Abstract

The notions of Galois and cleft extensions are generalized for coquasi-Hopf algebras. It is shown that such an extension over a coquasi-Hopf algebra is cleft if and only if it is Galois and has the normal basis property. A Schneider type theorem ([33]) is proven for coquasi-Hopf algebras with bijective antipode. As an application, we generalize Schauenburg’s bialgebroid construction for coquasi-Hopf algebras.

1 Introduction

The study of Hopf Galois extensions started last century with the papers of Chase, Harrison and Rosenberg ([15]) and of Chase and Sweedler ([16]). Later, their definition was improved by Kreimer and Takeuchi ([23]) and knew since a continuous development, mainly because their relation to different areas of mathematics. But in the last decade, examples of extensions which were not Galois but behaved like such had appeared. An explanation was necessary, and it became soon clear that this was possible only by generalization. The replacement of the Hopf algebra by a coalgebra (or more generally by a coring) has led to the notion of a Galois extension by a coalgebra, first formulated by Brzézinski and Hajac ([9]). Another generalization was obtained considering Galois extensions over a coacting bialgebroid (over a non-commutative ground ring) ([21], [8]).

All structures cited above are generalizations of bialgebras or Hopf algebras. Another such objects are the (co)quasi-Hopf algebras. They have been introduced by Drinfeld ([19]), respectively by Majid ([24]) and have lately attracted much attention in both mathematics and physics ([3], [25]). So it is natural to see if it is possible to generalize the Galois theory also to the case of coquasi-Hopf algebras.

The definition of a coquasi-Hopf algebra $H$ ensures that the category of right $H$-comodules $\mathcal{M}^H$ is monoidal, with usual tensor product over the base field. The difference between a coquasi-Hopf algebra and a Hopf algebra is that the associativity of tensor product in the monoidal category does not coincide with the usual associativity of tensor product in the category of vector spaces. Consequently, the multiplication of a coquasi-Hopf algebra is no longer associative, but associative up to conjugation by an invertible element $\omega \in (H \otimes H \otimes H)^*$ (the reassociator). But is this main feature of coquasi-Hopf algebras, namely the monoidality of corepresentations, which made possible generalizations of major properties from Hopf algebras (the existence and uniqueness of integrals, the Nichols-Zoeller Theorem, construction of the Drinfeld double, etc.). Hence it seems natural to continue with the Galois theory for coquasi-Hopf algebras.

† Key words and phrases: coquasi-Hopf algebra, monoidal category, Galois extension
The present paper begins with a short review of the known results about coquasi-Hopf algebras, their categories of comodules and about algebras and modules within these monoidal categories mentioned above. As for Hopf algebras, to each right comodule algebra $A$ (which is an algebra in the monoidal category of right comodules) one can assign a pair of adjoint functors, namely the functor of coinvariants and the induced functor. Our purpose is to generalize their well-known properties from Hopf algebras to coquasi-Hopf algebras.

In the second part it is defined the notion of Galois extension. A right comodule algebra $A$ is a Galois extension over its coinvariants ring $A^{cH}$ (which is associative, although $A$ fails to be) if a certain map is bijective. This is a natural generalization of the author’s previous paper ([6]), where only finite dimensional quasi-Hopf algebras were considered. It should be noticed that this definition for Galois extensions works only for coquasi-Hopf algebras, as it involves the presence of the antipode. Although this may look restrictive, we shall see that this definition for the Galois map allows us to recover all principal results from the classical Hopf-Galois theory. A Galois extension is invariant to any gauge transformation. As an example of Galois extension, we take a group algebra, and view it as a coquasi-Hopf algebra by a 3-cocycle. Then a comodule algebra is a graded space with a multiplication non-necessarily associative, which is Galois over its invariants if and only if it is strongly graded. This was known from long time for Hopf algebras ([35]). Moreover, any crossed product ([5]) coming from an associative algebra endowed with a 2-cocycle and a weak action is also a Galois extension.

Recall that in the Hopf algebra case, the functor of coinvariants is a $Hom$ functor, and the Galois map is just the evaluation for a certain relative Hopf module. We show that these results, slightly modified by the presence of a twist, hold also in the coquasi-case. We give thus an explanation for the formula of the Galois map from Definition 8. Although the results are the same, it is much more difficult to obtain them. The structure of the relative Hopf module $A \otimes H$ (which is the link between the Galois map can and the adjunction of categories $\mathcal{M}_B \overset{\sim}{\cong} \mathcal{M}^{cH}_A$) is not obvious. The classical formulas do not work anymore, and an isomorphism is required in order to get the desired structure by transport.

We introduce next the notion of a cleft extension. As this involves the convolution product (which is no longer associative), the invertibility of the cleaving map has to be translated now in relations involving the antipode and the linear maps $\alpha, \beta$.

As a generalization of theorems of Doi and Takeuchi ([17]), and Blattner and Montgomery ([7]), we obtain the first main result of this paper, namely the equivalence between cleft extensions, and Galois extensions with the normal basis property.

The second main part of this section concerns the equivalence between the category of relative Hopf modules and modules over the subalgebra of coinvariants. It starts with an analogue of the Schneider’s imprimitivity theorem of [33]. A key problem in the proof is how to show that the bijectivity of the Galois map implies the bijectivity of the corresponding map for any relative right $(A, H)$-Hopf module. As $A$ is not an associative algebra, this is not obvious and requires some special considerations about the tensor product over the algebra $A$ in the monoidal category of right comodules (Lemma 29). The proof of the theorem uses the Five Lemma applied twice to some commutative diagrams, but unlike the Hopf algebra case, the commutativity of those is not an easy fact and requires special attention care when dealing with the reassociator $\omega$ and of the elements $\alpha$ and $\beta$ (from the definition of the antipode).

Next, we prove a coquasi-version of the affineness criteria for affine algebraic groups schemes, where the surjectivity of the Galois map of the extension is related to relative injectivity of the $H$-comodule $A$ and to the equivalence between the category of relative Hopf modules and modules over the subalgebra of coinvariants.

In the last section, we generalize Schauenburg’s bialgebroid construction. This is an illustration of how the Galois theory, combined with monoidally arguments can raise to new structures.
2 Preliminaries

In this section we recall some definitions and results and fix notations. Throughout the paper we work over some base field \( k \). Tensor products, algebras, linear spaces, etc. will be over \( k \). Unadorned \( \otimes \) means \( \otimes_k \). We shall use dots to indicate the module or comodule structure on the tensor product. An introduction to the study of quasi-bialgebras and quasi-Hopf algebras and their duals (coquasi-bialgebras, respectively coquasi-Hopf algebras) can be found in \([25]\). A good reference for monoidal categories is \([22]\), while actions of monoidal categories are exposed in \([28], [29]\).

**Definition 1.** A coquasi-bialgebra \((H, m, u, \omega, \Delta, \varepsilon)\) is a coassociative coalgebra \((H, \Delta, \varepsilon)\) together with coalgebra morphisms: the multiplication \( m : H \otimes H \rightarrow H \) (denoted \( m(h \otimes g) = hg \)), the unit \( u : k \rightarrow H \) (denoted \( u(1) = 1_H \)), and a convolution invertible element \( \omega \in (H \otimes H \otimes H)^{\ast} \) such that:

\[
\begin{align*}
h_1(g_1k_1)\omega(h_2,g_2,k_2) &= \omega(h_1,g_1,k_1)(h_2g_2)k_2 \\
1_H h &= h1_H = h \\
\omega(h_1,g_1,k_1)\omega(h_2g_2,k_2,l_2) &= \omega(g_1,k_1,l_1)\omega(h_1,g_2k_2,l_2)\omega(h_2,g_3,k_3) \\
\omega(h,1_H,g) &= \varepsilon(h)\varepsilon(g)
\end{align*}
\]

hold for all \( h, g, k, l \in H \).

As a consequence, we have also \( \omega(1_H, h, g) = \omega(h, g, 1_H) = \varepsilon(h)\varepsilon(g) \) for each \( g, h \in H \).

**Definition 2.** A coquasi-Hopf algebra is a coquasi-bialgebra \( H \) endowed with a coalgebra antihomomorphism \( S : H \rightarrow H \) (the antipode) and with elements \( \alpha, \beta \in H^\ast \) satisfying

\[
\begin{align*}
S(h_1)\alpha(h_2)h_3 &= \alpha(h)1_H \\
h_1\beta(h_2)S(h_3) &= \beta(h)1_H \\
\omega(h_1\beta(h_2),S(h_3),\alpha(h_4)h_5) &= \omega^{-1}(S(h_1),\alpha(h_2)h_3\beta(h_4),S(h_5)) = \varepsilon(h)
\end{align*}
\]

for all \( h \in H \).

These relations imply also \( S(1_H) = 1_H \) and \( \alpha(1_H)\beta(1_H) = 1 \), so by rescaling \( \alpha \) and \( \beta \), we may assume that \( \alpha(1_H) = 1 \) and \( \beta(1_H) = 1 \). The antipode is unique up to a convolution invertible element \( U \in H^\ast \): if \((S', \alpha', \beta')\) is another triple with the above properties, then according to \([25]\) we have

\[
S'(h) = U(h_1)S(h_2)U^{-1}(h_3), \quad \alpha'(h) = U(h_1)\alpha(h_2), \quad \beta'(h) = \beta(h_1)U^{-1}(h_2)
\]

for all \( h \in H \).

We shall use in this paper the monoidal structure of the right \( H \)-comodule category \( \mathcal{M}^H \) and of the left \( H \)-comodule category \( \mathcal{M}^H \): the tensor product is over the base field and the comodule structure (left or right) of the tensor product is the codiagonal one. The reassociators are

\[
\phi_{U,V,W} : (U \otimes V) \otimes W \rightarrow U \otimes (V \otimes W)
\]

\[
\phi_{U,V,W}((u \otimes v) \otimes w) = u_0 \otimes (v_0 \otimes w_0)\omega(u_1, v_1, w_1)
\]

for \( u \in U, v \in V, w \in W \) and \( U, V, W \in \mathcal{M}^H \), respectively

\[
\phi_{U,V,W} : (U \otimes V) \otimes W \rightarrow U \otimes (V \otimes W)
\]

\[
\phi_{U,V,W}((u \otimes v) \otimes w) = \omega^{-1}(u_{-1}, v_{-1}, w_{-1})u_0 \otimes (v_0 \otimes w_0)
\]

for \( u \in U, v \in V, w \in W \) and \( U, V, W \in \mathcal{M}^H \).
Together with a coquasi-Hopf algebra with bijective antipode \( H = (H, \Delta, \varepsilon, m, 1_H, \omega, S, \alpha, \beta) \), we also have \( H^{op}, H^{cop} \), and \( H^{op,cop} \) as coquasi-Hopf algebras, where "op" means opposite multiplication and "cop" means opposite comultiplication. The coquasi-Hopf structures are obtained by putting \( \omega_{cop} = \omega^{-1}, \omega_{op} = (\omega^{-1})^{321}, \omega_{op,cop} = \omega^{321}, S_{op} = S_{cop} = (S_{op,cop})^{-1} = S^{-1}, \alpha_{cop} = \beta S^{-1}, \alpha_{op} = \alpha S^{-1}, \alpha_{op,cop} = \beta, \beta_{cop} = \alpha S^{-1}, \beta_{op} = \beta S^{-1} \) and \( \beta_{op,cop} = \alpha \). Here \( \omega^{321}(h, g, k) = \omega(k, g, h) \).

For \( H \) a coquasi-bialgebra, the linear dual \( H^* = Hom(H, k) \) becomes an associative algebra with multiplication given by the convolution product

\[
(h^* g^*)(h) = h^*(h_1)g^*(h_2) \quad \forall h \in H \quad \text{s.t.} \quad h^*, g^* \in H^*
\]

and unit \( \varepsilon \). This algebra is acting on \( H \) by the formulas:

\[
h^* \cdot h = h_1 h^*(h_2), \quad h \cdot h^* = h^*(h_1) h_2
\]

for any \( h^* \in H^*, h \in H \).

Now, recall from [27] the following: for \( \tau \in (H \otimes H)^* \) a convolution invertible map such that \( \tau(1, h) = \tau(h, 1) = \varepsilon(h) \) for all \( h \in H \) (\( \tau \) is called a twist or a gauge transformation), one can define a new structure of coquasi-Hopf algebra on \( H \), denoted \( H_\tau \), by taking

\[
\begin{align*}
h \cdot \tau g &= \tau(h_1, g_1) h_2 g_2 \tau^{-1}(h_3, g_3) \\
\omega_\tau(h, g, k) &= \tau(g_1, k_1) \tau(h_1, g_2 k_2) \omega(h_2, g_3, k_3) \tau^{-1}(h_3 g_4, k_4) \tau^{-1}(h_4, g_5) \\
\alpha_\tau(h) &= \tau^{-1}(S(h_1), \alpha(h_2) h_3) \\
\beta_\tau(h) &= \tau(h h_3 \beta(h_2), S(h_3))
\end{align*}
\]

for all \( h, g, k \in H \), and keeping the unit, the comultiplication, the counit and the antipode unchanged.

**Remark 3.** There is a monoidal isomorphism \( \mathcal{M}^H \cong \mathcal{M}^{H_\tau} \), which is the identity on objects and on morphisms, with monoidal structure given by \( V \otimes W \rightarrow V \otimes W, v \otimes w \rightarrow v_0 \otimes w_0 \tau^{-1}(v_1, w_1) \), where \( v \in V, w \in W, V, W \in \mathcal{M}^H \).

