p)=2(n ; p)+n ; \quad(n ; p)=2(n ; p)+n \quad d_{f}: \tag{43}
\end{equation*}
$$

The fractal dim ension $d_{f}$ of the curve is related to the dim ension of the curve creating operator 0;1 [1]_]

$$
\begin{equation*}
\mathrm{d}_{\mathrm{f}}=2 \quad 2 \mathrm{~h}_{0 ; 1}: \tag{44}
\end{equation*}
$$

Finally, we get the follow ing relation

$$
\begin{equation*}
(n ; p)=2(n ; p)+n+2 h_{0 ; 1} \quad 2: \tag{45}
\end{equation*}
$$

$$
\begin{equation*}
(n ; p)=\quad(n) \frac{1}{4} \frac{p^{2}}{(n)+b^{2}} \text {; } \tag{46}
\end{equation*}
$$

where

$$
\begin{align*}
(n) & =2(n)+n+2 h_{0 ; 1} \quad 2=\frac{1}{2} p \frac{}{{ }_{2}^{2}+n}+p_{0_{0}^{2}+1}^{2} \quad 2\left({ }_{0}^{2}+1\right) \\
& =\frac{n \quad 1}{2}+\frac{25 c}{24} \frac{24 n+1 \mathrm{c}}{25 \mathrm{c}} \tag{47}
\end{align*}
$$

is them ultifractal spectrum of the harm on ic m easure (see Eq. (6.32) in Ref. EG]), and

$$
\mathrm{b}=2(0 ; 1 \quad 0)^{2}+2 \quad 2 \mathrm{~h}_{0 ; 1}=2\left(\begin{array}{l}
2  \tag{48}\\
0
\end{array}+1\right)=\frac{25 \mathrm{c}}{12}:
$$

Formula ( $\overline{4} \overline{-1}$ ) is exactly the sam e as Eq. (14) for ( $n ; p$ ) in Ref. [1]
G eneralized exponents $k\left(\mathrm{fn}_{\mathrm{i}} \mathrm{g} ; \mathrm{p}\right)$ can be de ned sim ilarly to Eq. (4i-1 $\left.{ }_{1}^{1}\right)$ :

$$
\begin{equation*}
E^{h}{ }_{k \text { stars }}^{e^{p}\left(z_{1} ; r\right)^{Y^{k}}} H_{i=1}^{n_{i}}\left(z_{i} ; r\right)^{i} / r^{k\left(f_{n} g ; p\right)}: \tag{49}
\end{equation*}
$$

In this de nition the points $z_{i}$ are the same as in Eq. $\left.\overline{2} \overline{2} \bar{q}\right)$, and $H\left(z_{i} ; r\right)$ denotes harm on ic $m$ easure on the portion of the star inside the $i$-th sector up to radius r. A s we have argued in Section $1 \overline{2}, \mathrm{k}$ - -legged stars w ith $\mathrm{k}>4$ $m$ ay appear spontaneously in a critical system, even though in a subset of the realization of the statistical ensem ble w ith the totalm easure zero. T he
origins of the $k$-legged stars have a certain fractal dim ension $d_{k}$. In full analogy w th Eq. (4U), the fractal dim ension $d_{k}$ is related to the scaling dim ension $2 h_{0 ; k=2}$ of the operator $0 ; k=2$ :

$$
\begin{equation*}
d_{k}=2 \quad 2 h_{0 ; k=2}: \tag{50}
\end{equation*}
$$

$N$ otice that, consistent w ith the discussion in Section in $d_{k}$ is negative for $\mathrm{k}>4$.

A ssum ing ergodicity and the scaling $H\left(z_{i} ; r\right) \quad r \dot{j}^{0}\left(z_{i}\right) j$ as before, we can relate the generalized exponents $k\left(f n_{i} g ; p\right)$ to ${ }_{k}\left(f n_{i} g ; p\right)$ :

$$
\left.k\left(f n_{i} g ; p\right)=k_{k}\left(f n_{i} g ; p\right)\right)^{X} n_{i}+2 h_{0 ; k=2} \quad 2:
$$

$$
\begin{equation*}
k\left(f n_{i} g ; p\right)=k\left(f n_{i} g\right) \quad \frac{1}{4} \frac{p^{2}}{k\left(f n_{i} g\right)+b} ; \tag{52}
\end{equation*}
$$

where

$$
\begin{align*}
k\left(f n_{i} g\right) & =k\left(f n_{i} g\right)+{ }^{X} n_{i}+2 h_{0 ; k=2} 2 \\
& =\frac{1}{2} \frac{k}{2} 0+P \frac{{ }^{i}}{{ }_{0}^{2}+1}+P{ }_{i} \frac{p}{{ }_{0}^{2}+n_{i}} 2\left(\begin{array}{l}
2 \\
0
\end{array}+1\right) \tag{53}
\end{align*}
$$

 vince oneself of the equivalence, one needs to substitute $20=(1 \quad)^{1=2}$, where 60 is the so-called string susceptibility exponent.)
 analyzed in detail in Ref. [2, 12. H ere we only mention that the Legendre transform softhese exponents (the so called singularity spectra) have a direct geom etricalm eaning of fractal dim ensions of subsets of points with a given local scaling of harm onic $m$ easure and $w$ inding.

In conclusion, we have shown how a detailed description of stochastic geom etry of critical conform ally-invariant curves in term $s$ of their harm on ic $m$ easure and winding can be obtained by m eans of CFT, from correlation functions of certain prim ary operators. T he inclusion of winding (rotations) $m$ akes it necessary to consider operators $w$ ith com plex weights.
