ON A THREE-DIMENSIONAL RIEMANNIAN MANIFOLD WITH AN ADDITIONAL Structure

Georgi Dzhelepov, Iva Dokuzova, Dimitar Razpopov

Abstract. We consider a 3-dimensional Riemannian manifold $M$ with a metric tensor $g$, and affinors $q$ and $S$. We note that the local coordinates of these three tensors are circulant matrices. We have that the third degree of $q$ is the identity and $q$ is compatible with $g$. We discuss the sectional curvatures in case when $q$ is parallel with respect to the connection of $g$.

Key words: Riemannian metric, affinor structure, sectional curvatures
Mathematics Subject Classification 2000: 3C05, 53B20

1. Introduction

Many papers in the differential geometry have been dedicated on the problems in the differential manifolds admitting an additional affinor structure $f$. In the most of them $f$ satisfies some identities of the second degree $f^2 = id$, or $f^2 = -id$. We note two papers [7], [8] where $f$ satisfies the equation of the third degree $f^3 + f = 0$.

Let a differential manifold admit an affine connection $\nabla$ and an affinor structure $f$. If $\nabla f$ satisfies some equation there follows an useful curvature identity. Such identities and assertions were obtained in the almost Hermitian geometry in [2]. Analogous results have been discussed for the almost complex manifolds with Norden metric in [1], [3] and [4], and for the almost contact manifolds with $B$-metric in [5] and [6].

In the present paper we are interested in a three-dimensional Riemannian manifold $M$ with an affinor structure $q$. The structure satisfies the identity $q^3 = id$, $q \neq \pm id$ and $q$ is compatible with the Riemannian metric of $M$. Moreover, we suppose the local coordinates of these structures are circulant. We search conditions the structure $q$ to be parallel with respect to the Riemannian connection $\nabla$ of $g$ (i.e. $\nabla q = 0$). We get some curvature identities in this case.

2. Preliminaries

It is known from the linear algebra, that the set of circulant matrices of type $(n \times n)$ is a commutative group. In the present paper we use four circulant matrices of type $(3 \times 3)$ for geometrical considerations, as follows:

\begin{equation}(g_{ij}) = \begin{pmatrix} A & B & B \\ B & A & B \\ B & B & A \end{pmatrix}, \quad A > B > 0,\end{equation}
where \( A = A(X^1, X^2, X^3) \), \( B = B(X^1, X^2, X^3) \); and \( X^1, X^2, X^3 \in \mathbb{R} \).

\[
(2) \quad (g^{ij}) = \frac{1}{D} \begin{pmatrix}
A + B & -B & -B \\
-B & A + B & -B \\
-B & -B & A + B
\end{pmatrix}, \quad D = (A - B)(A + 2B),
\]

\[
(3) \quad (q^i_j) = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},
\]

\[
(4) \quad (S^i_j) = \begin{pmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{pmatrix}.
\]

We choose the form in (3) of the matrix \( q \) because of the next assertion:

**Lemma 1.** Let \((m_{ij})\), \(i, j = 1, 2, 3\) be a circulant non-degenerate matrix and its third degree is the unit matrix.

Then \((m_{ij})\) has one of the following forms:

\[
(5) \quad \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}.
\]

**Proof.** If \((m_{ij})\) has the form

\[
(m_{ij}) = \begin{pmatrix} a & b & c \\ c & a & b \\ b & c & a \end{pmatrix},
\]

then from the condition \((m_{ij})^3 = E\) (\(E\) is the unit matrix) we get the system

\[
\begin{align*}
a^3 + b^3 + c^3 + 6abc &= 1 \\
a^2b + ac^2 + b^2c &= 0 \\
ab^2 + ca^2 + c^2b &= 0.
\end{align*}
\]

The all solutions of this system are (5).

