Simple polytopes arising from finite graphs

Hidefumi Ohsugi and Takayuki Hibi

Abstract

Let $G$ be a finite graph allowing loops, having no multiple edge and no isolated vertex. We associate $G$ with the edge polytope $P_G$ and the toric ideal $I_G$. By classifying graphs whose edge polytope is simple, it is proved that the toric ideals $I_G$ of $G$ possesses a quadratic Gröbner basis if the edge polytope $P_G$ of $G$ is simple. It is also shown that, for a finite graph $G$, the edge polytope is simple but not a simplex if and only if it is smooth but not a simplex. Moreover, the Ehrhart polynomial and the normalized volume of simple edge polytopes are computed.

Introduction

Let $G$ be a finite graph on the vertex set $V(G) = \{1, \ldots, d\}$ allowing loops, having no multiple edge and no isolated vertex. Let $E(G) = \{e_1, \ldots, e_n\}$ denote the set of edges (and loops) of $G$. If $e = \{i, j\}$ is an edge of $G$ between $i \in V(G)$ and $j \in V(G)$, then we define $\rho(e) = e_i + e_j$. Here $e_i$ is the $i$th unit coordinate vector of $\mathbb{R}^d$. In particular, for a loop $e = \{i, i\}$ at $i \in V(G)$, one has $\rho(e) = 2e_i$. The edge polytope of $G$ is the convex polytope $P_G (\subset \mathbb{R}^d)$ which is the convex hull of the finite set $\{\rho(e), \ldots, \rho(e_n)\}$. If $e = \{i, j\}$ is an edge of $G$, then $\rho(e)$ cannot be a vertex of $P_G$ if and only if $i \neq j$ and $G$ has a loop at each of the vertices $i$ and $j$. With considering this fact, throughout the present paper, we assume that $G$ satisfies the following condition:

(*): If $i, j \in V(G)$ and if $G$ has a loop at each of $i$ and $j$, then the edge $\{i, j\}$ belongs to $G$.

Let $K[t] = K[t_1, \ldots, t_d]$ denote the polynomial ring in $d$ variables over $K$. If $e = \{i, j\}$ is an edge of $G$, then $t^e$ stands for the monomial $t_it_j$ belonging to $K[t]$. Thus in particular, if $e = \{i, i\}$ is a loop of $G$ at $i \in V(G)$, then $t^e = t_i^2$. The edge ring of $G$ is the affine semigroup ring $K[G] (\subset K[t])$ which is generated by $t_1^{e_1}, \ldots, t_d^{e_n}$ over $K$. Let $\mathcal{R}_G = K[\{x_{ij}\}_{i,j \in E(G)}]$ denote the polynomial ring in $n$ variables over $K$. The toric ideal of $G$ is the ideal $I_G (\subset \mathcal{R}_G)$ which is the kernel of the surjective ring homomorphism $\pi : \mathcal{R}_G \rightarrow K[G]$ defined by setting $\pi(x_{ij}) = t_it_j$ for $\{i, j\} \in E(G)$. A convex polytope $\mathcal{P}$ of dimension $d$ is simple if each vertex of $\mathcal{P}$ belongs to exactly $d$ edges of $\mathcal{P}$. A simple polytope $\mathcal{P}$ is smooth if at each vertex of $\mathcal{P}$, the primitive edge directions form a lattice basis.

Our goal is as follows: (i) To classify graphs whose edge polytope is simple (Theorem 1.8), (ii) To show the existence of a quadratic and squarefree initial ideal of toric ideals arising from simple edge polytopes (Theorem 2.1), (iii) To compute the Ehrhart polynomial and the normalized volume of simple edge polytopes (Theorem 3.1).
1 Simple edge polytopes

In this section, we classify all finite graphs $G$ for which the edge polytope $P_G$ is simple.

A closed walk of $G$ of length $q$ is a sequence $(e_1, e_2, \ldots, e_q)$ of edges of $G$, where $e_k = \{u_k, v_k\}$ for $k = 1, \ldots, q$, such that $v_k = u_{k+1}$ for $k = 1, \ldots, q-1$ together with $v_q = u_1$. Such a closed walk is called a cycle of length $q$ if $u_k \neq u_{k'}$ for all $1 \leq k < k' \leq q$. In particular, a loop is a cycle of length 1. Let $\Gamma = (e_G)$ be an even closed walk of $G$. Then it is easy to see that $f_\Gamma = \prod_{t=1}^q x_{u_{2t-1}v_{2t-1}} - \prod_{t=1}^q x_{u_{2t}v_{2t}}$ belongs to $I_G$. An even closed walk $\Gamma$ of $G$ is called trivial if $f_\Gamma = 0$. It is known [3 Lemma 1.1] that

**Proposition 1.1.** Let $G$ be a finite graph. Then $\{f_\Gamma \mid \Gamma$ is a nontrivial even closed walk of $G\}$ is a set of generators of $I_G$. In particular, $G$ has no nontrivial even closed walk if and only if $I_G = (0)$. In addition, if $G$ has at most one loop, then its edge polytope $P_G$ is a simplex if and only if $I_G = (0)$.

Let $\tilde{G}$ denote the subgraph of $G$ with the edge set $E(\tilde{G}) = E(G) \setminus \{\{i, j\} \in E(G) \mid i \neq j \text{ and } \{i, j\}, \{j, j\} \in E(G)\}$. Then we have $P_G = P_{\tilde{G}}$. The following Propositions are known [2, 3].

**Proposition 1.2.** Let $G$ be a finite graph. Then $P_G$ is a simplex if and only if $\tilde{G}$ satisfies both (i) each connected component of $\tilde{G}$ has at most one cycle and (ii) the length of any cycle of $\tilde{G}$ is odd.

**Proposition 1.3.** Let $G$ be a finite graph and let $G_1, \ldots, G_r$ denote connected components of $G$. Then, for each $1 \leq i \leq r$, $\dim P_{G_i}$ equals to

\[
\begin{cases}
|V(G_i)| - 2 & \text{if } G_i \text{ has no odd cycle} \\
|V(G_i)| - 1 & \text{otherwise}
\end{cases}
\]

and $\dim P_G = r - 1 + \sum_{i=1}^r \dim P_{G_i} = |V(G)| - r' - 1$ where $r'$ is the number of connected components of $G$ having no odd cycle.

