On a Commutative Ring of Two Variable Differential Operators with Matrix Coefficients

A.E. Mironov

1 Introduction

In this work, we construct commutative rings of two variable matrix differential operators that are isomorphic to a ring of meromorphic functions on a rational manifold obtained from the $\mathbb{C}P^1 \times \mathbb{C}P^1$ by identification of two lines with the pole on a certain rational curve.

The commutation condition for differential operators is equivalent to a system of non-linear equations in the operators’ coefficients. For selected operator coefficients, the commutation equations reduce to known soliton equations such as the Korteweg-de Vries equation, the Kadomtsev-Petviashvili equation, the sin-Gordon equation and others.

The problem of classifying commuting ordinary differential operators was solved in [1]. If two differential operators

$$L_1 = \partial_x^n + u_{n-1}\partial_x^{n-1} + \ldots + u_0(x), \quad L_2 = \partial_x^m + v_{m-1}\partial_x^{m-1} + \ldots + v_0(x)$$

commute, then by the Burchnall-Chaundy lemma [2] there exists a non-zero polynomial $Q(\lambda, \mu)$ of two commuting variables $\lambda$ and $\mu$ such that

$$Q(L_1, L_2) = 0.$$ 

The smooth compactification of the curve given in $\mathbb{C}^2$ by the equation

$$Q(\lambda, \mu) = 0$$

is called spectral curve. If $\psi$ — is a common eigen-function, and $\lambda$ and $\mu$ — the corresponding eigen-values

$$L_1 \psi = \lambda \psi, \quad L_2 \psi = \mu \psi,$$
then point $P = (\lambda, \mu)$ lies on the spectral curve. In this way, the spectral curve parametrizes the common eigen-functions of the operators $L_1$ and $L_2$. The function $\psi(x, P)$ (the Baker-Akhiezer function) has a unique essential singularity on the spectral curve, and outside of this point it is meromorphic. The Baker-Akhiezer function one can find uniquely from its spectral data, i.e. from the set of poles, the essential singular point and certain relations of the residues in the poles. In this way, the commutative rings of differential operators correspond to the sets of spectral data. There is no such classification for operators depending on more than one variable. In the multidimensional case we have the Burchnall-Chaundy lemma analogue proven by Krichever [3]. If the operators $L_1, \ldots, L_{n+1}$ in $n$ variables whose lead symbols have constant coefficients, do commutate pairwise, then there exists a polynomial $Q(\lambda_1, \ldots, \lambda_{n+1})$ in the commutative variables $\lambda_1, \ldots, \lambda_{n+1}$, such that

$$Q(L_1, \ldots, L_{n+1}) = 0.$$ 

As in the one-dimensional case, the manifold given in $\mathbb{C}^{n+1}$ by equation $Q(\lambda_1, \ldots, \lambda_{n+1}) = 0$ parametrizes the common eigen-functions of operators $L_1 \psi = \lambda_1 \psi, \ldots, L_{n+1} \psi = \lambda_{n+1} \psi$.

The question of how to correctly compactify this spectral manifold and to correctly assign the spectral data for unique recovery of the Baker-Akhiezer function, and, consequently, the commutative ring of differential operators, remains entirely open.

In [4], [5], the authors find a formal generalization of the Krichever construction in the two-dimensional case.

There are several approaches to the construction of multidimensional commutative operators ([6] offers insight into some of them). Sometimes, for operators of a certain kind the commutation equation can be integrated (see e.g. [7]). In [8], [9] (see also the references in these papers) the authors propose a method to recover the Baker-Akhiezer function by the affine part of certain rational manifolds. The enumerated examples are very interesting since the commutative rings contain Schrödinger operators.

Nakayashiki [10] (see also [11]) found spectral data corresponding to commuting differential operators in $g$ variables with matrix coefficients (the matrix size being $g! \times g!$), with principle polarized Abelian manifolds with a non-singular theta-divider serving as spectral manifolds. For $g = 2$ these
operators have been studied in [12], [13]. Note the main distinction between
the one-dimensional case from the multidimensional one: Even if we could
construct operators $L_1$ and $L_2$, with a sufficiently large family of common
eigen-functions, e.g. a family of parametrized points of a certain algebraic
manifold, then, in contrast to the one-dimensional case this does not imply
that operators $L_1$ and $L_2$ commute, because the kernel of the commutator
$[L_1, L_2]$ is in the general case infinite dimensional. This difficulty is overcome
in [10] as follows. Nakayashiki constructs a module $M$ (the Baker-Akhiezer
module) above a ring of differential operators $D_g = \mathcal{O}[\partial_{x_1}, \ldots, \partial_{x_g}]$, where
$\mathcal{O}$ is a ring of analytic functions in variables $x_1, \ldots, x_g$ in the neighborhood
of $0 \in \mathbb{C}^g$, which consists of functions that depend on $x = (x_1, \ldots, x_g)$ and
$P \in X$, and which possesses the following two remarkable characteristics:

1. $M$ is a free module above $D_g$ of rank $g!$

2. For any meromorphic function $\lambda$ on $X$ with pole on a theta-divisor
and for any function $\varphi \in M$, function $\lambda \varphi$ also lies in $M$.

