Abstract

This text is a survey of recent results obtained by the author and collaborators on different problems for non-self-adjoint operators. The topics are: Kramers-Fokker-Planck type operators, spectral asymptotics in two dimensions and Weyl asymptotics for the eigenvalues of non-self-adjoint operators with small random perturbations. In the introduction we also review the notion of pseudo-spectrum and its relation to non-self-adjoint spectral problems.

1 Introduction

1.1 Some background

For self-adjoint and more generally normal operators on some complex Hilbert space $\mathcal{H}$ we have a nice theory, including the spectral theorem and a nice estimate on the norm of the resolvent:

$$\|(z - P)^{-1}\| \leq (\text{dist} (z, \sigma(P)))^{-1}, \quad \sigma(P) = \text{the spectrum of } P. \quad (1.1)$$

This has a consequence for the corresponding evolution problem: If $\sigma(P) \subset \{ z \in \mathbb{C}; \Re z \geq \lambda_0 \}$, then

$$\|e^{-tP}\| \leq e^{-\lambda_0 t}, \quad t \geq 0. \quad (1.2)$$

However, non-normal operators appear frequently: Scattering poles, Convection-diffusion problems, Kramers-Fokker-Planck equation, damped wave equations, linearized operators in fluid dynamics. Then typically, $\|(z - P)^{-1}\|$ may be very large even when $z$ is far from the spectrum. This implies mathematical difficulties:

- When studying the distribution of eigenvalues,
- When studying functions of the operator, like $e^{-tP}$ and its norm.

It also implies numerical difficulties like:

- Eigenvalue instability.

There are (in the author’s opinion) two ways out:

- Change the Hilbert space norm to make the operators look more normal. (Complex scaling methods.)
- Recognize that the region of the $z$-plane where $\|(z - P)^{-1}\|$ is large, has its own interest. (Pseudospectrum.)

The option to choose depends on the problem.
• In some problems, like those related to scattering poles, there is no obvious choice of Hilbert space and we are free to make the most natural one. This option is particularly natural when considering a differential operator with analytic coefficients.

• In other problems the canonical Hilbert space is $L^2$ and we are at most allowed to change the norm into an equivalent one. Here the notion of pseudospectrum is likely to be important.

Let $P : \mathcal{H} \to \mathcal{H}$ be closed, densely defined, $\mathcal{H}$ a complex Hilbert space and let $\rho(P) = \mathbb{C} \setminus \sigma(P)$ denote the resolvent set. The notion of pseudospectrum is important in numerical analysis and we refer to L.N. Trefethen [52], Trefethen–M. Embree [54] and further references given there. Thanks to works of E.B. Davies [5], [7], M. Zworski [57] and others it has become popular in the non-self-adjoint spectral theory of differential operators.

**Definition 1.1** Let $\epsilon > 0$. The $\epsilon$-pseudospectrum of $P$ is

$$\sigma_\epsilon(P) := \sigma(P) \cup \{z \in \rho(P); \|z - P\|^{-1} > 1/\epsilon\}.$$ 

Unlike the spectrum, the pseudospectrum will in general change when we change the norm on $\mathcal{H}$. Moreover, it can be characterized as a set of spectral instability as follows from the following version of a theorem of Roch-Silberman [43]:

**Theorem 1.2**

$$\sigma_\epsilon(P) = \bigcup_{Q \in L(\mathcal{H}, \mathcal{H}) \atop \|Q\|<\epsilon} \sigma(P + Q).$$

In his survey [52] L.N. Trefethen discusses some linearized operators from fluid dynamics:

• Orr-Sommerfeld equation (Orzag, Reddy, Schmid, Hennigson).

• Plane Poiseuille flow (L.N and A.N Trefethen, Schmid).

• Pipe Poiseuille flow (L.N and A.N Trefethen, Reddy, Driscoll),

and to what extent stability can be predicted from the study of the spectrum of these non-self-adjoint operators: Eigenvalue analysis alone leads in some cases to the prediction of stability for Reynolds numbers $R < 5772$. Experimentally however, we have stability only for $R < 1000$.

The rough explanation of this is that the $\epsilon$-pseudospectrum (for a suitable $\epsilon$) crosses the imaginary axis before the spectrum does, when $R$ increases.
Then $\|e^{-tP}\|$ will grow fast for a limited time even though the growth for very large times is determined by the spectrum. However, since $P$ appears as a linearization of a non-linear problem, that suffices to cause instability.

In the case of differential operators the pseudospectral phenomenon is very general and related to classical works in PDE on local solvability and non-hypoellipticity. E.B. Davies [5] studied the non-self-adjoint semiclassical Schrödinger operator with a smooth (complex-valued) potential in dimension 1 and showed under "generic" assumptions that one can construct quasimodes with the spectral parameter varying in an open complex set, containing points that are possibly very far from the spectrum (as can be verified in the case of the complex harmonic oscillator). M. Zworski [57] observed that this is essentially a rediscovery of an old result of Hörmander [32, 33], and was able to generalize considerably Davies’ result by adapting the one of Hörmander to the semi-classical case. With N. Dencker and M. Zworski [9] we also gave a direct proof and a corresponding adaptation of old results of Sato-Kawai-Kashiwara [44] to the analytic case:

**Theorem 1.3** ([57], [9]) Let

$$P(x,hD_x) = \sum_{|\alpha| \leq m} a_\alpha(x)(hD_x)^\alpha, \quad D_x = \frac{\partial}{\partial x}$$

have smooth coefficients in the open set $\Omega \subset \mathbb{R}^n$. Put $p(x,\xi) = \sum_{|\alpha| \leq m} a_\alpha(x)\xi^\alpha$. Assume $z = p(x_0,\xi_0)$ with the Poisson bracket $\{p,\overline{p}\}(x_0,\xi_0) > 0$. Then $\exists u = u_h \in C^\infty_0(\Omega)$, with $\|u\| = 1$, $\|(P - z)u\| = \mathcal{O}(h^\infty)$, when $h \to 0$.

**Analytic case:** Can replace "$h^\infty$" by "$e^{-1/Ch}$".

Here, we have used standard multi-index notation: $\xi^\alpha = \xi_1^{\alpha_1} \cdot \ldots \cdot \xi_n^{\alpha_n}$, $|\alpha| = \alpha_1 + \ldots + \alpha_n$, and the norms $\|\cdot\|$ are the ones of $L^2$ or $\ell^2$ if nothing else is indicated.

This result was subsequently generalized by K. Pravda-Starov, [42]. Notice that this implies that when the theorem applies and if the resolvent $(P - z)^{-1}$ exists then its norm is greater than any negative power of $h$ when $h \to 0$.

**Example 1.4** Let $P = -h^2\Delta + V(x)$, $p(x,\xi) = \xi^2 + V(x)$, $\xi^2 = \xi_1^2 + \ldots + \xi_n^2$. Then $\{p,\overline{p}\} = -4\xi \cdot \Im V'(x)$.

"Generically", if $z = p(x,\xi)$, then $\{p,\overline{p}\}(x,\xi) \neq 0$ and one can show quite generally that if this happens then there is also another point $(y,\eta)$ with $p(y,\eta) = z$ such that $\{p,\overline{p}\}(x,\xi)$ takes the opposite sign. This justifies the following simplified terminology in the semi-classical limit:
The semi-classical pseudospectrum of $P$ is the range $\mathcal{R}(p)$ of $p$.

In [9] we also showed under suitable assumptions (inspired from scattering theory and from the theory of sub-elliptic operators), that there is no spectrum near the boundary of the semi-classical pseudospectrum and that we may have quite a good control of the norm of the resolvent there. Generalizations to the case of systems were given by Dencker [8].

1.2 The topics of this survey

We will discuss three subjects involving non-self-adjoint differential and pseudodifferential operators. We will always work in the semi-classical limit, which means that our operators are of the form $P(x, hD; h)$, where $P$ is a suitable symbol and $0 < h \ll 1$. It is quite clear however that some of our results will also apply to non-semiclassical situations in the limit of large eigenvalues.

The subjects are:

- The Kramers-Fokker-Planck operator,
- Bohr-Sommerfeld rules in dimension 2,
- Weyl asymptotics for non-self-adjoint operators with small random perturbations.

and most of the works discussed are the results of collaborations with A. Melin, M. Hitrik, F. Hérau, C. Stolk, S. Vũ Ngọc and M. Hager.

In the first two topics we exploit the possibility of changing the Hilbert space norm by introducing exponential weights on phase space.

In the case of the Kramers-Fokker-Planck operator, we make no analyticity assumptions and the phase-space weights are correspondingly quite weak. In this case however our operator is a differential one, so we are allowed to apply strong exponential weights depending only on the base variables, and this is important when studying small exponential corrections of the eigenvalues via the so called tunnel effect.

For the Bohr-Sommerfeld rules, we make analyticity assumptions that allow stronger phase space weights. In both cases the effect of the exponential weights is to make the operator under consideration more normal.

In the third topic, we do not use any deformations of the given Hilbert space, but exponential weights play an important role at another level, namely to count zeros of holomorphic functions with exponential growth.

The pseudospectrum will not be discussed explicitly below. In the Kramers-Fokker-Planck case, the problems are located near the boundary of the semi-classical pseudospectrum, and it turns out that we have a very nice control
of the resolvent there. In the 2 dimensional Bohr-Sommerfeld rules, we have stronger exponential weights, reflecting stronger pseudospectral phenomena. Finally in the subject of Weyl asymptotics, we often have strong pseudospectral behaviour for the unperturbed operator. From the proofs it appears that the random perturbations will weaken the pseudospectral behaviour and this might have very interesting consequences for the associated evolution problems. This is still very much an open problem.