In [11], it was constructed a twist \( \tau \in (H \otimes H)^* \) which controls how far is \( S \) from a anti-algebra morphism:

\[
f(h_1, g_1) S(h_2 g_2) = S(g_1) S(h_1) f(h_2, g_2)
\]

If we denote

\[
\begin{align*}
p(h, g) &= \omega(S(g_2), S(h_2), h_4) \omega^{-1}(S(g_1) S(h_1), h_5, g_4) \alpha(h_3) \alpha(g_3) \\
q(h, g) &= \omega(h_1 g_1, S(g_5), S(h_4)) \omega^{-1}(h_2, g_2, S(g_4)) \beta(h_3) \beta(g_3)
\end{align*}
\]

then the twist \( f \) is given by

\[
f(h, g) = \omega^{-1}(S(g_1) S(h_1), h_3 g_3, S(h_5 g_5)) p(h_2, g_2) \beta(h_4 g_4)
\]

We have also that

\[
\begin{align*}
f(h_1, g_1) \alpha(h_2 g_2) &= p(h, g) \\
\beta(h_1, g_1) f^{(-1)}(h_2, g_2) &= q(h, g) \\
p(h_1, S(h_3)) \beta(h_2) &= \alpha S(h_2) \\
f(h_1, S(h_3)) \beta(h_2) &= \alpha S(h) \\
f^{(-1)}(S^{-1}(g_1), S^{-1}(h_1)) \omega^{-1}(g_4, \alpha S^{-1}(g_3) S^{-1}(g_2), S^{-1}(h_2)) &= f(g_5, S^{-1}(h_1 g_1)) \\
\omega^{-1}(h_2, g_2 \beta(g_3), S(g_4))
\end{align*}
\]
where in the last formula we assumed the bijectivity of the antipode. Relations (2.18) and (2.19) are from [14], (2.20) is an easy consequence of the formula of \( p \), (2.21) follows immediately from (2.20), while for (2.22) we use (2.12) and the fact that the associator \( \omega \) in the category \((a,b,c)\) is an easy consequence of the formula of \( p \), where in the last formula we assumed the bijectivity of the antipode. Relations (2.18) and (2.19) are from [13].

**Definition 4.** ([13]) A right \( H \)-comodule algebra \( A \) is an algebra in the monoidal category \( M^H \). This means \((A,\rho_A)\) is a right \( H \)-comodule, we have a multiplication map \( m_A : A \otimes A \to A \), denoted \( m_A(a \otimes b) = ab \), for \( a,b \in A \), and a unit map \( u_A : \mathbb{k} \to A \), where we put \( u_A(1) = 1_A \), which are both \( H \)-colinear, such that

\[
(ab)c = a_0(b_0c_0)\omega(a_1,b_1,c_1)
\]

holds for any \( a,b,c \in A \).

Similarly we may define a left \( H \)-comodule algebra as an algebra in \( \mathcal{M}^H \). Notice that \( A \) is a right \( H \)-comodule algebra if and only if \( A^{op} \) is a left \( H^{op,\text{cop}} \)-comodule algebra.

**Definition 5.** ([13]) For \( A \) a right \( H \)-comodule algebra, we may define the notion of right module over \( A \) in the category \( \mathcal{M}^H \). Explicitly, this is a right \( H \)-comodule \((M,\rho_M)\), endowed with a right \( A \)-action, denoted \( \mu_M(m,a) = ma \), such that

\[
(ma)b = m_0(a_0b_0)\omega(m_1,a_1,b_1) \quad m_1A = m \\
\rho_M(ma) = m_0a_0 \otimes m_1a_1
\]

hold for all \( m \in M \), \( a,b \in A \). The category of such objects, with morphisms the right \( H \)-colinear maps which respect the \( A \)-action, is called the **category of relative right \((H,A)\)-Hopf modules** and denoted \( \mathcal{M}^H_A \).

In the same way, we may define the category of left relative Hopf modules \( \mathcal{A}^H_A^\mathcal{M} \) for \( A \) a right \( H \)-comodule algebra. If \( A \) is a left \( H \)-comodule algebra we can define similarly the categories \( \mathcal{H}^H_A^\mathcal{M} \) and \( \mathcal{H}^A_M \). For later use, remark that the following categories are isomorphic:

\[
\mathcal{H}^A_M \simeq \mathcal{M}^{H_{A^{op}}} \quad (2.26)
\]

for any \( A \) a left \( H \)-comodule algebra ([13]).

**Remark 6.** It was proven in [13] that if \( \tau \) is a twist on \( H \), then the formula

\[
a \cdot \tau b = a_0b_0\tau^{-1}(a_1,b_1) \quad (2.27)
\]

for all \( a,b \in A \) defines a new multiplication such that \( A \), with this new multiplication (denoted \( A_{\tau^{-1}} \)) becomes a right \( H_{\tau} \)-comodule algebra. It is easy to see that the isomorphism of Remark 5 sends the algebra \( A \) of the monoidal category \( \mathcal{M}^H \) exactly to the algebra \( A_{\tau^{-1}} \) in \( \mathcal{M}^{H_{\tau}} \). But \( \mathcal{M}^{H_{\tau}} \) and \( \mathcal{M}^{H_{\tau^{-1}}} \) are monoidally isomorphic, therefore the categories of right relative Hopf modules \( \mathcal{H}^H_A \) and \( \mathcal{H}^{H_{\tau^{-1}}} \) will also be isomorphic.
Let $A$ be a right $H$-comodule algebra. Consider the space of coinvariants

$$B = A^{coH} = \{ a \in A | \rho_A(a) = a \otimes 1_H \}$$

It is immediate that this is an associative algebra with unit and multiplication induced by the unit and the multiplication of $A$.

Now for each $M \in \mathcal{M}_A^H$, denote $M^{coH} = \{ m \in M | \rho_M(m) = m \otimes 1_H \}$. Then $M^{coH}$ becomes naturally a right $B$-module, so we get the coinvariant functor

$$\mathcal{M}_A^H(-)^{coH} \rightarrow \mathcal{M}_B$$

Notice also the natural isomorphism

$$\text{Hom}_A^H(A, M) \simeq M^{coH}$$

for any $M \in \mathcal{M}_A^H$. Conversely, for $N \in \mathcal{M}_B$, we have $N \otimes_B A \in \mathcal{M}_A^H$ by

$$\rho(n \otimes_B a) = n \otimes_B a_0 \otimes a_1$$

$$(n \otimes_B a)b = n \otimes_B ab$$

As in the classical Hopf algebra case, we obtain the following:

**Proposition 7.** The induced functor $(-) \otimes_B A$ is a left adjoint for the functor of coinvariants $(-)^{coH}$:

$$\mathcal{M}_B (-) \otimes_B A \leftrightarrow (-)^{coH} \mathcal{M}_A$$

**Proof.** Straightforward. For later use, we mention the adjunction morphisms:

$$\varepsilon_M : M^{coH} \otimes_B A \rightarrow M, \quad \varepsilon_M(m \otimes_B a) = ma$$

$$u_N : N \rightarrow (N \otimes_B A)^{coH}, \quad u_N(n) = n \otimes_B 1_A$$

for each $N \in \mathcal{M}_B$ and $M \in \mathcal{M}_A^H$. Using the isomorphism form relation (2.28), we get that the counit of the adjunction is simply the evaluation.

Similarly we could define the left version of the adjunction between the induced and the coinvariant functor, namely $\mathcal{M}_B A \otimes_B (-) \leftrightarrow A \mathcal{M}_A$, using isomorphism form relation (2.28) we get that the counit of the adjunction is simply the evaluation.

In the next section we shall see necessary and sufficient conditions for these adjunctions to be equivalences.

### 3 Galois extensions

Let $H$ be a coquasi-Hopf algebra with antipode $S$ and $A$ a right $H$-comodule algebra. Denote as before $B = A^{coH}$.

**Definition 8.** The extension $B \subseteq A$ is $(H,S)$-**Galois** if the map $\mathrm{can}_S : A \otimes_B A \rightarrow A \otimes H$, given by

$$a \otimes_B b \mapsto a_0 b_0 \otimes b_4 \omega^{-1}(a_1, b_1 \beta(b_2), S(b_3))$$

is bijective.
Remark 9. (1) Although $A$ is not an associative algebra, we still keep the expression "extension $B \subseteq A$".

(2) Recall that for coquasi-Hopf algebras the antipode is unique up to conjugation to an invertible element. Therefore we need to check what is happening if we change $S$. Consider another triple $(S', \alpha', \beta')$ given by a convolution invertible element $U \in H^*$, as in (2.8). Then we have

$$
can_{S'}(a \otimes_B b) = a_0 b_0 \otimes \omega^{-1}(a_1, b_1 \beta'(b_2), S'(b_3))b_4
$$

$$
= a_0 b_0 \otimes \omega^{-1}(a_1, b_1 \beta(b_2)U^{-1}(b_3), U(b_4)S(b_5)U^{-1}(b_6))b_7
$$

$$
= a_0 b_0 \otimes \omega^{-1}(a_1, b_1 \beta(b_2), S(b_3))U^{-1}(b_4)b_5
$$

for every $a, b \in A$. If we define the linear map $\psi_U : A \otimes H \rightarrow A \otimes H$, $a \otimes h \rightarrow a \otimes U(h_1)h_2$, it is easy to see that this is bijective with inverse $a \otimes h \rightarrow a \otimes U^{-1}(h_1)h_2$ and that $can_{S'} = \psi_U \circ can_S$; therefore the two Galois maps will be simultaneously bijective. In the sequel, we shall fix the antipode $S$ and the elements $\alpha$, $\beta$, such that $\alpha(1) = \beta(1) = 1$, and write simply $can$.

In case of a Hopf algebra, the coassociator $\omega$ and the linear map $\beta$ vanish, and we recover the usual definition of the Galois map. But unlike the Hopf case, notice this time the presence of the antipode in the formula of $can$, which implies that this definition is possible only for coquasi-Hopf algebras, not also for coquasi-bialgebras. However, we shall see that this definition for the Galois map allows us to recover all principal results from the classical Hopf-Galois theory. In [26], Masuoka uses the classical definition of the $can$ map, $a \otimes_B b \rightarrow a b_0 \otimes b_1$, to show that a certain extension is Galois over a given coquasi-Hopf algebra (which is a bicrossed product associated to some cocycle data). It is only a matter of computation to see that in the quoted case, the formula (5.1) reduces to $a \otimes_B b \rightarrow a b_0 \otimes b_1$. Therefore [26] provides us a first example of a non-trivial Galois extension over a coquasi-Hopf algebra.

Example 10. (2) Let $G$ be any group and $\omega : G \times G \rightarrow k$ an invertible normalized cocycle. The the usual group algebra $H = kG$ becomes a coquasi-Hopf algebra by keeping the ordinary operations, but with coassociator $\omega$ (linearly extended to $kG^\otimes 3$) and linear maps $\alpha = \varepsilon$ and $\beta$ given by $\beta(g) = \omega^{-1}(g, g^{-1}, g)$, for any $g \in G$. As the coalgebra structure is not modified, a $kG$-coaction means precisely a $G$-gradation. Therefore, the notion of an $H$-comodule algebra becomes in this case: a $G$-graded vector space $A = \oplus_{g \in G} A_g$, endowed with a unit and a multiplication $\cdot : A \otimes A \rightarrow A$ such that $A_g A_h \subseteq A_{gh}$ for all $g, h \in G$, and associative in the sense that

$$(a \cdot b) \cdot c = a \cdot (b \cdot c)\omega(|a|, |b|, |c|)$$

for all homogeneous elements $a, b, c \in A$. The coinvariants $A^{coH}$ are exactly $A_e$, where $e$ is the neutral element of $G$. We have then the following:

Proposition 11. The extension $A_e \subseteq A$ is Galois (in the sense of Definition 8) if and only if it is strongly graded.

Proof. Notice first that $A$ is strongly graded $\iff A_g A_{g^{-1}} = A_e$ for any $g \in G$. One inclusion is obvious, and for the other we shall use the associativity rule of $A$:

$$A_{gh} \subseteq A_{gh} A_e \subseteq A_{gh} A_{h^{-1}} A_h = (A_{gh} A_{h^{-1}}) A_h \omega^{-1}(gh, h^{-1}, h)$$

$$\subseteq A_g A_h \omega^{-1}(gh, h^{-1}, h) \subseteq A_g A_h$$

Now the proof follows as in the Hopf case.

This result generalizes the Ulbrich’s well-known example in the Hopf algebra case ([35]), and it is the first confirmation of the fact that our definition of a Galois extension is the correct one.
Example 12. Another example of Galois extension can be found in [4]. Starting from a coquasi-Hopf algebra $H$ and an associative algebra $R$ endowed with an $H$-weak action and a 2-cocycle $\sigma : H \otimes H \to R$, we can construct the crossed product $R \#_\sigma H$, generalizing the Hopf case. This is a Galois extension of $R$ in the sense of Definition [5]. Also, the Galois extension mentioned above from [26] is precisely a particular case of our crossed product construction.