Let $W$ be a subset of $V(G)$. The induced subgraph of $G$ on $W$ is the subgraph $G_W$ on $W$ whose edges are those edges $e = \{i, j\} \in G(E)$ with $i \in W$ and $j \in W$. If $G'$ is an induced subgraph of $G$ with the edges $e_i, \ldots, e_q$, then we write $F_{G'}$ for the convex hull of $\{\rho(e_i), \ldots, \rho(e_q)\}$ in $\mathbb{R}^n$. It follows that $F_{G'}$ is a face of $P_G$. Hence, $F_{G'}$ is simple if $P_G$ is simple.

**Lemma 1.4.** Let $e$ and $f$ be edges of $G$ with $e \neq f$ and suppose that each of $\rho(e)$ and $\rho(f)$ is a vertex of $P_G$. Then the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $P_G$ if and only if one of the following is satisfied:

(i) Each of $e$ and $f$ is a loop of $G$;

(ii) $e = \{i, j\}$ with $i \neq j$ and $f$ is a loop at $i$;

(iii) $e = \{i, j\}, f = \{k, k\}$ with $|\{i, j, k\}| = 3$ such that either $\{i, k\} \notin E(G)$ or $\{j, k\} \notin E(G)$;
(iv) $e = \{i, j\}$, $f = \{j, k\}$ with $|\{i, j, k\}| = 3$ such that either $\{i, k\} \notin E(G)$ or $\{j, j\} \notin E(G)$;

(v) $e = \{i, j\}$ and $f = \{k, \ell\}$ with $|\{i, j, k, \ell\}| = 4$ such that the induced subgraph of $G$ on $\{i, j, k, \ell\}$ has a vertex of degree 1. (If the induced subgraph of $G$ on $\{i, j, k, \ell\}$ has no loop, then we can replace “a vertex of degree 1” with “no even cycle of the form $(e, e', f, f')$.”)

**Proof.** Let in general, $P$ be a convex polytope and $F$ a face of $P$. Then each face $F'$ of $F$ is a face of $P$. In addition, if $F$ and $F'$ are faces of $P$ with $F' \subset F$, then $F'$ is a face of $F$.

(i) Let $e$ be a loop at $i \in V(G)$ and $f$ a loop at $j \in V(G)$, where $i \neq j$. Let $G'$ be the induced subgraph of $G$ on $\{i, j\}$. By the condition $(*)$, we have $E(G') = \{e, f, \{i, j\}\}$. Hence the convex hull of $\{\rho(e), \rho(f)\}$ coincides with the face $F_{G'}$ of $P_G$. Thus the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $P_G$.

(ii) Let $G'$ be the induced subgraph of $G$ on $\{i, j\}$. Since $\rho(e)$ is a vertex of $P_G$, we have $\{j, j\} \notin E(G)$. Hence $E(G') = \{e, f\}$. As in (i), the convex hull of $\{\rho(e), \rho(f)\}$ coincides with the face $F_{G'}$ of $P_G$.

(iii) Suppose $\{i, k\} \in E(G)$ and $\{j, k\} \in E(G)$. Let $G'$ be a subgraph of $G$ with $E(G') = \{e, f, \{i, k\}, \{j, k\}\}$. Then the edge polytope $P_{G'}$ is a rectangle and the convex hull of $\{\rho(e), \rho(f)\}$ is its diagonal. Thus the convex hull of $\{\rho(e), \rho(f)\}$ cannot be an edge of $P_{G'}$. Since $P_{G'}$ is a subpolytope of $P_G$, $\{\rho(e), \rho(f)\}$ cannot be an edge of $P_G$.

On the other hand, suppose $\{i, k\} \notin E(G)$. Let $G''$ be the induced subgraph of $G$ on $\{i, j, k\}$. By the condition $(*)$, $E(G'')$ is one of the following: $\{e, f\}$, $\{e, f, \{j, k\}\}$ and $\{e, f, \{i, k\}, \{j, j\}\}$. In all three cases above, the face $F_{G''}$ is a simplex. Thus the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $P_{G}$.

(iv) If both $e' = \{i, k\}$ and $f' = \{j, j\}$ belongs to $E(G)$, then we have $\rho(e) + \rho(f) = \rho(e') + \rho(f')$. Thus the convex hull of $\{\rho(e), \rho(f)\}$ cannot be an edge of $P_{G}$.

On the other hand, suppose that either $\{i, k\} \notin E(G)$ or $\{j, j\} \notin E(G)$. Let $G'$ be the induced subgraph of $G$ on $\{i, j, k\}$. If $\{j, j\} \in E(G)$, then $\{i, k\} \notin E(G)$ and $G$ has a loop at neither $i$ nor $k$. Hence $E(G') = \{e, f, \{j, j\}\}$. Thus the face $F_{G'}$ is a triangle and the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $P_{G}$. If $\{j, j\} \notin E(G)$, then the face of $P_{G}$ arising from the supporting hyperplane $H = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid 2x_i + x_j + x_k = 3\}$ is the convex hull of $\{\rho(e), \rho(f)\}$.

(v) Let $G'$ be the induced subgraph of $G$ on $\{i, j, k, \ell\}$. Suppose that $G'$ has no vertex of degree 1. If $G'$ has an even cycle of the form $(e, e', f, f')$, then $\rho(e) + \rho(f) = \rho(e') + \rho(f')$. Thus the convex hull of $\{\rho(e), \rho(f)\}$ cannot be an edge of $P_{G}$. If $G'$ has no even cycle of the form $(e, e', f, f')$, then we may assume that $\{i, k\} \notin E(G)$ and $\{i, \ell\} \notin E(G)$. Since the degree of $i$ is not 1, we have $\{i, i\} \in E(G)$. Hence $G$ has a loop at none of $j$, $k$ and $\ell$. Since the degree of each of $k$ and $\ell$ is not 1, we have $\{j, k\} \in E(G)$ and $\{j, \ell\} \in E(G)$. Thus $E(G') = \{e, f, \{i, i\}, \{j, k\}, \{j, \ell\}\}$. Then we have $2\rho(e) + \rho(f) = \rho(\{i, i\}) + \rho(\{j, k\}) + \rho(\{j, \ell\})$ and hence the convex hull of $\{\rho(e), \rho(f)\}$ cannot be an edge of $P_{G}$.

