Explicit reduction modulo $p$ of certain 2-dimensional crystalline representations.

Kevin Buzzard, Toby Gee

July 13, 2021

Abstract

We use the $p$-adic local Langlands correspondence for GL$_2(\mathbb{Q}_p)$ to explicitly compute the reduction modulo $p$ of certain 2-dimensional crystalline representations of small slope, and give applications to modular forms.

1 Introduction.

Let $f = \sum_{n \geq 1} a_n q^n$ be a weight $k$ cusp form for the group $\Gamma_1(N) \subseteq \text{SL}_2(\mathbb{Z})$, and assume that $f$ is normalised ($a_1 = 1$), is an eigenform for all the Hecke operators, and has character $\psi$ (a Dirichlet character modulo $N$). The coefficients of $f$ are complex numbers, but are well-known to be algebraic over $\mathbb{Q}$ and hence can be regarded (after some choices) as elements of $\mathbb{Q}_p$, where $p$ is a prime number. Deligne associated to $f$ a $p$-adic Galois representation $\rho_f : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \text{GL}_2(\mathbb{Q}_p)$.

Let us normalise the construction so that if $f$ is associated to an elliptic curve over $\mathbb{Q}$ then $\rho_f$ is the Tate module of the curve; this choice of normalisation is sometimes not ideal, but our main results appear cleaner with this choice.

A lot of explicit information is known about the “local” structure of $\rho_f$, by which we mean $\rho_f|_{D_\ell}$, where $D_\ell$ denotes a decomposition group at some prime number $\ell$. For example if $\ell$ is a prime not dividing $Np$ then $\rho_f$ is unramified at $\ell$ and the characteristic polynomial of $\rho_f(\text{Frob}_\ell)$ (with $\text{Frob}_\ell$ an arithmetic Frobenius) is $X^2 - a_\ell X + \ell^{k-1}\psi(\ell)$. In particular the local structure of $\rho_f$ at $\ell$ is determined by the local structure of $f$ at $\ell$, which, because $\ell \nmid N$, can be interpreted as the triple $(a_\ell, k, \psi(\ell))$. This is visibly an explicit description of $\rho_f|_{D_\ell}$ (there is still a question regarding semisimplicity of $\rho_f(\text{Frob}_\ell)$ in the case where the two eigenvalues coincide, but conjecturally this should never occur in weight $k \geq 2$, and in weight 1 $\rho_f(\text{Frob}_p)$ is known to be semisimple anyway).

If $\ell|N$ but $\ell \neq p$ then the local Langlands conjecture for GL$_2$ (a bijection which can be explicitly written down in essentially all cases) and a “local-global” theorem of Carayol (following Deligne and Langlands) again gives us an explicit description of $\rho_f|_{D_\ell}$.

Let us now turn our attention to the local structure of $\rho_f$ at $p$. Now one might argue that the theorems describing $\rho_f|_{D_p}$ in terms of the data attached to $f$ are far from “explicit”—and indeed, how could one expect them to be explicit: a 2-dimensional $p$-adic representation of $D_p$ is a very complicated object. However the mod $p$ 2-dimensional representations of $D_p$ are easily classified: the reducible ones are, up to semisimplification, the sum of two characters, and the irreducible ones are all induced from characters of the absolute Galois group of the unramified quadratic extension of $\mathbb{Q}_p$. So using a little local class field theory it is easy to explicitly list all these representations. The following “practical” question then arises:

**Question 1.1.** If $f = \sum_{n \geq 1} a_n q^n$ is a normalised cuspidal level $N$ eigenform and $p$ is a prime, and if $\overline{\rho}_f$ is the associated semisimple representation

$$\overline{\rho}_f : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \text{GL}_2(\overline{\mathbb{F}}_p),$$

then...
then can one explicitly read off \((\overline{\rho}_f|_{D_p})^\text{ss}\) from the weight, character and \(q\)-expansion of \(f\)?

In this generality, the answer to the question is in some sense “no”. For example, if \(f\) is a
newform of level \(\Gamma_0(N)\) and \(p\) divides \(N\) exactly once, then to know \(\rho_f|_{D_p}\) is (essentially) to know
the value of the so-called \(L\)-invariant of \(f\) at \(p\), and this invariant is subtle: as far as anyone knows,
it cannot be easily read off from the \(q\)-expansion of \(f\), and is not a “local” invariant of the classical
automorphic representation attached to \(f\). Furthermore, the problem does not go away when
reducing mod \(p\): \(\overline{\rho}_f|_{D_p}\) also depends heavily on the \(L\)-invariant, even for small weight modular
forms: see for example Théorème 4.2.4.7 of [BM02] for some examples of how the
\(L\)-invariant affects the local mod \(p\) representation. If furthermore \(p\) divides \(N\) more than once, then even less
is known, and the explicit dictionary is no doubt even more complicated.

However, if \(p \nmid N\) the situation is much better. The local data attached to \(f\) at \(p\) is the
``prime to \(p\)'' forms: see for example Théorème 4.2.4.7 of [BM02] for some examples of how the
theory by identifying uniformisers with geometric Frobenii. Let \(\omega_p\) denote the cyclotomic
character, and let \(\omega : D_p \to \overline{\mathbb{F}}_p^\times\) denote the mod \(p\) reduction of \(\epsilon\). Let \(\omega_2 : \text{Gal}(\overline{\mathbb{Q}}_p/\mathbb{Q}_p) \to \overline{\mathbb{F}}_p^\times\)
denote a character such that the induced map \(\mathbb{Q}_p^\times \to \overline{\mathbb{F}}_p^\times\) sends \(p\) to 1 and such that the induced
map \(\mathbb{F}_p^{q^2} \to \overline{\mathbb{F}}_p^{q^2}\) is induced by a morphism of fields \(\mathbb{F}_p^{q^2} \to \overline{\mathbb{F}}_p^{q^2}\). There are two such choices for \(\omega_2\):
we fix one. We call \(\omega_2\) a “fundamental character of niveau 2”. The other fundamental character is
\(\omega_2^q\). Note that \(\omega_2^{q+1} = \omega_2\) on \(I_p\), the inertia subgroup of \(D_p\). Abusing notation, let us also use \(\omega_2\) to
mean \(\omega_2|_{I_p}\). By local class field theory we can also consider \(\omega\) and \(\omega_2\) as characters of \(\mathbb{Q}_p^\times\) and
\(\mathbb{Q}_p^{q^2}\) respectively.