Now, remember that a Hopf algebra $H$ can be seen as a right $H$-comodule algebra via $\Delta$ and usual multiplication. The coinvariants are $k1_H \simeq k$. Moreover, this extension is $H$-Galois (by [20]) (actually, any bialgebra $H$ is a comodule algebra in this way, and it is a Hopf algebra if and only if it is Galois). Now, working with a coquasi-Hopf algebra $H$ still gives us a right comodule, but no longer an algebra in the monoidal category $M^H$ with the usual multiplication. If we try to deform the multiplication on $H$ via a twist $\tau$ as in (2.27), then $(H, \bullet, \Delta)$ is a right $H$-comodule algebra if and only if $\omega_\tau$ is trivial, i.e. $H_\tau$ is a Hopf algebra. It is unclear to the author for the moment which multiplication structure should be defined on $H$ such that we get a right $H$-comodule algebra, which in the Hopf case should reduce to ordinary multiplication. Moreover, this multiplication structure should provide an example of Galois extension $k \subseteq H$.

Remark 13. Let $H$ a coquasi-Hopf algebra with bijective antipode and $A$ a right $H$-comodule algebra. Notice that $M^H \simeq H^{op}M$ as monoidal categories. Using also the isomorphism from (2.20), it follows that $A M^H \simeq M^{A^{\text{op}}}$ for $A$ a right $H$-comodule algebra. For completeness, we remark that the corresponding Galois map for $H^{op}$-extension $B^{op} \subseteq A^{op}$ will be

$$\text{can}'(a \otimes_B b) = a_0 b_0 \otimes a_4 \omega(S^{-1}(a_3) \beta S^{-1}(a_2), a_1, b_1)$$

Then we get:

Lemma 14. The map $\text{can}'$ is bijective if and only if $\text{can}'$ is bijective.

Proof. Consider the map $\Xi : A \otimes H \to A \otimes H$, $\Xi(a \otimes h) = a_0 \otimes a_3 S(h_1) \omega^{-1}(h_3, a_2 \beta(a_3), S(a_4)) f(h_2, S^{-1}(a_1))$. Then $\Xi \circ \text{can} = \text{can}'$. Also one may check that $\Xi$ is bijective, with inverse given by

$$\Xi^{-1}(a \otimes h) = a_0 \otimes S^{-1}(h_1) a_5 f^{-1}(S^{-1}(h_2), a_4) \omega(a_1 \beta(a_2), S(a_3), h_3)$$

Notice that in the case of a Hopf algebra the map $\text{can}'$ reduces to the usual formula $a \otimes_B b = a_0 b \otimes_B a_1$.

Remark 15. If $A$ is a right $H$-comodule algebra and $\tau$ a twist for $H$, we may consider the twisted comodule algebra $A_{\tau^{-1}}$ as in Remark 6. The comodule structure being the same, $A$ and $A_{\tau^{-1}}$ will have same coinvariants $B$ (but over different coquasi-Hopf algebras). Then we have the following:

Proposition 16. The extension $B \subseteq A$ is $H$-Galois if and only if $B \subseteq A_{\tau^{-1}}$ is $H_{\tau}$-Galois.

Proof. The canonical Galois map for the extension $B \subseteq A_{\tau^{-1}}$ is

$$\text{can}_{\tau}(a \otimes_B b) = a_0 \otimes \omega^{-1}(a_1, b_1 \beta(a_2), S(b_3)) b_4$$

for any $a, b \in A$. Consider now the linear map

$$\vartheta : A \otimes H \to A \otimes H, \vartheta(a \otimes h) = a_0 \otimes h_2 \tau(a_1, S(h_1))$$

It is easy to check that $\vartheta$ is bijective, with inverse $\vartheta^{-1}(a \otimes h) = a_0 \otimes h_2 \tau^{-1}(a_1, S(h_1))$. Then the following relation hold: $\text{can}_{\tau} = \vartheta \circ \text{can}'$, which tells us that both extensions will be simultaneously Galois.
It follows from the previous Remark that if $H$ is a Hopf algebra and $B \subseteq A$ is a $H$-Galois extension in the classical sense, then for any nontrivial twist $\tau \in (H \otimes H)^*$, the extension $B \subseteq A_{\tau^{-1}}$ will be $H_{\tau}$-Galois in the sense of our Definition. Hence all known examples of Hopf-Galois extensions fit in our picture.

**Example 17.** Again, let $G$ a group and $\tau : G \times G \rightarrow k$ an invertible normalized map. Then $H = kG$ is a Hopf algebra and $A = kG$ is an $H$-module algebra via comultiplication. Using the twist obtained by extending $\tau$, it follows that $H_\tau$ is a coquasi-Hopf algebra and $A_{\tau^{-1}}$ is an $H_{\tau}$-comodule algebra. According to Remark 15, $A_{\tau^{-1}}$ will be a Galois extension of $k$. In particular, taking $G = (\mathbb{Z}_2)^n$, it follows that all Cayley algebras (as in [1]) are Galois extensions over a coquasi-Hopf algebra.

**Remark 18.** In the Hopf algebra case, the Galois map arises naturally as the evaluation map $Hom^H_B(A, A \otimes H) \otimes_B A \rightarrow A \otimes H$, from the adjunction between the induced and the coinvariant functor, applied to the relative Hopf module $A_\bullet \otimes H_\bullet^*$. We shall see that a similar result holds here, explaining thus the formula chosen for $\tau$. We need first some work. For the beginning, it is not obvious which $(H, A)$-Hopf module structure can be defined on $A \otimes H$ to generalize the one in the Hopf case. We shall assume that the antipode of $H$ is bijective, and obtaining the following:

**Lemma 19.** The map
\[
\eta : H^* \otimes A^* \rightarrow A \otimes H^*;
\]
\[
h \otimes a \rightarrow a_0 \otimes \omega(h_1, a_3, \alpha S^{-1}(a_2)S^{-1}(a_1))h_2a_4
\]
is a right $H$-comodule isomorphism, where $H \otimes A$ is a comodule via the codiagonal structure (i.e. $\rho_{H \otimes A}(h \otimes a) = h_1 \otimes a_0 \otimes h_2a_4$) and $A \otimes H$ has the induced comodule structure from the one of $H$.

**Proof.** The inverse for $\eta$ is given by $\eta^{-1}(a \otimes h) = h_1S^{-1}(a_4) \otimes a_0 \omega^{-1}(h_2, S^{-1}(a_3)\beta S^{-1}(a_2), a_1)$. 

**Corollary 20.** Via the previous isomorphism, $A \otimes H$ becomes a right $A$-module in $\mathcal{M}^H$.

**Proof.** As $H$ is a right $H$-comodule via $\Delta$, $(H^* \otimes A^*)^*$ is naturally the right $A$-module induced in $\mathcal{M}^H$, with structures
\[
\rho_{H \otimes A}(h \otimes a) = h_1a_0 \otimes h_2a_4
\]
\[
(h \otimes a)b = h_1a_0b_0\omega(h_2, a_1, b_1)
\]
for all $h \in H, a, b \in A$. Using $\eta$, the $A$-module structure can be transferred on $A \otimes H$. Let’s see how the multiplication formula with elements of $A$ looks like:
\[
(a \otimes h) \otimes b \rightarrow [h_1S^{-1}(a_4) \otimes a_0 \omega^{-1}(h_2, S^{-1}(a_3)\beta S^{-1}(a_2), a_1)]b
\]
\[
= h_1S^{-1}(a_6) \otimes a_0b_0\omega(h_2S^{-1}(a_5), a_1, a_2)\omega^{-1}(h_3, S^{-1}(a_4)\beta S^{-1}(a_3), a_2)
\]
\[
(2.3), (2.6)
\]
\[
= h_1S^{-1}(a_6) \otimes a_0b_0\omega^{-1}(h_2S^{-1}(a_5), a_1, a_2)\omega(S^{-1}(a_4), a_2, b_2)\beta S^{-1}(a_3)
\]
\[
= a_0b_0 \otimes [h_2S^{-1}(a_{10})](a_4b_4)
\]
\[
\omega(h_1S^{-1}(a_{11}), a_3b_3, \alpha S^{-1}(a_{20})S^{-1}(a_1b_1))
\]
\[
\omega^{-1}(h_3, S^{-1}(a_9), a_5b_5)\omega(S^{-1}(a_8), a_6, b_6)\beta S^{-1}(a_7)
\]
\[
(2.1), (2.1), (2.6)
\]
\[
= a_0b_0 \otimes h_3b_0\omega(S^{-1}(a_7), a_5, b_5)\omega^{-1}(h_2, S^{-1}(a_8), a_4b_4)
\]
\[
\omega(h_1S^{-1}(a_9), a_3b_3, S^{-1}(a_1b_1))\alpha S^{-1}(a_{20})S^{-1}(a_6)
\]
\[
(2.1), (2.5)
\]
\[
= a_0b_0 \otimes h_3b_0\omega(S^{-1}(a_{10}), a_4b_4, S^{-1}(a_{20}))\omega(h_1, S^{-1}(a_9), a_5b_5),
\]
\[
S^{-1}(a_1b_1))\omega(S^{-1}(a_8), a_6, b_6)\alpha S^{-1}(a_3b_3)\beta S^{-1}(a_7)
\]
\[
(2.3), (2.6)
\]
\[
= a_0b_0 \otimes h_3b_7\omega(S^{-1}(a_8), a_4b_4, S^{-1}(a_{20}))\omega(S^{-1}(a_7), a_5, b_5)
\]
\[ \omega(h_1, b_6, S^{-1}(a_1 b_1)) \alpha S^{-1}(a_3 b_3) \beta S^{-1}(a_6) \]

Therefore, we have

\[ (a \otimes h)b = a_0 b_0 \otimes h_2 b_7 \omega(S^{-1}(a_8), a_3 b_4, \alpha S^{-1}(a_3 b_3) S^{-1}(a_2 b_2)) \omega(\beta S^{-1}(a_6) S^{-1}(a_7), a_5, b_5) \]

\[ \omega(h_1, b_6, S^{-1}(a_1 b_1)) \] (3.5)

for any \( h \in H, a, b \in A \). Seems to be complicated, but in the Hopf algebra case it simply reduces to \( (a \otimes h)b = ab_0 \otimes h b_1 \). \( \square \)

We come back now to the counit of the adjunction, applied to the Hopf module \( A \otimes H \). The coinvariants are \( (A \otimes H)^{coH} = A \otimes k1_H \cong A \), as the coaction takes place only on the second component and \( k \) is a commutative field. Hence

\[ \varepsilon_{A \otimes H} : A \otimes_B A \to A \otimes H \]

\[ \varepsilon_{A \otimes H}(a \otimes_B b) = a_0 b_0 \otimes b_5 \omega(S^{-1}(a_7), a_3 b_3, \alpha S^{-1}(a_2 b_2) S^{-1}(a_1 b_1)) \]

\[ \omega(\beta S^{-1}(a_5) S^{-1}(a_6), a_4, b_4) \]

\[ \varepsilon_{A \otimes H}(a \otimes_B b) = a_0 b_0 \otimes b_5 \omega(S^{-1}(a_7), a_3 b_3, \alpha S^{-1}(a_2 b_2) S^{-1}(a_1 b_1)) \]

\[ \omega(\beta S^{-1}(a_5) S^{-1}(a_6), a_4, b_4) \]

\[ (2.23) \]

\[ (2.24) \]

\[ (2.18), (2.10) \]

\[ (2.3), (2.11), (2.5), (2.6) \]

\[ (2.3), (2.5), (2.10), (2.4) \]

\[ (2.22) \]

But according to [3.3], this is precisely \( \text{can}_A \), the Galois map twisted by \( \tilde{f} \), where the twist \( \tilde{f} \) was introduced in relation (2.23). From the Remark 15 it follows that:

**Corollary 21.** The bijectivity of \( \varepsilon_{A \otimes H} \) implies that \( B \subseteq A \) is Galois.

**Remark 22.** We could had used formula [3.2] as an alternative Galois map, but we preferred the formula from Definition 8 to avoid the presence of the twist and simplify computations.

We shall further need some properties of the Galois map, analogs to those in [34]:

**Proposition 23.** The morphism can satisfies the following:

1. It is right \( H \)-colinear, where the right comodule structure on both spaces is given from the second tensorand.

2. For any \( a \in A \), \( \text{can}(1 \otimes_B a) = a_0 \otimes \beta(a_1)a_2 \).

3. It is also right \( H \)-colinear, but with respect to the following coactions: \( \tilde{\rho}(a \otimes_B b) = a_0 \otimes_B b \otimes a_1 \), for \( a \otimes_B b \in A \otimes_B A \), respectively \( \tilde{\rho}(a \otimes h) = a_0 \otimes h \otimes a_1 S(h_1) \), where \( a \otimes h \in A \otimes H \).
(4) If can is bijective, then
\[
(c \otimes 1_H)\text{can}^{-1}(d \otimes h) = \text{can}^{-1}(c_0d_0 \otimes h_2)\omega^{-1}(c_1, d_1, S(h_1))
\]
for any \(c, d \in A, h \in H\).

(5) If the extension is Galois, denote \(\text{can}^{-1}(1_A \otimes h) = \sum \lambda_i(h) \otimes_B r_i(h)\). Then
\[
\sum \lambda_i(h) \otimes_B r_i(h) = \sum \lambda_i(h_1) \otimes_B r_i(h_1) \otimes_B r_i(h_2).
\]

(5.1) \(\sum l_i(h_1) \otimes_B r_i(h_1) \otimes_B r_i(h_2) = \sum l_i(h)(h_1) \otimes_B r_i(h_1) \otimes_B r_i(h_2)\).