Suppose that the degree of a vertex $i$ of $G'$ is 1. Then, none of $\{i, i\}$, $\{i, k\}$ and $\{i, \ell\}$ belongs to $E(G)$. Since $G$ has no loop at either $k$ or $\ell$, we may assume that $G$ has no loop at $k$. Then the hyperplane $H' = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid 2x_i + x_j + 2x_k + x_\ell = 3\}$ is a supporting
hyperplane of $\mathcal{P}_G$ and the face $\mathcal{H}' \cap \mathcal{P}_G$ is either an edge or a triangle. Since both $\rho(e)$ and $\rho(f)$ belongs to $\mathcal{H}' \cap \mathcal{P}_G$, the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_G$.

\begin{lemma}
Suppose that $\mathcal{P}_G$ is simple, but not a simplex. Then $G$ is a connected graph having no vertex of degree 1. Moreover if an induced subgraph $G'$ of $G$ has no isolated vertex and $\mathcal{F}_{G'}$ is not a simplex, then $G'$ is a connected graph having no vertex of degree 1.

Proof. Suppose that $G$ is not connected. Since $\mathcal{P}_G$ is not a simplex, there exists a connected component $G'$ of $G$ such that $\mathcal{P}_{G'}$ is not a simplex. Then $G'$ has at least $\dim \mathcal{P}_{G'} + 2$ edges. Let $e = \{i, j\} \in E(G) \setminus E(G')$. Let $G''$ be the induced subgraph of $G$ on the vertex set $V(G') \cup \{i, j\}$. Thanks to Lemma 1.4 the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_{G''}$ for all $f \in E(G')$. Since $\dim \mathcal{P}_{G'} = \dim \mathcal{P}_{G'} + 1$, the face $\mathcal{P}_{G''}$ of $\mathcal{P}_G$ is not simple. Thus $\mathcal{P}_G$ is not simple. Suppose that $G$ has a vertex $i$ of degree 1. Let $e = \{i, j\} \in E(G)$. Thanks to Lemma 1.4 the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_G$ for all $(e \neq f) f \in E(G)$. Since $\mathcal{P}_G$ is not a simplex, this contradicts that $\mathcal{P}_G$ is simple. Moreover, the induced subgraph $G'$ satisfies the same condition since the face $\mathcal{F}_{G'}$ is also simple.

\begin{lemma}
Work with the same notation as above. If $\mathcal{P}_G$ is simple, but not a simplex, then $\tilde{G}$ is a connected graph having no vertex of degree 1.

Proof. It follows by the same argument as in Proof of Lemma 1.5 since $\mathcal{P}_G = \mathcal{P}_{\tilde{G}}$.

A finite graph $G$ on $V(G)$ is called bipartite if there is a decomposition $V(G) = V_1 \cup V_2$ such that every edge of $G$ is of the form $\{i, j\}$ with $i \in V_1$ and $j \in V_2$.

\begin{lemma}
Let $W$ be the set of those vertices $i \in V(G)$ such that $G$ has no loop at $i$ and $G'$ the induced subgraph of $G$ on $W$. Suppose that the face $\mathcal{F}_{G'}$ is not a simplex. Then $\mathcal{P}_G$ is simple if and only if the following conditions are satisfied:

\begin{enumerate}
  \item $G'$ is a complete bipartite graph with at least one cycle of length 4;
  \item If $G$ has a loop at $i$, then $\{i, j\} \in E(G)$ for all $j \in W$;
  \item $G$ has at most one loop.
\end{enumerate}

Proof. (“Only if”) Suppose that $\mathcal{P}_G$ is simple.

(i) Since $\mathcal{F}_{G'}$ is a face of $\mathcal{P}_G$, it follows that $\mathcal{F}_{G'}$ is simple. Lemma 1.4 (iv) and (v) say that, if $G'$ has no cycle of length 4, then the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{F}_{G'}$ for $e, f \in V(G')$ with $e \neq f$. Since $\mathcal{F}_{G'}$ is simple, if $G'$ has no cycle of length 4, then $\mathcal{F}_{G'}$ is a simplex. Since $\mathcal{F}_{G'}$ is not a simplex, it follows that $G'$ has a cycle $C$ of length 4. Let $G''$ denote the induced subgraph of $G$ on $V(C)$. Since $\mathcal{F}_{G''}$ is simple, by using Lemma 1.4 (iv), it follows easily that $G'' = C$. In other words,

(‡) every cycle $C'$ of length 4 of $G'$ coincides with the induced subgraph on $V(C')$.

Since $C$ is a complete bipartite graph, there exists a maximal (with respect to inclusion) complete bipartite subgraph $\Gamma$ of $G'$ with $C \subset \Gamma$. Thanks to (‡), $\Gamma$ is the induced subgraph of $G'$ on $V(\Gamma)$. Let $V(\Gamma) = V_1 \cup V_2$ be the partition of $V(\Gamma)$. Suppose that there is an edge $\{i, j\}$ of $G'$ with $\{i, j\} \notin E(\Gamma)$. If $i \notin V(\Gamma)$ and $j \notin V(\Gamma)$, then by applying Lemma 1.5
to the induced subgraph of \( G' \) on \( V(C) \cup \{i, j\} \), there exists an edge \( \{k, \ell\} \in E(G') \setminus E(\Gamma) \) with \( k \in \{i, j\} \) and \( \ell \in V(\Gamma) \). Thus we may assume that one of \( i \in V(\Gamma) \) and \( j \in V(\Gamma) \) holds. Say \( i \in V_1 \) and \( j \notin V(\Gamma) \). Let \( i' \in V_1 \) with \( i' \neq i \) and \( C' \) a cycle of length 4 in \( \Gamma \) with \( i, i' \in V(C') \), say \( V(C') = \{i, i', k, k'\} \) with \( k, k' \in V_2 \) and \( k \neq k' \). Let \( \Gamma' \) denote the induced subgraph of \( G \) on \( \{i, i', k, k', j\} \). Applying Lemma 1.4 to \( \Gamma' \), the degree of \( j \) is not 1 in \( \Gamma' \).

If \( \{i', j\} \in E(\Gamma') \), then thanks to \((\sharp)\), \( E(\Gamma') = E(C') \cup \{\{i, j\}, \{i', j\}\} \), i.e., \( \Gamma' \) is a complete bipartite graph. If \( \{i', j\} \notin E(\Gamma') \) and \( \{j, k\} \in E(\Gamma') \), then by Lemma 1.4 (iv) and (v), the convex hull of \( \{\rho(\{i, j\}), \rho(e)\} \) is an edge of \( \mathcal{F}_{\Gamma'} \) for all \( e \in E(C') \cup \{\{j, k\}\} \). Hence \( \rho(\{i, j\}) \) belongs to at least 5 edges of \( \mathcal{F}_{\Gamma'} \). Since \( \dim \mathcal{F}_{\Gamma'} = 4 \), \( \mathcal{F}_{\Gamma'} \) is not simple and this is a contradiction.