2 Kramers-Fokker-Planck type operators, spectrum and return to equilibrium

2.1 Introduction

There has been a renewed interest in the problem of “return to equilibrium” for various 2nd order operators. One example is the Kramers-Fokker-Planck operator:

\[ P = y \cdot h \partial_x - V'(x) \cdot h \partial_y + \frac{\gamma}{2} (-h \partial_y + y) \cdot (h \partial_y + y), \]  

(2.1)

where \( x, y \in \mathbb{R}^n \) correspond respectively to position and speed of the particles and \( h > 0 \) corresponds to temperature. The constant \( \gamma > 0 \) is the friction. (Since we will only discuss \( L^2 \) aspects we here present right away an adapted version of the operator, obtained after conjugation by a Maxwellian factor.)

The associated evolution equation is:

\[ (h \partial_t + P) u(t, x, y) = 0. \]

Problem of return to equilibrium: Study the rate of convergence of \( u(t, x, y) \) to a multiple of the “ground state” \( u_0(x, y) = e^{-(y^2/2 + V(x))}/h \) when \( t \to +\infty \), assuming that \( V(x) \to +\infty \) sufficiently fast when \( x \to \infty \) so that \( u_0 \in L^2(\mathbb{R}^{2n}) \). Notice here that \( P(u_0) = 0 \) and that the vector field part of \( P \) is \( h \) times the Hamilton field of \( y^2/2 + V(x) \), when we identify \( \mathbb{R}^{2n} \) with the cotangent space of \( \mathbb{R}^n \).

A closely related problem is to study the difference between the first eigenvalue (0) and the next one, \( \mu(h) \). (Since our operator is non-self-adjoint, this is only a very approximate formulation however.)

Some contributions: L. Desvillettes–C. Villani [10], J.P. Eckmann–M. Hairer [12], F. Hérau–F. Nier [27], B. Helffer–F. Nier [22], Villani [55]. In the work [27] precise estimates on the exponential rates of return to equilibrium were obtained with methods close to those used in hypoellipticity studies and this work was our starting point. With Hérau and C.Stolk [28] we made a study in
the semi-classical limit and studied small eigenvalues modulo $O(h^\infty)$. More recently with Hérau and M. Hitrik [25] we have made a precise study of the exponential decay of $\mu(h)$ when $V$ has two local minima (and in that case $\mu(h)$ turns out to be real). This involves tunneling, i.e. the study of the exponential decay of eigenfunctions. As an application we have a precise result on the return to equilibrium [26]. This has many similarities with older work on the tunnel effect for Schrödinger operators in the semi-classical limit by B. Helffer–Sjöstrand [23, 24] and B. Simon [45] but for the Kramers-Fokker-Planck operator the problem is richer and more difficult since $P$ is neither elliptic nor self-adjoint. We have used a supersymmetry observation of J.M. Bismut [1] and J. Tailleur–S. Tanase-Nicola–J. Kurchan [51], allowing arguments similar to those for the standard Witten complex [24].

2.2 Statement of the main results

Let $P$ be given by (2.1) where $V \in C^\infty(\mathbb{R}^n;\mathbb{R})$, and

\[ \partial^\alpha V(x) = O(1), \quad |\alpha| \geq 2, \quad (2.2) \]

\[ |\nabla V(x)| \geq 1/C, \quad |x| \geq C, \quad (2.3) \]

\[ V \text{ is a Morse function.} \quad (2.4) \]

We also let $P$ denote the graph closure of $P$ from $\mathcal{S}(\mathbb{R}^{2n})$ which coincides with the maximal extension of $P$ in $L^2$ (see [27, 22, 26]). We have $\Re P \geq 0$ and the spectrum of $P$ is contained in the right half plane. In [28] the spectrum in any strip $0 \leq \Re z \leq Ch$ (and actually in a larger parabolic neighborhood of the imaginary axis, in the spirit of [27]) was determined asymptotically mod ($O(h^\infty)$). It is discrete and contained in a sector $|\Im z| \leq C\Re z + O(h^\infty)$:

**Theorem 2.1** The eigenvalues in the strip $0 \leq \Re z \leq Ch$ are of the form

\[ \lambda_{j,k}(h) \sim h(\mu_{j,k} + h^{1/N_{j,k}}\mu_{j,k,1} + h^{2/N_{j,k}}\mu_{j,k,2} + ..) \quad (2.5) \]

where $\mu_{j,k}$ are the eigenvalues of the quadratic approximation (“non-selfadjoint oscillator”)

\[ y \cdot \partial_x - V''(x_j)x \cdot \partial_y + \frac{\gamma}{2}(-\partial_y + y) \cdot (\partial_y + y), \]

at the points $(x_j,0)$, where $x_j$ are the critical points of $V$. 

7
The $\mu_{j,k}$ are known explicitly and it follows that when $x_j$ is not a local minimum, then $\Re \lambda_{j,k} \geq \frac{h}{C}$ for some $C > 0$. When $x_j$ is a local minimum, then precisely one of the $\lambda_{j,k}$ is $\mathcal{O}(h^{\infty})$ while the others have real part $\geq \frac{h}{C}$. Furthermore, when $V \to +\infty$ as $x \to \infty$, then 0 is a simple eigenvalue. In particular, if $V$ has only one local minimum, then

$$\inf \Re(\sigma(P) \backslash \{0\}) \sim h(\mu_1 + h\mu_2 + \ldots), \quad \mu_1 > 0.$$ (or possibly an expansion in fractional powers) and we obtained a corresponding result for the problem of return to equilibrium. It should be added that when $\mu_{j,k}$ is a simple eigenvalue of the quadratic approximation then $N_{j,k} = 1$ so there are no fractional powers of $h$ in (2.5).

The following is the main new result that we obtained with F. Hérou and M. Hitrik in [25]:

**Theorem 2.2** Assume that $V$ has precisely 3 critical points: 2 local minima, $x_{\pm 1}$ and one “saddle point”, $x_0$ of index 1. Then for $C > 0$ sufficiently large and $h$ sufficiently small, $P$ has precisely 2 eigenvalues in the strip $0 \leq \Re z \leq \frac{h}{C}$, namely 0 and $\mu(h)$, where $\mu(h)$ is real and of the form

$$\mu(h) = h(a_1(h)e^{-2S_1/h} + a_{-1}(h)e^{-2S_{-1}/h}),$$ (2.6)

where $a_j$ are real,

$$a_j(h) \sim a_{j,0} + ha_{j,1} + \ldots, \quad h \to 0, \quad a_{j,0} > 0,$$

$$S_j = V(x_0) - V(x_j).$$

As for the problem of return to equilibrium, we obtained the following result with F. Hérou and M. Hitrik in [26]:

**Theorem 2.3** We make the same assumptions as in Theorem 2.2 and let $\Pi_j$ be the spectral projection associated with the eigenvalue $\mu_j$, $j = 0, 1$, where $\mu_0 = 0$, $\mu_1 = \mu(h)$. Then we have

$$\Pi_j = \mathcal{O}(1) : L^2 \to L^2, \quad h \to 0.$$ (2.7)

We have furthermore, uniformly as $t \geq 0$ and $h \to 0$,

$$e^{-tP/h} = \Pi_0 + e^{-t\mu_1/h}\Pi_1 + \mathcal{O}(1)e^{-t/C}, \quad \text{in } L(L^2, L^2),$$ (2.8)

where $C > 0$ is a constant.

Actually, as we shall see in the outline of the proofs, these results (as well as (2.5)) hold for more general classes of supersymmetric operators.
2.3 A partial generalization of [28]

Consider on $\mathbb{R}^n$ ($2n$ is now replaced by $n$):

$$
P = \sum_{j,k} hD_{x_j}b_{j,k}(x)hD_{x_k} + \frac{1}{2}\sum_j (c_j(x)h\partial_{x_j} + h\partial_{x_j} \circ c_j(x)) + p_0(x)
$$

$$
= P_2 + iP_1 + P_0,
$$

where $b_{j,k}, c_j, p_0$ are real and smooth. The associated symbols are:

$$
p(x, \xi) = p_2(x, \xi) + ip_1(x, \xi) + p_0(x),
$$

$$
p_2 = \sum b_{j,k} \xi_j \xi_k, \quad p_1 = \sum c_j \xi_j.
$$

Assume,

$$
p_2 \geq 0, \quad p_0 \geq 0,
$$

$$
\partial_x^\alpha b_{j,k} = O(1), \quad |\alpha| \geq 0,
$$

$$
\partial_x^\alpha c_j = O(1), \quad |\alpha| \geq 1,
$$

$$
\partial_x^\alpha p_0 = O(1), \quad |\alpha| \geq 2.
$$

Assume that

$$
\{x; p_0(x) = c_1(x) = .. = c_n(x) = 0\}
$$

is finite $= \{x_1, ..., x_N\}$ and put $C = \{\rho_1, ..., \rho_n\}, \rho_j = (x_j, 0)$. Put

$$
\tilde{p}(x, \xi) = \langle \xi \rangle^{-2} p_2(x, \xi) + p_0(x), \quad \langle \xi \rangle = \sqrt{1 + |\xi|^2}
$$

$$
\langle \tilde{p} \rangle_{T_0} = \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} \tilde{p} \circ \exp(tH_{p_1})dt, \quad T_0 > 0 \text{ fixed.}
$$

Here in general we let $H_a = a'_\xi \cdot \frac{\partial}{\partial \xi} - a'_x \cdot \frac{\partial}{\partial x}$ denote the Hamilton field of the $C^1$-function $a = a(x, \xi)$.

Dynamical assumptions: Near each $\rho_j$ we have $\langle \tilde{p} \rangle_{T_0} \sim |\rho - \rho_j|^2$ and in any compact set disjoint from $C$ we have $\langle \tilde{p} \rangle_{T_0} \geq 1/C$. (Near infinity this last assumption has to be modified slightly and we refer to [25] for the details.) The following result from [25] is very close to the main result of [28] and generalizes Theorem 2.1.