The following theorems were proved by global methods:

**Theorem 1.2.** (1) (Deligne-Serre) If \(k = 1\) then \(\rho_f\) is unramified at \(p\), and \(\rho_f(\text{Frob}_p)\) is semisimple
with characteristic polynomial \(X^2 - a_pX + \psi(p)\).

(2) (Deligne) If \(k \geq 2\) and \(a_p\) is a \(p\)-adic unit then \(\rho_f|_{D_p}\) is reducible (and may or may not be
semisimple), and the semisimplification of \(\rho_f|_{D_p}\) is isomorphic to \(\mu_{a_p} \oplus e^{k-1} \mu_{a_p}/\psi(p)\).

(3) (Fontaine, Edixhoven) If \(2 \leq k \leq p+1\) and \(a_p\) is not a \(p\)-adic unit then \(\overline{\rho}_f|_{D_p}\) is irreducible,
and \(\overline{\rho}_f|_{I_p} \cong \omega_2^{k-1} \oplus \omega_2^{e^{k-1}}\).

**Remark 1.3.** Part (1) of the theorem was proved by Deligne to Serre in [DS74]. Part (2) was
proved in a 1974 letter from Deligne to Serre which apparently has never been published, although
published proofs are now in the literature (see for example Theorem 2 of [Wi88]). Part (3) was
proved (for \(k \leq p\)) in 1979 by Fontaine in two letters to Serre, but as far as we know the first
published proof was given by Edixhoven in [Edi92] and this proof uses global methods. Note finally
the relative strengths of the results: (1) and (2) describe the \(p\)-adic representation, and (2) has no
restrictions on the weight, whereas (3) only describes the mod \(p\) representation and only for small
weights—this is because parts (1) and (2) concern ordinary modular forms, and the situation is
much more complicated in the non-ordinary case.

The problem with extending these global methods to the higher weight non-ordinary case is
that they typically rely on the arithmetic of mod \(p\) modular forms and the geometry of modular
curves over \(\overline{\mathbb{F}}_p\), and hence find it very hard to distinguish between \(a_p,s\) with positive valuations.
However for \(k > p+1\) one can easily find examples on a computer of modular forms \(f_1\) and \(f_2\)
of the same weight and level (prime to \(p\)) and character, with \(v(a_p(f_1)) > 0\), \(v(a_p(f_2)) > 0\) and
\((\overline{\rho}_{f_1}|_{I_p})^\text{ss} \neq (\overline{\rho}_{f_2}|_{I_p})^\text{ss}\). In particular, vaguely speaking, the mod \(p\) Galois representation associated to
a modular form, locally at \(p\), depends on more than the mod \(p\) reduction of the local data
attached to the form at \(p\).

There is however a completely different and far more local way of approaching the problem,
which relies on a coincidence in \(p\)-adic Hodge Theory which is very specific to 2-dimensional
representations of $\text{Gal}(\overline{\mathbb{Q}}_p/\mathbb{Q}_p)$. Let $f$ be a normalised cuspidal eigenform of level $N$ prime to $p$. Then $\rho_f|_{D_p}$ is a crystalline Galois representation, and we would like to say something concrete about $\rho_f|_{D_p}$. Because of Theorem 1.2 above, we may now restrict our attention to the case $k \geq 2$ and $v(a_p) > 0$. Moreover, after an unramified twist we may assume $\psi(p) = 1$. The coincidence is that if we furthermore assume that the roots of $X^2 - a_pX + p^{k-1}$ are distinct (or equivalently that $a_p^2 \neq 4p^{k-1}$, an inequality which always holds if $k = 2$ and conjecturally holds for any $k \geq 2$) then there is up to isomorphism a unique $\overline{\mathbb{Q}}_p$-vector space $D_{k,a_p}$ equipped with a semisimple linear Frobenius $\phi$ with characteristic polynomial $X^2 - a_pX + p^{k-1}$ and a weakly admissible filtration with jumps at 0 and $k - 1$. In this case we have the following theorem which follows from Scholl’s work on modular forms and the $p$-adic comparison isomorphism:

**Theorem 1.4.** (Scholl, Faltings)
If $k \geq 2$, if $v(a_p) > 0$, and furthermore if $a_p^2 \neq 4p^{k-1}$, then $D_{\text{cris}}((\rho_f|_{D_p})^*) \cong D_{k,a_p}$.

Note that the omitted case $a_p^2 = 4p^{k-1}$ does not occur if $k = 2$ and should not occur if $k > 2$ (it would contradict a conjecture of Tate: see [CE98]). Note also that we need to take the $\overline{\mathbb{Q}}_p$-dual of $\rho_f$; this is because of our conventions.

Again under the assumptions $k \geq 2$, $a_p \in \overline{\mathbb{Q}}_p$ with $|a_p| < 1$ and $a_p^2 \neq 4p^{k-1}$, let $V_{k,a_p}$ denote the crystalline representation $V$ such that $D_{\text{cris}}(V_{k,a_p}^*) \cong D_{k,a_p}$. Our conclusion is that (with notation as above) $\rho_f|_{D_p} \cong V_{k,a_p}$, and in particular the mod $p$ reduction of $\rho_f|_{D_p}$ is determined by the local data $(a_p, k)$ associated to $f$. But this reconstruction is far from explicit! It leads us to formulate the explicit purely local

**Question 1.5.** Say $k \geq 2$ and $a_p \in \overline{\mathbb{Q}}_p$ with $v(a_p) > 0$ and $a_p^2 \neq 4p^{k-1}$. What is the isomorphism class of $V_{k,a_p}$ (the semisimplification of the reduction of the $D_p$-representation $V_{k,a_p}$) as an explicit function of $k$ and $a_p$?