Thus the induced subgraph \( \Gamma'' \) of \( G \) on \( V(\Gamma) \cup \{j\} \) is a complete bipartite graph with \( \{i, j\} \in E(\Gamma'') \). This contradicts the maximality of \( \Gamma \). Hence \( E(\Gamma) = E(G') \). After the proof of (iii), we will prove that \( V(\Gamma) = V(G') (= W) \), that is, there exists no isolated vertex in \( G' \).

(ii) We will prove that if \( G \) has a loop at \( i \), then \( \{i, j\} \in E(G) \) for all \( j \in V(\Gamma) \). Since \( \Gamma \) is a complete bipartite graph with at least one cycle of length 4, it is enough to show that, for any cycle \( C' \) of length 4 in \( \Gamma \), \( \{i, j\} \in E(G) \) for all \( j \in V(C') \). Let \( \mathcal{G}'' \) denote the induced subgraph of \( G \) on \( V(C') \cup \{i\} \). Then \( \mathcal{G}'' \) is simple.

Let \( E(C') = \{\{j, k\}, \{j, k'\}, \{j', k\}, \{j', k'\}\} \). Let \( a \) denote the number of vertices \( \ell \in \{j, j'\} \) with \( \{\ell, i\} \in E(G) \) and \( b \) the number of vertices \( \ell' \in \{k, k'\} \) with \( \{\ell', i\} \in E(G) \). Then by using Lemma 1.4, the number of edges of \( \mathcal{G}'' \) to which \( \rho(e) \) belongs is \( a + b + 4 - ab \). Since \( \dim \mathcal{G}'' = 4 \) and \( \mathcal{G}'' \) is simple, we have \( a + b + 4 - ab \leq 4 \), that is, \( 1 \leq (a - 1)(b - 1) \). Since \( 0 \leq a, b \leq 2 \), it follows that either \( a = b = 0 \) or \( a = b = 2 \). If \( a = b = 0 \), then \( \dim \mathcal{G}'' = 3 \) and \( a + b + 4 - ab = 4 > 3 \). Hence the face \( \mathcal{G}'' \) cannot be simple. Thus \( a = b = 2 \).

(iii) Suppose that \( G \) has more than one loop. Let \( \{i, i\}, \{i', i'\} \in E(G) \) with \( i \neq i' \) and let \( C' \) an even cycle of length 4 in \( \Gamma \). Let \( \mathcal{G}'' \) denote the induced subgraph of \( G \) on \( \{i, i'\} \cup V(C') \). By using (ii) which we already proved, \( E(G'') = \{\{i, i\}, \{i', i'\}, \{i, i'\}\} \cup E(C') \cup \{\{j, k\} | j \in \{i, i'\}, k \in V(C')\} \). Then Lemma 1.4 (iv) and (v) guarantee that for each \( e \in E(C') \), the vertex \( \rho(e) \) belongs to 6 edges of \( \mathcal{G}'' \). Since \( \dim \mathcal{G}'' = 5 \), the face \( \mathcal{G}'' \) cannot be simple. This is a contradiction and hence \( G \) has at most one loop.

Finally, since \( G \) has at most one loop and has no vertex of degree 1, \( G' \) has no isolated vertex. Thus \( \Gamma = G' \), as desired.

(“If”) Suppose that the conditions (i), (ii) and (iii) are satisfied.

First, if \( G \) has no loop, then \( G \) is a complete bipartite graph on \( W = \{1, \ldots, d\} \) with at least one cycle of length 4. Let \( W = W_1 \cup W_2 \) be the decomposition of \( W \) such that each edge of \( G \) is of the form \( \{i, j\} \) with \( i \in W_1 \) and \( j \in W_2 \), where \( |W_1| \geq 2 \) and \( |W_2| \geq 2 \). Fix an edge \( e = \{i_0, j_0\} \) of \( G \). Let \( f = \{i, j\} \in E(G) \) with \( e \neq f \). Lemma 1.4 (iv) and (v) say that the convex hull of \( \{\rho(e), \rho(f)\} \) is an edge of \( \mathcal{P}_G \) if and only if either \( i = i_0 \) or \( j = j_0 \). Hence each vertex of \( \mathcal{P}_G \) to \( d - 2 \) edges of \( \mathcal{P}_G \). Since \( \mathcal{P}_G \) is of dimension \( d - 2 \), it follows that \( \mathcal{P}_G \) is simple.

Second, suppose that \( G \) has exactly one loop. Let \( e \) be a loop of \( G \) at \( d \). Then each edge \( \{i, d\} \) with \( 1 \leq i < d \) belongs to \( G \).

Fix an edge \( e_0 = \{i_0, j_0\} \) of \( G' \). Let \( f = \{i, d\} \) with \( 1 \leq i < d \). Then by using Lemma 1.4,
(iv) and (v) the convex hull of \( \{\rho(e_0), \rho(f)\} \) is an edge of \( P_G' \) if and only if either \( i = i_0 \) or \( i = j_0 \). In addition, by using Lemma 1.4 (iii) the convex hull of \( \{\rho(e_0), \rho(e)\} \) cannot be an edge of \( P_G \). Hence \( \rho(e_0) \) belongs to \((d - 3) + 2 = d - 1\) edges of \( P_G \).

Fix \( f_0 = \{i_0, d\} \in E(G) \) with \( i_0 \in W_1 \). Let \( f \in E(G) \). Then the convex hull of \( \{\rho(f_0), \rho(f)\} \) is an edge of \( P_G \) if and only if \( f = \{i_0, j\} \) with \( j \in W_2 \), or \( f = \{i, d\} \) with \( i_0 \neq i \in W_1 \), or \( f = e \). Hence \( \rho(f_0) \) belongs to \((d - 2) + 1 = d - 1\) edges of \( P_G \).

Let \( f \in E(G) \setminus \{e\} \). Then the convex hull of \( \{\rho(e), \rho(f)\} \) is an edge of \( P_G \) if and only if \( f = \{i, d\} \) with \( 1 \leq i < d \). Hence \( \rho(e) \) belongs to \( d - 1\) edges of \( P_G \).

Since the dimension of \( P_G \) is \( d - 1 \), it follows that \( P_G \) is simple, as desired.

