Introduction

It is shown in Quantum statistical mechanics [1] that the spectral function of one-particle states in general case can be represented in the form

\[ A(p, \omega) = \frac{\gamma(p, \omega)}{(\omega - \sigma(p, \omega))^2 + \frac{\omega^2}{4} \gamma(p, \omega)^2}, \]

where real functions \( \gamma \) and \( \sigma \) are related through Hilbert’s transform [2]. The spectral function plays central role in Quantum statistics. It was proved [1] that

\[ \frac{1}{2\pi} \int_{-\infty}^{\infty} A(p, \omega) \, d\omega = 1 \]

for any \( p \).

Recently, H. S. Köhler [3] has stated a Conjecture: The sufficient condition for the validity of the above equality is that the functions \( \gamma \) and \( \sigma \) be related through the Hilbert transform.

A proof of the Conjecture is not known to exist. In the present paper we concern only pure mathematical aspects of the question. We show that in general case the Conjecture is not valid: for a certain set of functions \( \gamma \) and \( \sigma \), the equality holds while for some others it fails.

1 Formulation of the problem

Let \( f(x) \) be a real function defined for \( x \in (-\infty, +\infty) \) and \( g(x) \) be its Hilbert transform:

\[ g(x) = \frac{1}{\pi} \text{PV} \int_{-\infty}^{+\infty} \frac{f(t) \, dt}{x - t}, \quad (1) \]
where the integral is understood as Cauchy principal value. Hilbert transform
exists at least for continuous functions tending rapidly to zero at infinity.

We define the spectral function, $S(x)$, by the formula

$$S(x) = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{f(t)}{(x-t+g(t))^2 + (f(t))^2} dt. \quad (2)$$

It will be shown that the Conjecture in general case is not valid, thus the
next problem arises: Describe the subset of functions $f(x)$ which satisfy the
equality

$$\int_{-\infty}^{+\infty} S(x) \, dx = 1. \quad (3)$$

## 2 Exact results

We offer three examples where the spectral integral $\int_{-\infty}^{+\infty} S(x) \, dx = 1$ can
be calculated explicitly. In first two cases the integral is exactly equal to 1
independently of the scale factor $\alpha$, while the third example reveals the case
when the integral is strictly less than 1.

**Example 1.** Let $f(x) = \alpha \sqrt{|x|}$ with a positive constant $\alpha$. It is easy to
show that

$$g(t) = -\alpha \sqrt{|t|} \text{sign}(t), \quad \text{sign}(t) = \begin{cases} -1, & t < 0 \\ 0, & t = 0 \\ 1, & t > 0 \end{cases}.$$

The spectral integral

$$\int_{-\infty}^{+\infty} S(x) \, dx = \frac{\alpha}{\pi} \int_{-\infty}^{+\infty} \frac{\sqrt{|x|}}{(|x| + \alpha \sqrt{|x|})^2 + \alpha^2 |x|} \, dx$$

by means of the substitution $\sqrt{x} = \alpha y$ is reduced to

$$\frac{4}{\pi} \int_{0}^{\infty} \frac{dt}{(y+1)^2 + 1},$$

which equals 1.

**Example 2.** Let $f(x) = \frac{\alpha}{x^2+1}$, $\alpha > 0$, then $g(t) = \frac{\alpha t}{t^2+1}$. The spectral
integral can be simplified to

$$\frac{1}{\pi} \int_{-\infty}^{+\infty} \frac{\alpha \, dx}{(x^2 - \alpha^2 + x^2}.$$
which can be evaluated in term of residues. The result is exactly 1 for any \( \alpha > 0 \).

**Example 3.** Let \( f(x) = \frac{\alpha x^2}{(x^2+1)^2}, \alpha > 0 \), then \( g(t) = \frac{\alpha t(t^2-1)}{2(t^2+1)^2} \). The spectral integral can be reduced to

\[
\frac{4}{\pi} \int_{-\infty}^{+\infty} \frac{\alpha \, dx}{(2x^2 + 2 - \alpha)^2 + 8\alpha}.
\]

Using residues, we get ultimately \( \frac{\alpha}{2+\alpha} \). We see that the integral is strictly less than 1 for any \( \alpha > 0 \).