From this construction follows that there exists an imbedding of the ring
$A_\theta$ of meromorphic functions on $X$ with pole on the theta-divisor into a ring
of differential operators on $g$ variables with matrix coefficients. Take base
$\psi_1(x, P), \ldots, \psi_g(x, P)$ in the $D_g$-module $M$. Denote the vector function
$\psi(x, P)$

$$(\psi_1(x, P), \ldots, \psi_g(x, P))^\top$$

by $\psi(x, P)$. Then for any meromorphic function $\lambda(P) \in A_\theta$ there exists a
unique differential operator $D(\lambda)$ such that

$$D(\lambda)\psi(x, P) = \lambda(P)\psi(x, P).$$

Since $\lambda$ and $\mu$ do not depend on $x$, equality

$$D(\lambda)D(\mu)\psi = D(\mu)D(\lambda)\psi = D(\mu \lambda)\psi = \mu \lambda \psi,$$

holds for any two functions $\lambda, \mu \in A_\theta$.

$$D(\lambda)D(\mu)\psi = D(\mu)D(\lambda)\psi = D(\mu \lambda)\psi = \mu \lambda \psi,$$

consequently, by virtue of the differential operators’ uniqueness we have

$$D(\lambda)D(\mu) = D(\mu)D(\lambda) = D(\mu \lambda),$$
i.e., operators $D(\lambda)$ and $D(\mu)$ commute.

Rothstein [14] (see also [15]) shows that a ring of meromorphic functions on a Fano surface with a certain fixed pole can be imbedded into a ring of matrix differential operators.

In this work, we construct an analogue of Nakayashiki’s construction for the following spectral manifold.

Let $\Gamma$ denote a manifold derived from the $\mathbb{C}P^1 \times \mathbb{C}P^1$ identification of two straight lines

$$p_1 \times \mathbb{C}P^1 \sim \mathbb{C}P^1 \times p_2.$$ 

Namely, upon assigning coordinates $(z_1 : w_1, z_2 : w_2)$ on $\mathbb{C}P^1 \times \mathbb{C}P^1$, we identify the following points:

$$(a_1 : b_1, t_1 : t_2) \sim (t_1 : t_2, a_2 : b_2),$$

with $(a_i : b_i)$ being coordinates of $p_i$, $p_1 \neq p_2$, $(t_1 : t_2) \in \mathbb{C}P^1$. Let $f(P)$ denote the following form on $\mathbb{C}P^1 \times \mathbb{C}P^1$

$$f(P) = \alpha z_1 z_2 + \beta z_1 w_2 + \gamma z_2 w_1 + \delta w_1 w_2, \quad P = (z_1 : w_1, z_2 : w_2) \in \Gamma,$$

$\alpha, \beta, \gamma, \delta \in \mathbb{C}$, and suppose that identity

$$f(a_1 : b_1, t_1 : t_2) - Af(t_1 : t_2, a_2 : b_2) = 0, \quad A \in \mathbb{C}^*.$$  \hspace{1cm} (1)

holds for all $(t_1 : t_2)$

Equality (1) restricts the choice of constants $a_i, b_i, \alpha, \beta, \gamma, \delta$ and means that form $f(P)$ is a section of a line bundle on $\Gamma$.

Let $A_f$ denote a ring of meromorphic functions on $\Gamma$ with a pole on a curve given by equation $f(P) = 0$. The main result of this work is

**Theorem 1** There exists an embedding

$$D : A_f \rightarrow Mat(2, D)$$

of a ring of meromorphic functions $A_f$ on $\Gamma$ into the ring $2 \times 2$-matrix differential operators in the variables $x$ and $y$.

In section 2, we introduce a Baker-Akhiezer module corresponding to the manifold $\Gamma$. In section 3, we present theorem 2 and show that this module is
free of rank 2. Theorem 1 follows directly from theorem 2. In section 3 we also give explicit examples of commuting operators. It is remarkable that by rationality of $\Gamma$, the operator coefficients are elementary functions.

Acknowledgement

The author would like to thank ESF Research Network MISGAM for partial support of the ISLAND-3 conference, where the main results of this work were obtained, and also appreciate to Oleg Chalyh and Alexander Veselov for useful discussions of this work. The author is thankful to Atsushi Nakayashiki for the invitations in Kyushu University, useful discussions of our results, promotional interest, and important remark proposed to this work (see paragraph 2.1). The author is also grateful to Grant-in-Aid for Scientific Research (B) 17340048 for financial support of the visits in Kyushu University.