### 3. A Parallel Structure

Let \( M \) be a 3-dimensional Riemannian manifold and \( \{e_1, e_2, e_3\} \) be a basis of the tangent space \( T_pM \) at a point \( p(X^1, X^2, X^3) \in M \). Let \( g \) be a metric tensor and \( q \) be an affinor, which local coordinates are given in (1) and (3), respectively. Let \( A \) and \( B \) from (1) be smooth functions of a point \( p \) in some coordinate neighborhood \( F \subset \mathbb{R}^3 \). We will use the notation \( \Phi_i = \frac{\partial \Phi}{\partial X^i} \) for every smooth function \( \Phi \), defined in \( F \). We verify that the following identities are true

\[
(6) \quad q^3 = E; \quad g(qx, qy) = g(x, y), \quad x, y \in \chi M,
\]
as well as

(7) \[ g_{is} g^{js} = \delta_i^j. \]

Let \( \nabla \) be the Riemannian connection of \( g \) and \( \Gamma^s_{ij} \) be the Christoffel symbols of \( \nabla \). It is well known the next formula

(8) \[ 2\Gamma^s_{ij} = g^{as} (\partial_i g_{aj} + \partial_j g_{ai} - \partial_a g_{ij}). \]

Using (1), (2), (7), (8), after long computations we get the next equalities:

\[
\Gamma^i_{ii} = \frac{1}{2D} ((A + B)A_i - B(4B_i - A_j - A_k)), \\
\Gamma^k_{ii} = \frac{1}{2D} ((A + B)(2B_i - A_k) - B(2B_i - A_j + A_i)), \\
\Gamma^i_{ij} = \frac{1}{2D} ((A + B)A_j - B(-B_k + B_i + B_j + A_i)), \\
\Gamma^k_{ij} = \frac{1}{2D} ((A + B)(-B_k + B_i + B_j) - B(A_i + A_j)),
\]

where \( i \neq j \neq k \) and \( i = 1, 2, 3, j = 1, 2, 3, k = 1, 2, 3 \).

**Theorem 1.** Let \( M \) be the Riemannian manifold, supplied with a metric tensor \( g \), and affinors \( q \) and \( S \), defined by (1), (3) and (4), respectively. The structure \( q \) is parallel with respect to the Riemannian connection \( \nabla \) of \( g \), if and only if

(10) \[ \text{grad} A = \text{grad} B.S. \]

**Proof.**

a) Let \( q \) be a parallel structure with respect to \( \nabla \), i.e.

(11) \[ \nabla q = 0. \]

In terms of the local coordinates, the last equation implies

\[ \nabla_i q_j^s = \partial_i q_j^s + \Gamma^a_{ia} q_j^a - \Gamma^a_{ij} q_a^s = 0, \]

which, by virtue of (3), is equivalent to

(12) \[ \Gamma^a_{ia} q_j^s = \Gamma^a_{ij} q_a^s. \]

Using (3), (9) and (12), we get 18 equations which all imply (10).

b) Vice versa, let (10) be valid. Then from (9) we get

\[
\Gamma^1_{11} = \Gamma^2_{12} = \Gamma^3_{13} = \Gamma^1_{22} = \Gamma^2_{23} = \Gamma^3_{33} = \frac{1}{2D} (AA_1 + B(-3B_1 + B_2 + B_3)), \\
\Gamma^3_{11} = \Gamma^1_{12} = \Gamma^2_{13} = \Gamma^2_{22} = \Gamma^3_{23} = \Gamma^1_{33} = \frac{1}{2D} (AA_2 + B(B_1 - 3B_2 + B_3)), \\
\Gamma^2_{11} = \Gamma^3_{12} = \Gamma^1_{13} = \Gamma^1_{22} = \Gamma^2_{23} = \Gamma^3_{33} = \frac{1}{2D} (AA_3 + B(B_1 + B_2 - 3B_3)).
\]

Now, we can verify that (12) is valid. That means \( \nabla_i q_j^s = 0 \), i.e. \( \nabla q = 0 \). 

\( \square \)
Remark. In fact (10) is a system of three partial differential equations for the functions $A$ and $B$. Let $p(X^1, X^2, X^3)$ be a point in $M$. We assume $B = B(p)$ as a known function and then we can say that (10) has a solution. Particularly, we give a simple (but non-trivial example) for both functions, satisfying (10), as follows $A = (X^1)^2 + (X^2)^2 + (X^3)^2; B = X^1 X^2 + X^1 X^3 + X^2 X^3$, where $A > B > 0$.