(5.2) \(\sum l_i(h) r_i(h) = \alpha(h) 1_A\).

(5.3) \(\sum l_i(h_1) \otimes_B r_i(h_2) \otimes_B r_i(h_3) = \sum l_i(h_2) \otimes_B r_i(h_2) \otimes B(h_1)\).

(5.4) \(\sum a_0\beta(a_1) l_i(a_2) \otimes_B r_i(a_2) = 1_A \otimes_B a\).

(5.5) \(\sum l_i(h_0) \otimes_B r_i(h_2) \otimes_B r_i(h_2) = \sum f^{-1}(h_1, g_1) l_i(g_2) l_j(h_2) \otimes_B r_j(h_2) r_i(g_2)\)

for all \(h, g \in H, a \in A\).

(6) The map can' from Remark \(\text{can}'\) is also right \(H\)-colinear, where the right comodule structure on \(A \otimes_B A\)

is given from the first tensorand, and \(A \otimes H\) is a right \(H\)-comodule via \(I_A \otimes \Delta\).

Proof. (1) We have
\[
(I \otimes \Delta)\text{can}(a \otimes_B b) = a_0b_0 \otimes \omega^{-1}(a_1, b_1\beta(b_2), S(b_3))b_4 \otimes b_5 = \text{can}(a \otimes_B b_0) \otimes b_1
\]

(2) Obvious.

(3) Remark first that \(\hat{\rho}\) and \(\tilde{\phi}\) are indeed right \(H\)-comodule structures. Then, for any \(a, b \in A\), we compute
\[
\hat{\rho}\text{can}(a \otimes_B b) = \hat{\rho}(a_0b_0 \otimes \omega^{-1}(a_1, b_1\beta(b_2), S(b_3))b_4) = a_0b_0 \otimes b_0 \otimes (a_1 b_1) S(b_5) \omega^{-1}(a_2, b_2\beta(b_3), S(b_4))
\]

(4) We get that
\[
\text{can}(ca \otimes_B b) = (c_0a_0) b_0 \otimes \omega^{-1}(c_1a_1, b_1\beta(b_2), S(b_3)) b_4
\]

\[
= (c_0a_0) b_0 \otimes \omega^{-1}(c_1a_1, b_1) \omega^{-1}(c_2, a_2b_2, S(b_6)) \omega^{-1}(a_3, b_3, S(b_7))
\]

\[
= (c_0a_0) b_0 \otimes \omega^{-1}(c_1a_1, b_1) \omega^{-1}(c_2, a_2b_2, S(b_6)) \omega^{-1}(a_3, b_3, S(b_7))
\]

\[
= (c_0a_0) b_0 \otimes \omega^{-1}(c_1a_1, b_1) \omega^{-1}(c_2, a_2b_2, S(b_6)) \omega^{-1}(a_3, b_3, S(b_7))
\]

\[
= c_0(a_0b_0) \otimes \omega^{-1}(c_1a_1, b_1, b_3, S(b_7)) \omega^{-1}(a_2, b_2, S(b_4)) \beta(b_4) b_7
\]

for any \(a, b, c \in A\). Now, if we denote \(\text{can}^{-1}(d \otimes h) = \sum \lambda_i \otimes_B b_i\), then
\[
(\rho_A \otimes \Delta)(d \otimes h) = \sum \lambda_i a_0b_0 \otimes a_0b_1 \otimes \omega^{-1}(a_2, b_2\beta(b_3), S(b_4)) b_5 \otimes b_6
\]

11
Using this, we easily deduce that
\[ can(c \cdot can^{-1}(d \otimes h)) = can(\sum_i c_{a_i} \otimes_B b_i) \]
\[ = c_0(a_0 b_0) \otimes \omega^{-1}(c_1, b_1) \omega^{-1}(a_2, b_2, b_3) b_6 \]
\[ = c_0 d_0 \omega^{-1}(c_1, d_1, S(h_1)) \otimes h_2 \]

(5.1) It follows from (1).

(5.2) We shall check first the formula:
\[ \sum_i l_i(h) r_i(h) = (I_A \otimes \varepsilon)(l_i(h) \otimes h_0 \otimes r_i(h)_{r_1(h)_{r_1(h)}}, S(r_i(h)_0), \alpha(r_i(h)_7) r_i(h)) \]
\[ \omega^{-1}(l_i(h)_2, r_i(h)_2 \beta(r_i(h)_3), S(r_i(h)_4) r_i(h)) \]

The left hand side can be also written as:
\[ \sum_i (I_A \otimes \varepsilon)(l_i(h)_0 r_i(h)_0 \otimes \omega(l_i(h)_1 r_i(h)_1, S(r_i(h)_0), \alpha(r_i(h)_7) r_i(h))) \]
\[ \omega^{-1}(l_i(h)_2, r_i(h)_2 \beta(r_i(h)_3), S(r_i(h)_4)) \]
\[ = \sum_i l_i(h) \omega^{-1}(l_i(h)_1, r_i(h)_1, S(r_i(h)_3) r_i(h)_{r_1(h)_7}) \omega(r_i(h)_2, S(r_i(h)_5), r_i(h)) \]
\[ = \sum_i l_i(h) r_i(h)_0 \varepsilon(r_i(h)_1) \]

But \( \sum_i l_i(h) \otimes \omega^{-1}(l_i(h)_1, r_i(h)_1 \beta(r_i(h)_2), S(r_i(h)_3) r_i(h)_4 = 1_A \otimes h, \) therefore
\[ \sum_i l_i(h) r_i(h) = (I_A \otimes \varepsilon)(1_A \otimes h \omega(1_H, S(h_2), \alpha(h_3) h_4)) \]
\[ = 1_A \alpha(h) \]

(5.3) It results from (3).

(5.4) We compute
\[ can(\sum_i a_0 \beta(a_1) l_i(a_2) \otimes_B r_i(a_2)) = [a_0 \beta(a_2) l_i(a_3)_0, r_i(a_3)_0 \otimes r_i(a_3)] \]
\[ \omega^{-1}(a_1 l_i(a_3)_1, r_i(a_3)_1 \beta(r_1(a_3)_2), S(r_i(a_3)_3)) \]
\[ = a_0 [l_i(a_4)_0 r_i(a_4)_0 \beta(a_3) \omega(a_1, l_i(a_4)_1, r_i(a_4)_1)] \otimes r_i(a_4)_5 \]
\[ \omega^{-1}(a_2 l_i(a_4)_2, r_i(a_4)_2 \beta(r_1(a_4)_3), S(r_i(a_4)_4)) \]
\[ = a_0 [l_i(a_4)_0 r_i(a_4)_0 \beta(a_3) \otimes r_i(a_4)_8] \]

12
\( \omega^{-1}(a_1, l_i(a_4) r_i(a_4), S(r_i(a_4))) \beta(r_i(a_4)) \)
\( \omega^{-1}(l_i(a_4), r_i(a_4), S(r_i(a_4))) \)
\( \omega(a_2, l_i(a_4)^3, r_i(a_4)^3 S(r_i(a_4)) \)
\( = a_0 [l_i(a_3) a r_i(a_3)] \beta(a_2) \otimes r_i(a_3) \)
\( \omega^{-1}(a_1, l_i(a_3)^1 r_i(a_3), S(r_i(a_3))) \)
\( \omega^{-1}(l_i(a_3), r_i(a_3), S(r_i(a_3))) \beta(r_i(a_3)) \)
\( = a_0 \beta(a_2) 1_A \otimes a_4 \omega^{-1}(a_1, 1_H, S(a_3)) \)
\( = a_0 \beta(a_1) \otimes a_2 \)
\( = \text{can}(1_A \otimes B) \)

(5.5) It is a consequence of the previous properties of \textit{can} and of the properties (2.15) - (2.22) of the twist \( f \).

(6) Easy.

**Remark 24.** As a consequence of Proposition (23) and (24), we obtain that \textit{can} is a morphism of left Hopf modules, where \( A^* \otimes_B A \) is an object in \( A^* \mathcal{M}^H \) with structures given by the first tensorand, while \( A^* \otimes H^{S*} \) is the induced module in \( A^* \mathcal{M}^H \). Here \( H^{S*} \) is the right comodule structure of \( H \) deformed by the antipode \( S \) (i.e. \( A^* \otimes H^{S*} \) is a left Hopf module with structure morphisms \( a \otimes h \rightarrow a_0 \otimes h_2 \otimes a_1 S(h_1), a(b \otimes h) = a_0 b_0 \otimes h_2 \omega^{-1}(a_1, b_1, S(h_1)) \).

**Definition 25.** Let \( A \) a right \( H \)-comodule algebra and \( \gamma : H \rightarrow A \) a colinear map. The extension \( B \subseteq A \) is \((H, S)\)-cleft with respect to the cleaving map \( \gamma \) if there is a linear map \( \delta_{\gamma, S} : H \rightarrow A \) such that

\[
\rho(\delta_{\gamma, S}(h)) = \delta_{\gamma, S}(h_2) \otimes S(h_1) \quad (3.7)
\]
\[
\delta_{\gamma, S}(h_1) \gamma(h_2) = a(h) 1_A \quad (3.8)
\]
\[
\gamma(h_1) \beta(h_2) \delta_{\gamma, S}(h_3) = \varepsilon(h) 1_A \quad (3.9)
\]

**Remark 26.** (1) This definition of cleftness is slightly different from the classical one. In the Hopf case, it is only required that \( \gamma \) is convolution invertible (denote by \( \delta \) the convolution inverse of \( \gamma \) and \( H \)-colinear. The property (3.7) appears naturally by passing from a bialgebra to a Hopf algebra. Unfortunately, in our case the convolution product on \( \text{Hom}(H, A) \) is no longer associative, therefore a left inverse for \( \gamma \) is not necessarily a right inverse and the property (3.7) does not seem to result from the other properties of \( \gamma \). So we had to state it separately.

(2) For a left comodule algebra \( A \), the application \( \delta_{\gamma, S} \) depends on the antipode. If we change it to \((S', \alpha', \beta')\) as in (23) and define \( \delta_{\gamma, S'}(h) = U(h_1) \delta_{\gamma, S}(h_2) \), then it follows immediately that \( A \) is also \((H, S')\)-cleft. In the sequel, we shall drop the subscripts for simplicity, considering the antipode and the elements \( \alpha, \beta \) fixed once for all.

Recall that the "normal basis property" states that there is an isomorphism of left \( B \)-modules, right \( H \)-comodules \( A \simeq B \otimes H^* \), where the dots are indicating the corresponding structures for the tensor product. We shall keep the same definition for coquasi-Hopf algebras, as nothing is changed.

**Theorem 27.** Let \( H \) be a coquasi-Hopf algebra with bijective antipode, \( A \) a right \( H \)-comodule algebra with \( B \) the subalgebra of coinvariants. Then the following statements are equivalent:

(1) The extension \( B \subseteq A \) is \( H \)-cleft;

(2) The Weak Structure Theorem holds and the extension has the normal basis property;

(3) The extension \( B \subseteq A \) is \( H \)-Galois and has the normal basis property.

In this case, the categories \( \mathcal{M}_B \) and \( \mathcal{M}_A^A \) are equivalent (the Strong Structure Theorem holds).
Proof. The proof of this theorem follows closely the original one for Hopf algebras, due to Doi and Takeuchi ([17]), and Blattner and Montgomery ([7]), but we shall do the computations in detail, because of their degree of difficulty.

(1) \implies (2) Define
\[ \nu : B \otimes H \longrightarrow A, \quad \nu(b \otimes h) = b\gamma(h) \] (3.10)

It is obvious \(B\)-linear. As \(\gamma\) is \(H\)-colinear, \(\nu\) will also be. We need an inverse for \(\nu\). We take
\[ \nu^{-1}(a) = a_0\delta(a_1 \leftarrow \beta) \otimes a_2, \quad a \in A \] (3.11)

We need to show first that it is well-defined. For all \(a \in A\), we have
\[
\begin{align*}
\rho_A(a_0\delta(a_1 \leftarrow \beta)) &= a_0\delta(a_1 \leftarrow \beta)_0 \otimes a_0\delta(a_1 \leftarrow \beta)_1 \\
&= a_0\beta(a_1)\delta(a_2) \otimes 1_H \\
&= a_0\delta(a_1 \leftarrow \beta) \otimes 1_H
\end{align*}
\] (3.12)

meaning that \(\text{Im}\, \nu^{-1} \subseteq B \otimes H\). Let’s check now that \(\nu\) and \(\nu^{-1}\) are indeed inverses to each other: for all \(a \in A\), we compute
\[
\begin{align*}
(\nu \circ \nu^{-1})(a) &= \nu(a_0\delta(a_1 \leftarrow \beta) \otimes a_2) \\
&= [a_0\delta(a_1 \leftarrow \beta)]\gamma(a_2) \\
&= a_0\delta(a_2 \leftarrow \beta)_0\gamma(a_3)_0\omega(a_1, \delta(a_2 \leftarrow \beta)_1, \gamma(a_3)_1) \\
&= a_0\delta(a_4)\gamma(a_5)_1\omega(a_1, S(a_3), a_6)\beta(a_2) \\
&= a_0\omega(a_1, S(a_3), a_5)\beta(a_2)\alpha(a_4) \\
&= a
\end{align*}
\] (3.13)

Conversely, for \(b \in B\) and \(h \in H\) we get
\[
\begin{align*}
\nu^{-1} \circ \nu(b \otimes h) &= \nu^{-1}(b\gamma(h)) \\
&= b\gamma(h)_0\delta((\gamma(h))_1 \leftarrow \beta) \otimes \gamma(h)_2 \\
&= b\gamma(h_1)\beta(h_2)\delta(h_3) \otimes h_4 \\
&= b \otimes h
\end{align*}
\] (3.9)

Hence the extension \(B \subseteq A\) has the normal basis property. It remains only to show the bijectivity of the adjunction counit from Proposition [7]. For a Hopf module \(M \in M^H_A\), define the map \(t_M : M \longrightarrow M\) by \(t_M(m) = m_0\delta(m_1 \leftarrow \beta)\). Then we can see as in (3.12) that the image of \(t_M\) is in \(M^{coH}\). Define now \(\chi : M \longrightarrow M^{coH} \otimes_B A, \chi(m) = t_M(m_0) \otimes_B \gamma(m_1)\). Computing as in (3.13), we get that \(\chi\) is an inverse for \(\varepsilon_M\).