A few years ago this question seemed to be regarded as almost intractable for weights $k > p$: as far as we know, the only results for high weights were those of Berger, Li and Zhu [BLZ04] who showed that for $v(a_p)$ sufficiently large (an explicit bound depending on $k$) the answer was the same as for the case $a_p = 0$ (which was already known). Not only that, computational evidence collected by one of us (KB) seemed to indicate that the answer to the question was in general rather subtle.

However, recent work of Breuil, Berge and Colmez on the $p$-adic and mod $p$ local Langlands correspondence for $\text{GL}_2(\mathbb{Q}_p)$ gives us a completely new approach for attacking this problem. We now summarise what we need to know about the $p$-adic and mod $p$ Langlands correspondence for $\text{GL}_2(\mathbb{Q}_p)$ here (although we do not go into the details of extension classes, an important subtlety which we will not need here, and we shall only discuss the case of crystalline $p$-adic representations; much is now known in more general cases but we shall not need these results). Note also that from this point on, our notational conventions will be that a bar over a $\mathbb{Q}_p$-vector space (a Galois representation, or a representation of $\text{GL}_2(\mathbb{Q}_p)$) will mean (some sensible variant of) “take a stable lattice, reduce, and then semisimplify”, whereas a bar over a “lattice” (for example the $\mathbb{Z}_p$-module $\Theta_{k,a_p}$ that we shall see later on) will mean “reduce mod $p$ and don’t semisimplify”.

Breuil in [Bre03] has classified the irreducible smooth admissible representations of $\text{GL}_2(\mathbb{Q}_p)$ over $\mathbb{F}_p$. Furthermore he also wrote down an explicit injective map $V \mapsto LL(V)$ from the set of isomorphism classes of semisimple 2-dimensional $\mathbb{F}_p$-representations of $\text{Gal}(\overline{\mathbb{Q}}_p/\mathbb{Q}_p)$ to the set of isomorphism classes of semisimple finite length admissible smooth representations of $\text{GL}_2(\mathbb{Q}_p)$, the idea being that this map should be the “correct” version of the Local Langlands correspondence in this setting. Note that the image of the map $LL$ does not contain every irreducible representation of $\text{GL}_2(\mathbb{Q}_p)$ and it does contain some reducible ones. In particular the situation is not quite as simple as the classical local Langlands correspondence.

Now let $V$ denote an irreducible 2-dimensional crystalline representation of $\text{Gal}(\overline{\mathbb{Q}}_p/\mathbb{Q}_p)$ over $\overline{\mathbb{Q}}_p$. Berger and Breuil in [BB08] associate to $V$ a $p$-adic Banach space $B(V)$ equipped with a unitary action of $\text{GL}_2(\mathbb{Q}_p)$, such that $B(V)$ is topologically irreducible (see Corollaire 5.3.2 of [BB08]). The map $B$ should be thought of as a $p$-adic local Langlands correspondence. If one chooses an
open \(GL_2(Q_p)\)-stable lattice in this Banach space and then tensors the lattice with \(F_p\), one obtains a finite length \(F_p\)-representation of \(GL_2(Q_p)\) whose semisimplification \(\overline{B}(V)\) depends only on \(V\).

A crucial theorem of Berger (Théorème A of [Ber08]) is that \(\overline{B}(V) \cong LL(\overline{\nabla})\), where \(\overline{\nabla}\) denotes the semisimplification of the \(F_p\)-reduction of \(V\). In words, the \(p\)-adic and mod \(p\) local Langlands dictionaries are compatible. In particular \(\overline{B}(V)\) actually only depends on \(\overline{\nabla}\).

The final ingredient in our approach is the following. We have our data \((a_p, k)\) with as usual \(k \geq 2\), \(v(a_p) > 0\) and \(a_p^2 \neq 4p^{k-1}\). Given this data, Breuil constructs an irreducible (algebraic) \(\overline{Q}_p\)-representation \(\Pi_{k,a_p}\) of the group \(GL_2(Q_p)\), and this representation stabilises a lattice \(\Theta_{k,a_p}\), so \(\overline{\Theta}_{k,a_p} := \Theta_{k,a_p} \otimes F_p\) is an \(F_p\)-representation of \(GL_2(Q_p)\) (we will see explicit definitions later; the constructions were made in [Bre03] and the proofs of the assertions we are making here are in loc. cit. and in section 5 of [BB08]). Breuil and Berger have shown (again in section 5 of [BB08]) that \(B(V_{k,a_p})\) is a certain completion of \(\Pi_{k,a_p}\) and it follows that \(\overline{\Theta}_{k,a_p} \cong \overline{B}(V_{k,a_p})\). In particular, \(\overline{\Theta}_{k,a_p}^{ss}\) is in the image of \(LL\). This opens up the possibility of computing it via a process of elimination: if we examine the image of \(LL\) and manage to rule out all but one element of it as a possibility for \(\overline{\Theta}_{k,a_p}^{ss}\) then we have computed \(\overline{\Theta}_{k,a_p}^{ss}\) and hence \(V_{k,a_p}\)!

Note that this approach relies heavily on both Breuil’s classification and the explicit happy \((\phi, \Gamma)\)-module coincidences for \(GL_2(Q_p)\) implicit in Berger’s work, and hence seems to be restricted to the case of \(2\)-dimensional representations of \(\text{Gal}(Q_p/Q_p)\), but it does enable us to give the first explicit computations of \(V_{k,a_p}\) valid in the non-ordinary case where \(v(a_p)\) is small and \(k\) is unbounded. We remark that Paskunas independently proved similar results using similar ideas.

Note that if \(1 \leq t \leq p\) then \(\text{ind}(\omega^t_2)\) (induction from \(\text{Gal}(Q_p/Q_p)\) to \(\text{Gal}(Q_p/Q_p)\)) is an irreducible \(2\)-dimensional representation of \(\text{Gal}(Q_p/Q_p)\) with determinant \(\omega^t\) whose restriction to \(I_p\) is \(\omega^t \otimes \omega^p\). For \(n \in \mathbb{Z}\) let \([n]\) denote the unique integer in \(\{0, 1, 2, \ldots, p-2\}\) congruent to \(n\) modulo \(p\) - 1. We prove the following result in this paper, via the technique explained above:

**Theorem 1.6.** If \(k \geq 2\) and \(0 < v(a_p) < 1\), and \(t = \lceil k - 2 \rceil + 1\), then either \(V_{k,a_p} \cong \text{ind}(\omega^t_2)\) is irreducible, or \(k \equiv 3 \mod p - 1\), and \(V_{k,a_p}|_{L_p} \cong \omega \oplus \omega\).

