Introduction

The Lewis-Zagier correspondence [12, 13, 14], see also [2], is a bijection between the space of Maaß wave forms of a fixed Laplace-eigenvalue $\lambda$ and the space of real-analytic functions on the line satisfying a functional equation which involves the eigenvalue. The latter functions are called period functions. In [4] this correspondence has been extended to subgroups $\Gamma$ of finite index in the full modular group $\Gamma(1)$. One can assume $\Gamma$ to be normal in $\Gamma(1)$. The central idea of the latter paper is to consider the action of the
finite group \( \Gamma(1)/\Gamma \), and in this way to consider Maaß forms for \( \Gamma \) as vector-valued Maaß forms for \( \Gamma(1) \). This technique can be applied to higher order forms \([3, 5, 6, 7, 8, 9, 10]\) as well, turning the somewhat unfamiliar notion of a higher order invariant into the notion of a classical invariant of a twist by unipotent representation. This viewpoint has, in the case of Eisenstein series, already been used in [11]. The general framework of higher order invariants and unipotent twists is described in the first section of the present paper. This way of viewing higher order forms has the advantage that it allows techniques of classical automorphic forms to be applied in the context of higher order forms. The example of the trace formula will be subject of further investigations by the current author in the near future. In the present, we apply this technique to extend the Lewis-Zagier correspondence to higher order forms.

We define the corresponding spaces of automorphic forms of higher order in the second section. Holomorphic forms of higher order have been defined by various authors. Maaß forms are more subtle, as it is not immediately clear, how to establish the \( L^2 \)-structure on higher order invariants. In the paper [6], the authors resorted to the obvious \( L^2 \)-structure for the quotient spaces of consecutive higher order forms, which however is unsatisfactory because one wishes to view \( L^2 \)-higher order forms as higher order invariants themselves. In the present paper this flaw is remedied, as we give a space of locally square-integrable functions on the universal cover of the Borel-Serre compactification whose higher order invariants give the sought for \( L^2 \)-invariants.

In this paper we use a common definition of higher order forms which insists on full invariance under parabolic elements. In the language of our present Section 1 that means that we take the subgroup \( P \) to be the subgroup generated by all parabolic elements. It is an open question, whether the contents of this paper can be extended to the case \( P = \{1\} \), i.e., full higher order invariants. In this case, Fourier expansions have to be replaced with Fourier-Taylor expansions and thus it is unclear, how the correspondence should be defined.
1 Higher order invariants and unipotent representations

In this section we describe higher order forms by means of invariants in unipotent representations.

Let $\Gamma$ be a group and let $W$ be a $C[\Gamma]$-module. We here take the field $C$ of complex numbers as base ring. Most of the general theory works over any ring, but our applications are over $C$. Let $I_\Gamma$ be the augmentation ideal in $C[\Gamma]$ this is the kernel of the augmentation homomorphism $A : C[\Gamma] \to C$; $\sum_\gamma c_\gamma \gamma \mapsto \sum_\gamma c_\gamma$. The ideal $I_\Gamma$ is a vector space with basis $(\gamma - 1)_{\gamma \in \Gamma \setminus \{1\}}$.

In the sequel, we will need two simple properties of the augmentation ideal which, for the convenience of the reader, we will prove in the following lemma. A set $S$ of generators of the group $\Gamma$ is called symmetric, if $s \in S \Rightarrow s^{-1} \in S$.

It is easy to see that

- $C[\Gamma] = C \oplus I_\Gamma$.
- For any given set of generators $S$ of $\Gamma$ one has

$$I_\Gamma = \sum_{s \in S} C[\Gamma](s - 1).$$

We also fix a normal subgroup $P$ of $\Gamma$. We let $I_P$ denote the augmentation ideal of $P$ and $\tilde{I}_P = C[\Gamma]I_P$. As $P$ is normal, $\tilde{I}_P$ is a two-sided ideal of $C[\Gamma]$.