4. Sectional Curvatures

Let $M$ be the Riemannian manifold with a metric tensor $g$ and a structure $q$, defined by (1) and (3), respectively. Let $R$ be the curvature tensor field of $\nabla$, i.e $R(x, y)z = \nabla_x \nabla_y z - \nabla_y \nabla_x z - \nabla_{[x, y]} z$. We consider the associated tensor field $R$ of type $(0, 4)$, defined by the condition

$$R(x, y, z, u) = g(R(x, y)z, u), \quad x, y, z, u \in \chi M.$$  

Theorem 2. If $M$ is the Riemannian manifold with a metric tensor $g$ and a parallel structure $q$, defined by (1) and (3), respectively, then the curvature tensor $R$ of $g$ satisfies the identity:

$$R(x, y, q^2 z, u) = R(x, y, z, qu), \quad x, y, z, u \in \chi M.$$

Proof. In terms of the local coordinates (11) implies

$$R^{i}_{kji} q^k_s = R^{i}_{kjs} q^j_s.$$  

Using (3), we verify $q^i_j = q^i_a q^a_j$ and then from (11), (2) and (14) we obtain (13).

Let $p$ be a point in $M$ and $x, y$ be two linearly independent vectors on $T_pM$. It is known that the quantity

$$\mu(L; p) = \frac{R(x, y, x, y)}{g(x, x)g(y, y) - g^2(x, y)}$$

is the sectional curvature of 2-plane $L = \{x, y\}$.

Let $p$ be a point in $M$ and $x = (x^1, x^2, x^3)$ be a vector in $T_pM$. The vectors $x, qx, q^2 x$ are linearly independent, when

$$3 x^1 x^2 x^3 \neq (x^1)^3 + (x^2)^3 + (x^3)^3.$$

Then we define 2-planes $L_1 = \{x, qx\}, L_2 = \{qx, q^2 x\}$ and $L_3 = \{q^2 x, x\}$ and we prove the following

Theorem 3. Let $M$ be the Riemannian manifold with a metric tensor $g$ and a parallel structure $q$, defined by (1) and (3), respectively. Let $p$ be a point in $M$ and $x$ be an arbitrary vector in $T_pM$ satisfying (10). Then the sectional curvatures of 2-planes $L_1 = \{x, qx\}, L_2 = \{qx, q^2 x\}$, $L_3 = \{q^2 x, x\}$ are equal.
Proof. From (13) we obtain
\[(17) \quad R(x, y, z, u) = R(x, y, qz, qu) = R(x, y, q^2 z, q^2 u).\]

In (17) we set the following substitutions: a) \(z = x, y = u = qx\); b) \(x \sim qx, z = qx, y = u = q^2 x;\) c) \(x \sim q^2 x, z = q^2 x, y = u = x\). Comparing the obtained results, we get
\[R(x, qx, q^2 x, x) = R(x, qx, qx, q^2 x) = R(q^2 x, x, qx, q^2 x)\]
(18)
and
\[R(x, qx, x, qx) = R(q^2 x, x, qx, q^2 x) = R(x, qx, x, qx)\]
(19)
\[R(x, qx, x, qx) = R(q^2 x, x, qx, q^2 x) = R(q^2 x, x, qx, q^2 x) = R(x, qx, x, qx).\]

Equalities (6), (15), (16) and (19) imply
\[\mu(L_1; p) = \mu(L_2; p) = \mu(L_3; p) = \frac{R(x, qx, x, qx)}{g^2(x, x) - g^2(x, qx)}.\]

By virtue of the linear independence of \(x\) and \(qx\), we have
\[g^2(x, x) - g^2(x, qx) = g^2(x, x)(1 - \cos \varphi) \neq 0,\]
where \(\varphi\) is the angle between \(x\) and \(qx\).

\[\square\]

5. An Orthonormal \(q\)-Base of Vectors in \(T_p M\)

Let \(M\) be the Riemannian manifold with a metric tensor \(g\) and a structure \(q\), defined by (1) and (3), respectively. We note that the only real eigenvalue and the only eigenvector of the structure \(q\) are \(\lambda = 1\) and \(x(x^1, x^1, x^1)\), respectively.

Now, let
\[x = (x^1, x^2, x^3)\]
(20)
be a non-eigenvector vector of the structure \(q\). We have
\[g(x, x) = \|x\|^2 \cos 0 = \|x\|^2, \quad g(x, qx) = \|x\|^2 \|qx\| \cos \varphi = \|x\|^2 \cos \varphi,\]
where \(\|x\|\) and \(\|qx\|\) are the norms of \(x\) and \(qx\); and \(\varphi\) is the angle between \(x\) and \(qx\).