**Theorem 1.8.** Let \( W \) denote the set of those vertices \( i \in V(G) \) such that \( G \) has no loop at \( i \) and \( G' \) the induced subgraph of \( G \) on \( W \). Then the following conditions are equivalent:

(i) \( P_G \) is simple, but not a simplex;

(ii) \( P_G \) is smooth, but not a simplex;

(iii) \( W \neq \emptyset \) and \( G \) is one of the following graph:

\[
\begin{align*}
(\alpha) & \quad G \text{ is a complete bipartite graph with at least one cycle of length 4;} \\
(\beta) & \quad G \text{ has exactly one loop, } G' \text{ is a complete bipartite graph and if } G \text{ has a loop at } i, \\
& \quad \text{then } \{i, j\} \in E(G) \text{ for all } j \in W; \\
(\gamma) & \quad G \text{ has at least two loops, } G' \text{ has no edge and if } G \text{ has a loop at } i, \text{ then } \{i, j\} \in E(G) \\
& \quad \text{for all } j \in W.
\end{align*}
\]

**Proof.** ("(ii) \( \Rightarrow \) (i)"") Obvious.

("(i) \( \Rightarrow \) (iii)"") Suppose that the edge polytope \( P_G \) is simple, but not a simplex. By Lemma 1.5 \( G \) is connected. Moreover, by Lemma 1.6 we have \( W \neq \emptyset \). If \( F_{G'} \) is not a simplex, then thanks to Lemma 1.7 \( G \) satisfies either \((\alpha)\) or \((\beta)\).

Suppose that \( F_{G'} \) is a simplex. Since \( P_G \) is not a simplex, \( G \) has at least one loop. Let \( G'_1, \ldots, G'_{q} \) denote the connected components of \( G' \). Since \( F_{G'} \) is a simplex, it follows that each of the faces \( F_{G'_1}, \ldots, F_{G'_q} \) is a simplex and that \( I_{G'_i} = \emptyset \) for \( i = 1, \ldots, q \), that is, each of the connected components \( G'_1, \ldots, G'_q \) has no nontrivial even closed walk.

Since \( G \) is connected and has at least one loop, for each \( G'_r \), there exists a loop \( e = \{i, j\} \in E(G) \) such that \( \{i, j\} \in V(G'_r) \) belongs to \( E(G) \). Suppose that \( G'_r \) contains a cycle of odd length. Let \( f = \{j, j'\} \in E(G'_r) \). Let \( G'' \) denote the induced subgraph of \( G \) on \( V(G'_r) \cup \{i\} \). Let \( a \) denote the dimension of the face \( F_{G'_r} \). Then the dimension of \( F_{G''} \) is \( a + 1 \). However, the number of edges of the face \( F_{G''} \) to which the vertex \( \rho(f) \) belongs is \( a + 2 \). This contradiction shows that either \( E(G'_r) = \emptyset \) or \( G'_r \) is a tree for all \( r \). (A tree is a connected graph with no cycle.)

**Case 1.** \( E(G'_1) = \cdots = E(G'_q) = \emptyset \).

By Lemma 1.5 the degree of each vertex in \( W \) is at least 2. Hence \( G \) has at least 2 loops. Let \( e \) be a loop at \( i \in V(G) \) and \( e' \) a loop at \( i' \in V(G) \), where \( i \neq i' \). Let \( U_e = \{j \in W \mid \{i, j\} \in E(G)\} \) and \( U_{e'} = \{j \in W \mid \{i', j\} \in E(G)\} \). We show that, if \( U_e \cap U_{e'} \neq \emptyset \), then \( U_e = U_{e'} \). To see why this is true, let \( j_e \in U_e \cap U_{e'} \) and \( j_s \in U_e \setminus U_{e'} \). Let \( G'' \) denote the
induced subgraph of $G$ on $\{i, i', j, j_s\}$. Then the dimension of the face $F_{\mathcal{G}'}$ is 3. However, the vertex $\rho(\{i, j_s\})$ belongs to 4 edges of $F_{\mathcal{G}'}$. Hence $F_{\mathcal{G}'}$ cannot be simple. Thus $U_e = W_e$.

Thanks to Lemma 1.6 it follows that $U_e = W$ holds for any loop $e$ of $G$. Then $G$ satisfies the condition ($\gamma$).

Case 2. $E(G'_0) \neq \emptyset$.

Let $e$ be a loop at $i \in V(G)$ and $e'$ a loop at $i' \in V(G)$ with $i \neq i'$. Suppose that $\{i, j\}$ with $j \in V(G'_0)$ and $\{i', j'\}$ with $j' \in V(G'_0)$ belong to $E(G)$. Let $f = \{j, j'\} \in E(G'_0)$. Let $G''$ denote the induced subgraph of $G$ on $V(G'_0) \cup \{i, i'\}$. Let $a$ denote the dimension of the face $F_{\mathcal{G}''}$. Then the dimension of $F_{\mathcal{G}''}$ is $a + 3$. However, the number of edges of the face $F_{\mathcal{G}''}$ to which the vertex $\rho(f)$ belongs is at least $a + 4$. This contradiction shows that if $\{i, j\}$ with $j \in V(G'_0)$ and $\{i', j'\}$ with $j' \in V(G'_0)$ belongs to $E(G)$, then $E(G'_0) = \emptyset$. Thus, in particular, there exists exactly one loop $e_0 = \{i_0, i_0\}$ of $G$ such that $\{i_0, j\}$ with $j \in V(G'_0)$ belongs to $E(G)$.

We will show that $G$ has no loop except for $e_0$. Suppose that $G$ has at least two loops. Thanks to Lemma 1.5, all loops of $G$ and $E(G'_0)$ are in the connected graph $\widetilde{G}$. Hence there exists a loop $e = \{i, j\}$ of $G$ with $e \neq e_0$ such that both $\{i_0, j_s\}$ and $\{i, j_s\}$ belongs to $E(G)$ for some $E(G'_0) = \emptyset$ with $V(G'_0) = \{j_s\}$. Let $f \in E(G'_0)$. Let $G''$ denote the induced subgraph of $G$ on $V(G'_0) \cup \{j_s, i_0, i\}$. Let $a$ denote the dimension of the face $F_{\mathcal{G}''}$. Then the dimension of $F_{\mathcal{G}''}$ is $a + 4$. However, the number of edges of the face $F_{\mathcal{G}''}$ to which the vertex $\rho(f)$ belongs is at least $a + 5$. This is a contradiction. Thus $G$ has exactly one loop $e_0 = \{i_0, i_0\}$.