(2) \implies (3) It follows from Corollary [21].

(3) \implies (1) Let \(\nu : B \otimes H \longrightarrow A\) be the isomorphism given by the normal basis property. Define \(\gamma(h) = \nu(1_A \otimes h)\). As \(\nu\) is \(H\)-colinear, \(\gamma\) will also be.

In order to get the second map \(\delta\), we need some work first. Consider the map \(\Gamma = (I_A \otimes \varepsilon)\nu^{-1} : A \longrightarrow B\). Then \(\Gamma\) is left \(B\)-linear, as \(\nu^{-1}\) is \(B\)-linear, and
\[
\begin{align*}
\Gamma\gamma(h) &= (I_A \otimes \varepsilon)\nu^{-1}\nu(1_A \otimes h) \\
&= \varepsilon(h)1_A
\end{align*}
\] (3.14)
Now we may take \( \delta(h) = m_A(I_A \otimes_B \Gamma) \)\( \text{can}^{-1}(1 \otimes h) = \sum_i l_i(h)\Gamma(r_i(h)) \), where \( m_A \) is the multiplication on \( A \). We may then compute
\[
\gamma(h_1)\beta(h_2)\delta(h_3) = \gamma(h_1)m_A(I_A \otimes_B \Gamma) \text{can}^{-1}(1_A \otimes \beta(h_2)h_3)
\]
\[
\in A
\]
\[
m_A(I_A \otimes_B \Gamma)[\gamma(h_1) \text{can}^{-1}(1_A \otimes \beta(h_2)h_3)]
\]

(Proposition \( \text{Proposition} 23 \))
\[
m_A(I_A \otimes_B \Gamma) \text{can}^{-1}(\gamma(h_1) \otimes \beta(h_2)h_3)
\]

(\( \gamma \) is colinear)
\[
m_A(I_A \otimes_B \Gamma) \text{can}^{-1}(\gamma(h_0) \otimes \beta(\gamma(h_1) \gamma(h_2))
\]

(Proposition \( \text{Proposition} 23 \))
\[
m_A(I_A \otimes_B \Gamma)(1_A \otimes_B \gamma(h))
\]
\[
\Gamma \gamma(h)
\]
\[
\varepsilon(h)1_A
\]

For the last formula, notice first that \( H \)-colinearity of \( \nu \) implies
\[
\nu^{-1} = (I_B \otimes \varepsilon \otimes I_H)(I_B \otimes \Delta)\nu^{-1}
\]
\[
= (I_B \otimes \varepsilon \otimes I_H)(\nu^{-1} \otimes I_H)\rho_A
\]
\[
= (\Gamma \otimes I_H)\rho_A \tag{3.15}
\]

Now we may compute
\[
\delta(h_1)\gamma(h_2) = [m_A(I_A \otimes_B \Gamma) \text{can}^{-1}(1_A \otimes h_1)]\nu(1_A \otimes h_2)
\]
\[
= \sum_{i} l_i(h_1)\Gamma(r_i(h_1))\nu(1_A \otimes h_2)
\]

(Proposition \( \text{Proposition} 23 \))
\[
= \sum_{i} l_i(h_1)\Gamma(r_i(h_0))\nu(1_A \otimes r_i(h))
\]
\[
= \sum_{i} l_i(h_1)\nu(\Gamma(r_i(h_0) \otimes r_i(h))
\]
\[
= \sum_{i} l_i(h_1)\nu(\Gamma(r_i(h_0) \otimes r_i(h))
\]
\[
\text{Proposition } 23
\]
\[
= \alpha(h)1_A
\]

for all \( h \in H \).

Finally, for any \( h \in H \) we have
\[
\rho_A\delta(h) = \rho_A m_A(I_A \otimes_B \Gamma) \text{can}^{-1}(1_A \otimes h)
\]
\[
= \rho_A(\sum_{i} l_i(h)\Gamma(r_i(h)))
\]
\[
= \sum_{i} l_i(h)0\Gamma(r_i(h)) \otimes l_i(h)_1
\]

(Proposition \( \text{Proposition} 23 \))
\[
= \sum_{i} l_i(h_2)\Gamma(r_i(h_2)) \otimes S(h_1)
\]
\[
= \delta(h_2) \otimes S(h_1)
\]
For the remaining of the theorem, the proof is the same as in [17], so we omit it.

We shall prove now an imprimitivity statement which is the analogue of Doi’s and Takeuchi’s theorem ([18]) and Schneider’s theorem ([33]) for coquasi-Hopf algebras.

**Theorem 28.** Let $H$ be a coquasi-Hopf algebra with bijective antipode, $A$ a right $H$-comodule algebra with $B$ the algebra of coinvariants. Then the following are equivalent:

1. $A$ is faithfully flat as a left $B$-module, and $A$ is a Galois extension of $B$.
2. The functor of coinvariants and the induction functor are a pair of inverse equivalences between $\mathcal{M}_A^H$ and $\mathcal{M}_B$.

Proof. (1) $\implies$ (2) We need first a Lemma:

**Lemma 29.** Let $H$ be a coquasi-Hopf algebra and $A$ a right comodule algebra. Then the Galois map can induces a natural right colinear morphism $\text{can}_M : M \otimes_B A^* \to M \otimes H^*$, $\text{can}_M(m \otimes_B a) = m_0a_0 \otimes \omega^{-1}(m_1, a_1\beta(a_2), S(a_3))a_4$. If $\text{can}$ is bijective, then $\text{can}_M$ is also bijective.

Proof. (of the Lemma) The definition of $\text{can}_M$ allows us to easily check its colinearity. The hard part is the proof of the naturality and of the bijectivity of $\text{can}_M$. This is not obvious at all, because $A$ is no longer an associative algebra and the classical argument (i.e. tensoring over $A$) is not working. In this case it is more appropriate to work in the monoidal category of comodules. We refer to [3] for details about tensor product over an algebra in a monoidal category. As $A$ is an algebra in the monoidal abelian category $\mathcal{M}_A^H$, we may form the tensor product $M \circ A M'$ for any $M \in \mathcal{M}_A^H$, $M' \in \mathcal{M}_A^H$ as the following equalizer

$$
(M \otimes A) \otimes M' \xrightarrow{\mu_M \otimes I_{M'}} \xrightarrow{(I_M \otimes M') \phi_{M,A,M'}} M \otimes M' \to M \circ A M' \to 0
$$

where $\mu_M$ and $\mu_M'$ are the $A$-module structure maps and $\phi$ is the coassociator.

We need now two particular left Hopf modules. One of them is $A^* \otimes_B A$, with right $H$-coaction and left $A$-action on the first component. For the other one, notice first that $S$ is a coalgebra map. Therefore we may take $H$ as an object in $\mathcal{M}_A^H$ with $h \to h_2 \otimes S(h_1)$, denoted $H^S$. Then we get an induced left Hopf module $A^* \otimes H^{S,*} \in \mathcal{M}_A^H$, with structure maps

$$
\begin{align*}
(a \otimes h) &\to a_0 \otimes h_2 \otimes a_1 S(h_1) \\
(a(b \otimes h)) &= a_0b_0 \otimes h_2 \omega^{-1}(a_1, b_1, S(h_1))
\end{align*}
$$

We can construct now the following diagram for any $M \in \mathcal{M}_A^H$:

$$
\begin{align*}
\begin{array}{ccc}
(M \otimes A) \otimes (A \otimes B A) & \xrightarrow{\mu_M \otimes (I_A \otimes_B I_A)} & M \otimes (A \otimes_B A) \\
(I_M \otimes (m_A \otimes_B I_A)) \phi_{M,A,A \otimes_B A} & \downarrow & \downarrow I_M \otimes \text{can} \\
(M \otimes A) \otimes (A \otimes H) & \xrightarrow{\mu_M \otimes (I_A \otimes_B I_A)} & M \otimes (A \otimes H) \\
(I_M \otimes \mu_A \otimes_H) \phi_{M,A,A \otimes H} & & \downarrow I_M \otimes \text{can}
\end{array}
\end{align*}
$$

The two rows are exact by definition of $\circ A$. The application $F_1 : M^* \otimes (A^* \otimes_B A) \to M^* \otimes_B A$, $F_1(m \otimes (a \otimes_B b)) = ma \otimes_B b$ is well-defined, right $H$-colinear and

$$
F_1(\mu_M \otimes (I_A \otimes_B I_A)) = F_1((I_M \otimes (m_A \otimes_B I_A)) \phi_{M,A,A \otimes_B A}
$$

16
(here \(M^* \otimes_B A\) is a right comodule via \(\rho_M \otimes_B I_A\), while \(M^* \otimes (\bullet A^* \otimes_B A)\) has the diagonal comodule structure). Hence there is a right \(H\)-comodule morphism \(\bar{F}_1 : M \circ_A (A \otimes B) \rightarrow M \otimes_B A\) such that \(\bar{F}_1 \pi_1 = F_1\). Moreover, \(F_1\) is an isomorphism with inverse \(F_1^{-1} = \pi_1 G_1\), where \(G_1(m \otimes_B a) = m \otimes (1_A \otimes_B a)\).

As \(\bullet A^* \otimes H S^*\) is an \(H\)-module induced in \(M^H\), the colinear map \(\bar{F}_2 : M^* \otimes (\bullet A^* \otimes H S^*) \rightarrow M^* \otimes H S^*\), \(\bar{F}_2(m \otimes (a \otimes h)) = m a_0 \otimes h_2 \omega^{-1}(m_1, a_1, S(h_1))\) factors through an isomorphism of right \(H\)-comodules \(\bar{F}_2 : M \circ_A (A \otimes H) \simeq M \otimes H\), with inverse \(\bar{F}_2^{-1} = \pi_2 G_2\), where \(G_2(m \otimes h) = m \otimes (1_A \otimes h)\) (on \(M^* \otimes H S^*\) we have again the diagonal comodule structure).

According to Remark 24, the map \(\text{can} : \bullet A^* \otimes_B A \rightarrow \bullet A^* \otimes H S^*\) is a morphism in \(A M^H\). Then \(I_M \otimes \text{can}\) induces a colinear map \(I_M \circ_A \text{can} : M \circ_A (A \otimes_B A) \rightarrow M \circ_A (A \otimes_B A)\).

Composing now the morphisms from the last column in the above diagram, we obtain a natural map \(\text{can}_M : M \otimes_B A \rightarrow M \otimes H\), which can be written as \(\text{can}_M = \bar{F}_2(I_M \circ_A \text{can}) \bar{F}_1^{-1} = \bar{F}_2(I_M \otimes \text{can}) G_1\). This implies

\[
\text{can}_M(m \otimes_B a) = F_2(I_M \otimes \text{can}) G_1(m \otimes_B a)
= F_2(I_M \otimes \text{can})(m \otimes (1_A \otimes_B a))
= F_2(m \otimes (a_0 \otimes \beta(a_1)a_2))
= m a_0 \otimes \omega^{-1}(m_1, a_1 \beta(a_2), S(a_3))a_4
\]

The last part of the Lemma is now obvious. □

(Proof of the Theorem) As in Lemma 14, we are able to show that for any \(M \in \mathcal{M}^H\), \(M \otimes H\) becomes an object in \(\mathcal{M}^H\), with structure morphisms as in Remark 20 (replacing the elements of \(A\) with elements of \(M\)). For later use, we write down explicitly the used isomorphisms:

\[
\begin{align*}
\eta_M & : H^* \otimes M^* \xrightarrow{\eta_M} M \otimes H^*, \\
\eta_M^{-1} & : M \otimes H \xrightarrow{\eta_M} H^* \otimes M^*,
\end{align*}
\]

\[
\begin{align*}
\eta_M(h \otimes m) & = m_0 \otimes \omega(h_1, m_3, \alpha S^{-1}(m_2)S^{-1}(m_1))h_2m_4, \\
\eta_M^{-1}(m \otimes h) & = h_1 S^{-1}(m_4) \otimes m_0 \omega^{-1}(h_2, S^{-1}(m_3)\beta S^{-1}(m_2), m_1).
\end{align*}
\]