**Theorem 2.4** Under the above assumptions, the spectrum of $P$ is discrete in any band $0 \leq \Re z \leq Ch$ and the eigenvalues have asymptotic expansions as in (2.7).
Put
\[ q(x, \xi) = -p(x, i\xi) = p_2(x, \xi) + p_1(x, \xi) - p_0(x). \]

The linearization of the Hamilton field \( H_q \) at \( \rho_j \) (for any fixed \( j \)) has eigenvalues \( \pm \alpha_k, \ k = 1, \ldots, n \) with real part \( \neq 0 \). Let \( \Lambda_+ = \Lambda_{+, j} \) be the unstable manifold through \( \rho_j \) for the \( H_q \)-flow. Then \( \Lambda_+ \) is Lagrangian and of the form \( \xi = \phi_+(x) \) near \( x_j \) (\( \phi_+ = \phi_{+, j} \)), where
\[ \phi_+(x_j) = 0, \quad \phi_+(x_j) = 0, \quad \phi''_+(x_j) > 0. \]

The next result is from [25]:

**Theorem 2.5** Let \( \lambda_{j,k}(h) \) be a simple eigenvalue as in (2.5) and assume there is no other eigenvalue in a disc \( D(\lambda_{j,k}, h/C) \) for some \( C > 0 \). Then, in the \( L^2 \) sense, the corresponding eigenfunction is of the form \( e^{-\frac{1}{h}}(a(x; h) + O(h^\infty)) \) near \( x_j \), where \( a(x; h) \) is smooth in \( x \) with an asymptotic expansion in powers of \( h \). Away from a small neighborhood of \( x_j \) it is exponentially decreasing.

The proof of the first theorem uses microlocal weak exponential estimates, while the one of the last theorem also uses local exponential estimates.

### 2.4 Averaging and exponential weights.

The basic idea of the proof of Theorem 2.4 is taken from [28], but we reworked it in order to allow for non-hypoelliptic operators. We will introduce a weight on \( T^*R^n \) of the form
\[ \psi_\epsilon = -\int J(t)\tilde{p}_\epsilon \exp(tH_{p_1})dt, \quad (2.9) \]
for \( 0 < \epsilon \ll 1 \). Here \( J(t) \) is the odd function given by
\[ J(t) = \begin{cases} 0, & |t| \geq \frac{1}{2}, \\ \frac{1}{2} - t, & 0 < t \leq \frac{1}{2}, \end{cases} \quad (2.10) \]
and we choose \( \tilde{p}_\epsilon(\rho) \) to be equal to \( \tilde{p}(\rho) \) when \( \text{dist}(\rho, C) \leq \epsilon \), and flatten out to \( \epsilon \tilde{p} \) away from a fixed neighborhood of \( C \) in such a way that \( \tilde{p}_\epsilon = O(\epsilon) \). Then
\[ H_{p_1}\psi_\epsilon = (\tilde{p}_\epsilon)_{T_0} - \tilde{p}_\epsilon. \quad (2.11) \]

We let \( \epsilon = Ah \) where \( A \gg 1 \) is independent of \( h \). Then the weight \( \exp(\psi_\epsilon/h) \) is uniformly bounded when \( h \to 0 \). Indeed, \( \psi_\epsilon = O(h) \).

Using Fourier integral operators with complex phase, we can define a Hilbert space of functions that are “microlocally \( O(\exp(\psi_\epsilon/h)) \) in the \( L^2 \)
sense”. The norm is uniformly equivalent to the one of $L^2$, but the natural leading symbol of $P$, acting in the new space, becomes

$$p(\exp(iH_\psi)(\rho)), \rho \in T^*\mathbb{R}^n \quad (2.12)$$

which by Taylor expansion has real part $\approx p_2(\rho) + p_0(\rho) + \langle \tilde{p}_\epsilon \rangle - \tilde{p}_\epsilon$. 

Very roughly, the real part of the new symbol is $\geq \epsilon$ away from $C$ and behaves like $\text{dist}(\rho, C)^2$ in a $\sqrt{\epsilon}$-neighborhood of $C$. This can be used to show that the spectrum of $P$ (viewed as an operator on the weighted space) in a band $0 \leq \Re z < \epsilon/C$ comes from an $\sqrt{\epsilon}$-neighborhood of $C$. In such a neighborhood, we can treat $P$ as an elliptic operator and the spectrum is to leading order determined by the quadratic approximation of the dilated symbol $(2.12)$. This gives Theorem 2.4.

We next turn to the proof of Theorem 2.5 and we work near a point $\rho_j = (x_j, \xi_j) \in C$. Recall that $\Lambda_+: \xi = \phi'_+(x)$ is the unstable manifold for the $H_q$-flow, where $q(x, \xi) = -p(x, i\xi)$. We have $q(x, \phi'_+(x)) = 0$.

In general, if $\psi \in C^\infty$ is real, then $P\psi := e^{\psi/h} \circ P \circ e^{-\psi/h}$ has the symbol $p_\psi(x, \xi) = p_2(x, \xi) - q(x, \psi'(x)) + i(q'_+(x, \psi'(x)) : \xi) \quad (2.13)$

- As long as $q(x, \psi'(x)) \leq 0$, we have $\Re p_\psi \geq 0$ and we may hope to establish good a priori estimates for $P\psi$.

- This is the case for $\psi = 0$ and for $\psi = \phi_+$. Using the convexity of $q(x, \cdot)$, we get suitable weights $\psi$ with $q(x, \psi'(x)) \leq 0$, equal to $\phi_+(x)$ near $x_j$, strictly positive away from $x_j$ and constant outside a neighborhood of that point.

- It follows that the eigenfunction in Theorem 2.5 is (roughly) $O(e^{-\phi_+(x)/h})$ near $x_j$ in the $L^2$ sense.

- On the other hand, we have quasi-modes of the form $a(x; h)e^{-\phi_+(x)/h}$ as in [23].

- Applying the exponentially weighted estimates, indicated above, to the difference of the eigenfunction and the quasi-mode, we then get Theorem 2.5.

2.5 Supersymmetry and the proof of Theorem 2.2

We review the supersymmetry from [1], [51], see also G. Lebeau [36]. Let $A(x) : T_x^*\mathbb{R}^n \rightarrow T_x^*\mathbb{R}^n$ be linear, invertible and smooth in $x$. Then we have the nondegenerate bilinear form

$$\langle u|v\rangle_{A(x)} = \langle \wedge^k A(x)u|v\rangle, \ u, v \in \wedge^k T_x^*\mathbb{R}^n,$$
and we also write \((u|v)_{A(x)} = \langle u|v \rangle_{A(x)}\).

If \(u, v\) are smooth \(k\)-forms with compact support, put
\[
(u|v)_A = \int (u(x)|v(x))_{A(x)} dx.
\]

The formal “adjoint” \(Q^A,*\) of an operator \(Q\) is then given by
\[
(Qu|v)_A = (u|Q^A,*v)_A.
\]

Let \(\phi : \mathbb{R}^n \to \mathbb{R}\) be a smooth Morse function with \(\partial^\alpha \phi\) bounded for \(|\alpha| \geq 2\) and with \(|\nabla \phi| \geq 1/C\) for \(|x| \geq C\). Introduce the Witten-De Rham complex:
\[
d\phi = e^{-\phi/h} \circ h d \circ e^{\phi} = \sum_j (h \partial x_j + \partial x_j \phi) \circ dx_j^\wedge,
\]
where \(d\) denotes exterior differentiation and \(dx_j^\wedge\) left exterior multiplication with \(dx_j\). The corresponding Laplacian is then: \(-\Delta_A = d^A,*d\phi + d\phi d^A,*\). Its restriction to \(q\)-forms will be denoted by \(-\Delta_A^{(q)}\). Notice that:
\[
-\Delta_A^{(0)}(e^{-\phi/h}) = 0.
\]

Write \(A = B + C\) with \(B' = B\), \(C' = -C\). \(-\Delta_A\) is a second order differential operator with scalar principal symbol in the semi-classical sense \((\frac{h}{i} \frac{\partial}{\partial x_j} \mapsto \xi_j)\) of the form:
\[
p(x, \xi) = \sum_{j,k} b_{j,k} (\xi_j \xi_k + \partial_{x_j} \phi \partial_{x_k} \phi) + 2i \sum_{j,k} c_{j,k} \partial_{x_k} \phi \xi_j.
\]

**Example.** Replace \(n\) by \(2n\), \(x\) by \((x, y)\), let
\[
A = \frac{1}{2} \begin{pmatrix} 0 & I \\ -I & \gamma \end{pmatrix}.
\]
Then
\[
-\Delta_A^{(0)} = h(\phi'_y \cdot \partial_{x} - \phi'_x \cdot \partial_{y})
+ \frac{\gamma}{2} \sum_j (-h \partial_{y_j} + \partial_{y_j} \phi)(h \partial_{y_j} + \partial_{y_j} \phi).
\]
When \(\phi = y^2/2 + V(x)\) we recover the KFP operator \((2.1)\).

The results of Subsection 2.3 apply, if we make the additional dynamical assumptions there; \(-\Delta_A^{(q)}\) has an asymptotic eigenvalue \(= o(h)\) associated to
the critical point $x_j$ precisely when the index of $x_j$ is equal to $q$ (as for the Witten complex and analogous complexes in several complex variables). In order to cover the cases $q > 0$ we also assume that

$$A = \text{Const.} \quad (2.14)$$

**The Double well case.** Keep the assumption (2.14). Assume that $\phi$ is a Morse function with $|\nabla \phi| \geq 1/C$ for $|x| \geq C$ such that $-\Delta_A$ satisfies the extra dynamical conditions of Subsection 2.3 and having precisely three critical points, two local minima $U_{\pm 1}$ and a saddle point $U_0$ of index 1.