Since $G$ has no vertex of degree 1 by Lemma 1.5, we have $E(G'_0) \neq \emptyset$ for all $i$. Next we will show $q = 1$. Suppose that $\{i_0, j\}$ and $\{i_0, j'\}$ with $j, j' \in V(G'_0)$ and $j \neq j'$ belong to $E(G)$. Let $f \in E(G'_0)$ with $s \neq r$. Let $G''$ denote the induced subgraph of $G$ on $V(G'_r) \cup V(G'_s)$ and $G''$ the induced subgraph of $G$ on $V(G'_r) \cup V(G'_s) \cup \{i_0\}$. Let $a$ denote the dimension of the face $F_{\mathcal{G}''}$. Then the dimension of $F_{\mathcal{G}''}$ is $a + 2$. However, the number of edges of the face $F_{\mathcal{G}''}$ to which the vertex $\rho(f)$ belongs is at least $a + 3$. This contradiction shows that if $\{i_0, j\}, \{i_0, j'\} \in E(G)$, where $j, j' \in V(G'_0)$ with $j \neq j'$, and if there is $s \neq r$ with $E(G'_s) \neq \emptyset$, then $j = j'$. Hence, if $q \geq 2$, then at most one vertex of $G'_0$ is incident to the loop $e_0$. Then there exists a vertex of degree 1 and hence it contradicts to Lemma 1.5. Thus $q = 1$ and at least two vertices of $G'_1 = G'$ are incident to the loop $e_0$.

Since $q = 1$, $G'$ is a tree on the vertex set $W$ and $V(G) = W \cup \{i_0\}$. Let $U = \{j \in W \mid \{i_0, j\} \in E(G)\}$. Then, $|U| \geq 2$, dim $\mathcal{P}_G = |V(G)| - 1 = |W|$, and dim $\mathcal{P}_{G'} = |W| - 2$. If there is an edge $f = \{k, \ell\} \in E(G')$ with $k \not\in U$ and $\ell \not\in U$, then the number of edges of $\mathcal{P}_G$ to which the vertex $\rho(f)$ belongs is at least $|W| + 1$, a contradiction. Hence, if $\{k, \ell\}$ is an edge of $G'$, then either $k \in U$ or $\ell \in U$.

Suppose that $U \neq W$. Let $j \in W \setminus U$. Since $G$ has no vertex of degree 1, the degree of $j$ in the graph $G'$ is at least 2. Hence suppose that $\{j, i_1\}$ and $\{j, i_2\}$ belong to $E(G')$. Since $j \not\in U$, we have $i_1, i_2 \in U$. Then the induced subgraph $\widetilde{G}$ on $\{i_0, j, i_1, i_2\}$ satisfies $E(\widetilde{G}) = \{\{i_0, i_0\}, \{j, i_1\}, \{j, i_2\}, \{i_0, i_1\}, \{i_0, i_2\}\}$. Since the face $F_{\mathcal{G}}$ is not simple, this is a contradiction. Thus, we have $U = W$.

Let $\{k, k'\} \in E(G')$ and suppose that $\{k, k'\} \cap \{\ell, \ell'\} = \emptyset$. Since $G'$ has no cycle of length 4, we may assume that $\{k, \ell\} \not\in E(G)$ and $\{k', \ell'\} \not\in E(G)$. Then the number of edges of $\mathcal{P}_G$ to which the vertex $\rho(\{k, k'\})$ belongs is at least $|W| + 1$, a contradiction. Hence if $\{k, k'\}, \{\ell, \ell'\} \in E(G)$, then $\{k, k'\} \cap \{\ell, \ell'\} \neq \emptyset$. Since $G'$ is a tree, it follows that $G'$ has
a vertex $j_0$ such that each edge of $G'$ is of the form $\{j_0, j\}$. Hence $G'$ is a complete bipartite graph and $G$ satisfies the condition $\beta$.

(“iii) $\Rightarrow$ (ii)” Thanks to Proposition 12, $\mathcal{P}_G$ is not a simplex. We will show that $\mathcal{P}_G$ is smooth. For each vertex $v$ of $\mathcal{P}_G$, let $M_v$ denote the matrix whose columns are set of all primitive edge directions at $v$. Let $1 = (1, \ldots, 1)$ and let $E_m$ be the identity matrix.

(α) Suppose that $G$ is a complete bipartite graph. Let $e = \{1, 1'\} \in E(G)$. For $f \in E(G)$, the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_G$ if and only if either $f = \{1, i'\}$ with $i' \neq 1'$ or $f = \{i, 1'\}$ with $i \neq 1$. Then $M_{\rho(e)} = \begin{pmatrix} -1 & 0 \\ E_m & -1 \\ -1 & E_{m'} \end{pmatrix}$. Since they form a lattice basis, $\mathcal{P}_G$ is smooth.

(β) Suppose that $G$ has exactly one loop and $G'$ is a complete bipartite graph with vertex set $V_1 \cup V_2$. Let $\{1, 1\} \in E(G)$, $V_1 = \{2, \ldots, m\}$ and $V_2 = \{m + 1, \ldots, d\}$.

Let $e = \{1, 1\}$. For $f = \{i, j\} \in E(G)$, the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_G$ if and only if $i = 1$. Hence $M_{\rho(e)} = \begin{pmatrix} -1 \\ E_{d-1} \end{pmatrix}$ and columns of $M_{\rho(e)}$ form a lattice basis.

Let $e = \{1, 2\} \in E(G)$. For $f \in E(G)$ with $e \neq f$, the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_G$ if and only if $f$ belongs to $\{\{1, 1\}\} \cup \{\{1, j\} \mid j \in V_1 \setminus \{2\}\} \cup \{\{2, j\} \mid j \in V_2\}$. Hence $M_{\rho(e)} = \begin{pmatrix} 1 \\ -1 \\ -1 \\ E_{m-2} \end{pmatrix}$ and columns of $M_{\rho(e)}$ form a lattice basis.

Let $e = \{2, m + 1\} \in E(G)$. For $f = \{i, j\} \in E(G)$ with $e \neq f$, the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_G$ if and only if either $i = 2$ or $i = m + 1$. Hence $M_{\rho(e)} = \begin{pmatrix} 1 \\ -1 \\ -1 \\ E_{m-2} \end{pmatrix}$ and columns of $M_{\rho(e)}$ form a lattice basis.

Thus, in all cases, columns of $M_{\rho(e)}$ form a lattice basis and hence $\mathcal{P}_G$ is smooth.