2 The Baker-Akhiezer module

In this section we point to some obvious and necessary conditions that should be fulfilled by the spectral data of commutative rings of multidimensional differential operators. Also, we construct a Baker–Akhiezer module on manifold $\Gamma$.

2.1 General construction

As noted before, in many significant examples of commutative rings of differential operators the common eigen-functions are parametrized by points of a spectral manifold $X$, the ring of operators itself being isomorphic to a ring $A_Y$ of meromorphic functions on $X$ with pole on a hypersurface $Y \subset X$. Let the operators have matrix size $k \times k$ coefficients, with $\psi(x, P) = (\psi_1(x, P), \ldots, \psi_k(x, P))^\top$ being a common vector-eigen-function (for sake of simplicity we consider the case of rank 1 operators, i.e. where to every point of the spectral manifold there corresponds a unique common eigen-function) and let $x = (x_1, \ldots, x_n), \ P \in X$ be a spectral parameter. For all examples, the unique differential operator $D(\lambda)$ can be recovered by means of the meromorphic function $\lambda \in A_Y$ such that

$$D(\lambda)\psi = \lambda \psi. \quad (2)$$
Let’s consider module $M$ over $\mathcal{D}_n$, generated by functions $\psi_1, \ldots, \psi_k$

$$M = \{d_1\psi_1 + \ldots + d_k\psi_k, \ d_i \in \mathcal{D}_n\}.$$ 

As follows from the uniqueness of operator $D(\lambda)$, which satisfies equality (2), the $\mathcal{D}_n$-module $M$ is free. Actually, suppose that there exist operators $d_1, \ldots, d_k$ such that

$$d_1\psi_1 + \ldots + d_k\psi_k = 0.$$ 

Let $d$ denote an matrix operator with operators $d_1, \ldots, d_k$ in all rows. Then we have

$$(D(\lambda) + d)\psi = \lambda\psi,$$

which contradicts the uniqueness of $D(\lambda)$. We show that if $\psi_0 \in M, \lambda \in \mathcal{A}_Y$, then $\lambda\psi_0 \in M$. Let

$$\psi_0 = d_1\psi_1 + \ldots + d_k\psi_k.$$ 

By multiplying equality (2) from the left by a vector-row made up by operators $d_1, \ldots, d_k$, we get

$$(d_1, \ldots, d_k)D(\lambda)\psi = (d_1, \ldots, d_k)\lambda\psi = \lambda(d_1, \ldots, d_k)\psi = \lambda\psi_0,$$

consequently, $\lambda\psi_0 \in M$. Thus, apparently to every commutative ring there connects a Baker-Akhiezer module which satisfies the conditions 1,2 (see introduction).

In all examples the Baker-Akhiezer function has an essential singularity on $Y$ and has the form

$$\psi(x, P) = g(x, P) \exp(x_1F_1(P) + \ldots + x_nF_n(P)),$$

where $F_i(P), i = 1, \ldots, n$ are meromorphic (in the general case many-valued functions) on $X$ with pole on $Y$,

$$g(x, p) = (g_1(x, P), \ldots, g_k(x, P))^\top,$$

g_i(x, P) are meromorphic sections of the line bundle $L$ on $U \times X$, $U$ is an open subset in $\mathbb{C}^n$ with pole on $\tilde{Y} = U \times Y$. The line bundle $L$ possesses connections

$$\nabla_i = \partial_{x_i} + F_i(P).$$
It is clear that $\nabla_j g_i(x, P)$ is a section of bundle $L \otimes [\tilde{Y}]^s$, $s > 0$. In this way, we represent module $M$ in the form $M = \bigcup_{m=1}^{\infty} M(m)$, where $M(m)$ consists of functions

$$M(m) = \{ \tilde{g}(x, P) \exp(x_1 F_1(P) + \ldots + x_n F_n(P)), \tilde{g}(x, P) \in H^0(L \otimes [\tilde{Y}]^m) \}.$$  

What is more, mappings

$$\partial_{x_j} : M(m) \to M(m + 1)$$

hold.

Further, for simplicity we assume that $n = 2$.