For any integer $q \geq 0$ we set

$$J_q = I_\Gamma^q + \tilde{I}_P.$$

The set of $\Gamma$-invariants $W^T = H^0(\Gamma, W)$ in $W$ can be described as the set of all $w \in W$ with $I_\Gamma w = 0$. For $q = 1, 2, \ldots$ we define the set of invariants of type $P$ and order $q$ to be

$$H^0_{q,P}(\Gamma, W) = \{w \in W : J_q w = 0\}.$$ 

Then $H^0_{q,P} = H^0_{q,P}(\Gamma, W)$ is a submodule of $W$ and we have a natural filtration

$$0 \subset H^0_{1,P} \subset H^0_{2,P} \subset \cdots \subset H^0_{q,P} \subset \cdots,$$

and as $I_\Gamma H^0_{q,P} \subset H^0_{q-1,P}$, the group $\Gamma$ acts trivially on $H^0_{q,P}/H^0_{q-1,P}$. 
A representation \((\eta, V_\eta)\) of \(\Gamma\) on a complex vector space \(V_\eta\) is called a \textit{unipotent length }\(q\textit{ representation},\) if \(V_\eta\) has a \(\Gamma\)-stable filtration
\[0 \subset V_{\eta,1} \subset \cdots \subset V_{\eta,q} = V_\eta,\]
such that \(\Gamma\) acts trivially on each quotient \(V_{\eta,k}/V_{\eta,k-1}\) where \(k = 1, \ldots, q\) and \(V_{\eta,0} = 0.\)

Let a unipotent length \(q\) representation \((\eta, V_\eta)\) be given. We also assume that it is \(P\)-trivial, i.e., the restriction to the subgroup \(P\) is the trivial representation. There is a natural map
\[\Phi_\eta : \text{Hom}_\Gamma (V_\eta, W) \otimes V_\eta \to W\]
given by \(\alpha \otimes v \mapsto \alpha(v).\)

\textbf{Lemma 1.1} Let \(W\) be a \(\mathbb{C}[\Gamma]\)-module. The submodule \(H^0_{q,P}(\Gamma, W)\) constitutes a \(P\)-trivial, unipotent length \(q\) representation of \(\Gamma\). If the group \(\Gamma\) is finitely generated, then the space \(H^0_{q,P}(\Gamma, W)\) is the sum of all images \(\Phi_\eta\) when \(\eta\) runs over the set of all \(P\)-trivial, unipotent length \(q\) representations which are finite dimensional over \(\mathbb{C}\).

\textbf{Proof:} The first assertion is clear. Assume now that \(\Gamma\) is finitely generated. The space \(H^0_{q,P}(\Gamma, W)\) needn’t be finite dimensional. We use induction on \(q\) to show that for each \(w \in H^0_{q,P}(\Gamma, W)\) the complex vector space \(\mathbb{C}[\Gamma]w\) is finite dimensional. For \(q = 1\) we have \(\mathbb{C}[\Gamma]w = \mathbb{C}w\) and the claim follows. Next let \(w \in H^0_{q+1,P}(\Gamma, W)\) and let \(S\) be a finite set of generators of \(\Gamma\). Then
\[\mathbb{C}[\Gamma]w = \mathbb{C}w + I_\Gamma w = \mathbb{C}w + \sum_{s \in S} \mathbb{C}[\Gamma](s-1)w.\]
The element \((s-1)w\) lies in \(H^0_{q,P}(\Gamma, W)\), so by induction hypothesis, the claim follows. \(\square\)

Assume from now on that \(\Gamma\) is finitely generated. The philosophy pursued in the rest of the paper is this:

\textit{Once you know }\text{Hom}_\Gamma (V_\eta, W)\textit{ for every }\text{P-trivial, finite dimensional unipotent length }q\textit{ representation, you know the space }H^0_{q,P}(\Gamma, W).
So, instead of investigating $H^0_{q,P}(\Gamma, W)$ one should rather look at
\[ \text{Hom}_\Gamma(V, W) \cong (V^* \otimes W)^\Gamma, \]
which is often easier to handle. In fact, it is enough to restrict to a generic set of $\eta$. As an example of this philosophy consider the case $q = 2$. For each group homomorphism $\chi : \Gamma/P \to (\mathbb{C}, +)$ one gets a $P$-trivial, unipotent length $q$ representation $\eta_\chi$ on $\mathbb{C}^2$ given by $\eta_\chi(\gamma) = \left(^1 \chi(\gamma) \right)$.