It follows that \(\varepsilon_{M \otimes H} = (\text{can}_M)_{\bar{\rho}}\) is bijective. Repeating the argument with \(M \otimes H\) instead of \(M\), we obtain the bijectivity of \(\varepsilon_{(M \otimes H) \otimes H} = (\text{can}_{M \otimes H})_{\bar{\rho}}\). Now the trick is to put this three maps together in a commutative diagram using their naturality:

\[
\begin{array}{c}
0 \longrightarrow M^{coH} \otimes_B A \xrightarrow{\varepsilon_M} M \otimes_B A \\
\varepsilon_M \downarrow \quad \varepsilon_M \downarrow \quad \varepsilon_{(M \otimes H) \otimes H} \downarrow \\
0 \longrightarrow M \xrightarrow{\bar{\rho}_M} M \otimes H \xrightarrow{I_M \otimes \bar{\Delta}} (M \otimes H) \otimes H
\end{array}
\]

(3.18)

On the bottom row, \(\bar{\rho}_M(m) = m_0 \otimes \alpha S^{-1}(m_1)m_2\) and \(\bar{\Delta}(h) = h_1 \otimes \alpha S^{-1}(h_2)h_3\) for \(m \in M, h \in H\). The upper row contains their images via the functor \((-)^{coH} \otimes_B A\). We need to see that \(\bar{\rho}_M, \bar{\rho}_M \otimes I_H\) and \(I_M \otimes \bar{\Delta}\) are morphisms of Hopf modules and the bottom row is exact. It is easy to check the colinearity of these maps, as the comodule structure on the tensor products \(M \otimes H\) and \(M \otimes H \otimes H\) comes from the last tensorand. The difficult part is the right \(A\)-linearity, because of the unpleasant formula (3.5) (applied to \(M\), respectively \(M \otimes H\)). Instead of checking it directly, we shall use the isomorphism which leads to the mentioned formula. For \(\bar{\rho}_M\), we have:

\[
M \xrightarrow{\bar{\rho}_M} M \otimes H \xrightarrow{\eta_M^{-1}} H \otimes M
\]
and

\[ m \rightarrow m_0 \otimes \alpha S^{-1}(m_1)m_2 \stackrel{\eta_M}{\rightarrow} m_0 \alpha S^{-1}(m_3)S^{-1}(m_4) \otimes m_0 \omega^{-1}(m_5, S^{-1}(m_3) \beta S^{-1}(m_2), m_1) \]

\[ = \alpha S^{-1}(m_4)1_H \otimes m_0 \omega^{-1}(m_5, S^{-1}(m_3) \beta S^{-1}(m_2), m_1) \]

\[ = 1_H \otimes m \quad (3.19) \]

Remembering that the \( A \)-module structure of \( H \otimes M \) is the one induced by \( M \) (i.e. \( (h \otimes m)a = h_1 \otimes m_0 \alpha_0 \omega(h_2, m_1, a_1) \)), it is now easy to verify the \( A \)-linearity for the composed map \( \eta_M^{-1} \bar{\rho}_M \).

For \( \bar{\rho}_M \otimes I_H \), we need to compose three times with the following isomorphisms

\[ H^* \otimes M; \, \eta_M \cong M; \otimes H^*; \, \bar{\rho}_M \otimes I_H \rightarrow (M; \otimes H^*) \otimes H^*; \eta_M \otimes H^* \otimes (M; \otimes H^*) \rightarrow I_H \otimes \eta_M^{-1} \rightarrow H^* \otimes (H^* \otimes M;). \]

We use dots to indicate the structures (although the right \( A \)-structures are not the classical ones, we find the notation more suggestive). We obtain

\[ h \otimes m \rightarrow m_0 \otimes \omega(h_1, m_3, \alpha S^{-1}(m_2)S^{-1}(m_1))h_2m_4 \]

\[ = m_0 \otimes \alpha S^{-1}(m_1)m_2 \otimes \omega(h_1, m_5, \alpha S^{-1}(m_4)S^{-1}(m_3))h_2m_6 \]

\[ = h_1 \otimes m_0 \otimes \alpha S^{-1}(m_1)m_2 \omega^{-1}(h_3, m_9, S^{-1}(m_5) \beta S^{-1}(m_4), m_3) \omega(h_2, m_8 \alpha S^{-1}(m_7), S^{-1}(m_6)) \]

\[ = h_1 \otimes m_0 \otimes \alpha S^{-1}(m_1)m_2 \omega^{-1}(h_2, m_1 S^{-1}(m_9), m_3) \omega^{-1}(h_4, S^{-1}(m_8), m_4) \]

\[ = \omega(h_3, m_{10}, S^{-1}(m_5)m_3) \beta S^{-1}(m_6) \alpha S^{-1}(m_{10}) \]

\[ = h \otimes m_0 \otimes \alpha S^{-1}(m_1)m_2 \omega^{-1}(h_5, S^{-1}(m_5)m_3) \beta S^{-1}(m_4) \alpha S^{-1}(m_6) \]

\[ = h \otimes m_0 \otimes \alpha S^{-1}(m_1)m_2 \]

\[ = h \otimes 1_H \otimes m \]

and this is again right \( A \)-linear.

Finally, we repeat the above composition with \( I_M \otimes \bar{\Delta} \) instead of \( \bar{\rho}_M \otimes I_H \). We obtain

\[ h \otimes m \rightarrow m_0 \otimes \omega(h_1, m_3, \alpha S^{-1}(m_2)S^{-1}(m_1))h_2m_4 \]

\[ = m_0 \otimes \omega(h_1, m_3, \alpha S^{-1}(m_2)S^{-1}(m_1))h_2m_4 \otimes \alpha S^{-1}(m_3)m_5 h_4m_6 \]

\[ = h_8 m_1 \alpha S^{-1}(h_7 m_9)S^{-1}(h_6 m_8) \otimes m_0 \otimes \omega(h_1, m_3, \alpha S^{-1}(m_2)S^{-1}(m_1))h_2m_4 \]

\[ = \omega^{-1}(h_9 m_11, S^{-1}(h_5 m_7) \beta S^{-1}(h_4 m_6), h_3 m_5) \]

\[ = 1_H \otimes m_0 \otimes \omega(h_1, m_3, \alpha S^{-1}(m_2)S^{-1}(m_1))h_2m_4 \omega^{-1}(h_7 m_9, S^{-1}(h_5 m_7) \beta S^{-1}(h_4 m_6), h_3 m_5) \]

\[ = 1_H \otimes m_0 \otimes \omega(h_1, m_3, \alpha S^{-1}(m_2)S^{-1}(m_1))h_2m_4 \]

\[ = 1_H \otimes h \otimes m \]

which respects the multiplication with elements of \( A \).

We have to show now the exactness of the sequence. For the injectivity of \( \bar{\rho}_M \): take \( m \in M \) such that \( m_0 \otimes \alpha S^{-1}(m_1)m_2 = 0 \). Now apply \( \rho_M \otimes [(I_H \otimes \bar{\Delta}) \Delta] \) to get

\[ 0 = m_0 \otimes m_1 \otimes \alpha S^{-1}(m_2)m_3 \otimes m_4 \otimes m_5 \]

Finally, act on this by \( I_M \otimes \omega^{21}(S^{-1} \otimes I_H \otimes \beta S^{-1} \otimes S^{-1}) \). By (2.7) it follows \( 0 = m_0 \varepsilon_m(m_1) = m \).

Let’s check now the exactness in \( M \otimes H \). It is straightforward to see that \( (I_M \otimes \bar{\Delta}) \bar{\rho}_M = (\bar{\rho}_M \otimes I_H) \bar{\rho}_M \). Conversely, let \( \sum_i m_i \otimes h_i \in M \otimes H \) such that \( \sum_i m_i \otimes h_{i1} \otimes \alpha S^{-1}(h_{i2})h_{i3} = \sum_i m_{i0} \otimes \alpha S^{-1}(m_{i1})m_{i2} \otimes h_i \).
Apply $\Delta$ and $(I_H \otimes \Delta)\Delta$ on the second, respectively last component, then act by $I_M \otimes I_H \otimes \omega^{321}(S^{-1} \otimes I_H \otimes \beta S^{-1} \otimes S^{-1})$. Again using (2.7) we obtain

$$\sum_i m_i \otimes h_i = \sum_i m_{i0} \otimes \alpha S^{-1}(m_{i1})m_{i2}\omega(S^{-1}(h_{i3})\beta S^{-1}(h_{i2}), h_{i1}, S^{-1}(m_{i3}))$$

$$= \tilde{\beta}_M(\sum_i m_{i0}\omega(S^{-1}(h_{i3})\beta S^{-1}(h_{i2}), h_{i1}, S^{-1}(m_{i1})))$$

Therefore the diagram (3.18) is commutative by the naturality of $\varepsilon(-)$. The upper row is exact because $(-)^{\text{co}H}$ is exact and $A$ is a faithfully flat $B$-module. As explained above, $\varepsilon_{M \otimes H}$ and $\varepsilon_{(M \otimes H)^{\otimes H}}$ are bijective, hence $\varepsilon_M$ is too, by the Five Lemma.

We move now to the unit $u(-)$ of the adjunction. Let $N$ be a right $B$-module. Consider the maps $i_1, i_2 : N \otimes_B A \rightarrow N \otimes_B A \otimes_B A$, $i_1(n \otimes_B a) = n \otimes_B 1_A \otimes_B a$, $i_2(n \otimes_B a) = n \otimes_B a \otimes_B 1_A$ and the short sequence

$$0 \rightarrow N \rightarrow N \otimes_B A \xrightarrow{i_1} N \otimes_B A \otimes_B A \xrightarrow{i_2} N \otimes_B A \otimes_B A$$

where the first morphism is sending $n$ to $n \otimes_B 1_A$. As $A$ is $B$-flat, this map is injective. Although the associativity of $A$ fails, the faithfully flatness property and the existence of the multiplication and of the unit for $A$ allow us to show, as in the classical case, the exactness of the sequence in the middle term $N \otimes_B A$ (we tensor over $B$ one more time with $A$, this is easy to see that is exact, and by faithfully flatness of $A$ we go back to our sequence). Therefore we may consider the diagram with the top row exact

$$0 \rightarrow N \xrightarrow{i_1} N \otimes_B A \xrightarrow{i_2} N \otimes_B A \otimes_B A$$

and the short sequence

$$N \otimes_B A \otimes_B A \xrightarrow{I_N \otimes_B \tilde{\beta}_a} N \otimes_B A \otimes_B A \xrightarrow{I_N \otimes_B \tilde{\beta}_a} N \otimes_B A \otimes_B A \xrightarrow{I_N \otimes_B \tilde{\beta}_a} N \otimes_B A \otimes_B A \xrightarrow{I_N \otimes_B \tilde{\beta}_a} N \otimes_B A \otimes_B A$$

In the bottom row, the map $\tilde{\beta}_A$ is given by $\tilde{\beta}_A(a) = a_0 \otimes \beta(a_1)a_2$. We need to check the exactness of this row. Consider $\sum_i n_i \otimes_B a_i \in (N \otimes_B A)^{\text{co}H}$. Then $\sum_i n_i \otimes_B a_i \otimes a_i = \sum_i n_i \otimes_B a_i \otimes 1_H$ implies

$$(I_N \otimes_B \tilde{\beta}_A - I_N \otimes_B I_A \otimes u_H)(\sum_i n_i \otimes_B a_i) = \sum_i n_i \otimes_B a_i \otimes \beta(a_{i1})a_{i2} - \sum_i n_i \otimes_B a_i \otimes 1_H$$

= 0

Conversely, let $\sum_i n_i \otimes_B a_i \in N \otimes_B A$ which satisfies $\sum_i n_i \otimes_B a_i \otimes \beta(a_{i1})a_{i2} = \sum_i n_i \otimes_B a_i \otimes 1_H$, and apply $\rho_A$ and $(\Delta \otimes I_H \otimes I_H)(\Delta \otimes I_H)\Delta$ on the second, respectively last component of the tensor product. We obtain

$$\sum_i n_i \otimes_B a_i \otimes a_{i1} \otimes \beta(a_{i2})a_{i3} \otimes a_{i4} \otimes a_{i5} \otimes a_{i6} = \sum_i n_i \otimes_B a_i \otimes a_{i1} \otimes 1_H \otimes 1_H \otimes 1_H$$

Now act by $S$ and $\alpha$ on the forth, respectively fifth tensorand and apply $\omega$ on the result. It follows that

$$\sum_i n_i \otimes_B a_i \otimes \omega(a_{i1}, \beta(a_{i2})S(a_{i3})\alpha(a_{i4}), a_{i5}a_{i6}) = \sum_i n_i \otimes_B a_i \otimes \omega(a_{i1}, S(1_H)\alpha(1_H), 1_H)1_H$$
meaning
\[ \sum_i n_i \otimes_B a_i \otimes a_{i1} = \sum_i n_i \otimes_B a_i \otimes 1_H \]

Therefore, the bottom row is exact. The top row is exact by the previous remarks, while the commutativity of the whole diagram can be easily checked. Therefore, \( u_N \) is bijective by the Five Lemma.

(2) \implies (1) Follows as in the Hopf case, using also Corollary \([21]\).

**Remark 30.** In the proof of the bijectivity of the counit, we have replaced the Galois maps with \( \varepsilon_{M \otimes H} \) and \( \varepsilon_{(M \otimes H) \otimes H} \). Although in the Hopf algebra case they coincide, in our context the presence of the twist made very difficult to check directly the commutativity of both diagrams. Therefore we have chosen a functorial approach, with appropriately changed morphisms. For the proof of the bijectivity of the second adjunction map \( u_N \), where \( N \in \mathcal{M}_B \), a change of morphisms in the horizontal rows was also necessary.