First, we consider the case $k = 1$. Let the $D_2$-module $M$ be generated by the function $\psi$. We can assume that $\psi \in M(1)$. Since the rank of the $\mathcal{O}$-module of differential operators is of an order no higher than $m - 1$ equal to $\frac{m(m+1)}{2}$, by virtue of freeness of $M$ we have the obvious equality

$$\text{rank}_\mathcal{O} M(m) = \frac{m(m+1)}{2}.$$ 

Since for any meromorphic function $\lambda$ with pole of order $m$ on $Y$ there should be a unique differential operator $D(\lambda)$ of order $m$ such that equality (2) is satisfied, so in the general case equality

$$\text{rank}_\mathcal{O} H^0(U \times X, L \otimes [\tilde{Y}]^m) = \frac{m(m+1)}{2}$$

should be fulfilled. In this way, for the theory of commuting two variable differential operators with scalar coefficients, the following problem is important:

**Classification of algebraic manifolds $X$ of dimension 2, such that**

$$\dim H^0(X, E \otimes [Y]^m) = \frac{m(m+1)}{2}, \ m > 0,$$

**where $E$ is a certain line bundle over $X$**.

Let $k = 2, \psi_1, \psi_2$ be the basis in the $D_2$-module $M$. We can assume that $\psi_1 \in M(1), \psi_2 \in M(m_0), m_0 \geq 1$. Then, by virtue of freeness of $M$ we have

$$\text{rank}_\mathcal{O} M(m) = \frac{m(m+1)}{2} + \frac{(m - m_0 + 1)(m - m_0 + 2)}{2}, \ m > m_0.$$
Analogically, in order to find commuting two variable differential operators with matrix coefficients of size $2 \times 2$, the following problem is important: $2 \times 2$:

Classification of algebraic manifolds $X$ of dimension 2 such that

$$\dim H^0(X, E \otimes [Y]^m) = \frac{m(m+1)}{2} + \frac{(m-m_0+1)(m-m_0+2)}{2},$$

(3)

$m > m_0$.

Exactly in the same way we can examine the general case for arbitrary $n$ and $k$.

**Example** (A. Nakayashiki [10]). Let $X^g = \mathbb{C}^g/\{\mathbb{Z}^g + \Omega \mathbb{Z}^g\}$ be a principle polarized Abelian variety, with $\Omega$ being a symmetric complex matrix with a positively defined imaginary part. As subset $Y \subset X^g$ we consider a theta-divisor given by the zeroes of a theta function that is defined by the absolutely convergent series

$$\theta(z) = \sum_{n \in \mathbb{Z}^g} \exp(\pi i \langle m, \Omega m \rangle + 2\pi i \langle m, z \rangle), \ z \in \mathbb{C}^g.$$  

Assume that the theta divisor is a non-singular subvariety. The Baker-Akhiezer module has the form $M = \bigcup_{m=1}^{\infty} M(m)$,

$$M(m) = \{ g(z, x) \exp \left( -x_1 \partial_{z_1} \log \theta(z) \ldots - x_g \partial_{z_g} \log \theta(z) \right) \},$$

where $f(x, z)$ is a meromorphic function on $\mathbb{C}^g$ with a pole of order not larger than $m$ on the theta-divisor, and also periodic:

$$g(x, z + \Omega m + n) = \exp(-2\pi i \langle m, c + x \rangle)g(x, z), \ m, n \in \mathbb{Z}^g,$$

$c \in \mathbb{C}^g \backslash \{0\}$ being a fixed point

- $M$ is a free $\mathcal{D}_g$-module of rank $g!$.

Besides,

$$\text{rank}_\mathcal{O} M(m) = m^g.$$  

In this way, for $g = 2$ in formula (3) we have $m_0 = 2$.

**Remark.** Speaking more precisely, the conditions formulated on increasing of $\dim H^0(X, E \otimes [Y]^m)$ are necessary for the $\text{gr}\mathcal{D}$-module $\text{gr} M$ to be free, where the graduation is respectively induced by the degree of the operator and the order of pole on $Y$ (see details in [10]). Maybe it is possible that free $\mathcal{D}$ modules $M$ exists, but $\text{gr}\mathcal{D}$-modules $\text{gr} M$ at the same time are not free.
2.2 The Baker-Akhiezer module corresponding to the manifold $\Gamma$

Now turn to our construction. The form $f(P)$ (see introduction) is the section of the line bundle $\tilde{E}$ on $\mathbb{C}P^1 \times \mathbb{C}P^1$, if identity (1) holds, it can be interpreted as a section of the line bundle on $\Gamma$ derived from $\tilde{E}$ by identification of the fibres over double points. Let’s introduce two forms

$$f_i(P) = \alpha_i z_1 z_2 + \beta_i z_1 w_2 + \gamma_i z_2 w_1 + \delta_i w_1 w_2, \quad \alpha_i, \beta_i, \gamma_i, \delta_i \in \mathbb{C}, \quad i = 1, 2,$$

such that for $(t_1 : t_2) \in \mathbb{C}P^1$ identity

$$\frac{f_i(a_1 : b_1, t_1 : t_2)}{f(a_1 : b_1, t_1 : t_2)} - \frac{f_i(t_1 : t_2, a_2 : b_2)}{f(t_1 : t_2, a_2 : b_2)} - c_i = 0, \quad c_i \in \mathbb{C}. \quad (4)$$

holds. The dimension of spaces of such forms equals 3. By virtue of (1) identity (4) is equivalent to

$$f_i(a_1 : b_1, t_1 : t_2) - Af_i(t_1 : t_2, a_2 : b_2) - Ac_i f(t_1 : t_2, a_2 : b_2) = 0.$$