### 3 Numerical experiments

We tested with the help of a computer the following functions \( f(x) \):

1. **Gaussian function** \( \alpha e^{-x^2/2} \);
2. **Valley function** \( \alpha(x^2 + b)/(x^2 + 1)^2 \);
3. **Rectangle function** \( \alpha \phi(x) \), where \( \phi(x) = \begin{cases} 1, & -1 \leq x \leq 1 \\ 0, & |x| > 1 \end{cases} \);
4. **Peak function** \( \alpha \psi(x) \), where \( \psi(x) = \begin{cases} 1 + x, & -1 \leq x < 0 \\ 1 - x, & 0 \leq x \leq 1 \\ 0, & |x| > 1 \end{cases} \).

Hilbert transform for each of the above functions can be easily found analytically. We computed the spectral integral using the mathematical packages Maple and Derive; the computation was done with the accuracy of 12–20 digits.

#### 3.1 Gaussian function

If \( f(x) = \alpha e^{-x^2/2}, \alpha > 0 \), then \( g(t) = \alpha \sqrt{\frac{\pi}{2}} e^{-x^2/2} \int_0^x e^{t^2/2} \, dt \).

Reliable results were obtained for values of \( \alpha \) from 0.0001 to 40; the spectral integral proved to be equal to 1 with high precision. For \( \alpha \) greater than 40, the results became unstable.

#### 3.2 Valley function

If \( f(x) = \frac{\alpha(x^2+b)}{(x^2+1)^2}, \alpha > 0, b > 0 \), then \( g(t) = \frac{\alpha t}{2(t^2+1)^2} \left( t^2(b + 1) + 3b - 1 \right) \).
We computed the spectral integral for $0.001 \leq b \leq 10$ and $0 < \alpha < 10000$; it appeared to be equal to 1 with high precision.

### 3.3 Rectangle function

If $f(x) = \begin{cases} \alpha, & -1 \leq x \leq 1 \\ 0, & |x| > 1 \end{cases}$, then $g(t) = \frac{\alpha}{\pi} \ln |\frac{1+t}{1-t}|$.

The computations show that the spectral integral $I(\alpha)$ is a monotonously decreasing function. In particular,

$I(0.00001) = 0.999999680, \ I(0.1) = 0.999476, \ I(0.5) = 0.955, \ I(0.65) = 0.8644, \ I(1) = 0.6225, \ I(5) = 0.1112, \ I(10) = 0.0540$.

### 3.4 Peak function

If $f(x) = \begin{cases} \alpha(1+x), & -1 \leq x < 0 \\ \alpha(1-x), & 0 \leq x \leq 1 \\ 0, & |x| > 1 \end{cases}$

then $g(t) = \frac{\alpha}{\pi} \left[ (1+x) \ln |1+x| - (1-x) \ln |1-x| - x \ln(x^2) \right]$.

The equality (3) is valid not for all $\alpha > 0$, in particular, for $0 < \alpha \leq 2.26$, it holds with high precision, but for $\alpha = 2.27$, the equality suddenly fails: $I(2.27) = 0.6945, \ I(3) = 0.2799$ and so on.

### 4 Conclusion

It seems that the set of functions which contain the scale factor $\alpha$ can be divided into two subsets: first one, where the formula (3) holds with any value of $\alpha$, and the other one, where the validity of (3) is conditioned by the value of $\alpha$.

It is interesting to notice that in most examples considered above the graph of the spectral function $S(x)$ has, for small values of $\alpha$, the form of a sharp peak centered around $x = 0$, see the Figure 1: it looks like the Dirac delta-function $\delta(x)$. The parameter $\alpha$ being larger, the peak becomes lower and wider. At some values of $\alpha$ it is transforming into two "hills" located symmetrically with respect to the origin. When $\alpha$ is increasing further, the two hills go farther from each other and become more and more sharp like two delta-functions.
Another interesting observation concerns the function \( f(x) \) represented as the sum of two nonnegative functions, \( f(x) = f_1(x) + f_2(x) \): if the spectral integral for each of the summed equals 1. This property looks somewhat strange since the spectral integral is an essentially nonlinear functional of \( f(x) \). Moreover, let a nonnegative function \( f(x) \) give to the spectral integral a value less than one, and \( f_2(x) = \frac{\alpha}{x^2+1} \) with arbitrary small positive \( \alpha \), then the sum \( f_1(x) + f_2(x) \) provides that the spectral integral is again 1.

The observations described in the present paper can probably stimulate the research of conditions sufficient for validity of the formula (3).