Note that the theorem is true but vacuous if \(p = 2\). Note also that for \(p > 2\), work of Breuil and Berger completely determines \(V_{k,a_p}\) (for all \(a_p\)) in the case \(k \leq 2p + 1\) (see for example Théorème 3.2.1 of [Ber08]). Our contribution is hence the case \(k \geq 2p + 2\) and \(p > 2\), where the assumption \(v(a_p) < 1\) of the theorem implies that the roots of \(X^2 - a_p X + p^{k-1}\) cannot have ratio 1 or \(p\), which helps our exposition somewhat because these correspond to “special cases” in the theory that sometimes have to be dealt with separately.

If \(k \neq 3\) modulo \(p - 1\) then the theorem tells you \(V_{k,a_p}\), but if \(k \equiv 3 \mod p - 1\) then there are two possibilities in the conclusion of the theorem and we know of no neat criterion to distinguish between them. This initially surprising special case actually has a simple global explanation. Take a weight 3 newform of level \(\Gamma_1(N) \cap \Gamma_0(p)\); it will have slope 1/2. Moreover the local mod \(p\) representation attached to this newform is “hard” to determine, because it requires knowledge of the \(L\)-invariant of the form. Now any classical eigenform in a Coleman family sufficiently close to this newform will be old at \(p\), have weight congruent to 3 \(mod p - 1\), and will still have slope 1/2, and hence the mod \(p\) Galois representation attached to this eigenform is also “hard” to determine and in particular will depend on more than the slope of the form. On the positive side, if \(p > 2\) then we at least know what is happening for \(k\) small: if \(k = 3\) or \(k = p + 2\) then the reducible case can never occur, and if \(k = 2p + 1\) then a computation of Breuil explains exactly when the reducible case occurs: see Théorème 3.2.1 of [Ber08].

## 2 The mod \(p\) and \(p\)-adic Langlands correspondences for \(GL_2(Q_p)\).

We recall some results on the mod \(p\) representations of \(GL_2(Q_p)\). Nothing in this section is due to the authors. Let \(p\) be a prime, let \(\mathbb{Z}_p\) be the integers in \(\overline{Q}_p\) and let \(F_p\) be the residue field of
Say \( r \in \mathbb{Z}_{\geq 0} \). Let \( K \) be the group \( \text{GL}_2(\mathbb{Z}_p) \), and for \( R \) a \( \mathbb{Z}_p \)-algebra let \( \text{Sym}^r(\mathbb{R}^2) \) denote the space \( \oplus_{i=0}^r R x^{-i} y^i \) of homogeneous polynomials in two variables \( x \) and \( y \), with the action of \( K \) given by

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} x^{-i} y^i = (ax + cy)^{r-i} (bx + dy)^i.
\]

Set \( G = \text{GL}_2(\mathbb{Q}_p) \), and let \( Z \) be its centre. If \( V \) is an \( R \)-module with an action of \( K \), then extend the action of \( K \) to the group \( KZ \) by letting \( (\mathbb{I}_p) \) act trivially, and let \( I(V) \) denote the representation \( \text{ind}_{KZ}^G(V) \) (compact induction). Explicitly, \( I(V) \) is the space of functions \( f : G \to V \) which have compact support modulo \( Z \) and which satisfy \( f(kg) = k.(f(g)) \) for all \( k \in KZ \). This space has a natural action of \( G \), defined by \( (gf)(\gamma) = f(\gamma g) \). Note that \( \S 2.2 \) of [BL94] explains how an \( R \)-linear \( G \)-endomorphism of \( I(V) \) can be interpreted as a certain function \( G \to \text{End}_R(V) \) (by Frobenius reciprocity).

If \( V = \text{Sym}^r(\mathbb{R}^2) \) for some integer \( r \geq 0 \) and \( \mathbb{Z}_p \)-algebra \( R \), then, using the dictionary mentioned above, Barthel and Livné identified a certain endomorphism \( \Pi(\mathbb{I}_p) \), which corresponds to the function \( G \to \text{End}_R(V) \) which is supported on \( KZ(\mathbb{I}_p)KZ \) and sends \( (\mathbb{I}_p) \) to the endomorphism of \( \text{Sym}^r(\mathbb{R}^2) \) sending \( F(x,y) \) to \( F(px,py) \). We refer to Lemme 2.1.4.1 of [Bre03a] and the remarks following this lemma for many basic facts about this endomorphism.

We now recall the classification of smooth irreducible mod \( p \) representations of \( \text{GL}_2(\mathbb{Q}_p) \), due to Breuil and Barthel-Livné. For \( r,n \in \mathbb{Z}_{\geq 0} \) set \( \sigma_r := \text{Sym}^r(\mathbb{F}_p^2) \) and set \( \sigma_r(n) := \text{det} \otimes \text{Sym}^r(\mathbb{F}_p^2) \). These are \( \mathbb{F}_p \)-representations of \( K \), irreducible if \( 0 \leq r \leq p-1 \). If \( R \) is a ring and \( t \in R^\times \), then let \( \mu_t \) denote the map \( \text{GL}_1(\mathbb{Q}_p) \to R^\times \) which is trivial on \( \mathbb{Z}_p \) and which sends \( p \) to \( t \). If \( \chi : \mathbb{Q}_p^\times \to \mathbb{F}_p^\times \) is a character, if \( \lambda \in \mathbb{F}_p^\times \) and if \( 0 \leq r \leq p-1 \) then define

\[
\pi(r,\lambda,\chi) := (I(\sigma_r)/(T-\lambda)) \otimes (\chi \circ \text{det}).
\]

The classification is due to Barthel-Livné and Breuil, and is as follows (see for example Théorème 2.7.1 of [Bre03a], which summarises results in [BL94], and also Corollaire 4.1.1, Corollaire 4.1.4 and Corollaire 4.1.5 of loc. cit.).