Chose $f_1$ and $f_2$ such $f_1$, $f_2$ and $f$ are linearly independent (any other form that satisfies condition (4) with a certain constant $c_i$ is a linear combination of $f_1$, $f_2$ and $f$). Let

$$F_1(P) = \frac{f_1(P)}{f(P)}, \quad F_2(P) = \frac{f_2(P)}{f(P)}.$$

Let $M(n)$ denote a set of functions of the form

$$M(n) = \left\{ \psi = \frac{\tilde{f}(P, x, y)}{f^n(P)} \exp (xF_1(P) + yF_2(P)) \right\},$$

for which the identity

$$\psi(a_1 : b_1, t_1 : t_2, x, y) - \Lambda \psi(t_1 : t_2, a_2 : b_2, x, y) = 0, \quad \Lambda \in \mathbb{C}, \quad (5)$$

is fulfilled for all $(t_1 : t_2) \in \mathbb{C}P^1$, where $\tilde{f}$ is a form of the following kind:

$$\tilde{f} = \sum_{k,l=0}^{n} \frac{k^l}{k!} z_1^{n-k} z_2^l w_1^{n-l} f_{kl}(x, y). \quad (6)$$
The set of functions from $M(n)$ forms a module above a ring of analytic functions $O$ on variables $x, y$ in the neighbourhood of $0 \in \mathbb{C}^2$. The rank of module $M(n)$ above $O$ (dimension of the space of functions from $M(n)$ for fixed $x, y$) is equal to
\[
\text{rank}_OM(n) = n(n + 1).
\]

Actually, the dimension of the space of forms of kind (6) is equal to $(n + 1)^2$. Note that by virtue of (1) and (4) identity (5) is equivalent to
\[
\tilde{f}(a_1 : b_1 : t_1 : t_2, x, y) - \tilde{f}(t_1 : t_2, a_2 : b_2, x, y) \Lambda A^n \exp(-xc_1 - yc_2) = 0.
\]
The last equality signifies that the coefficients of the homogeneous polinomial on $t_1, t_2$ of $n$-th power standing in the left-hand part equal zero. This imposes a $(n + 1)$ restriction on the choice of the coefficients of form $\tilde{f}$. In this way, $\text{rank}_OM(n) = (n + 1)^2 - (n + 1) = n(n + 1)$ and, consequently, in formula (3) for the manifold $\Gamma m_0 = 1$.

Note that since $\Lambda$ does not depend on $x, y$ identity (5) preserves its form at differentiation of $\psi$ by $x, y$. Consequently, we have two mappings
\[
\partial_x : M(n) \to M(n + 1), \quad \partial_y : M(n) \to M(n + 1).
\]
In this way, the structure of the Baker-Akhiezer module above the ring of differential operators
\[
\mathcal{D} = O[\partial_x, \partial_y].
\]
is given on the set
\[
M = \cup_{n=1}^{\infty} M(n)
\]

\section{Proof of theorem 1}

\subsection{Proof of freeness of the Baker-Akhiezer module}

Choose two functions $\psi_1$ and $\psi_2$ in $M(1)$
\[
\psi_i = \frac{h_i(P, x, y)}{f(P)} \exp(xF_1(P) + yF_2(P)),
\]
which are independent over $O$ where
\[
h_i(P, x, y) = a_i(x, y)z_1z_2 + b_i(x, y)z_1w_2 + c_i(x, y)w_1z_2 + d_i(x, y)w_1w_2, \quad i = 1, 2.
\]
Functions \( h_i \) satisfy the identity

\[
h_i(a_1 : b_1, t_1 : t_2, x, y) - h_i(t_1 : t_2, a_2 : b_2, x, y) \Lambda A \exp(-xc_1 - yc_2) = 0.
\]

Let \( P_1 \) and \( P_2 \) denote the intersection points of the curves given by equations \( f_1(P) = 0 \) and \( f(P) = 0 \), and by \( Q_1 \) and \( Q_2 \) the intersection points of the curves given by equations \( f_2(P) = 0 \) and \( f(P) = 0 \). For their bulkiness, we do not cite the explicit formulae for the point coordinates. \( P_1, P_2 \) and \( Q_1, Q_2 \). By small movements of \( c_1 \) and \( c_2 \) we can achieve these points to be mutually distinct.

The following theorem holds:

**Theorem 2** For any function \( \varphi \in M \) there exist two unique differential operators \( d_1, d_2 \in D \) such that

\[
d_1 \psi_1 + d_2 \psi_2 = \varphi,
\]

i.e. \( M \) is a free module over the ring of differential operators \( D \) of rank two, generated by functions \( \psi_1, \psi_2 \).