From (11), (20) and (21) we calculate
\[g(x, x) = A \left((x^1)^2 + (x^2)^2 + (x^3)^2\right) + 2B \left(x^1 x^2 + x^1 x^3 + x^2 x^3\right),\]
(22)
\[g(x, qx) = B \left((x^1)^2 + (x^2)^2 + (x^3)^2\right) + (A + B) \left(x^1 x^2 + x^1 x^3 + x^2 x^3\right).\]
(23)
The above equations imply \(\|x\| = \|qx\| > 0\).

**Theorem 4.** Let \(M\) be the Riemannian manifold with a metric tensor \(g\) and an affinor structure \(q\), defined by (7) and (3), respectively. Let
If \( \varphi \) is the angle between \( x \) and \( qx \), then we have \( \varphi \in \left(0, \frac{2\pi}{3}\right) \).

Proof. We apply equations (22) and (23) in \( \cos \varphi = \frac{g(x, qx)}{g(x, x)} \), and we get

\[
\cos \varphi = \frac{(x^1)^2 + (x^2)^2 + (x^3)^2 + (A + B)(x^1x^2 + x^1x^3 + x^2x^3)}{A((x^1)^2 + (x^2)^2 + (x^3)^2) + 2B(x^1x^2 + x^1x^3 + x^2x^3)}.
\]

Also we have \( x(x^1, x^2, x^3) \neq (x^1, x^1, x^1) \) because \( x \) is a non-eigenvector of \( q \).

We suppose that \( \varphi \geq \frac{2\pi}{3} \), i.e. \( \cos \varphi \leq -\frac{1}{2} \). The last condition and (24) imply

\[
\frac{B((x^1)^2 + (x^2)^2 + (x^3)^2) + (A + B)(x^1x^2 + x^1x^3 + x^2x^3)}{A((x^1)^2 + (x^2)^2 + (x^3)^2) + 2B(x^1x^2 + x^1x^3 + x^2x^3)} \leq -\frac{1}{2}
\]

that gives the inequality

\[
(2B + A)((x^1)^2 + (x^2)^2 + (x^3)^2 + 2(x^1x^2 + x^1x^3 + x^2x^3)) \leq 0.
\]

From the condition \( A + 2B > 0 \) we get that

\[
(x^1)^2 + (x^2)^2 + (x^3)^2 + 2(x^1x^2 + x^1x^3 + x^2x^3) \leq 0
\]

and \( (x^1 + x^2 + x^3)^2 \leq 0 \). The last inequality has no solution in the real set. Then we have \( \cos \varphi > -\frac{1}{2} \).

Immediately, from Theorem 4, we establish that an orthonormal \( q \)-base \((x, qx, q^2x)\) in \( T_p M \) exists. Particularly, we verify that the vector

\[
x = \left(\frac{\sqrt{A - B} + \sqrt{A + 3B}}{2\sqrt{A^2 + AB - 2B^2}}, \frac{\sqrt{A - B} - \sqrt{A + 3B}}{2\sqrt{A^2 + AB - 2B^2}}, 0\right)
\]

satisfies the conditions

\[
g(x, x) = 1, \quad g(x, qx) = 0.
\]

The base \((x, qx, q^2x)\), where \( x \) satisfies (25), is an example of an orthonormal \( q \)-base in \( T_p M \).

**Theorem 5** Let \( M \) be the Riemannian manifold with a metric tensor \( g \) and a parallel structure \( q \), defined by (1) and (3), respectively. Let \((x, qx, q^2x)\) be an orthonormal \( q \)-base in \( T_p M \), \( p \in M \), and \( u = \alpha \cdot x + \beta \cdot qx + \gamma \cdot q^2x \), \( v = \delta \cdot x + \zeta \cdot qx + \eta \cdot q^2x \) be arbitrary vectors in \( T_p M \). For the sectional curvature \( \mu(u, v) \) of 2-plane \( \{u, v\} \) we have

\[
\mu(u, v) = \frac{(\alpha \zeta - \beta \delta + \delta \gamma - \alpha \eta + \beta \eta - \gamma \zeta)^2}{(\alpha^2 + \beta^2 + \gamma^2)(\delta^2 + \zeta^2 + \eta^2) - (\alpha \delta + \beta \zeta + \gamma \eta)^2} \mu(x, qx).
\]
Proof. We calculate

\[(28) \quad g(u, u) = \alpha^2 + \beta^2 + \gamma^2, \quad g(v, v) = \delta^2 + \zeta^2 + \eta^2, \]
\[\quad g(u, v) = \alpha \delta + \beta \zeta + \gamma \eta.\]