(i) If \( \lambda \neq 0 \) and \( (r,\lambda) \not\in \{(0,\pm 1),(p-1,\pm 1)\} \) then \( \pi(r,\lambda,\chi) \) is irreducible.

(ii) There is a certain infinite-dimensional representation \( St \) of \( G \), called the Steinberg representation. For \( r \in \{0,p-1\} \) and \( \lambda = \pm 1 \), \( \pi(r,\lambda,\chi) \) has two Jordan-Hoelder factors, one \( 1 \)-dimensional and isomorphic to \( \chi \mu_{\lambda} \circ \text{det} \) and the other equal to a twist of the Steinberg representation by this same character.

(iii) The representations \( \pi(r,0,\chi) \) are all irreducible, and are called the supersingular representations of \( G \) (we remark that this is the result due to Breuil and it is this part which does not generalise to local fields other than \( \mathbb{Q}_p \)). No Jordan-Hoelder factor of \( \pi(r,\lambda,\chi) \) with \( \lambda \neq 0 \) is supersingular.

(iv) We have just seen that all the representations \( \pi(r,\lambda,\chi) \) have finite length. Conversely, any smooth irreducible \( \mathbb{F}_p \)-representation of \( G \) with a central character is a Jordan-Hoelder constituent of \( \pi(r,\lambda,\chi) \).

(v) The only isomorphisms between the representations \( \pi(r,\lambda,\chi) \) are the following:

(a) If \( \lambda \neq 0 \) and \( (r,\lambda) \not\in \{(0,\pm 1),(p-1,\pm 1)\} \), then \( \pi(r,\lambda,\chi) \cong \pi(r,-\lambda,\chi\mu_{-1}) \).

(b) If \( \lambda \neq 0 \) and \( \lambda \neq \pm 1 \) then \( \pi(0,\lambda,\chi) \cong \pi(p-1,\lambda,\chi) \) (and these are also isomorphic to \( \pi(0,-\lambda,\mu_{-1}\chi) \) and \( \pi(p-1,-\lambda,\mu_{-1}\chi) \) as already mentioned).

(c) \( \pi(r,0,\chi) \cong \pi(r,0,\chi\mu_{-1}) \cong \pi(p-1-r,0,\chi\omega^{r}) \cong \pi(p-1-r,0,\chi\omega^{r}_{\mu_{-1}}) \).

Note that the Jordan-Hoelder factors of \( \pi(0,\lambda,\chi) \) and \( \pi(p-1,\lambda,\chi) \) coincide even if \( \lambda = \pm 1 \).

We now move on to the \( p \)-adic part of the story. Say \( k \geq 2 \) and \( \alpha_p \in \mathbb{Z}_p \) with \( |\alpha_p| < 1 \), as usual.

We now furthermore make the assumption that the roots of \( X^2 - \alpha_p X + p^{k-1} \) do not have ratio 1 or \( p \); in other words we assume \( \alpha_p^2 \neq 4p^{k-1} \) and \( \alpha_p \neq \pm (1 + p)p(k-2)/2 \). These assumptions are not always necessary, but they make for a slightly cleaner exposition, and in our final application we have \( k \geq p+2 \) and \( v(\alpha_p) < 1 \) and so they will be satisfied.

**Definition 2.1.** Let \( \Pi_k,\alpha_p := \text{ind}_{KZ}^G \text{Symm}^{k-2}(\mathbb{Q}_p^2)/(T - \alpha_p) \) (compact induction, as before), and let \( \Theta_k,\alpha_p \) be the image of \( \text{ind}_{KZ}^G \text{Symm}^{k-2}(\mathbb{Z}_p^2) \) in \( \Pi_k,\alpha_p \).
Alternatively, $\Theta_{k,a}$ is the quotient of $\text{ind}^G_{\mathbb{Z}} \text{Symm}^{k-2}(\mathbb{Z})/(T-a_p)$ by its torsion. Then $\Pi_{k,a}$ is irreducible by Proposition 3.3(i) of [Bre03a] and $\Theta_{k,a}$ is a lattice in it, by Corollaire 5.3.4 of [BB08].

The $p$-adic Langlands correspondence associates a unitary $p$-adic Banach space representation $B(V)$ of $\text{GL}_2(\mathbb{Q}_p)$ to an irreducible crystalline representation $V$, and $B(V_{k,a})$ (under our assumptions on $k$ and $a_p$ above) is isomorphic to the completion of $\Pi_{k,a}$ with respect to the gauge of $\Theta_{k,a}$. We deduce that $\overline{B}(V_{k,a})$ (the semisimplification of the reduction of an open $\text{GL}_2(\mathbb{Q}_p)$-stable lattice in $B(V_{k,a})$) is isomorphic to $\Omega_{k,a}^{ss}$, where $\Omega_{k,a} := \Theta_{k,a} \otimes \overline{\mathbb{F}}_p$. We now recall the explicit mod $p$ local Langlands correspondence for $\text{GL}_2(\mathbb{Q}_p)$ formulated by Breuil and the compatibility of the mod $p$ and $p$-adic Langlands correspondences for trianguline representations proved by Berger (see Théorème A of [Ber08]), and in particular what these things tell us about the situation in hand. Let $[x]$ be the unique integer in $[0, p-2]$ congruent to $x \in \mathbb{Z}$ modulo $p-1$.

**Theorem 2.2.** We have

$$V \cong (\text{ind}(\omega^{r+1})) \otimes \chi \iff B(V) \cong \pi(r, 0, \chi)$$

and

$$V \cong (\mu \omega^{r+1} \oplus \mu^{-1}) \otimes \chi \iff \overline{B}(V) \cong \pi(r, \lambda, \chi)^{ss} \oplus \pi([p-3-r], \lambda^{-1}, \chi \omega^{r+1})^{ss}.$$ 

In particular, if $k \geq 2$, $a_p \in \overline{\mathbb{Q}}_p$ with $v(a_p) > 0$, and if the roots of $X^2 - a_pX + p^{k-1}$ don’t have ratio 1 or $p^{k-1}$, we have

$$V_{k,a} \cong (\text{ind}(\omega^{r+1})) \otimes \chi \iff (\overline{\Theta}_{k,a})^{ss} \cong \pi(r, 0, \chi)$$

and

$$V_{k,a} \cong (\mu \omega^{r+1} \oplus \mu^{-1}) \otimes \chi \iff (\overline{\Theta}_{k,a})^{ss} \cong \pi(r, \lambda, \chi)^{ss} \oplus \pi([p-3-r], \lambda^{-1}, \chi \omega^{r+1})^{ss}.$$ 

### 3 Lemmas about mod $p$ representations of $\text{GL}_2(\mathbb{Q}_p)$.

Our strategy for proving Theorem 1.6 is to compute $V_{k,a}$ when $0 < v(a_p) < 1$ by analysing $\overline{\Theta}_{k,a}$ and its possible Jordan-Hoelder factors. The following lemma follows directly from the explicit description of the Jordan-Hoelder factors of $\pi(r, \lambda, \chi)$ given in the previous section.