Theorem 1 follows directly from theorem 2.

Let \( N \) denote the module over \( D \), generated by the functions \( \psi_1, \psi_2 \)

\[
N = \{d_1 \psi_1 + d_2 \psi_2, d_1, d_2 \in D\}.
\]

Theorem 2 follows from lemma 1 and lemma 2. In lemma 1 we show that the \( D \)-module \( N \) is free of rank 2, and in lemma 2 we show that \( D \)-moduli \( M \) and \( N \) coincide.

The following lemma holds:

**Lemma 1** The module \( N \) is free over the ring of differential operators \( D \), generated by functions \( \psi_1, \psi_2 \).

**Proof of lemma 1.** Suppose that this module is not free, i.e. there exist two differential operators \( d_1, d_2 \in D \) of order \( n \) and \( k \)

\[
d_1 = \alpha_n(x, y) \partial^n_x + \alpha_{n-1}(x, y) \partial^{n-1}_x \partial_y + \ldots + \alpha_0(x, y) \partial^n_y + \ldots,
\]

\[
d_2 = \beta_k(x, y) \partial^k_x + \gamma_{k-1}(x, y) \partial^{k-1}_x \partial_y + \ldots + \delta_0(x, y) \partial^k_y + \ldots,
\]

where \( \alpha_n, \alpha_{n-1}, \ldots, \alpha_0 \), \( \beta_k, \gamma_{k-1}, \ldots, \delta_0 \) are smooth functions of \( x \) and \( y \), and the order of \( d_1 \) and \( d_2 \) is related to the order of the \( D \)-module \( M \).
\[
d_2 = \beta_k(x, y) \partial^k_x + \beta_{k-1}(x, y) \partial^{k-1}_x \partial_y + \ldots + \beta_0(x, y) \partial^k_y + \ldots,
\]
such that
\[
d_1 \psi_1 + d_2 \psi_2 = 0. \tag{7}
\]
First, consider the case of \(n \neq k\). For sake of definiteness, let \(n > k\). Divide equality (7) by \(\exp(x F_1(P) + y F_2(P))\), multiply by \(f^{n+1}(P)\) and after this confine the resulting equality to a curve \(f(P) = 0\). Get
\[
h_1(P, x, y)(\alpha_n(x, y) f^n_1(P) + \alpha_{n-1}(x, y) f^{n-1}_1(P) f_2 + \ldots + \\
\alpha_0(x, y) f^n_2(P)) = 0. \tag{8}
\]
Substitute the resulting equality with point \(P_1\)
\[
h_1(P_1, x, y) \alpha_0(x, y) f^n_2(P_1) = 0.
\]
Direct verification shows that function \(h_1(P_1, x, y)\) is not identically equal to 0, consequently, \(\alpha_0(x, y) = 0\). Divide (8) by \(f_1\) and substitute again point \(P_1\)
\[
h_1(P_1, x, y) \alpha_1(x, y) f^{n-1}_2(P_1) = 0,
\]
consequently, \(\alpha_1 = 0\). Analogically, we can show that
\[
\alpha_2 = \ldots = \alpha_n = 0.
\]
Now consider the case of \(k = n\). For \(P \in \{f(P) = 0\}\) in place of (8) get
\[
h_1(P, x, y)(\alpha_n(x, y) f^n_1(P) + \alpha_{n-1}(x, y) f^{n-1}_1(P) f_2 + \ldots + \alpha_0(x, y) f^n_2(P)) + \\
h_2(P, x, y)(\beta_n(x, y) f^n_1(P) + \beta_{n-1}(x, y) f^{n-1}_1(P) f_2 + \ldots + \beta_0(x, y) f^n_2(P)). \tag{9}
\]
In (9) replace points \(P = P_1\) and \(P = P_2\). From this
\[
h_1(P_1, x, y) \alpha_0(x, y) f^n_2(P_1) + h_2(P_1, x, y) \beta_0(x, y) f^n_2(P_1) = 0,
\]
\[
h_1(P_2, x, y) \alpha_0(x, y) f^n_2(P_2) + h_2(P_2, x, y) \beta_0(x, y) f^n_2(P_2) = 0.
\]
Consequently,
\[
\frac{h_1(P_1, x, y)}{h_2(P_1, x, y)} = \frac{h_1(P_2, x, y)}{h_2(P_2, x, y)} = \frac{\beta_0(x, y)}{\alpha_0(x, y)}.
\]
By direct verification find that
\[
\frac{h_1(P_1, x, y)}{h_2(P_1, x, y)} \neq \frac{h_1(P_2, x, y)}{h_2(P_2, x, y)} \tag{10}
\]
(here, for their bulkiness we do not cite explicit formulae for $\frac{h_1(P_1, x, y)}{h_2(P_1, x, y)}$. For simplicity we do this for a concrete example (see below)). Consequently, $\alpha_0 = \beta_0 = 0$. Dividing (9) by $f_1$ yields $\alpha_1 = \beta_1 = 0$. Analogically

$$\alpha_2 = \ldots = \alpha_n = \beta_2 = \ldots = \beta_n = 0.$$ 

Consequently, there exist no such operators $d_1$ and $d_2$. Lemma 1 is proven.