Then $-\Delta_A^{(0)}$ has precisely 2 eigenvalues: 0, $\mu$ that are $o(h)$ while $-\Delta_A^{(1)}$ has precisely one such eigenvalue: $\mu$. (Here we use as in the study of the Witten complex, that $d\phi$ and $d_A^{*\phi}$ intertwine our Laplacians in degree 0 and 1. The detailed justification is more complicated however.) $e^{-\phi(x)/h}$ is the eigenfunction of $\Delta_A^{(0)}$ corresponding to the eigenvalue 0. Let $S_j = \phi(U_0) - \phi(U_j)$, $j = \pm 1$, and let $D_j$ be the connected component of $\{x \in \mathbb{R}^n; \phi(x) < \phi(U_0)\}$ containing $U_j$ in its interior.

Let $E^{(q)}$ be the corresponding spectral subspaces so that $\dim E^{(0)} = 2$, $\dim E^{(1)} = 1$. Truncated versions of the function $e^{-\phi(x)/h}$ can be used as approximate eigenfunctions, and we can show:

**Proposition 2.6** $E^{(0)}$ has a basis $e_1, e_{-1}$, where

$$e_j = \chi_j(x)e^{-\frac{1}{h}(\phi(x) - \phi(U_j))} + O(e^{-\frac{1}{h}(S_j - \epsilon)}), \text{ in the } L^2\text{-sense.}$$

Here, we let $\chi_j \in C_0^\infty(D_j)$ be equal to 1 on $\{x \in D_j; \phi(x) < \phi(U_0) - \epsilon\}$.

The theorems 2.4, 2.5 can be adapted to $-\Delta_A^{(1)}$ and lead to:

**Proposition 2.7** $E^{(1)} = Ce_0$, where

$$e_0(x) = \chi_0(x)a_0(x; h)e^{-\frac{1}{h}\phi_+(x)} + O(e^{-\epsilon_0/h}),$$

$\phi_+(x) \sim (x - U_0)^2$, $\epsilon_0 > 0$ is small enough, $a_0$ is an elliptic symbol, $\chi_0 \in C_0^\infty(\mathbb{R}^n)$, $\chi_0 = 1$ near $U_0$.

Let the matrices of $d\phi : E^{(0)} \to E^{(1)}$ and $d_A^{*\phi} : E^{(1)} \to E^{(0)}$ with respect to the bases $\{e_{-1}, e_1\}$ and $\{e_0\}$ be

$$\begin{pmatrix} \lambda_{-1} & \lambda_1 \\ \lambda_1^* & \lambda_{-1}^* \end{pmatrix} \text{ and } \begin{pmatrix} \lambda_{-1}^* & \lambda_1 \\ \lambda_1 & \lambda_{-1} \end{pmatrix} \text{ respectively.}$$

Using the preceding two results in the spirit of tunneling estimates and computations of Helffer–Sjöstrand ([23] [24]) we can show:
Proposition 2.8 Put $S_j = \phi(U_0) - \phi(U_j)$, $j = \pm 1$. Then we have
\[
\left( \begin{array}{c} \lambda_{-1} \\ \lambda_1 \end{array} \right) = h^{\frac{1}{2}}(I + O(e^{-\frac{1}{4n}})) \left( \begin{array}{c} \ell_{-1}(h)e^{-S_{-1}/h} \\ \ell_1(h)e^{-S_{1}/h} \end{array} \right),
\]
\[
\left( \begin{array}{c} \lambda^*_{-1} \\ \lambda^*_1 \end{array} \right) = h^{\frac{1}{2}}(I + O(e^{-\frac{1}{4n}})) \left( \begin{array}{c} \ell^*_{-1}(h)e^{-S_{-1}/h} \\ \ell^*_1(h)e^{-S_{1}/h} \end{array} \right),
\]
where $\ell_{\pm 1}$, $\ell^*_{\pm 1}$ are real elliptic symbols of order 0 such that $\ell_j \ell_j^* > 0$, $j = \pm 1$.

From this we get Theorem 2.3 since $\mu = \lambda^*_{-1}\lambda_{-1} + \lambda^*_1\lambda_1$. \[\square\]

Thanks to the fact that we have only two local minima, certain simplifications were possible in the proof. In particular it was sufficient to control the exponential decay of general eigenfunctions in some small neighborhood of the critical points. For more general configurations, it might be necessary to get such a control also further away and this seems to lead to interesting questions, involving degenerate and non-symmetric Finsler distances.

2.6 Return to equilibrium, ideas of the proof of Theorem 2.3

Keeping the same assumptions, let $\Pi_0$, $\Pi_1$ be the rank 1 spectral projections corresponding to the eigenvalues $\mu_0 := 0$, $\mu_1 := \mu$ of $-\Delta_\lambda^{(0)}$ and put $\Pi = \Pi_0 + \Pi_1$. Then $e_{-1}, e_1$ is a basis for $R(\Pi)$ and the restriction of $P$ to this range, has the matrix
\[
\left( \begin{array}{c} \lambda^*_{-1} \\ \lambda^*_1 \end{array} \right) \left( \begin{array}{cc} \lambda_{-1} & \lambda_1 \end{array} \right) = \left( \begin{array}{cc} \lambda^*_{-1}\lambda_{-1} & \lambda^*_{-1}\lambda_1 \\ \lambda^*_1\lambda^{-1}_{-1} & \lambda^*_1\lambda_1 \end{array} \right)
\]
with the eigenvalues 0 and $\mu = \lambda^*_{-1}\lambda_{-1} + \lambda^*_1\lambda_1$. A corresponding basis of eigenvectors is given by
\[
v_0 = \frac{1}{\sqrt{\mu_1}}(\lambda_1e_{-1} - \lambda_{-1}e_{-1}) \quad (2.16)
\]
\[
v_1 = \frac{1}{\sqrt{\mu_1}}(\lambda^*_{-1}e_{-1} + \lambda^*_1e_{-1}).
\]

The corresponding dual basis of eigenfunctions of $P^*$ is given by
\[
v^*_0 = \frac{1}{\sqrt{\mu}}(\lambda^*_1e^*_{-1} - \lambda^*_{-1}e^*_{-1}) \quad (2.17)
\]
\[
v^*_1 = \frac{1}{\sqrt{\mu}}(\lambda_{-1}e^*_{-1} + \lambda_1e^*_1),
\]

14
where \( e^*_1, e^*_1 \in \mathcal{R}(\Pi^*) \) is the basis that is dual to \( e_{-1}, e_1 \). It follows that \( v_j, v^*_j = O(1) \) in \( L^2 \), when \( h \to 0 \).

From this discussion we conclude that \( \Pi_j = (v^*_j v_j) \), are uniformly bounded when \( h \to 0 \). A non-trivial fact, based on the analysis described in Subsections 2.3, 2.4, is that after replacing the standard norm and scalar product on \( L^2 \) by certain uniformly equivalent ones, we have

\[
\Re(Pu|u) \geq \frac{h}{C} \|u\|^2, \quad \forall u \in \mathcal{R}(1 - \tilde{\Pi}),
\]

(2.18)

where \( \tilde{\Pi} \) is the spectral projection corresponding to the spectrum of \( P \) in \( D(0, Bh) \) for some \( B \gg 1 \).

This can be applied to the study of \( u(t) := e^{-tP/h}u(0) \), where the initial state \( u(0) \in L^2 \) is arbitrary: Write

\[
u(0) = \Pi_0 u(0) + \Pi_1 u(0) + (1 - \Pi)u(0) =: u^0 + u^1 + u^\perp.
\]

(2.19)

Then

\[
\|u^0\|, \|u^1\|, \|u^\perp\| \leq \mathcal{O}(1)\|u(0)\| \quad (2.20)
\]

\[
\|e^{-tP/h}u^\perp\| \leq Ce^{-t/C}\|u(0)\| \quad (2.21)
\]

\[
e^{-tP/h}u_j = e^{-t\mu_j/h}u_j, \quad j = 0, 1.
\]

(2.22)

Here (2.21) follows if we write \( u^\perp = (1 - \tilde{\Pi})u + (\Pi - \tilde{\Pi})u \), apply (2.18) to the evolution of the first term, and use that the last term is the (bounded) spectral projection of \( u \) to a finite dimensional spectral subspace of \( P \), for which the corresponding eigenvalues all have real part \( \geq h/C \).

\[\square\]

3 Spectral asymptotics in 2 dimensions

3.1 Introduction

This section is mainly based on recent joint works with S. Vũ Ngọc and M. Hitrik [29, 30], but we shall start by recalling some earlier results that we obtained with A. Melin [40] where we discovered that in the two dimensional case one often can have Bohr-Sommerfeld conditions to determine all the individual eigenvalues in some region of the spectral plane, provided that we have analyticity. This was first a surprise for us since in the self-adjoint case such results are known only in 1 dimension and in very special cases for higher dimensions.

Subsequently, with M. Hitrik we have studied small perturbations of self-adjoint operators. First we studied the case when the classical flow of the
unperturbed operator is periodic, then also with S. Vũ Ngọc we looked at the
more general case when it is completely integrable, or just when the energy
surface contains some invariant diophantine Lagrangian tori.