We are going to prove now an affineness condition for coquasi-Hopf algebras. First we need the following

**Proposition 31.** Let \( H \) be a coquasi-Hopf algebra with bijective antipode, \( A \) an \( H \)-comodule algebra and \( B = A^{coH} \). Assume that there exists \( \gamma : H \rightarrow A \) a total integral (i.e. a colinear map satisfying \( \gamma(1_H) = 1_A \)). Then \( u_N : N \rightarrow (N \otimes_B A)^{coH} \), \( u_N(n) = n \otimes_B 1_A \), is an isomorphism of right \( B \)-modules for all \( N \in \mathcal{M}_B \).

**Proof.** We shall define first an analogue of the trace map, namely \( t_A : A \rightarrow B \), \( t_A(a) = a_0\beta(a_1)\gamma S(a_2) \). This is well defined, because

\[
\rho t_A(a) = a_0\beta(a_1)\gamma S(a_2) = a_0\beta(a_1)\gamma S(a_2) = a_0\beta(a_1)\gamma S(a_2) \otimes 1_H
\]

where we have used that \( S \) is an antimorphism of coalgebras and relation \([2.6]\). Then using again relation \([2.6]\) one can check that the map \( (N \otimes_B A)^{coH} \rightarrow N \), \( \sum_i n_i \otimes_B a_i \rightarrow n_i t_A(a_i) \) is the inverse of \( u_N \). \( \square \)

We may state now the announced affineness criterion:

**Theorem 32.** Let \( H \) be a coquasi-Hopf algebra with bijective antipode, \( A \) an \( H \)-comodule algebra and \( B = A^{coH} \). Assume that

1. There exists \( \gamma : H \rightarrow A \) a total integral;
2. The canonical map \( \varepsilon : A \otimes_B A \rightarrow A \otimes H \) is surjective.

Then the functor of coinvariants and the induction functor form a pair of inverse equivalences between \( \mathcal{M}_A^H \) and \( \mathcal{M}_B \).

**Proof.** From the previous Proposition, we know that the unit of the adjunction is bijective. It remains to show that \( \varepsilon : M^{coH} \otimes_B A \rightarrow M \) is an isomorphism for any Hopf module \( M \in \mathcal{M}_A^H \). We shall follow here the approach from \([32]\).

Recall that Bulacu and Nauwelaerts \([13]\) have proven the equivalence between the existence of a total integral on a comodule algebra \( A \) and the injectivity of any Hopf module as a right \( H \)-comodule. Their result is stated for right Hopf modules, but it holds also for \( A \mathcal{M}_B^H \) because the antipode is bijective and \( A \mathcal{M}_B^H \approx A_{co}^{op} \mathcal{M}_B^{coH} \).

From Remark \([24]\) we know that \( can \) is a morphism of left Hopf modules. The composition

\[ \tilde{can} : \bullet A^* \otimes A \rightarrow \bullet A^* \otimes_B A \xrightarrow{can} \bullet A^* \otimes H_S^* \]
will be a surjective left Hopf module map, therefore it splits as an $H$-comodule map via a colinear morphism $\theta : \mathcal{A}^\bullet \otimes H^{S\bullet} \longrightarrow \mathcal{A}^\bullet \otimes A$ with $\text{counit}_\theta = I_{A \otimes H}$. Denote $\theta(1_A \otimes h) = \sum_i \tilde{I}_i(h) \otimes \tilde{r}_i(h)$ as an extension of the notation from Proposition 22. It follows that analogues of properties (5.1)-(5.4) hold:

\begin{equation}
\sum_i \tilde{I}_i(h_1) \otimes \tilde{r}_i(h_1) \otimes h_2 = \sum_i \tilde{I}_i(h) \otimes \tilde{r}_i(h_0) \otimes \tilde{r}_i(h_1) \quad (3.20)
\end{equation}

\begin{equation}
\sum_i \tilde{I}_i(h) \tilde{r}_i(h) = \alpha(h)1_A \quad (3.21)
\end{equation}

\begin{equation}
\sum_i \tilde{I}_i(h_0) \otimes \tilde{r}_i(h) \otimes \tilde{I}_i(h_1) = \sum_i \tilde{I}_i(h_2) \otimes \tilde{r}_i(h_2) \otimes S(h_1) \quad (3.22)
\end{equation}

\begin{equation}
\sum_i a_0 \beta(a_1) \tilde{I}_i(a_2) \otimes \tilde{r}_i(a_2) = 1_A \otimes a \quad (3.23)
\end{equation}

Relation (3.22) implies $\sum_i m_0 \beta(m_1) \tilde{I}_i(m_2) \otimes_B \tilde{r}_i(m_2) \in M^{coH} \otimes A$. Now we can define $\chi_M : M \longrightarrow M^{coH} \otimes B A$, $\chi_M(m) = \sum_i m_0 \beta(m_1) \tilde{I}_i(m_2) \otimes_B \tilde{r}_i(m_2)$. We claim that this is an inverse for $\varepsilon_M$, for any $M \in \mathcal{M}_A^H$. Indeed

\begin{equation}
\chi_M \varepsilon_M(m \otimes_B a) = \chi_M(m) = \sum_i m_0 \beta(a_1) \tilde{I}_i(a_2) \otimes_B \tilde{r}_i(a_2) \quad (3.23) = m \otimes_B a
\end{equation}

for all $m \otimes_B a \in M^{coH} \otimes B A$ and

\begin{equation}
\varepsilon_M \chi_M(m) = \varepsilon_M(\sum_i m_0 \beta(m_1) \tilde{I}_i(m_2) \otimes_B \tilde{r}_i(m_2))
\end{equation}

\begin{equation}
= \sum_i [m_0 \beta(m_1) \tilde{I}_i(m_2)] \tilde{r}_i(m_2)
\end{equation}

\begin{equation}
= \sum_i m_0 \tilde{I}_i(m_3) \tilde{I}_i(m_3) \omega(m_1, \tilde{I}_i(m_3), \tilde{r}_i(m_3)) \beta(m_2)
\end{equation}

\begin{equation}
= \sum_i m_0 \tilde{I}_i(m_4) \tilde{r}_i(\sigma_3) \omega(m_1, S(m_3), \tilde{r}_i(m_4)) \beta(m_2)
\end{equation}

\begin{equation}
= \sum_i m_0 \omega(m_1, S(m_3), \tilde{r}_i(m_4)) \beta(m_2) \alpha(m_4)
\end{equation}

\begin{equation}
= m
\end{equation}

for all $m \in M$. It follows that $\varepsilon_M$ is bijective.

We can state now all our previous results in the form of the following theorem:

**Theorem 33.** Let $H$ be a coquasi-Hopf algebra with bijective antipode, $A$ an $H$-comodule algebra and $B = A^{coH}$. Then the following are equivalent:

1. There exists a total integral $\gamma : H \longrightarrow A$ and the map $\gamma : A \otimes_B A \longrightarrow A \otimes H$ is surjective;
2. The functor of coinvariants and the induction functor are a pair of inverse equivalences between $\mathcal{M}_A^H$ and $\mathcal{M}_B$;

\[21\]
(3) The functor of coinvariants and the induction functor are a pair of inverse equivalences between $A M^H$ and $B M$;
(4) $A$ is faithfully flat as a left $B$-module, and $A$ is a Galois extension of $B$;
(5) $A$ is faithfully flat as a right $B$-module, and $A$ is a Galois extension of $B$.

Proof. (1) $\iff$ (2) follows from Theorem 22. (2) $\iff$ (4) is Theorem 28. (4) $\implies$ (1) uses the same argument as in [33], because can’ is also bijective by Lemma 14 and is a morphism of left $B$-modules, right $H$-comodules by Proposition 23(6). The sequence of isomorphisms ($A$ is flat $B$-module)

$$(A^* \Box_H V) \otimes_B A \simeq (A^* \otimes_B A) \Box_H V \simeq (A \otimes H^*) \Box_H V \simeq A \otimes V$$

for each $V \in H M$, together with the left $B$-faithful flatness of $A$ imply that $A$ is right $H$-coflat, or equivalently, that $A$ is $H$-injective (here $\Box_H$ is the cotensor product over $H$).

(1) $\iff$ (3) $\iff$ (5) We simply apply the above to $A^{op}$ as a right $H^{op}$-comodule algebra, since the antipode is bijective. $\blacksquare$

4 A bialgebroid associated to a faithfully flat Galois extension

Let $H$ be a coquasi-bialgebra (without any assumption on the antipode) and $A$ a right $H$-comodule algebra. On the tensor product $A \otimes A^{op}$ we consider the codiagonal right $H$-comodule structure $\rho (a \otimes b) = a_0 \otimes b_0 \otimes a_1 b_1$. Denote $L = (A \otimes A^{op})^{co H}$. Then

**Proposition 34.** $L$ is an associative $B \otimes B^{op}$-algebra with unit $1_A \otimes 1_A$ and multiplication

$$(a \otimes b)(c \otimes d) = a_0 c_0 \otimes d_0 b_0 \omega^{-1}(a_1, c_1, d_1 b_1) \omega(c_2, d_2, b_2)$$

for $a \otimes b, c \otimes d \in L$.

**Proof.** We shall suppress the $\sum$ symbol when referring to elements of $L$ for simplicity.

After a short calculation, it follows that the multiplication is well-defined, with values in $L$. Moreover, the maps $b \in B \longrightarrow b \otimes 1_A \in A \otimes A^{op}, b \in B^{op} \longrightarrow 1_A \otimes b \in A \otimes A^{op}$ take values in $L$ and are multiplicative.

It is easy to check that $1_A \otimes 1_A \in L$ and that it is a unit for the given multiplication. The most difficult part to show is the associativity. Take $a \otimes b, c \otimes d, e \otimes f \in L$ (summation understood). Then we compute

$$(a \otimes b)(c \otimes d)(e \otimes f) = (a_0 c_0 \otimes d_0 b_0) (e \otimes f) \omega^{-1}(a_1, c_1, d_1 b_1) \omega(c_2, d_2, b_2)$$

(4.1) $\implies$

$$= (a_0 c_0 e_0 f_0 (d_0 b_0) \omega^{-1}(a_1, c_1, d_1 b_1) \omega(c_2, d_2, b_2)$$

$$\omega^{-1}(a_2, c_2, d_3 b_3) \omega(c_3, d_4, b_4)$$

(2.1) $\implies$

$$= (a_0 c_0 e_0 f_0 (d_0 b_0) \omega^{-1}(a_1, c_1, d_1 b_1) \omega^{-1}(f_2, d_2, b_2)$$

$$\omega(c_2, f_3, d_3 b_3) \omega^{-1}(a_2, c_2, d_4 b_4) \omega(c_3, d_5, b_5)$$

(2.3) $\implies$

$$= (a_0 c_0 e_0 f_0 (d_0 b_0) \omega^{-1}(a_1, c_1, d_1 b_1) \omega(e_2, f_2 d_2, b_2)$$

$$\omega(e_3, f_3, d_3) \omega^{-1}(e_4 f_4, d_4, b_5) \omega^{-1}(a_2, c_2, d_5 b_5) \omega(c_3, d_6, b_6)$$

(2.5) $\implies$

$$(e \otimes f \in L) = (a_0 c_0 e_0 f_0 (d_0 b_0) \omega^{-1}(a_1, c_1, d_1 b_1) \omega(e_2, f_2 d_2, b_2)$$

$$\omega(e_3, f_3, d_3) \omega^{-1}(a_2, c_2, d_4 b_4) \omega(c_3, d_5, b_5)$$

(2.7) $\implies$

$$= (a_0 c_0 e_0 f_0 (d_0 b_0) \omega((a_1 c_1) e_1, f_1 d_1, b_1) \omega^{-1}(a_2 c_2, e_2, f_2 d_2)$$

$$\omega^{-1}(a_3 c_3, e_3 f_3 d_3, b_2) \omega(e_4, f_4, d_4) \omega^{-1}(a_4 c_4, d_5 b_5)$$

$$\omega(c_5, d_6, b_6)$$

(2.8) $\implies$

$$(e \otimes f \in L) = (a_0 c_0 e_0 f_0 (d_0 b_0) \omega((a_1 c_1) e_1, f_1 d_1, b_1) \omega^{-1}(a_2 c_2, e_2, f_2 d_2)$$

$$\omega(c_5, d_6, b_6)$$
\[ (2.3), \quad (c \otimes d) \in L \] = \[ \omega(e_3, f_3, d_3) \omega^{-1}(a_3c_3, d_4, b_2) \omega^{-1}(a_4, c_2, b_2) \omega^{-1}(a_4, c_4, d_4) \]

\[ (2.4) = a_0(c_0 e_0) \otimes (f_0 d_0) b_0 \omega(a_1 c_1, f_1 d_1, b_1) \omega(a_2, c_2, b_2) \omega^{-1}(a_3, c_3, d_3, b_4) \]

Apparently this leads nowhere. But let's evaluate also

\[ (a \otimes b)[(c \otimes d)(e \otimes f)] = (a \otimes b)(c_0 e_0 \otimes f_0 d_0) \omega^{-1}(c_1, f_1 d_1) \omega(e_2, f_2 d_2) \]

\[ (2.3) = a_0(c_0 e_0) \otimes (f_0 d_0) b_0 \omega^{-1}(a_1 c_1, f_1 d_1, b_1) \omega(e_2, f_2 d_2) \omega^{-1}(a_3, c_3, d_3, b_4) \]

\[ (2.4) = a_0(c_0 e_0) \otimes (f_0 d_0) b_0 \omega(a_1 c_1, f_1 d_1, b_1) \omega(a_2, c_2, b_2) \omega^{-1}(a_3, c_3, d_3, b_4) \]

\[ (c \otimes d) \in L = a_0(c_0 e_0) \otimes (f_0 d_0) b_0 \omega(a_1 c_1, f_1 d_1, b_1) \omega(a_2, c_2, b_2) \omega^{-1}(a_3, c_3, d_3, b_4) \]

hence we have obtained the same as above. \qed

**Proposition 35.** Let \( H \) be a coquasi-Hopf algebra with bijective antipode and \( A \) a right \( H \)-comodule algebra, left faithfully flat and Galois over \( B = A^{op} \). Then the left \( L \)-module category \( L \mathcal{M} \) is equivalent to the category of two sided \((H, A)\)-Hopf modules \( \mathcal{M}^H_A \) (i.e. \( A \)-bimodules in \( \mathcal{M}^H \)).