**Lemma 3.1.** If $\lambda \neq 0$ and $\pi(r, \lambda, \chi)$ and $\pi(r', \lambda', \chi')$ have a common Jordan-Hoelder factor, then $\lambda' \neq r' \equiv r \mod p-1$, and $\chi/\chi'$ is unramified.

The next lemma is a straightforward strengthening of Proposition 32 of [BL94].

**Lemma 3.2.** If $0 \leq r \leq p-1$ and $F$ is a quotient of $I(\sigma_r)$ which has finite length as an $\mathbb{F}_p[G]$-module, then every Jordan-Hoelder factor of $F$ is a subquotient of $I(\sigma_r)/(T-\lambda) = \pi(r, \lambda, 1)$ for some $\lambda$ (with $\lambda$ possibly depending on the factor).

**Proof.** Induction on the length of $F$. If $F$ is irreducible then Théorème 2.7.1(i) of [Bre03a] shows that in fact $F$ is a quotient of some $\pi(r, \lambda, 1)$, and in particular a subquotient. Assume now that $F$ has length greater than one, so that $F$ has an irreducible quotient $J$, and the kernel $K$ has smaller length. Again by loc. cit., the composite map $I(\sigma_r) \to F \to J$ factors as $I(\sigma_r) \to \pi(r, \lambda, 1) \to J$ for some $\lambda$. Let $\gamma$ denote this latter arrow.

Now consider the following commutative diagram:

$$
\begin{array}{cccccc}
I(\sigma_r) & \xrightarrow{T-\lambda} & I(\sigma_r) & \xrightarrow{\alpha} & \pi(r, \lambda, 1) & \longrightarrow 0 \\
& & \downarrow{\beta} & & \downarrow{\gamma} & \\
0 & \longrightarrow & K & \longrightarrow & F & \longrightarrow J & \longrightarrow 0
\end{array}
$$
Since $\beta$ is surjective, the snake lemma implies that $\text{coker}(\alpha)$ is a subquotient of $\pi(r, \lambda, 1)$ and hence each of its Jordan-Hoelder factors are too. Moreover, the inductive hypothesis tells us that every Jordan-Hoelder factor of $\text{im}(\alpha)$ is a subquotient of $\pi(r, \lambda', 1)$ for some $\lambda'$ (depending on the factor), hence any Jordan-Hoelder factor of $K$ and hence of $F$ is a subquotient of $\pi(r, \lambda', 1)$ for some $\lambda'$ and we are done. \hfill \square

The following proposition will be crucial for us. It uses the previous lemma to conclude that we can say a lot about a finite length $\mathbb{F}_p$-representation of $GL_2(\mathbb{Q}_p)$ which is a quotient of $I(W)$ for some irreducible $W$, and whose semisimplification is in the image of $LL$. Note that any supersingular representation of $GL_2(\mathbb{Q}_p)$ is a quotient of $I(W)$ for some irreducible $W$; the point is that almost no other elements of the image of $LL$ are. Recall that if $W$ is an irreducible $\mathbb{F}_p$-representation of $K$ then $W = \sigma_s(n)$ for some $0 \leq s \leq p-1$.

**Proposition 3.3.** If $V$ is an irreducible crystalline representation of $\text{Gal}(\overline{\mathbb{Q}}_p/\mathbb{Q}_p)$, if $\Theta$ is an open $GL_2(\mathbb{Q}_p)$-stable lattice in $B(V)$ and if there is a surjection $I(\sigma_s(n)) \rightarrow \Theta$ for some $s$ with $0 \leq s \leq p-1$, then either $V \cong \text{ind}(\omega_2^{s+1}(p+1)n)$ is irreducible, or $V$ is reducible and scalar on inertia. If $p > 2$ then in the reducible case we must furthermore have $s = p-2$ and $V|_{I_p} = \omega^n \oplus \omega^n$.

**Remark 3.4.** If $p = 2$ then this proposition is vacuous, as if $p = 2$ then every semisimple 2-dimensional mod $p$ representation of $\text{Gal}(\overline{\mathbb{Q}}_p/\mathbb{Q}_p)$ is either irreducible or scalar on inertia.

**Proof.** Firstly observe that $I(\sigma_s(n)) \cong I(\sigma_s) \otimes (\omega \circ \text{det})^n$ as $GL_2(\mathbb{Q}_p)$-representations, so (twisting $V$ by an appropriate power of the cyclotomic character) we may assume that $n = 0$ (as $LL$ is compatible with twists).

We know that $\overline{\Theta}^e$ must be in the image of $LL$. Hence if $\overline{\Theta}^e$ is irreducible then it is of the form $\pi(r, 0, \chi)$ for some $r, \chi$. However Lemma 3.2 tells us that any irreducible quotient of $I(\sigma_s)$ must be a Jordan-Hoelder factor of $\pi(s, \lambda, 1)$ for some $\lambda$, and by the classification theorem we must have $\pi(r, 0, \chi) \cong \pi(s, 0, 1)$. By Theorem 2.2 we deduce $V \cong \text{ind}(\omega_2^{s+1})$ in this case.