For the sectional curvature of 2-plane \(\{u, v\}\) we have

\[(29) \quad \mu(u, v) = \frac{R(u, v, u, v)}{g(u, u)g(v, v) - g^2(u, v)}.\]

Using the linear properties of the metric \(g\) and the curvature tensor field \(R\) after long calculations we get

\[(30) \quad R(u, v, u, v) = (\alpha \zeta - \beta \delta)^2 R(x, qx, x, qx)\]
\[\quad + (\delta x - \alpha \eta)^2 R(x, q^2 x, x, q^2 x)\]
\[\quad + (\beta \eta - \gamma \zeta)^2 R(q x, q^2 x, qx, q^2 x)\]
\[\quad + 2(\alpha \zeta - \beta \delta)(\delta \gamma - \alpha \eta)R(x, qx, q^2 x, x)\]
\[\quad + 2(\delta \gamma - \alpha \eta)(\beta \eta - \gamma \zeta)R(q^2 x, x, qx, q^2 x)\]
\[\quad + 2(\alpha \zeta - \beta \delta)(\beta \eta - \gamma \zeta)R(x, qx, qx, q^2 x).\]

From (18), (19) and (30) we obtain

\[(31) \quad R(u, v, u, v) = ((\alpha \zeta - \beta \delta) + (\delta \gamma - \alpha \eta) + (\beta \eta - \gamma \zeta))^2 R(x, qx, x, qx).\]

From (28), (29) and (31) we get

\[\mu(u, v) = \frac{(\alpha \zeta - \beta \delta + \delta \gamma - \alpha \eta + \beta \eta - \gamma \zeta)^2}{(\alpha^2 + \beta^2 + \gamma^2)(\delta^2 + \zeta^2 + \eta^2) - (\alpha \delta + \beta \zeta + \gamma \eta)^2} R(x, qx, x, qx).\]

The last equation and (26) imply (27).

\[\square\]

Corollary 1. Let \(u\) be an arbitrary non-eigenvector in \(T_p M, p \in M\), and \(\theta\) be the angle between \(u\) and \(qu\).

Then we have

\[(32) \quad \mu(u, qu) = \mu(x, qx) \tan^2 \frac{\theta}{2}, \quad \theta \in \left(0, \frac{2\pi}{3}\right).\]

Proof. In (27) we substitute \(v = qu, \delta = \gamma, \zeta = \alpha, \eta = \beta\) and we obtain

\[\mu(u, qu) = \frac{(\alpha^2 + \beta^2 + \gamma^2 - \beta \gamma - \alpha \beta - \alpha \gamma)^2}{(\alpha^2 + \beta^2 + \gamma^2)^2 - (\alpha \gamma + \alpha \beta + \gamma \beta)^2} \mu(x, qx).\]

Then from (28) we get

\[\mu(u, qu) = \frac{(g(u, u) - g(u, qu))^2}{g^2(u, u) - g^2(u, qu)} \mu(x, qx),\]

i.e.

\[\mu(u, qu) = \frac{(1 - \cos \theta)^2}{1 - \cos^2 \theta} \mu(x, qx),\]

which implies (32).
Corollary 2. Let \( u, v \) be an arbitrary non-eigenvectors on \( T_p M, p \in M \), and \( \theta \) be the angle between \( u \) and \( qu \), and \( \psi \) be the angle between \( v \) and \( qv \). Then we have

\[
\mu(u, qu) \tan^2 \frac{\psi}{2} = \mu(v, qv) \tan^2 \frac{\theta}{2}, \quad \psi, \theta \in \left(0, \frac{2\pi}{3}\right).
\]

The proof follows immediately from (32).