3.2 Bohr-Sommerfeld rules in two dimensions

For (pseudo-)differential operators in dimension 1, we often have a Bohr-
Sommerfeld rule to determine the asymptotic behaviour of the eigenvalues.
Consider for instance the semi-classical Schrödinger operator

\[ P = -\hbar^2 \frac{d^2}{dx^2} + V(x), \]

with symbol \( p(x, \xi) = \xi^2 + V(x) \),

where we assume that \( V \in C^\infty(\mathbb{R}; \mathbb{R}) \) and \( V(x) \to +\infty, |x| \to \infty \). Let \( E_0 \in \mathbb{R} \) be a non-critical value of \( V \) such that (for simplicity) \( \{ x \in \mathbb{R}; V(x) \leq E_0 \} \) is an interval. Then in some small fixed neighborhood of \( E_0 \) and for \( h > 0 \) small enough, the eigenvalues of \( P \) are of the form \( E = E_k, k \in \mathbb{Z}, \)

\[ \frac{I(E)}{2\pi \hbar} = k - \theta(E; h), \quad I(E) = \int_{p^{-1}(E)} \xi \cdot dx, \quad \theta(E; h) \sim \theta_0(E) + \theta_1(E) h + ... \]

In the non-self-adjoint case we get the same results, provided that \( \Im V \) is
small and \( V \) is analytic. The eigenvalues will then be on a curve close to the
real axis.

For self-adjoint operators in dimension \( \geq 2 \) it is generally admitted that
Bohr-Sommerfeld rules do not give all eigenvalues in any fixed domain except
in certain (completely integrable) cases. Using the KAM theorem one can
sometimes describe some fraction of the eigenvalues.

With A. Melin we considered an \( h \)-pseudodifferential operator with
leading symbol \( p(x, \xi) \) that is bounded and holomorphic in a tubular neigh-
borhood of \( \mathbb{R}^4 \) in \( C^4 = C^2_x \times C^2_\xi \). Assume that

\[ \mathbb{R}^4 \cap p^{-1}(0) \neq \emptyset \text{ is connected.} \quad (3.1) \]

On \( \mathbb{R}^4 \) we have \( |p(x, \xi)| \geq 1/C, \) for \( |(x, \xi)| \geq C, \)

(3.2)

for some \( C > 0, \)

\[ d\Re p(x, \xi), d\Im p(x, \xi) \text{ are linearly independent for all } (x, \xi) \in p^{-1}(0) \cap \mathbb{R}^4. \quad (3.3) \]

(Here the boundedness assumption near \( \infty \) and \( (3.2) \) can be replaced by a
suitable ellipticity assumption.) It follows that \( p^{-1}(0) \cap \mathbb{R}^4 \) is a compact
(2-dimensional) surface.
Also assume that
\[ |\{\Re p, \Im p\}| \text{ is sufficiently small on } p^{-1}(0) \cap \mathbb{R}^4. \quad (3.4) \]
Here “sufficiently small” refers to some positive bound that can be defined whenever the other conditions are satisfied uniformly.

When the Poisson bracket vanishes on \( p^{-1}(0) \), this set becomes a Lagrangian torus, and more generally it is a torus. The following is a complex version of the KAM theorem without small divisors (cf T.W. Cherry [3](1928), J. Moser [41](1958)),

**Theorem 3.1** ([40]) There exists a smooth 2-dimensional torus \( \Gamma \subset p^{-1}(0) \cap \mathbb{C}^4 \), close to \( p^{-1}(0) \cap \mathbb{R}^4 \) such that \( \sigma|\Gamma = 0 \) and \( I_j(\Gamma) \in \mathbb{R}, j = 1, 2 \). Here \( I_j(\Gamma) := \int_{\gamma_j} \xi \cdot dx \) are the actions along the two fundamental cycles \( \gamma_1, \gamma_2 \subset \Gamma \), and \( \sigma = \sum_{j=1}^{2} d\xi_j \wedge dx_j \) is the complex symplectic \((2,0)\)-form.

Replacing \( p \) by \( p - z \) for \( z \) in a neighborhood of \( 0 \in \mathbb{C} \), we get tori \( \Gamma(z) \) depending smoothly on \( z \) and a corresponding smooth action function \( I(z) = (I_1(\Gamma(z)), I_2(\Gamma(z))) \), which are important in the Bohr-Sommerfeld rule for the eigen-values near \( 0 \) in the semi-classical limit \( h \to 0 \):

**Theorem 3.2** ([40]) Under the above assumptions, there exists \( \theta_0 \in (\frac{1}{2}\mathbb{Z})^2 \) and \( \theta(z; h) \sim \theta_0 + \theta_1(z)h + \theta_2(z)h^2 + .. \) in \( C^\infty(\text{neigh}(0, \mathbb{C})) \), such that for \( z \) in an \( h \)-independent neighborhood of \( 0 \) and for \( h > 0 \) sufficiently small, we have that \( z \) is an eigenvalue of \( P = p(x, hD_x) \) iff

\[
\frac{I(z)}{2\pi h} = k - \theta(z; h), \text{ for some } k \in \mathbb{Z}^2. \quad (BS)
\]

Recently, a similar result was obtained by S. Graffi, C. Villegas Bas [13].

An application of this result is that we get all resonances (scattering poles) in a fixed neighborhood of \( 0 \in \mathbb{C} \) for \( -h^2\Delta + V(x) \) if \( V \) is an analytic real potential on \( \mathbb{R}^2 \) with a nondegenerate saddle point at \( x = 0 \), satisfying \( V(0) = 0 \) and having \( \{(x, \xi) = (0, 0)\} \) as its classically trapped set in the energy surface \( \{p(x, \xi) = 0\} \).

### 3.3 Diophantine case

In this and the next subsection we describe a result from [30] and the main result of [29] about individual eigenvalues for small perturbations of a self-adjoint operator with a completely integrable leading symbol. We start with the case when only Diophantine tori play a role.
Let $P_\epsilon(x, hD; h)$ on $\mathbb{R}^2$ have the leading symbol $p_\epsilon(x, \xi) = p(x, \xi) + i\epsilon q(x, \xi)$ where $p, q$ are real and extend to bounded holomorphic functions on a tubular neighborhood of $\mathbb{R}^4$. Assume that $p$ fulfills the ellipticity condition near infinity and that

$$P_{\epsilon=0} = P(x, hD)$$

(3.5)

is self-adjoint. (The conditions near infinity can be modified and we can also replace $\mathbb{R}^2$ by a compact 2-dimensional analytic manifold.)

Also, assume that $P_\epsilon(x, \xi; h)$ depends smoothly on $0 \leq \epsilon \leq \epsilon_0$ with values in the space of bounded holomorphic functions in a tubular neighborhood of $\mathbb{R}^4$, and $P_\epsilon \sim p_\epsilon + h p_{1,\epsilon} + h^2 p_{2,\epsilon} + \ldots$, when $h \to 0$.

Assume

$$p^{-1}(0)$$

is connected and $dp \neq 0$ on that set. (3.6)

Assume complete integrability for $p$: There exists an analytic real valued function $f$ on $T^*\mathbb{R}^2$ such that $H_p f = 0$, with the differentials $df$ and $dp$ being linearly independent almost everywhere on $p^{-1}(0)$. ($H_p = p'_\xi \cdot \frac{\partial}{\partial \xi} - p'_x \cdot \frac{\partial}{\partial x}$ is the Hamilton field.)

Then we have a disjoint union decomposition

$$p^{-1}(0) \cap T^*\mathbb{R}^2 = \bigcup_{\Lambda \in J} \Lambda,$$

(3.7)

where $\Lambda$ are compact connected sets, invariant under the $H_p$ flow. We assume (for simplicity) that $J$ has a natural structure of a graph whose edges correspond to families of regular leaves; Lagrangian tori (by the Arnold-Mineur-Liouville theorem). The union of edges $J \setminus S$ possesses a natural real analytic structure.

Each torus $\Lambda \in J \setminus S$ carries real analytic coordinates $x_1, x_2$ identifying $\Lambda$ with $\mathbb{T}^2 = \mathbb{R}^2/2\pi\mathbb{Z}^2$, so that along $\Lambda$, we have

$$H_p = a_1 \frac{\partial}{\partial x_1} + a_2 \frac{\partial}{\partial x_2},$$

(3.8)

where $a_1, a_2 \in \mathbb{R}$. The rotation number is defined as the ratio $\omega(\Lambda) = [a_1 : a_2] \in \mathbb{RP}^1$, and it depends analytically on $\Lambda \in J \setminus S$. We assume that $\omega(\Lambda)$ is not identically constant on any open edge.

We say that $\Lambda \in J \setminus S$ is respectively rational, irrational, diophantine if $a_1/a_2$ has the corresponding property. Diophantine means that there exist $\alpha > 0$, $d > 0$ such that

$$|\langle a_1, a_2 \rangle \cdot k| \geq \frac{\alpha}{|k|^{2+d}},$$

(9.3)

$0 \neq k \in \mathbb{Z}^2$,
We introduce
\[ \langle q \rangle_T = \frac{1}{T} \int_{-T/2}^{T/2} q \circ \exp(tH_p)dt, \quad T > 0, \] (3.10)
and consider the compact intervals \( Q_\infty(\Lambda) \subset \mathbb{R}, \Lambda \in J, \) defined by,
\[ Q_\infty(\Lambda) = [\lim_{T \to \infty} \inf_{\Lambda} \langle q \rangle_T, \lim_{T \to \infty} \sup_{\Lambda} \langle q \rangle_T]. \] (3.11)

A first localization of the spectrum \( \sigma(P_\epsilon(x, hD_x; h)) \) is given by
\[ \Im(\sigma(P_\epsilon) \cap \{ z; |\Re z| \leq \delta \}) \subset \epsilon[\inf_{\Lambda \in J} \bigcup_{\Lambda \in J} Q_{\infty}(\Lambda) - o(1), \sup_{\Lambda \in J} \bigcup_{\Lambda \in J} Q_{\infty}(\Lambda) + o(1)], \] (3.12)
when \( \delta, \epsilon, h \to 0. \)

For each torus \( \Lambda \in J \setminus S, \) we let \( \langle q \rangle(\Lambda) \) be the average of \( q|_\Lambda \) with respect to the natural smooth measure on \( \Lambda, \) and assume that the analytic function \( J \setminus S \ni \Lambda \mapsto \langle q \rangle(\Lambda) \) is not identically constant on any open edge.