(γ) Let $V(G') = \{1, \ldots, m\}$ and $V(G) = \{1, \ldots, m, m + 1, \ldots, d\}$.

Let $e = \{1, 1\}$. For $f \in E(G)$ with $e \neq f$, the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_G$ if and only if either $f = \{i, i\}$ with $2 \leq i \leq m$ or $f = \{1, j\}$ with $m + 1 \leq j \leq d$. Hence $M_{\rho(e)} = \begin{pmatrix} -1 \\ E_{d-1} \end{pmatrix}$ and columns of $M_{\rho(e)}$ form a lattice basis.

Let $e = \{1, m + 1\}$. For $f \in E(G)$ with $e \neq f$, the convex hull of $\{\rho(e), \rho(f)\}$ is an edge of $\mathcal{P}_G$ if and only if $f$ belongs to $\{\{1, 1\}\} \cup \{\{i, m + 1\} \mid 1 < i \leq m\} \cup \{\{1, j\} \mid m + 1 < j \leq d\}$. Hence $M_{\rho(e)} = \begin{pmatrix} 1 \\ -1 \\ E_{m-1} \end{pmatrix}$ and columns of $M_{\rho(e)}$ form a lattice basis.

Thus, in all cases, columns of $M_{\rho(e)}$ form a lattice basis and hence $\mathcal{P}_G$ is smooth, as desired.
On the other hand, there exist graphs $G$ such that $\mathcal{P}_G$ is a simplex, but not smooth.

**Example 1.9.** The edge polytope of the graphs $G_1$ and $G_2$ is a simplex (triangle) but not smooth:

(i) $E(G_1) = \{\{1,1\}, \{1,2\}, \{2,2\}, \{1,3\}\}$.

(ii) $E(G_2) = \{\{1,1\}, \{1,2\}, \{2,2\}, \{3,4\}\}$.

**Theorem 1.10.** Let $G$ be a finite graph on the vertex set $V(G) = \{1, \ldots, d\}$ with $d \geq 2$. Suppose that $\mathcal{P}_G$ is a simplex. Then $\mathcal{P}_G$ is smooth if and only if $G$ satisfies one of the followings:

(i) $E(G) = \{\{i,j\} | 1 \leq i \leq j \leq d\}$;

(ii) $G$ satisfies the condition in Proposition 1.2 and has at most one loop.

**Proof.** ("Only if") Suppose that the edge polytope $\mathcal{P}_G$ of a graph $G$ is a simplex and smooth. Let $G^{(1)}, \ldots, G^{(r)}$ be the connected components of $G$.

Suppose that $G$ has at least two loops and that $G^{(1)}$ has a loop of $G$. Thanks to the condition (\star), all loops of $G$ are in $G^{(1)}$. Since $\mathcal{P}_G$ is smooth, any face of $\mathcal{P}_G$ is smooth. Hence none of the graphs $G_1$, $G_2$ in Example 1.9 is the induced subgraph of $G$. If $r \geq 2$, then a loop of $G^{(1)}$ together with an edge of $G^{(2)}$ form an induced subgraph of $G$. This contradicts that $G_2$ is not an induced subgraph of $G$. Hence $r = 1$, that is, $G$ is connected. Suppose that there exists a vertex $i$ such that $G$ has no loop at $i$. Since $G$ is connected, there exists a path from $i$ to a vertex $j$ where $G$ has a loop at $j$. Then it follows that $G_1$ is the induced subgraph of $G$. This is a contradiction. Thus $G$ has a loop at every vertex.

("If") Suppose that $G$ is a graph satisfying the condition (i). Since $G$ is the induced subgraph of a graph in Theorem 1.8 (iii) (\gamma), $\mathcal{P}_G$ is a face of a smooth polytope. Hence $\mathcal{P}_G$ is smooth.

Suppose that $G$ is a graph satisfying the condition (ii). Since $G$ has at most one loop, $\mathcal{P}_G \cap \mathbb{Z}^d$ coincides with the set of vertices of $\mathcal{P}_G$. It is well-known that, if $\sigma$ is an integral simplex having no lattice point except for its vertices, then we can transform $\sigma$ to the standard simplex of $\mathbb{R}^{\dim \sigma}$, that is, the convex hull of $\{0, e_1, \ldots, e_{\dim \sigma}\}$. Since the standard simplex is smooth, $\mathcal{P}_G$ is smooth. 

\[\blacksquare\]

### 2 Quadratic Gröbner bases

In this section, we discuss quadratic Gröbner bases of toric ideals arising from simple edge polytopes.

Let $\mathcal{R}_G = K[\{x_{ij}\}_{(i,j) \in E(G)}]$ be the polynomial ring in $n$ variables over $K$ and the *toric ideal* of $G$ is the ideal $I_G \subset \mathcal{R}_G$ which is the kernel of the surjective ring homomorphism $\pi : \mathcal{R}_G \to K[\pi]$ defined by setting $\pi(x_{ij}) = t_it_j$ for $(i, j) \in E(G)$. Let, as before, $W$ denote the set of those vertices $i \in V(G)$ such that $G$ has no loop at $i$ and $G'$ the induced subgraph of $G$ on $W$. 

\[\blacksquare\]
Suppose that the edge polytope $P_G$ is simple and $I_G \neq (0)$. Then, either $G$ satisfies one of ($\alpha$), ($\beta$) and ($\gamma$) in the condition (iii) of Theorem 1.3 or $G$ has at least two loops and satisfies the condition in Proposition 1.2. If $G$ satisfies ($\alpha$), then let $V(G) = V_1 \cup V_2 = \{1, \ldots, m\} \cup \{m + 1, \ldots, d\}$. If $G$ satisfies ($\beta$), then suppose that $G$ has a loop at 1 and let $V(G') = V_1 \cup V_2 = \{2, \ldots, m\} \cup \{m + 1, \ldots, d\}$. If $G$ satisfies ($\gamma$), then suppose that $G$ has a loop at each of $\{1, \ldots, m\}$ and let $V(G') = \{m + 1, \ldots, d\}$. If $P_G$ is a simplex with $I_G \neq (0)$, then suppose that $G$ has a loop at each of $\{1, \ldots, m\}$. Let $<_{\text{lex}}$ be a lexicographic order on $R_G$ satisfying that $x_{kl} <_{\text{lex}} x_{ii}$ where $k < \ell$ and that $x_{ij} <_{\text{lex}} x_{kl}$ where $i < j, k < \ell \Leftrightarrow$ either (i) $i < k$ or (ii) $i = k$ and $j > \ell$.

