Abstract

We invoke Carlson's theorem to justify and to confirm the results previously obtained on the validity of Riemann Hypothesis via the coupling constant spectrum of the zero energy S-wave Jost function a la N. N. Khuri, for the real, repulsive inverse-square potential in non-relativistic quantum mechanics in 3 dimensions.

In a previous note (hereinafter referred to as I) [1], we have exhibited the solution for the S-wave Jost function at zero energy (i.e., \( k^2 = 0 \)) for the real, repulsive inverse-square potential, \( V(r) = \frac{\lambda}{r^2} \) (\( \lambda > 0 \)). We then argued that it is justified to identify the S-wave Jost function, \( \mathcal{X}(s) \equiv F_\pm((s(s-1); k^2 = 0) \) with the Riemann \( \xi(s) \) function [2] (up to an entire function of order one, with No zeros) where the coupling constant \( \lambda \) is constrained to satisfy the relation, i.e.,

\[
\lambda = s(s-1)
\]

(1)

The argument hinged on demonstrating that the S-wave Jost function has only zeros on the line \( s_n = \frac{1}{2} + i\gamma_n, n = 1, 2, 3, \ldots \infty \). This was accomplished by first demonstrating that the analogue of Eq. (1.2) of Khuri’s paper [3] (without the presence of the potential \( V(r) \) under the sign of integration), i.e.,

\[
[Im\lambda_n(i\tau)] \int_0^\infty |f(\lambda_n(i\tau); i\tau; r)|^2 dr = 0
\]

(2)
holds, where the all-important constraint, i.e.,
\[ \int_0^\infty |f(\lambda_n(i\tau); i\tau; r)|^2 dr < \infty \] (3)
is satisfied, i.e.,
\[ \left[ \text{Im} \lambda_n(i\tau) \right] \frac{1}{\tau \pi} \int_0^\infty rK_{\nu(i\tau)}^2(r) dr = 0 \] (4)
where
\[ \int_0^\infty rK_{\nu(i\tau)}^2(r) dr = \frac{1}{8} \frac{\pi \nu(i\tau)}{\sin \nu(i\tau)} \] (5)
with \( \nu(i\tau) = \sqrt{\lambda(i\tau) + \frac{1}{4}} \), \( \nu(i\tau) \neq 1, 2, 3, \ldots \infty \). Then, Eq. (3) follows for \( \tau \neq 0 \) (\( \tau > 0 \)).

Thus,
\[ \text{Im} \lambda_n(i\tau) = 0 \] (6)
We then followed Khuri and arrived at the conclusion,
\[ \lambda_n(0) \equiv s_n(s_n - 1) \] (7)
for all \( n \), is real and negative. When \( \lambda_n(0) \), for all \( n \) is real and negative, (and by rescaling such that \( \lambda_n < -\frac{1}{4} \), \( \nu(0) = \sqrt{\lambda_n(0) + \frac{1}{4}} \) becomes imaginary and hence R.H.S. of Eq. (5) will become the ratio of \( \frac{\pi \nu(0)}{\sinh \nu(0)} \), at \( \tau = 0 \). In other words, the zero energy coupling spectrum lies on the negative real line for \( V(r) = \lambda V^*(r) \), \( V(r) = \frac{1}{r^2} \), \( V^* \geq 0 \). In view of Eq. (1), i.e., \( \lambda = s(s - 1) \), one then concluded that \( \lambda(s) \) has all its infinite number of nonzero zeros on the “critical” line, \( \text{Re } s_n = \frac{1}{2} \).

The key question arises whether or not, the positions \( \gamma_n \) of the infinite number of non-zero zeros on the critical line, coincide with the Riemann Hypothesis, i.e.,
\[ s_n = \frac{1}{2} \pm i\gamma_n, \ n = 1, 2, 3 \ldots \infty \]
(Recall that Hardy has proved that \( \xi(s) \) has infinite number of zeros on the critical line.)

In other words, one must demonstrate that the positions of the zeros obtained from the potential, \( V(r) = \frac{1}{r^2} \), i.e.,
\[ s'_n = \frac{1}{2} \pm i\gamma'_n, \ n = 1, 2, 3 \ldots \infty \]
coincide exactly with the positions \((\gamma_n)\) of the Riemann zeros. This was not done in our earlier note! **We propose to demonstrate this here.** Our tool is Carlson’s theorem \([4]\).

Recall,

\[
\mathcal{X}(s') = e^{\pi s'}.
\]

and

\[
\xi(s') = Ce^{A(s'+1)}
\]

for real \(s' \geq 0\), where we are stating the established fact that both \(\mathcal{X}(s)\) and \(\xi(s)\) are **entire** with **No zeros** for real \(s' > 0\).