By combining (3.8) with the Fourier series representation of \( q, \) we see that when \( \Lambda \) is irrational then \( Q_\infty(\Lambda) = \{ \langle q \rangle(\Lambda) \}, \) while in the rational case,
\[ Q_\infty(\Lambda) \subset \{ \langle q \rangle(\Lambda) \} + O\left(\frac{1}{(|n| + |m|)^\infty}\right)[-1, 1], \] (3.13)
when \( \omega(\Lambda) = \frac{m}{n} \) and \( m \in \mathbb{Z}, n \in \mathbb{N} \) are relatively prime.

Let \( F_0 \in \bigcup_{\Lambda \in J} Q_{\infty}(\Lambda) \) and assume that there exists a Diophantine torus \( \Lambda_d \) (or finitely many), such that
\[ \langle q \rangle(\Lambda_d) = F_0, \quad d_\Lambda \langle q \rangle(\Lambda_d) \neq 0. \] (3.14)

With M. Hitrik and S. Vũ Ngọc we obtained:

**Theorem 3.3 (30)** Assume also that \( F_0 \) does not belong to \( Q_{\infty}(\Lambda) \) for any other \( \Lambda \in J. \) Let \( 0 < \delta < K < \infty. \) Then \( \exists C > 0 \) such that for \( h > 0 \) small enough, and \( k^K \leq \epsilon \leq h^\delta, \) the eigenvalues of \( P_\epsilon \) in the rectangle \( |\Re z| < h^\delta/C, \ |\Im z - \epsilon \Re F_0| < \epsilon h^\delta/C \) are given by
\[ P^{(\infty)}(h(k - \frac{k_0}{4}) - \frac{S}{2\pi}, \epsilon; h) + O(h^\infty), \quad k \in \mathbb{Z}^2, \]

Here \( P^{(\infty)}(\xi, \epsilon; h) \) is smooth, real-valued for \( \epsilon = 0 \) and when \( h \to 0 \) we have
\[ P^{(\infty)}(\xi, \epsilon; h) \sim \sum_{\ell=0}^{\infty} h^{\ell} P^{(\infty)}(\xi, \epsilon), \quad P_0^{(\infty)} = p_\infty(\xi) + i\epsilon \langle q \rangle(\xi) + O(\epsilon^2), \] (3.15)
corresponding to action angle coordinates.
In [30] we also considered applications to small non-self-adjoint perturbations of the Laplacian on a surface of revolution. Thanks to (3.13) the total measure of the union of all $Q_\infty(\Lambda)$ over the rational tori is finite and sometimes small, and we could then show that there are plenty of values $F_0$, fulfilling the assumptions in the theorem.

### 3.4 The case with rational tori

Let $F_0$ be as in (3.14) but now also allow for the possibility that there is a rational torus (or finitely many) $\Lambda_r$, such that

$$F_0 \in Q_\infty(\Lambda_r), \quad F_0 \neq \langle q \rangle(\Lambda_r),$$

$$d_\Lambda(\langle q \rangle)(\Lambda_r) \neq 0, \quad d_\Lambda(\omega)(\Lambda_r) \neq 0.$$  

(3.16)

Assume also that

$$F_0 \notin Q_\infty(\Lambda), \text{ for all } \Lambda \in J \setminus \{\Lambda_d, \Lambda_r\}.$$  

(3.18)

With M. Hitrik we showed the following result:

**Theorem 3.4** ([30]) Let $\delta > 0$ be small and assume that $h \ll \epsilon \leq h^{\frac{4}{3}+\delta}$, or that the subprincipal symbol of $P$ vanishes and that $h^2 \ll \epsilon \leq h^{\frac{4}{3}+\delta}$. Then the spectrum of $P_\epsilon$ in the rectangle

$$\left[-\frac{\epsilon}{C}, \frac{\epsilon}{C}\right] + i\epsilon\left[F_0 - \frac{\epsilon^\delta}{C}, F_0 + \frac{\epsilon^\delta}{C}\right]$$

is the union of two sets: $E_d \cup E_r$, where the elements of $E_d$ form a distorted lattice, given by the Bohr-Sommerfeld rule (3.15), with horizontal spacing $\asymp h$ and vertical spacing $\asymp \epsilon h$. The number of elements $#(E_r)$ of $E_r$ is $\mathcal{O}(\epsilon^{3/2}/h^2)$.

NB that $#(E_d) \asymp \epsilon^{1+\delta}/h^2$.

This result can be applied to the damped wave equation on surfaces of revolution.

### 3.5 Outline of the proofs of Theorem 3.3 and 3.4

The principal symbol of $P_\epsilon$ is $p_\epsilon = p + i\epsilon q + \mathcal{O}(\epsilon^2)$. Put

$$\langle q \rangle_T = \frac{1}{T} \int_{-T/2}^{T/2} q \circ \exp(tH_p)dt.$$
As in Section 2 we will use an averaging of the imaginary part of the symbol. Let \( J(t) \) be the piecewise affine function with support in \([-\frac{1}{2}, \frac{1}{2}]\), solving
\[
J'(t) = \delta(t) - 1_{[-\frac{1}{2}, \frac{1}{2}]}(t),
\]
and introduce the weight
\[
G_T(t) = \int J(-\frac{t}{T}) q \circ \exp(t H_p) dt.
\]
Then \( H_p G_T = q - \langle q \rangle_T \), implying
\[
p \circ \exp(i \epsilon H_{G_T}) = p + i \epsilon \langle q \rangle_T + O_T(\epsilon^2).
\]
(3.19)

The left hand side of (3.19) is the principal symbol of the isospectral operator \( e^{-i \epsilon H_G(x, \partial_x)} \circ P_\epsilon \circ e^{-i \epsilon H_G(x, \partial_x)} \) and under the assumptions of Theorem 3.3 resp. 3.4 its imaginary part will not take the value \( i \epsilon F_0 \) on \( p^{-1}(0) \) away from \( \Lambda_d \) resp. \( \Lambda_d \cup \Lambda_r \). This means that we have localized the spectral problem to a neighborhood of \( \Lambda_d \) resp. \( \Lambda_d \cup \Lambda_r \).

Near \( \Lambda_d \) we choose action-angle coordinates so that \( \Lambda_d \) becomes the zero section in the cotangent space of the 2-torus, and
\[
p_\epsilon(x, \xi) = p(\xi) + i \epsilon q(x, \xi) + O(\epsilon^2).
\]
(3.20)

We follow the quantized Birkhoff normal form procedure in the spirit of V.F. Lazutkin and Y. Colin de Verdière [35, 4]: solve first
\[
H_p G = q(x, \xi) - \langle q(\cdot, \xi) \rangle,
\]
(3.21)

where the bracket indicates that we take the average over the torus with respect to \( x \). Composing with the corresponding complex canonical transformation, we get the new conjugated symbol
\[
p(\xi) + i \epsilon \langle q(\cdot, \xi) \rangle + O(\epsilon^2 + \xi^\infty).
\]

Here the Diophanticity condition is of course important.

Iterating the procedure we get for every \( N \),
\[
p_\epsilon \circ \exp(H_{G(\cdot)}^{(N)}) = p(\xi) + i \epsilon \langle q(\xi) + O(\epsilon, \xi) \rangle + O((\xi, \epsilon)^{N+1})
\]
independent of \( x \).

This procedure can be continued on the operator level, and up to a small error we see that \( P_\epsilon \) is microlocally equivalent to an operator \( P_\epsilon(hD_\xi, \epsilon; h) \). At least formally, Theorem 3.3 then follows by considering Fourier series expansions,
but in order to get a full proof we also have take into account that we have constructed complex canonical transformations that are quantized by Fourier integral operators with complex phase and study the action of these operators on suitable exponentially weighted spaces.

Near $\Lambda_r$ we can still use action-angle coordinates as in (3.20) but the homological equation (3.21) is no longer solvable. Instead, we use secular perturbation theory (cf the book [37]), which amounts to making a partial Birkhoff reduction.

After a linear change of $x$-variables, we may assume that $p(\xi) = \xi_2 + O(\xi^2)$ and in order to fix the ideas $= \xi_2 + \xi_1^2$. Then we can make the averaging procedure only in the $x_2$-direction and reduce $p_{\epsilon}$ in (3.20) to

$$\tilde{p}_{\epsilon}(x, \xi) = \xi_2 + \xi_1^2 + O(\epsilon) + O((\epsilon, \xi)\infty),$$

where $\langle q \rangle_2(x_1, \xi)$ denotes the average with respect to $x_2$.

Carrying out the reduction on the operator level, we obtain up to small errors an operator $\tilde{P}_{\epsilon}(x_1, hD_{x_1}, hD_{x_2}; h)$ and after passing to Fourier series in $x_2$, a family of non-self-adjoint operators on $S^1_{x_1}$: $\tilde{P}_{\epsilon}(x_1, hD_{x_1}, hk; h), k \in \mathbb{Z}$.

The non-self-adjointness and the corresponding possible wild growth of the resolvent makes it hard to go all the way to study individual eigenvalues. However, it can be shown that in the region $|\xi_1| \gg \epsilon^{1/2}$ (inside the energy surface $p = 0$) we can go further and (as near $\Lambda_d$) get a sufficiently good elimination of the $x$-dependence. This leads to the conclusion that the contributions from a vicinity of $\Lambda_r$ to the spectrum of $P_{\epsilon}$ in the rectangle

$$|\Re z| \leq \frac{\epsilon}{C}, \quad |\Im z - \epsilon F_0| \leq \frac{\epsilon^{1+\delta}}{C},$$

come from a neighborhood of $\Lambda_r$ of phase space volume $O(\epsilon^{3/2})$.

This explains heuristically why the rational torus will contribute with $O(\epsilon^{3/2}/h^2)$ eigenvalues in the rectangle.