So now say $\overline{\Theta}^e$ is reducible (and hence $V$ is reducible). The crucial point is that if $\lambda \in \mathbb{F}_p^\times$ then usually the Jordan-Hoelder factors of $\pi(r, \lambda, \chi)^e \oplus \pi((p-3-r), \lambda^{-1}, \chi^{r+1})^e$ (a general reducible element of the image of $LL$) cannot all be subquotients of $I(\sigma_s)$ for the same $s$. Indeed, applying Lemma 2.2 to $\Theta$ we see that if $V$ is reducible then the Jordan-Hoelder factors of $\pi(r, \lambda, \chi)$ and $\pi((p-3-r), \lambda^{-1}, \chi^{r+1})$ all have to be subquotients of $\pi(s, \lambda', 1)$ for varying $\lambda'$, and by Lemma 3.1 above we note that this forces both $\chi$ and $\chi^{r+1}$ to be unramified, so $r \equiv s \equiv p-2$ modulo $p-1$, and in this case we see from Theorem 2.2 that $V$ is unramified. \hfill \square

**4 The kernel of the map $I(\sigma_{k-2}) \rightarrow \overline{\Theta}_{k,a_p}$.**

Let us re-iterate our assumptions: $k \geq 2$, $\nu(a_p) > 0$ and the roots of $X^2 - a_p X + p^{k-1}$ do not have ratio 1 or $p^{k-1}$. It is clear from the definition that $\overline{\Theta}_{k,a_p}$ admits a surjection from $I(\sigma_{k-2})/(T)$ and in particular from $I(\sigma_{k-2})$. Note however that Proposition 3.3 does not apply to this situation, because $\sigma_{k-2}$ is not in general irreducible.

Let $X(k, a_p)$ denote the kernel of the surjection $I(\sigma_{k-2}) \rightarrow \overline{\Theta}_{k,a_p}$. In this section we will analyse $X(k, a_p)$, and as a consequence find, in certain cases, that $\overline{\Theta}_{k,a_p}$ does admit a surjection from $I(W)$ for some irreducible $\mathbb{F}_p$-representation $W$ of $K$, enabling us to apply Proposition 3.3.

Firstly, we establish some notation, following [Bre03b]. Recall that for $V$ a $\mathbb{Z}_p[K]$-module, the space $I(V)$ was defined previously to be a certain space of functions $G \rightarrow V$. We let $[g, v]$ denote the (unique) element of $I(V)$ which is supported on $KZg^{-1}$, and which satisfies $[g, v](g^{-1}) = v$. Note that $[gh, v] = [gh, v]$ for $g, h \in G$, that $[gk, v] = [g, kv]$ for $k \in K$, and that the $[g, v]$ span $I(V)$ as an abelian group, as $g$ and $v$ vary. For $\lambda \in \mathbb{Q}_p$ write $g^0_{1,\lambda} := \left( \begin{array}{c} p \\ \lambda \\ \end{array} \right)$, and set $\alpha := \left( \begin{array}{c} 0 \\ P \\ \end{array} \right)$. Now let $V = \text{Symm}^{k-2}(R^2)$ for some $\mathbb{Z}_p$-algebra $R$, thought of, as usual, as homogeneous polynomials in the variables $x$ and $y$ of degree $k-2$. An easy consequence of Lemma 2.2.1 of [Bre03b] is that
\( T([\text{Id}, v]) = T^+([\text{Id}, v]) + T^-([\text{Id}, v]) \) where 
\[
T^+([\text{Id}, v]) = \sum_{\lambda \in \mathbb{Z}_p : \lambda^p = \lambda} [g^0_{\lambda}, v(x, py - \lambda x)]
\]
and 
\[
T^-([\text{Id}, v]) = [\alpha, v(px, y)].
\]

For simplicity now, write \( r := k - 2 \in \mathbb{Z}_{\geq 0} \). Note that \( I \) is an exact functor, so if \( W \subseteq V \) are \( K \)-representations then \( I(W) \) is naturally a subset of \( I(V) \).

**Lemma 4.1.** If \( r \geq p \) then \( T.I(\sigma_r) = I(W_r) \) where \( W_r \) is the \( \mathbb{F}_p[K] \)-submodule of \( \sigma_r \) generated by \( y^r \).

**Remark 4.2.** If \( r \leq p - 1 \) then the image of \( T \) is harder to describe. It is a minor miracle that one has such a succinct description of the image of \( T \) when \( r \geq p \).

**Proof.** It is clear that \( T.I(\sigma_r) \) is generated as an \( \mathbb{F}_p[G] \)-module by elements of the form \( T([\text{Id}, v]) \), for \( v \in \sigma_r \). By our explicit formula for \( T([\text{Id}, v]) \) above (which simplifies because \( p = 0 \) in this situation), we see that \( T([\text{Id}, v]) \) may be written as a sum of terms \([h, v] \), all of which have the property that the \( v \) are in \( \mathbb{F}_p.x^r \) or \( \mathbb{F}_p.y^r \). Because \( (\frac{1}{k})y^r = x^r \), we see that \( T.I(\sigma_r) \) is certainly contained in \( I(W_r) \).

For the converse inclusion, define
\[
\vartheta := xy^p - yx^p = x \prod_{\lambda : \lambda^p = \lambda} (y - \lambda x) \in \mathbb{F}_p[x, y].
\]
Then if \( f := [\text{Id}, y^r - p\vartheta/x] \in I(\sigma_r) \) we have \( T^+f = 0 \), and so \( Tf = T^-f = [\alpha, y^r] \), which is easily checked to generate \( I(W_r) \) as an \( \mathbb{F}_p[G] \)-module. \( \square \)

Recall that \( X(k, a_p) \) is the kernel of the map \( I(\sigma_r) \to \overline{\sigma}_{k,a_p} \). Multiplication by \( \vartheta \) induces a map \( \sigma_r \to \sigma_{r+p+1} \), which is \( K \)-equivariant when thought of as a map \( \sigma_r(1) \to \sigma_{r+p+1} \).

**Lemma 4.3.** If \( \nu(a_p) < 1 \) and \( r \geq p + 1 \) then \( I(\vartheta \sigma_{r-(p+1)}) \subseteq X(k, a_p) \).