Then, we invoke Hadamard’s factorization theorem to set

\[
e^{a + \frac{b s'}{m}} \mathcal{X}\left(\frac{s}{m}\right) - \xi\left(\frac{s}{m}\right) = 0, \quad \frac{s}{m} = 1, 2, 3, \ldots
\]

Eq. (10) is satisfied iff

\[
Ce^A = e^a \quad \text{and} \quad A = b + \pi
\]

We now **invoke Carlson’s theorem** \([4]\):

In order that each entire function \(f(z)\) satisfying the conditions

\[
f(z) = 0(1)e^{\alpha |z|}, \quad \text{for some} \ \alpha < \infty
\]

\[
f(iy) = 0(1)e^{\beta |y|}, \quad \text{for some} \ \beta < \pi
\]

\[
f(n) = 0 \quad \text{for each positive integer ‘}n’
\]

then \(f(z) \equiv 0\) !

Thus, we conclude that

\[
e^{a + \frac{b s'}{m}} \mathcal{X}\left(\frac{s}{m}\right) = \xi\left(\frac{s}{m}\right), \quad \text{all} \ s'
\]

Clearly Eq. (10) is satisfied for all \(\frac{s'}{m} > 0\), when Eq. (11) holds. An analytic (entire) function which vanishes in a subdomain of its region of analyticity, **must** necessarily vanish in its “entire” domain of analyticity, i.e., for all \(s'\)! Thus, in a sense, one need not invoke Carlson’s theorem to arrive at Eq. (16)!
It is now obvious that the zeros on the critical line of the zero energy Jost function \( \mathcal{X}(s) \) and the zeros (infinite number, established by G. H. Hardy) of Riemann’s \( \xi(s) \) function must necessarily coincide, i.e.,

\[
\begin{align*}
\frac{1}{2} \pm i\gamma_n &= s_n = \frac{1}{2} \pm i\gamma_n, \quad n = 1, 2, \ldots \infty.
\end{align*}
\]

We can explicitly verify this assertion as follows:

We invoke the Hadamard factorization for every entire function \( g(z) \) of order one and “infinite type” (which guarantees the existance of infinitely many non-zero zeros [valid for all \( z \! |\! 4 \):]

\[
g(z) = z^m e^{B} e^{Dz} \prod_{n=1}^{\infty} \left( 1 - \frac{z}{z_n} \right) \exp \left( \frac{z}{z_n} \right)
\]  

(17)

where ‘\( m \)’ is the multiplicity of the zeros (so that \( m = 0 \) for a simple zero).

We can now apply Eq. (17) to the zero energy Jost function \( \mathcal{X}(s') \) and the Riemann’s \( \xi(s') \) function, assuming, \( s'_n = \frac{1}{2} + i\gamma_n \) for \( \mathcal{X}(s') \) and \( s'_n = \frac{1}{2} + i\gamma_n \) for Riemann’s \( \xi(s') \).

This leads to the equality [Eq. (16)]:

\[
e^{H} e^{L \frac{s'}{m}} \prod_{n=1}^{\infty} \left( 1 - \frac{s'}{ms'_n} \right) \exp \left( \frac{s'}{ms'_n} \right)
= e^{J} e^{K \frac{s}{m}} \prod_{n=1}^{\infty} \left( 1 - \frac{s}{ms_n} \right) \exp \left( \frac{s}{ms_n} \right)
\]

(18)

First set \( s' = 0 \) in Eq. (18):

\[
\Rightarrow \quad H = J
\]

(19)

Next set, \( s' = ms_n, \) \( s_n = \frac{1}{2} + i\gamma_n \)

\[
\Rightarrow \quad e^{Ls_n} \prod_{n=1}^{\infty} \left( 1 - \frac{s_n}{s'_n} \right) \exp \left( \frac{s_n}{s'_n} \right)
= e^{Ks_n} \prod_{n=1}^{\infty} (1 - 1) \exp(1).
\]

(20)

Since RHS of Eq. (20) vanishes, we conclude that \( s_n \) must equal \( s'_n \):

\[
\therefore \gamma_n = \gamma'_n
\]

(21)
This establishes the key result that we set out to prove: The Riemann zeros on the critical line do coincide precisely with the zeros of the zero energy $S$ wave Jost function for $V(r) = \frac{\lambda}{r^2}$ ($\lambda > 0$) [5].

References and Footnotes:

See also, B. Ghusayni, Entire Functions of Order One and Infinite Type (preprint).

[5] We hasten to correct misstatements in Reference 1. The sentence immediately following Eq. (30) must be deleted. Eq. (40) and Eq. (41) must be replaced by

$$\alpha = \ln 2, \quad (40)$$
$$\beta = 0 \quad (41)$$

One arrives at this by setting $\chi(0) = \chi(1) = 1$ and $\xi(0) = \xi(1) = \frac{1}{2}$.