The actual proof is more complicated. We use a Grushin problem reduction in order to reduce the study near $\Lambda_r$ to that of a square matrix of size $O(\epsilon^{3/2}/h^2)$. However, even if we avoid the eigenvalues of such a matrix, the inverse can only be bounded by

$$\exp O(\epsilon^{3/2}/h^2).$$

What saves us is that away from $\Lambda_r \cup \Lambda_d$, we can conjugate the operator with exponential weights and show that the resolvent has an “off-diagonal decay”
like $\exp(-1/(Ch))$. This implies that we can confine the growth in (3.22) to a small neighborhood of $\Lambda_r$, if

$$\frac{1}{Ch} \gg \frac{\epsilon^3}{h^2},$$

leading to the assumption $\epsilon \ll h^{2/3}$ in Theorem 3.4.

4 Weyl asymptotics for non-self-adjoint operators

4.1 Introduction

For self-adjoint differential (pseudo)differential operators we have (under suitable assumptions) the Weyl law for the asymptotic distribution of eigenvalues, established in higher dimensions by H. Weyl [56] in 1912 in the case of second order elliptic boundary value problems.

In the semiclassical setting such results were obtained by J. Chazarain, B. Helffer–D. Robert, V. Ivrii and many others (see [11] and further references there). Under suitable additional assumptions it states that if $P = P^a(x, hD_x; h)$ is a self-adjoint $h$-pseudodifferential operator with leading (real) symbol $p(x, \xi)$, then if $\Omega \subset \mathbb{C}$ is a domain intersecting $\mathbb{R}$ along a bounded interval, the number of eigenvalues of $P$ in $\Omega$ (intersected with $\mathbb{R}$) satisfies

$$\#(\sigma(P) \cap \Omega) = \frac{1}{(2\pi h)^n}(\text{vol}(p^{-1}(\Omega)) + o(1)), \ h \to 0.$$

A simple example is provided by the semiclassical harmonic oscillator

$$\frac{1}{2}((hD_x)^2 + x^2)$$
on the real line which has the eigenvalues $(k + \frac{1}{2})h$, $k = 0, 1, ...$

In the non-self-adjoint case Weyl-asymptotics is known to hold in some cases close to the self-adjoint case or for normal operators.

We do not always have Weyl-asymptotics: Following Davies and Boul- ton (see [1]), we can consider the non-self-adjoint harmonic operator: $P = \frac{1}{2}((hD_x)^2 + ix^2)$ whose eigenvalues are given by $e^{i\pi/4}(k + \frac{1}{2})h$, $k \in \mathbb{N}$ ([16]):

The set of values of $p = \frac{1}{2}(\xi^2 + ix^2)$ is the closed first quadrant and if we choose the open bounded set $\Omega$ to intersect the 1st quadrant but not the line $\Im z = \Re z$, we get $\text{vol}(p^{-1}(\Omega)) > 0$, while there are no eigenvalues in $\Omega$.

More generally, $h$-differential operators with analytic coefficients often have their spectrum determined by complex-geometric quantities, and are likely not to obey the Weyl law. In particular, in the one dimensional case it often happens that the eigenvalues are concentrated to certain curves with branch points.
As we have seen in Theorem 1.3, we are often confronted with the pseudospectral phenomenon: On the image of $p$ the resolvent may be very large even far from the spectrum. This causes the eigenvalues to be very sensitive to small perturbations of the operator (by Theorem 1.2).

In her thesis M. Hager (see [18]) considered a class of perturbed $h$-pseudodifferential operators on the real line of the form $P_δ = P(x, hD; h) + δq_ω(x)$, where $P$ is analytic and $q_ω$ is a random linear combination of the $C/h$ first eigenfunctions of an auxiliary operator. She showed that with probability very close to 1 when $h → 0$, $P_δ$ obeys Weyl asymptotics.

Here, we shall discuss a generalization to the multidimensional case obtained with Hager [21]. The results will be much more general in many ways, but the class of perturbations will be slightly different.

4.2 The result

a) The unperturbed operator. Let $m(ρ) ≥ 1, ρ = (x, ξ)$ be an order function on $\mathbb{R}^{2n}$, so that

$$0 < m(ρ) ≤ C_0(ρ - μ)^{N_0}m(μ),$$

we may assume that $m ∈ S(m) = \{u ∈ C^∞(\mathbb{R}^{2n}); \partial^α u = O_α(m), ∀α ∈ \mathbb{N}^{2n}\}$. Assume $m ≥ 1$ and let

$$P(ρ; h) ∼ p(ρ) + hp_1(ρ) + ... \text{ in } S(m).$$

Assume $\exists z_0 ∈ C, C_0 > 0$ such that

$$|p(ρ) - z_0| ≥ m(ρ)/C_0 \text{ (ellipticity)}.$$

Let

$$Σ = \overline{p(\mathbb{R}^{2n})} = p(\mathbb{R}^{2n}) ∪ Σ_∞,$$

$$Σ_∞ = \{\lim_{j→∞} p(ρ_j); \ \mathbb{R}^{2n} ∋ ρ_j → ∞\}.$$

We write: $P = P^w(x, hD; h)$.

Let $Ω ⊂⊂ C \setminus Σ_∞$ be open and simply connected containing $z_0$. Then using the pseudodifferential calculus, it is easy to show:

1) $σ(P) ∩ Ω$ is discrete when $h > 0$ is small enough.
2) $∀ε > 0, ∃h(ε) > 0$, such that $σ(P) ∩ Ω ⊂ Σ + D(0, ε), 0 < h ≤ h(ε)$.

b) The random perturbation. Let $0 < \tilde{m}, \hat{m} ≤ 1$ be square integrable order functions, one of which is integrable. Let $\tilde{S} ∈ S(\tilde{m}), \hat{S} ∈ S(\hat{m})$
be elliptic symbols. The corresponding operators are Hilbert-Schmidt with $\|\tilde{S}\|_{\text{HS}}, \|\hat{S}\|_{\text{HS}} = \mathcal{O}(h^{-n/2})$. Let
\[
Q_\omega = \hat{S} \circ \sum_{j,k} \alpha_{j,k}(\omega) \tilde{e}_j \tilde{e}_k^* \circ \tilde{S},
\]
where $\alpha_{j,k}$, $j,k \in \mathbb{N}$, are independent complex Gaussian random variables with expectation value 0 and variance 1, and $(\tilde{e}_j)_{1}^{\infty}$ and $(\hat{e}_j)^{\infty}$ are orthonormal bases in $L^2(\mathbb{R}^n)$, $\tilde{e}_k^* u = (u|\tilde{e}_k)\tilde{e}_j$.

Let $M = C_1 h^{-n}$ with $C_1 \gg 1$. Then with probability $\geq 1 - C e^{-h^{-2n}/C}$ the Hilbert-Schmidt and trace class norms of $Q$ fulfill:
\[
\|Q\|_{\text{HS}} \leq M, \|Q\|_{\text{tr}} \leq M^{3/2}
\] (4.1)

Let $\Gamma \subset \Omega$ be open with smooth boundary.

**Theorem 4.1** ([27]). Assume
\[
p(\rho) \in \partial \Gamma \Rightarrow dp(\rho), \overrightarrow{dp}(\rho) \text{ are linearly independent.} \tag{4.2}
\]
Let $\epsilon, \delta$ depend on $h$ with $0 < \epsilon \ll 1$,
\[
e^{-\epsilon h} \leq \delta \ll h^{3n+\frac{3}{2}}, C \gg 1
\]
(implying that $\epsilon \geq \text{Const.} h \ln \frac{1}{h}$). Then with probability $\geq 1 - \frac{C}{\sqrt{\epsilon}} e^{-\frac{1}{\epsilon h(2\pi h)^n}}$, we have
\[
|\#(\sigma(P_{\delta}) \cap \Gamma) - \frac{1}{(2\pi h)^n} \text{vol } (p^{-1}(\Gamma))| \leq C \sqrt{\epsilon} \frac{1}{h^n}. \tag{4.3}
\]

There is a similar result giving (4.3) simultaneously for all $\Gamma$ in a suitable family.

The assumption (4.2) implies that $\partial \Gamma \cap \partial \Sigma = \emptyset$, so if we want to count the eigenvalues near $\partial \Sigma$, we need to weaken that assumption. For $z \in \text{neigh } (\partial \Gamma)$, we put
\[
V_z(t) = \text{vol } \{ \rho \in \mathbb{R}^{2n}; |p(\rho) - z|^2 \leq t \}. \tag{4.4}
\]
Introduce the assumption
\[
\exists \kappa \in [0, 1], \text{ such that } V_z(t) = \mathcal{O}(t^\kappa), \text{ uniformly for } z \in \text{neigh } (\partial \Gamma), 0 \leq t \ll 1. \tag{4.5}
\]

**Example.** (4.2) $\Rightarrow$ (4.5) with $\kappa = 1$.

**Example.** The best that can happen when $\partial \Gamma \cap \partial \Sigma \neq \emptyset$ is that
\[
p(\rho) \in \partial \Gamma \Rightarrow \{p, \overrightarrow{p}\}(\rho) \neq 0 \text{ or } \{p, \overrightarrow{p}\}(\rho) \neq 0. \tag{4.6}
\]
It is easy to see that (4.6) implies (4.5) with $\kappa = 3/4$. (4.6) holds for the non-self-adjoint harmonic oscillator when $0 \notin \partial \Gamma$. 25
Theorem 4.2. (21) We assume (4.5). Let $\epsilon, \delta$ depend on $h$ with $0 < \epsilon \ll 1$, 
\[ e^{-\frac{\epsilon}{h}} \leq \delta \ll h^{3n+\frac{1}{2}}, \ C \gg 1, \]

implying that $\epsilon \geq \text{Const}.h^\kappa \ln \frac{1}{h}$. Then for $0 < r \ll 1$ we have with probability \[ \geq 1 - C r e^{-\frac{\epsilon}{2}} (2\pi h)^{-n} , \]
that
\[ \frac{C}{h^n} \left( \frac{\epsilon}{r} + C_N \left( r^N + \ln \left( \frac{1}{r} \right) \text{vol} \left( p^{-1}(\partial \Gamma + D(0, r)) \right) \right) \right) , \]

for every fixed $N \in \mathbb{N}$. 