We introduce the following notation
\[ \bar{H}^0_{q,P} = \bar{H}^0_{q,P}(\Gamma, W) = H^0_{q,P}(\Gamma, W)/H^0_{q-1,P}(\Gamma, W) = H^0_{q,P}/H^0_{q-1,P}. \]

**Proposition 1.2** The space $\bar{H}^0_{2,P}(\Gamma, W)$ is the sum over all images $\Phi_{\eta_\chi}$, where $\chi$ ranges in $\text{Hom}(\Gamma/P, \mathbb{C}) \setminus \{0\}$. For any two $\chi \neq \chi'$ one has
\[ \text{Im}(\Phi_{\eta_\chi}) \cap \text{Im}(\Phi_{\eta_{\chi'}}) = H^0(\Gamma, W). \]

In other words, one has
\[ \bar{H}^0_1 = \bigoplus_{\chi} \text{Im}(\Phi_{\eta_\chi})/H^0. \]

**Proof:** We make use of the order lowering operator
\[ \Lambda : \bar{H}^0_{q,P} \to \text{Hom}(\Gamma/P, \bar{H}^0_{q-1,P}) \cong \text{Hom}(\Gamma/P, \mathbb{C}) \otimes \bar{H}^0_{q-1,P}, \]
where the last isomorphism is due to the fact that $\Gamma$ is finitely generated. This operator is defined as
\[ \Lambda(w)(\gamma) = (\gamma - 1)w. \]

One sees that this indeed is a homomorphism in $\gamma$ by using the fact that
\[ (\gamma \tau - 1) \equiv (\gamma - 1) + (\tau - 1) \mod I^2 \]
for any two $\gamma, \tau \in \Gamma$. The map $\Lambda$ is clearly injective.

Let now $w \in \text{Im}(\Phi_{\eta_\chi}) \cap \text{Im}(\Phi_{\eta_{\chi'}})$ for $\chi \neq \chi'$. Then
\[ \Lambda(w) \in \chi \otimes H^0 \cap \chi' \otimes H^0, \]
and the latter space is zero as $\chi \neq \chi'$. For surjectivity, let $w \in H^0_1$. Then $\Lambda(w) = \sum_{i=1}^n \chi_i \otimes w_i$ with $w_i \in H^0_i$, and so $w \in \sum_{i=1}^n \text{Im}(\phi_{\eta_{\chi_i}}).$ \qed
2 Higher order forms

We next define some spaces of automorphic forms of higher order, like holomorphic modular forms or Maaß wave forms [3, 5, 6, 7, 8, 9, 10]. The holomorphic case has been treated in various other places. Maaß forms are more subtle, as it is not immediately clear, how to establish the $L^2$-structure on higher order invariants. In the paper [6] the authors resorted to the obvious $L^2$-structure for the quotient spaces $\overline{H}_{q,P}^0$, which however is unsatisfactory because one wishes to view $L^2$-higher order forms as higher order invariants themselves. In the present paper this flaw is remedied, as we give a space of locally square-integrable functions on the universal cover of the Borel-Serre compactification whose higher order invariants give the sought for $L^2$-invariants. We also give a guide how to set up higher order $L^2$-invariants in more general cases, like general lattices in locally compact groups, when there is no such gadget as the Borel-Serre compactification around. In that case, Lemma 2.1 tells you how to define the $L^2$-structure once you have chosen a fundamental domain for the group action.

Let $G$ denote the group $\text{PSL}_2(\mathbb{R}) = \text{SL}_2(\mathbb{R})/\{\pm 1\}$. It has the group $K = \text{PSO}(2) = \text{SO}(2)/\{\pm 1\}$ as a maximal compact subgroup. Let $\Gamma(1) = \text{PSL}_2(\mathbb{Z})$ be the full modular group. Let $\Gamma \subset \Gamma(1)$ be a normal subgroup of finite index which is torsion-free. For every cusp $c$ of $\Gamma$ fix $\sigma_c \in \Gamma(1)$ such that $\sigma_c \infty = c$ and $\sigma_c^{-1} \Gamma_c \sigma_c = \pm \left( \begin{smallmatrix} 1 & N_c \mathbb{Z} \\ 0 & 1 \end{smallmatrix} \right)$. The number $N_c \in \mathbb{N}$ is uniquely determined and is called the width of the cusp $c$. Let $\mathbb{H} = \{z \in \mathbb{C} : \text{Im}(z) > 0\}$ be the upper half plane and let $O(\mathbb{H})$ be the set of holomorphic functions on $\mathbb{H}$. We fix a weight $k \in 2\mathbb{Z}$ and define a (right-) action of $G$ on functions $f$ on $\mathbb{H}$ by

$$f|_k \gamma(z) = (cz + d)^{-k} f \left( \frac{az + b}{cz + d} \right), \quad \gamma = \left( \begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right).$$

We define the space $O^M_{\Gamma,k}(\mathbb{H})$ to be the set of all $f \in O(\mathbb{H})$, such that for every cusp $c$ of $\Gamma$ the function $f|_k \sigma_c$ is, in the domain $\{\text{Im}(z) > 1\}$, bounded by a constant times $\text{Im}(z)^A$ for some $A > 0$.