**Theorem 2.1.** Work with the same notation as above. If the edge polytope $P_G$ is simple and $I_G \neq (0)$, then the reduced Gröbner basis of the toric ideal $I_G$ with respect to $<_{\text{lex}}$ consists of quadratic binomials with squarefree initial monomials.

**Proof.** Suppose that $P_G$ is not a simplex. Let $G_d$ be a graph with the edge set $E(G_d) = \{|i,j| \mid 1 \leq i \leq j \leq d\}$. Then, $K[G_d]$ is called the second Veronese subring of $K[t] = K[t_1, \ldots, t_d]$. It is known [5, Chapter 14] that, with respect to a “sorting” monomial order, the toric ideal $I_{G_d}$ has a quadratic Gröbner basis $G_d = \{x_{ij}x_{kl} - x_{ik}x_{j\ell} \mid i \leq j < k \leq \ell\} \cup \{x_{ii}x_{jk} - x_{ik}x_{j\ell} \mid i < j < k < \ell\}$ where the initial monomial of each $g \in G_d$ is the first monomial of $g$ and squarefree. See also [4]. Since the initial monomial of $g \in G_d$ with respect to $<_{\text{lex}}$ is also the first monomial, $G_d$ is a Gröbner basis with respect to $<_{\text{lex}}$. It then follows that if either $x_{ij}x_{kl}$ or $x_{ik}x_{j\ell}$ belongs to $R_G$, then $x_{ik}x_{j\ell}$ belongs to $R_G$. By the elimination property of $<_{\text{lex}}$, $G_d \cap R_G$ is a Gröbner basis of $I_G$ with respect to $<_{\text{lex}}$.

Suppose that $P_G$ is a simplex with $I_G \neq (0)$. Let $G^{(1)}, \ldots, G^{(r)}$ be the connected components of $G$. Let $G^{(1)}$ have a loop of $G$. Then thanks to the condition ($\ast$), all loops of $G$ are in $G^{(1)}$. By virtue of the condition ($\ast$) together with Propositions 1.1 and 1.2, we have $R_G/I_G = (R_{G_m}/I_{G_m})[\{x_{ij}\}_{(i,j) \in E(G) \setminus E(G_m)}]$ and hence $I_G, I_{G^{(1)}}$ and $I_{G_m}$ have the same minimal set of binomial generators. Thus $G_m$ is a Gröbner basis of $I_G$.  

3 Ehrhart polynomials

If $P \subset \mathbb{R}^d$ is an integral convex polytope, then we define $i(P, m)$ by $i(P, m) = \frac{|mP \cap \mathbb{Z}^d|}{|mP \cap \mathbb{Z}^d|}$. It is known that $i(P, m)$ is a polynomial in $m$ of degree $\dim P$. We call $i(P, m)$ the Ehrhart polynomial of $P$. If $\text{vol}(P)$ is the normalized volume of $P$, then the leading coefficient of $i(P, m)$ is $\text{vol}(P)/(\dim P)!$. We refer the reader to [1] for the detailed information about Ehrhart polynomials of convex polytopes.

**Theorem 3.1.** Let $G$ be a graph in Theorem 2.1 (iii). Let $W$ denote the set of those vertices $i \in V(G)$ such that $G$ has no loop at $i$ and $G'$ the induced subgraph of $G$ on $W$. Then the Ehrhart polynomial $i(P_G, m)$ and the normalized volume $\text{vol}(P_G)$ of the edge polytope $P_G$ are as follows:

\( (\alpha) \) If $G$ is the complete bipartite graph on the vertex set $V_1 \cup V_2$ with $|V_1| = p$ and $|V_2| = q$, then we have $i(P_G, m) = \binom{p+m-1}{p-1}\binom{q+m-1}{q-1}$ and $\text{vol}(P_G) = \binom{p+q-2}{p-1}$.
(β) If $G'$ is the complete bipartite graph on the vertex set $V_1 \cup V_2$ with $|V_1| = p$ and $|V_2| = q$, then we have $i(P_G, m) = \binom{p+m}{p} \binom{q+m}{q}$ and $\text{vol}(P_G) = \binom{p+q}{p}$.

(γ) If $G$ possesses $p$ loops and $V(G) = d$, then we have $i(P_G, m) = \sum_{j=1}^{p} \binom{j+m-2}{j-1} \binom{d-j+m}{d-j}$ and $\text{vol}(P_G) = \sum_{j=1}^{p} \binom{d-1}{j-1}$.

Proof. Since $I_G$ possesses a squarefree initial ideal, $K[G]$ is normal. (It is known [2, Corollary 2.3] that $K[G]$ is normal if and only if $G$ satisfies the “odd cycle condition.”) Hence, the Ehrhart polynomial $i(P_G, m)$ coincides with the Hilbert function $\dim_k(K[G])_m$ of the homogeneous $K$-algebra $K[G] = \bigoplus_{m=0}^{\infty} (K[G])_m$. The squarefree quadratic initial ideal of Theorem 2.1 guarantees that the set of monomials $x_{i_1,j_1}x_{i_2,j_2} \cdots x_{i_m,j_m}$ with each $\{i_r, j_r\} \in E(G)$ such that $1 \leq i_1 \leq \cdots \leq i_m \leq j_1 \leq \cdots \leq j_m \leq d$ is a $K$-basis of $(K[G])_m$.

(a) See, e.g., [4, Corollary 2.7 (b)]. (β) Let $V(G') = \{1, \ldots, p\} \cup \{p+2, \ldots, d\}$ and $G$ has a loop at $p+1$. Then $\{i_r, j_r\} \in E(G)$ if and only if $i_r \leq p+1$ and $j_r \geq p+1$. Hence, the number of sequence above is $i(P_G, m) = \binom{p+m}{p} \binom{q+m}{q}$. Thus, the leading coefficient of $(d-1)i(P_G, m)$ is $\binom{p+q}{p}$. (γ) Let $V(G) \setminus W = \{1,2,\ldots,p\}$. Then $\{i_r, j_r\} \notin E(G)$ if and only if $i_r, j_r > p$. Since the number of sequence above with $i_m = j$ is $\binom{j+m-2}{j-1} \binom{d-j+m}{d-j}$, we have the required formula for $i(P_G, m)$. Hence, the leading coefficient of $(d-1)i(P_G, m)$ is $\sum_{j=1}^{p} \binom{d-1}{j-1}$. \hfill \Box