If $\kappa > \frac{1}{2}$, we have \[ \text{vol} \left( p^{-1}(\partial \Gamma + D(0, r)) \right) = O(r^{2\kappa - 1}) \] with $2\kappa - 1 > 0$ and in all cases we may assume that $\ln \left( \frac{1}{r} \right) \text{vol} \left( p^{-1}(\partial \Gamma + D(0, r)) \right) = O(r^{a_0})$, where $a_0 > 0$. Then we choose $N \gg 1$, $r = \epsilon^{1/(1+a_0)}$ and the right hand side of (4.7) becomes \[ O(1) r^{a_0/(1+a_0)} h^{-n} . \]

Again we have a similar theorem where the conclusion (4.7) is valid simultaneously for all $\Gamma$ in a suitable family.

Recently, the author obtained similar results when $Q_\omega$ is an operator of multiplication, see [49].

4.3 Outline of the proofs

We can construct $\bar{P} \in S(m)$ such that $\bar{P}(\rho; h) = P(\rho; h)$ for $|\rho| \gg 1$ and $|\bar{P}(\rho; h) - z| \geq m(\rho)/C$ for $\rho \in \mathbb{R}^{2n}, z \in \Omega$. The eigenvalues of $P$ in $\Omega$ coincide with the zeros of the holomorphic function

\[ F(z; h) = \det P_z , \quad (4.8) \]
\[ P_z = (\bar{P}(x, hD; h) - z)^{-1}(P(x, hD; h) - z) \]

The same remark holds for $P_\delta$ and $F_\delta$ defined as in (4.8) with $P$ replaced by $P_\delta$, provided that (1.1) holds.

For $z \in \text{neigh}(\partial \Gamma)$, put $Q = P_z^* P_z$. Let $1_\alpha(E) = \max(E, \alpha)$, where $\alpha = Ch, C \gg 1$. Using semiclassical analysis, we can show that under the assumption (1.5) (cf. [38])

\[ \ln \det Q \leq \ln \det 1_\alpha(Q) = \frac{1}{(2\pi h)^n} \left( \int \int \ln q dx d\xi + O(1) h^\kappa \ln \frac{1}{h} \right) , \quad (4.9) \]

where $q = |p_z|^2$ is the leading symbol of $Q$. 26
Since
\[ \ln \det Q = \ln \det P_z^* P_z = \ln |F(z; h)|^2 \]
we have
\[ \ln |F(z; h)| \leq \frac{1}{(2\pi h)^n} \left( \int \int \ln |p_z| dx d\xi + O(1)h^\kappa \ln \frac{1}{h} \right), \quad (4.10) \]
For \( \delta > 0 \) small enough, we get the same upper bound for \( \ln |F_{\delta}(z; h)| \) (provided that \( (4.1) \) holds).

The main step in the proof is to get a corresponding lower bound for each fixed \( z \) with a probability close to 1. In the multidimensional case this boils down to a question about random determinants. Let \( z \in \text{neigh}(\partial\Gamma) \).

Let \( e_1, e_2, \ldots \) be the first eigen-functions of \( Q = P_z^* P_z \) and let \( f_1, f_2, \ldots \) be the first eigen-functions for \( P_z P_z^* \). The two operators have the same eigenvalues \( 0 \leq \lambda_1 \leq \lambda_2 \leq \ldots \).

We can arrange so that
\[ P_z e_j = \sqrt{\lambda_j} f_j, \quad P_z^* f_j = \sqrt{\lambda_j} e_j. \]
Let \( N = N(\alpha) = \#\{j; \lambda_j \leq \alpha\} \) \( (\alpha = Ch, C \gg 1) \). Semiclassical analysis gives that
\[ N = O(h^{\kappa-n}). \]

Consider
\[ P^0 = \begin{pmatrix} P_z & R_- \\ R_+ & 0 \end{pmatrix} : L^2 \times C^N \to L^2 \times C^N, \]
\[ R_+ : L^2 \to C^N, \quad R_+ u(j) = \sqrt{\alpha}(u|e_j), \]
\[ R_- : C^N \to L^2, \quad R_- = \sqrt{\alpha} \sum_{j=1}^N u_-(j)f_j. \]
\( P^0 \) has an inverse
\[ E^0 = \begin{pmatrix} E^0_+ & E^0_- \\ E^0_+ & E^0_+ \end{pmatrix} = O\left(\frac{1}{\sqrt{\alpha}}\right), \]
with \( E^0_+, E^0_-, E^0_{++} \) ”explicit”, and
\[ \ln |\det P^0|^2 = N \ln \alpha + \det 1_{\alpha}(P_z^* P_z). \]
For \( P_\delta = P + \delta Q_\omega \), we form
\[ P_{\delta z} = (\tilde{P} - z)^{-1}(P - z + \delta Q_\omega) = P_z + \delta \tilde{Q}_\omega, \]
and since $\delta \|Q_\omega\| \leq \delta C_0 h^{-n} \ll 1$,

$$P_\delta := \left( \begin{array}{cc} P_\delta & R_- \\ R_+ & 0 \end{array} \right)$$

is invertible with inverse

$$E_\delta = \left( \begin{array}{cc} E_\delta & E_\delta^+ \\ E_\delta^- & E_\delta^{++} \end{array} \right) \approx E^0.$$  

Here

$$E_\delta^{++} = E_\delta^0 + \delta E_\omega^0 \tilde{Q}_\omega E_\omega^0 + " \text{small"},$$  

and we can show by perturbative arguments that

$$\ln \det P_\delta = \ln \det P_0^0 + \mathcal{O}(\frac{\delta}{\sqrt{\alpha}} M^{3/2}),$$

leading to

$$\ln |\det P_\delta| = \frac{1}{(2\pi h)^n} \left( \int \int |p_z| dx d\xi + \mathcal{O}(h^n \ln \frac{1}{h}) \right).$$

On the other hand, computations in [50] can be used to get

$$\ln |\det P_\delta^+| = \ln |\det P_\delta^0| + \ln |\det E_\delta^{++}|.$$  

Using (4.11), we can view $E_\delta^{++}$ as a random matrix of size $\mathcal{O}(h^{n-n})$, close in a suitable sense to one with independent Gaussian random variables as its entries. This can be used to show:

For every $z \in \text{neigh}(\partial \Gamma)$, we have a nice lower bound on $\ln |\det E_\delta^{++}|$ with probability close to 1. (4.13) then gives a corresponding lower bound on $\ln |\det P_\delta^+|$.  

To complete the proof of Theorem 4.1 we can apply the following result of M. Hager [17, 18] with $\tilde{h} = h^{n}$:

**Proposition 4.3** ([17, 18]). Let $\Gamma$ and $\Omega$ be as above. Let $\phi \in C(\Omega; \mathbb{R})$ be smooth near $\partial \Gamma$. Let $f = f(z; \tilde{h})$ be holomorphic in $\Omega$ with

$$|f(z; \tilde{h})| \leq e^{\phi(z)/\tilde{h}}, \ z \in \text{neigh}(\partial \Gamma), \ 0 < \tilde{h} \ll 1.$$  

Assume there exist $\epsilon = \epsilon(\tilde{h}) \ll 1$, $z_k = z_k(\tilde{h}) \in \Omega$, $k \in J = J(\tilde{h})$, such that

$$\partial \Gamma \subset \bigcup_{k \in J} D(z_k, \sqrt{\epsilon}), \ \# J = \mathcal{O}(\frac{1}{\sqrt{\epsilon}}),$$

$$|f(z_k; \tilde{h})| \geq e^{(\phi(z_k) - \epsilon)/\tilde{h}}, \ k \in J.$$
Then,

\[ #(f^{-1}(0) \cap \Gamma) = \frac{1}{2\pi\hbar} \iint_{\Gamma} (\Delta \phi) d(\mathbb{R}z) d(\mathbb{I}z) + \mathcal{O}\left(\frac{\sqrt{\epsilon}}{\hbar}\right). \]

For the proof of Theorem 1.2 we use an improved version of this result, see \[21\].

### 4.4 Comparison with Theorem 3.2

From the example with the non-self-adjoint harmonic oscillator in dimension 1, we have seen that Weyl asymptotics does not always hold for differential operators in one dimension, when the coefficients are analytic. If we add a small random perturbation to the non-self-adjoint harmonic oscillator, the theorems above and the main result in \[18\] show that with probability close to 1 the eigenvalues will no longer be confined to a half-line but will tend to fill up the range of the principal symbol \( p \) with a density that is given by 

\[ (2\pi\hbar)^{-n} p_\ast(dv), \]

where \( dv \) denotes the symplectic volume element on \( \mathbb{R}^{2n} \) and \( p_\ast(dv) \) is the direct image under \( p \).

From this simple one-dimensional example it is easy to build examples in higher dimension when Weyl asymptotics does not hold. In the 2-dimensional case, we can also consider the situation when the unperturbed operator \( P \) satisfies the assumptions of Theorem 3.2. It is then natural to compare the distribution law given by Theorem 3.2 for \( P \) and the one given by the theorems 4.1, 4.2 for the random perturbations. To leading order in \( \hbar \), we get Weyl asymptotics already for \( P \) in the (close to normal) case when \( \{p, \overline{p}\} \) vanishes identically. In general however, we get different asymptotic distributions already to leading order (\[18\]).