The following holds:

**Lemma 2** Modules $M$ and $N$ coincide.

**Proof of Lemma 2** Let $N(n)$ denote the following subset in $N$

$$N(n) = \{d_1\psi_1 + d_2\psi_2, d_1, d_2 \in \mathcal{D}, \text{ ord } d_1, \text{ ord } d_2 \leq n - 1\}.$$ 

Since the $\mathcal{D}$-module $N$ is free,

$$\text{rank}_\mathcal{O} N(n) = 2 \text{rank}_\mathcal{O}\{d\psi_i, d \in \mathcal{D}, \text{ ord } d \leq n - 1\} = n(n + 1).$$ 

Consequently,

$$\text{rank}_\mathcal{O} M(n) = \text{rank}_\mathcal{O} N(n).$$ 

By virtue of the obvious inclusion

$$N(n) \subset M(n),$$ 

get

$$M = N.$$ 

Thus, Lemma 2 is proven, jointly with theorem 2.

### 3.2 Explicit formulas for commuting differential operators

In this section, we give an example of commuting differential operators and common vector eigen-functions which are parametrized by the spectral manifold $\Gamma$.

Let points $p_1, p_2 \in \mathbb{C}P^1$ have the following coordinates

$$p_1 = (1 : 0), \ p_2 = (0 : 1).$$
We introduce three forms

\[ f(P) = z_1 z_2 + z_1 w_2 + w_1 w_2, \]
\[ f_1(P) = z_1 z_2 + 2 w_1 z_2 - w_1 w_2, \]
\[ f_2(P) = -z_1 z_2 + 2 w_1 z_2 + w_1 w_2. \]

By direct verification find that form \( \theta(P) \) satisfies identification (1) for \( A = 1 \), and forms \( f_1(P) \) and \( f_2(P) \) satisfy identity (4), with \( c_1 = 1 \) and \( c_2 = -1 \), respectively.

Curves \( f(P) = 0 \) and \( f_1(P) = 0 \) intersect in points

\[ P_1 = (-2 - \sqrt{2} : 1, -\frac{1}{\sqrt{2}} : 1), \quad P_2 = (-2 + \sqrt{2} : 1, \frac{1}{\sqrt{2}} : 1), \]

and curves \( f(P) = 0 \) and \( f_2(P) = 0 \) — in points

\[ Q_1 = (-\sqrt{2} : 1, -1 + \frac{1}{\sqrt{2}} : 1), \quad Q_2 = (\sqrt{2} : 1, -1 - \frac{1}{\sqrt{2}} : 1), \]

Take base \( \psi_1, \psi_2 \) in the \( \mathcal{D} \)-module \( M \)

\[ \psi_1 = \frac{w_1 z_2}{f(P)} \exp(x F_1(P) + y F_2(P)), \]
\[ \psi_2 = \frac{z_1 z_2 e^{y-x} + z_1 w_2 + w_1 w_2 e^{x-y}}{f(P)} \exp(x F_1(P) + y F_2(P)). \]

Then,

\[ \frac{h_1(P_1, x, y)}{h_2(P_1, x, y)} = -\frac{e^{x+y}}{\sqrt{2}(e^y - e^x)(-e^x + (1 + \sqrt{2})e^y)}, \]
\[ \frac{h_1(P_2, x, y)}{h_2(P_2, x, y)} = -\frac{e^{x+y}}{\sqrt{2}(e^y - e^x)(e^x + (-1 + \sqrt{2})e^y)}, \]

thus, inequality (10) holds.

The four most simple meromorphic functions on \( \Gamma \) with poles on the curve \( f(P) = 0 \) have the form

\[ \lambda_1 = \frac{w_1 z_2}{f(P)}, \quad \lambda_2 = \frac{z_1 w_1 z_2^2}{f(P)^2}, \quad \lambda_3 = \frac{z_1 z_2 w_1 w_2}{f(P)^2}, \quad \lambda_4 = \frac{z_1 w_1 w_2^2 + z_1^2 z_2 w_2}{f(P)^2}. \]
The pairwise commutating operators corresponding to this function have the form

\[ D(\lambda_1) = \left( \frac{1}{4}(\partial_x + \partial_y), \frac{1}{4}(\partial_x + \partial_y) \right). \]

\[ [D(\lambda_2)]_{11} = \frac{e^x}{8(e^x - e^y)}(\partial_x^2 - \partial_y^2) - \frac{e^{x+y}}{4(e^x - e^y)^2}(\partial_x + \partial_y), \]