**Proof.** Set \( \theta := x^py - yx^p \in \mathbb{C}_p[x, y] \). For \( g \in \mathbb{C}_p[x, y] \) of degree \( r - (p + 1) \), set \( f = [\text{Id}, a_p^{-1}\theta g] \in \text{ind}_{KZ}^G(\text{Symm}^r(\mathbb{C}_p)) \). Clearly the image of \( Tf - a_pf \) in \( \Pi_{k,a_p} \) is zero. On the other hand, \( \theta(x, py - \lambda x) \) (for \( \lambda \in \mathbb{Z}_p \)) and \( \theta(px, y) \) are in \( p\mathbb{Z}_p[x, y] \), and so by the explicit formula for \( T \) above one deduces that \( Tf \in (p/a_p)\text{ind}_{KZ}^G(\text{Symm}^r(\mathbb{C}_p)) \). In particular \( Tf \) is zero in \( \overline{\sigma}_{k,a_p} \). Yet \( apf \) is \( [\text{Id}, \theta g] \), so \( Tf - a_pf \) is in \( \text{ind}_{KZ}^G(\text{Symm}^r(\overline{\mathbb{C}}_p)) \), and \( [\text{Id}, \vartheta \theta] \) is in \( X(k, a_p) \). \( \square \)

**Remark 4.4.** Although we will not use these results here (but they could be used if one were trying to formulate an analogue of Theorem 4.6 for larger \( v(a_p) \)), we note that similar tricks show that if \( v(a_p) < t \in \mathbb{Z}_{\geq 1} \) and \( r \geq t(p + 1) \) then \( I(\vartheta \sigma_{r-(p+1)}) \subseteq X(k, a_p) \) (set \( f = [\text{Id}, a_{p-1}^{-1}\theta^t g] \)) and that if \( v(a_p) > n \in \mathbb{Z}_{\geq 0} \), if \( 0 \leq i \leq n \) and \( r \geq i(p + 1) + p \) then \( I((x^iy^{r-i})_K) \subseteq X(k, a_p) \), where \( (x^iy^{r-i})_K \) denotes the sub-\( K \)-representation of \( \sigma_r \) generated by \( x^iy^{r-i} \) (set \( f = [\text{Id}, (\theta/p)^i\theta/x]y^{r-i(p+1)-p} \)).

5 Analysis of \( 0 < v < 1 \).

If \( k \geq p + 3 \) and \( 0 < v(a_p) < 1 \) then the roots of \( X^2 - a_pX + p^{k-1} \) cannot have ratio 1 or \( p^{\pm 1} \) so the results of the preceding sections give

**Corollary 5.1.** If \( 0 < v(a_p) < 1 \) and \( k \geq p + 3 \) then \( X(k, a_p) \) contains \( \text{ind}_{KZ}^G(\text{Y}) \) where \( \text{Y} \) is the sub-\( K \)-representation of \( \sigma_r \) generated by \( \sigma_{r-(p+1)} \) and \( y^r \). In particular the map \( \text{ind}_{KZ}^G(\sigma_r) \to \overline{\sigma}_{k,a_p} \) factors through the induction \( \text{ind}_{KZ}^G(\sigma_r/Y) \) of the irreducible representation \( \sigma_r/Y \). We have \( \sigma_r/Y \cong \sigma_s(r) \) where \( 0 \leq s \leq p - 2 \) and \( s \equiv p - 1 - r \mod p - 1 \).
Proof. The first part follows from Lemmas B.1 and B.3. The rest of the Corollary follows once one knows the isomorphism $\sigma_r/Y \cong \sigma_s(r)$, which follows from Lemma 3.2(a) and (c) of [AS86].

Corollary 5.2. Theorem 1.6 is true.

Proof. By the comments following the statement of the theorem, we need only deal with the case $p > 2$ and $k \geq 2p+2$. In fact we prove the result for $p > 2$ and $k \geq p + 3$. First fix $s$ such that $0 \leq s < p - 2$ and $s \equiv 2 - k \mod p - 1$. By Corollary 5.1 we see $\overline{\rho}_{k,ap}$ is a quotient of $I(\sigma_s(k-2))$. The result now follows from Proposition 3.3 and some elementary arithmetic.

Corollary 5.3. If $f$ is a modular form of weight $k \geq p + 3$, level prime to $p$, and $0 < v(a_p) < 1$, and if $0 \leq g \leq p - 2$ with $g \equiv k - 2 \mod p - 1$, then either $(\overline{\rho}_{f|D_p})^{ss} \cong \text{ind}(\omega_{g+1}^2)$, or $k \equiv 3 \mod p - 1$ and $(\overline{\rho}_{f|D_p})^{ss} \cong \omega \oplus \omega$.

Proof. This follows from the preceding corollary and Theorem 1.4.

Remark 5.4. For $k \leq p + 2$ slightly stronger results are known (for example if $k \leq p + 2$ and $p > 2$ then the results of [Bre99b] show that the reducible case can’t occur). On the other hand when $k = 2p + 1$ and $p > 2$, unpublished calculations of Breuil, and numerical examples due to one of us (KB) show that when $v(a_p) = 1/2$ both reducible and irreducible possibilities can occur.

Corollary 5.5. If $2 \leq p \leq 53$, then the slopes of level 1 modular forms of all weights are never in the range $(0, 1)$.

Proof. If $p = 2$ this follows from the results of [Hat79]. If $p$ is odd then the congruence $k = 3 \mod p - 1$ implies that $k$ is odd, and there are no level 1 forms of odd weight. The corollary would follow if we knew that for $f$ a modular form of level 1 and $p \leq 53$ then $\overline{\rho}_{f|D_p}$ is always reducible. But Corollary 3.6 of [AS86] reduces this statement to a finite check (we only need to check level 1 eigenforms of weight at most $p + 1 \leq 54$), and by Theorem 1.2 we see that what we must verify is that if $2 < p \leq 53$ then the $T_p$-eigenvalues on the space of cusp forms of level 1 and weight $k \leq p + 1$ are all $p$-adic units, which is easily checked nowadays on a computer.

Remark 5.6. If $p = 59$ and $f$ is the normalised level 1 weight 16 cusp form then $f$ is non-ordinary at $p$, the local mod $p$ representation is irreducible, and there do exist level 1 modular forms with slope equal to $1/2$ (for example, in weight 74).