**Proof.** Let \( N \) be any left \( L \)-module. By restriction, \( N \) is a left \( B^{op} \)-module, that is, a right \( B \)-module. We can use then the category equivalence \( \mathcal{M}_B \simeq \mathcal{M}_A^H \) from Theorem 28. It follows that \( N \otimes_B A^* \in \mathcal{M}^H_A \). But we still need the left \( A \)-module structure on \( N \otimes_B A^* \). For this, we shall use the inverse of the Galois map with notations from Proposition 23

\[ a \otimes (n \otimes_B b) = \sum_i [a_0 \otimes b_0 \omega(a_1, b_1, \beta(a_2 b_2) S(a_3 b_3)) l_i(a_4 b_4)] n \otimes_B r_i(a_3 b_4) \] (4.2)

for any \( a, b \in A, n \in N \). We should check first if this is well-defined. For this, consider \((A^* \otimes A^*) \otimes_B A \) as a right \( H \)-comodule with coaction on the first component. We can compute

\[ \rho([a_0 \otimes b_0 \omega(a_1, b_1, \beta(a_2 b_2) S(a_3 b_3)) l_i(a_4 b_4)] \otimes_B r_i(a_4 b_4)) = \sum_i [a_0 \otimes b_0 \omega(a_2, b_2, \beta(a_3 b_3) S(a_4 b_4)) l_i(a_5 b_5)] \otimes_B r_i(a_6 b_6) \otimes a_1 [b_1 l_i(a_5 b_5)] \]

\[ (\text{Proposition 23 5.3}), (2.1), (2.6) = \sum_i [a_0 \otimes b_0 \omega(a_1, b_1, \beta(a_2 b_2) S(a_3 b_3)) l_i(a_4 b_4)] \otimes_B r_i(a_4 b_4) \otimes 1_H \]
By the left $B$-flatness of $A$, it follows that
\[
\sum_i [a_0 \otimes b_0 \omega(a_1, b_1, \beta(a_2 b_2)S(a_3 b_3)) l_i(a_4 b_4)] \otimes_B r_i(a_4 b_4) \in (A^* \otimes A^*)^{coH} \otimes_B A
\]

Therefore, relation (4.2) is correct. We still need to check that the formula defines on $N \otimes_B A^*$ an $A$-bimodule structure in $M^H$. The left $A$-multiplication is $H$-colinear and
\[
1_A \otimes (n \otimes_B b) = \sum_i [1_A \otimes b_0 \beta(b_1) | l_i(b_2)] n \otimes_B r_i(b_2)
\]

(Proposition 23(5.4)) = $(1_A \otimes 1_A)n \otimes_B b = n \otimes_B b$

Now we compute
\[
a_0 \otimes (b_0 \otimes (n \otimes_B c_0)) \omega(a_1, b_1, c_1) = \sum_i a_0 \otimes \left[ |b_0 \otimes c_0 \omega(b_1, c_1, \beta(b_2 c_2)S(b_3 c_3))
\right.
\]

l_i(b_4 c_4)] n \otimes_B r_i(b_4 c_4)] \omega(a_1, b_5, c_5)

(Proposition 23(5.1)) = \sum_{i,j} (a_0 \otimes r_i(b_4 c_4) l_j(a_4 (b_8 c_8))) (b_0 \otimes c_0 l_i(b_4 c_4)) n

\otimes_B r_j(a_4 (b_8 c_8)) \omega(b_1, b_5, c_5, S(a_4 (b_7 c_7))
\omega(b_1, c_1, S(b_3 c_3)) \otimes_B (b_2 c_2) \beta(b_2 c_2) \beta(a_2 (b_6 c_6))

(4.1), (Proposition 23(5.1), (5.3)) = \sum_{i,j} \left\{ a_0 b_0 \otimes c_0 l_i(b_8 c_8) | r_i(b_8 c_8) l_j(a_7 (b_16 c_16)) \right\} n

\otimes_B r_j(a_7 (b_16 c_16)) \omega^{-1}(a_1, b_1, c_1 S(b_7 c_7)) (b_3 c_9)
\omega(a_6 (b_15 c_15)) \omega(b_2, c_2 S(b_6 c_6), (b_10 c_10)
\omega(a_5 (b_13 c_13)) \omega(a_2, b_1 c_11, S(a_4 (b_13 c_13))

\omega(b_3, c_3, S(b_5 c_5)) \beta(b_4 c_4) \beta(a_3 (b_12 c_12))

(2.3), (2.1), (2.25) = \sum_{i,j} \left\{ a_0 b_0 \otimes c_0 l_i(b_8 c_8) | r_i(b_8 c_8) l_j(a_8 (b_18 c_18)) \right\} n

\otimes_B r_j(a_8 (b_18 c_18)) \omega^{-1}(a_1, b_1, c_1 S(b_7 c_7)) (b_8 c_9)
\omega(a_7 (b_17 c_17)) \omega(b_2, c_2 S(b_6 c_6), (b_10 c_10)
\omega(a_6 (b_16 c_16)) \omega(b_3, c_3, S(b_5 c_5), (b_11 c_11)

\omega(a_5 (b_15 c_15)) \omega(a_2, b_1 c_12, S(a_4 (b_14 c_14))

(2.3), (2.25), (Proposition 23(5.2), (2.3) = \sum_{i,j} \left\{ a_0 b_0 \otimes c_0 l_j(a_9 (b_17 c_17)) \right\} n \otimes_B r_j(a_9 (b_17 c_17))

\omega^{-1}(a_1, b_1, c_1 S(a_9 (b_16 c_16))
\omega(b_2, c_2, S(a_7 (b_15 c_15))
\omega^{-1}(S(b_6 c_6), b_8 c_8, S(a_6 (b_14 c_14)) \omega(b_3 c_3, S(b_5 c_5),
(b_9 c_9) S(a_5 (b_13 c_13)) \omega(a_2, b_10 c_10, S(a_4 (b_12 c_12))

\beta(b_4 c_4) \beta(a_3 (b_11 c_11))

(2.3), (2.25), (2.0), (2.7) = \sum_{j} \left\{ a_0 b_0 \otimes c_0 l_j(a_7 (b_8 c_8)) \right\} n \otimes_B r_j(a_7 (b_8 c_8))
The counit are easily checked to be morphisms in the restricted categories. Therefore we get the category.

Hence $N \otimes_B A$ is a left $A$-module in $\mathcal{M}^H$. We only have to show the compatibility between the two $A$-module structures:

$$a_0 \circ (n \otimes_B b_0) c_0 \omega(a_1, b_1, c_1) = \sum_{i} [a_0 \otimes (b_0 c_0) l_i] (a_4 b_4 c_4)] n \otimes_B r_i(a_4 (b_4 c_4)) \omega(a_1, b_1, S(a_3 b_3)) \omega(a_5 b_5, c_5) \beta(a_2 b_2 c_2))

$$

Hence $N \otimes_B A \in \mathcal{A} \mathcal{M}^H_A$. It is easy to see that a map $L$-linear $\eta : N_1 \rightarrow N_2$ induces a morphism $\eta \otimes_B I_A$ in $\mathcal{A} \mathcal{M}^H_A$. We get then a functor $F : L \mathcal{M} \rightarrow \mathcal{A} \mathcal{M}^H_A$. For the inverse construction, let $M \in \mathcal{A} \mathcal{M}^H_A$. Then $M^{coH} \in \mathcal{M}_B = B^{coH} \mathcal{M}$. For any $m \in M^{coH}$ and $a \otimes b \in L$, we may define

$$(a \otimes b)m = a(mb) \quad m \in M^{coH} \quad (am)b

$$

Using this multiplication, $M^{coH} \in L \mathcal{M}$ and we have a functor $G : \mathcal{A} \mathcal{M}^H_A \rightarrow L \mathcal{M}$.

Notice that these two functors are obtained simply restricting the ones in Theorem 28. The unit and the counit are easily checked to be morphisms in the restricted categories. Therefore we get the category equivalence $L \mathcal{M} \simeq \mathcal{A} \mathcal{M}^H_A$.

**Corollary 36.** The category $L \mathcal{M}$ is monoidal.

**Proof.** As $\mathcal{A} \mathcal{M}^H_A$ is monoidal with $\otimes_A$ the tensor product over $A$ in the comodule category, it remains only to transport the monoidal structure.
Remark 37. The previous theorem generalizes Schauenburg’s result in the Hopf algebra case [30]. In [31], he gave a categorical proof, using actions of monoidal categories. All his arguments were purely categorical, explaining why Schauenburg’s construction can also be performed for coquasi-Hopf algebras. But in order to avoid long and tedious computations, we preferred the direct approach.

In [30] it was also shown that there is a $\times_B$-bialgebra (in the sense of Takeuchi) structure on $L$, using precisely the monoidal structure given by the above corollary. Let see now that a similar result holds also in the coquasi case. But first we have an inconvenient: we cannot tensor over $A$, as this is not an associative algebra. This can be avoided by considering suitable tensor product, namely in the monoidal category of comodules.

Lemma 38. Let $H$ be a coquasi-bialgebra, $A$ a right $H$-comodule algebra and $B = A^{coH}$. For any right $B$-module $N$ and any left Hopf module $M \in A^{M^H}$, we have $(N \otimes_B A^\bullet) \otimes_A M^\bullet \simeq N \otimes_B M^\bullet$ as comodules, where $\otimes_A$ denotes the tensor product over $A$ in the monoidal category $M^H$, $N \otimes_B A^\bullet$ is the induced right Hopf module and $N \otimes_B M^\bullet$ carries the comodule structure given by that of $M$.

Proof. Recall that the tensor product over $A$ is the equalizer (in the category of right comodules) of the following morphisms $j_1, j_2 : (N \otimes_B A) \otimes M \rightarrow (N \otimes_B A) \otimes M$, where

\[
\begin{align*}
&j_1([(n \otimes_B a) \otimes b] \otimes m) = n \otimes_B ab \otimes m \\
&j_1([(n \otimes_B a) \otimes b] \otimes m) = n \otimes_B a_0 \otimes b_0 m_0 \omega(a_1, b_1, m_1)
\end{align*}
\]

Now define $\varphi : (N \otimes_B A) \otimes M \rightarrow N \otimes_B M$, $\varphi((n \otimes_B a) \otimes m) = n \otimes_B am$. Then $\varphi$ is colinear and $\varphi j_1 = \varphi j_2$. Hence it induces the desired isomorphism.$\square$

Corollary 39. Let $H$ be a coquasi-Hopf algebra with bijective antipode and $A$ a right $H$-comodule algebra, left faithfully flat and Galois over $B = A^{coH}$. Then the equivalence $M_A^{coH} \simeq M_B$ induces a monoidal functor $(-)^{coH} : A^{M^H} \simeq B . M_B$.

Proof. It follows by the previous Lemma and from [30], Lemma 6.1.$\square$

As the monoidal structure of $\mathcal{L} \mathcal{M}$ comes from the one of $A^{M^H}$ and the functorial diagram

\[
\begin{array}{ccc}
A^{M^H} & \mapsto & \mathcal{L} \mathcal{M} \\
(-)^{coH} & & \leftarrow \\
B^{op} \mathcal{M} & \mapsto & \mathcal{U}
\end{array}
\]

commutes, where $\mathcal{U}$ is the forgetful functor, from Corollary 38 it follows that there $\mathcal{U}$ is also monoidal. But according to [30] and [10], a $B \otimes B^{op}$-algebra $L$ such that the forgetful functor $\mathcal{L} \mathcal{M} \rightarrow B . M_B$ is (strictly) monoidal is precisely a $\times_B$-bialgebra (in the sense of Takeuchi) or equivalently, a bialgebroid. Therefore we have obtained a new structure object $L$, whose properties (mainly for the case $B = k$) will make the purpose of an author’s forthcoming paper. Having in mind the Hopf algebra case, where the biGalois extensions and torsors are involved, it is expected that this will clarify more about the connections between various generalizations of Hopf algebras.

Acknowledgement. The author would like to thank Prof. C. Năstăsescu and F. Panaite for their useful comments which improved this paper.