\[ [D(\lambda_2)]_{12} = \frac{e^{x+y}}{16(e^x - e^y)^2}(\partial_x + \partial_y)^2; \]

\[ [D(\lambda_2)]_{21} = \frac{1}{8}(e^{y-x} - e^{-y-x})\partial_x^2 + \frac{1}{8}(e^{-y-x} - e^{y-x})\partial_y^2 + \frac{1}{2}\partial_x\partial_y + \frac{e^x + e^{2y-x} + 5e^y - e^{y-x}}{4(e^x - e^y)}\partial_x + \frac{3e^x - e^{2y-x} + 3e^y + e^{2y-x}}{4(e^y - e^x)}\partial_y - \frac{e^y(2e^x + e^y)}{(e^x - e^y)^2}, \]

\[ [D(\lambda_2)]_{22} = \frac{e^x}{8(e^y - e^x)}\partial_x^2 - \frac{1}{4}\partial_x\partial_y + \frac{e^y - 2e^y}{8(e^y - e^x)}\partial_y^2 + \frac{e^y(2e^x + e^y)}{8(e^x - e^y)^2}(\partial_x + \partial_y). \]

The operator corresponding to the function \( \lambda_3 \) has the form

\[ [D(\lambda_3)]_{11} = \frac{(e^x + e^y)}{8(e^y - e^x)}(\partial_x^2 - \partial_y^2) + \frac{(e^{2x} + e^{2y})}{4(e^y - e^x)^2}(\partial_x + \partial_y), \]

\[ [D(\lambda_3)]_{12} = \frac{e^{x+y}}{8(e^y - e^x)^2}(\partial_x - \partial_y)^2; \]

\[ [D(\lambda_3)]_{21} = \frac{1}{4}(2 + e^{x-y} - e^{y-x})\partial_x^2 - \partial_x\partial_y + \frac{1}{4}(2 - e^{x-y} + e^{y-x})\partial_y^2 + \frac{2e^x + e^{2y-x} + 4e^y - e^{2y-x}}{2(e^y - e^x)}\partial_x + \frac{4e^x - e^{2y-x} + 2e^y + e^{2y-x}}{2(e^x - e^y)}\partial_y + \frac{2e^x + e^{2y} + 4e^{x+y}}{(e^x - e^y)^2}, \]

\[ [D(\lambda_3)]_{22} = \frac{3e^x - e^y}{8(e^y - e^x)}\partial_x^2 + \frac{1}{2}\partial_x\partial_y + \frac{e^x - 3e^y}{8(e^x - e^y)}\partial_y^2 - \frac{3e^{x+y}}{2(e^y - e^x)^2}(\partial_x + \partial_y). \]

The operator corresponding to the function \( \lambda_4 \) has the form

\[ [D(\lambda_4)]_{11} = \frac{e^x + 3e^y}{4(e^x - e^y)}\partial_x^2 + \frac{1}{2}\partial_x\partial_y - \frac{3e^x + e^y}{4(e^x - e^y)}\partial_y^2 - \frac{e^{2x} + 3e^{2y}}{2(e^x - e^y)^2}\partial_x - \frac{3e^{2x} + e^{2y}}{2(e^x - e^y)^2}\partial_y - \frac{2e^{x+y}}{(e^y - e^x)^2}. \]
\[ [D(\lambda_1)]_{12} = \frac{e^{x+y}}{2(e^y - e^x)^2}((\partial_x + \partial_y)^2 + \partial_x + \partial_y), \]

\[ [D(\lambda_1)]_{21} = (e^{y-x} - e^{x-y} - 2)\partial_x^2 + 4\partial_x\partial_y + (e^{x-y} - e^{y-x} - 2)\partial_y^2 + \]

\[ \frac{5e^x + e^{2x-y} + 9e^y - 3e^{2y-x}}{e^x - e^y}\partial_x + \frac{9e^x - 3e^{2x-y} + 5e^y + e^{2y-x}}{e^x - e^y}\partial_y + \]

\[ \frac{2e^{-x-y}(e^{4x} + e^{4y} - 6e^{2(x+y)} - 4e^{3x+y} - 4e^{x+3y})}{(e^x - e^y)^2}, \]

\[ [D(\lambda_1)]_{22} = \frac{7e^x - 3e^y}{4(e^y - e^x)}\partial_x^2 - \frac{3}{2}\partial_x\partial_y + \frac{3e^x - 7e^y}{4(e^y - e^x)}\partial_y^2 - \]

\[ \frac{e^{2x} + 3e^{2y} - 16e^{x+y}}{2(e^x - e^y)^2}\partial_x - \frac{3e^{2x} + e^{2y} - 16e^{x+y}}{2(e^x - e^y)^2}\partial_y. \]