Further we consider the space $O^S_{\Gamma,k}(\mathbb{H})$ of all $f \in O(\mathbb{H})$, such that for every cusp $c$ of $\Gamma$ the function $f|_k \sigma_c$ is, in the domain $\{\text{Im}(z) > 1\}$, bounded by a constant times $e^{-A\text{Im}(z)}$ for some $A > 0$. 

These two spaces are preserved not only by \( \Gamma \), but also by the action of the full modular group \( \Gamma(1) \).

The normal subgroup \( P \) of \( \Gamma \) will be the subgroup \( \Gamma_{\text{par}} \) generated by all parabolic elements. We then write \( H^0_{q,\text{par}} \) for \( H^0_{q,P} \). We consider the space of modular functions of weight \( k \) and order \( q \),

\[
M_{k,q}(\Gamma) = H^0_{q,\text{par}}(\Gamma, \mathcal{O}^M_{\Gamma,k}(\mathbb{H})),
\]
as well as the corresponding space of cusp forms

\[
S_{k,q}(\Gamma) = H^0_{q,\text{par}}(\Gamma, \mathcal{O}^S_{\Gamma,k}(\mathbb{H})).
\]

Then every \( f \in M_{k,q}(\Gamma) \) possesses a Fourier expansion at every cusp \( c \) of the form

\[
f|_k \sigma_c(z) = \sum_{n=0}^{\infty} a_{c,n} e^{2\pi i n z N_c}.
\]

A function \( f \in M_{k,q}(\Gamma) \) belongs to the subset \( S_{k,q}(\Gamma) \) if and only if \( a_{c,0} = 0 \) for every cusp \( c \) of \( \Gamma \).

As the group \( \Gamma \) is normal in \( \Gamma(1) \), the latter group acts on the finite dimensional spaces \( M_{k,q}(\Gamma) \) and \( S_{k,q}(\Gamma) \). These therefore give examples of finite dimensional representations of \( \Gamma(1) \) which become unipotent length \( q \) when restricted to \( \Gamma \).

By a Maaß wave form for the group \( \Gamma \) and parameter \( \nu \in \mathbb{C} \) we mean a function \( u \in L^2(\Gamma\backslash \mathbb{H}) \) which is twice continuously differentiable and satisfies

\[
\Delta u = (\frac{1}{4} - \nu^2) u.
\]

By the regularity of solutions of elliptic differential equations this condition implies that \( u \) is real analytic. Let \( \mathcal{M}_\nu = \mathcal{M}_\nu(\Gamma) \) be the space of all Maaß wave forms for \( \Gamma \). Note that sometimes in the definition of Maaß forms, instead of the \( L^2 \)-condition, a weaker condition on the growth at the cusps is imposed.

Next we define Maaß-wave forms of higher order. First we need the higher order version of the Hilbert space \( L^2(\Gamma\backslash \mathbb{H}) \). For this recall the construction of the Borel-Serre compactification \( \Gamma\backslash \mathbb{H} \) of \( \Gamma\backslash \mathbb{H} \), see [1]. First one constructs a space \( \overline{\mathbb{H}_\Gamma} \) of \( \Gamma\backslash \mathbb{H} \) by attaching to each cusp \( c \) of \( \Gamma \) a real line to \( \mathbb{H} \) and then one equips this set with a suitable topology such that \( \Gamma \) acts properly discontinuously and the quotient \( \Gamma\backslash \overline{\mathbb{H}_\Gamma} \) is the Borel-Serre compactification. The
space $\mathbb{H}_\Gamma$ is constructed in such a way, that for a given (closed) fundamental domain $D \subset \mathbb{H}$ of $\Gamma \backslash \mathbb{H}$ which has finitely many geodesic sides, the closure $\overline{D}$ in $\mathbb{H}_\Gamma$ is a fundamental domain for $\Gamma \backslash \mathbb{H}_\Gamma$. By the discontinuity of the group action, this has the following consequence: For every compact set $K \subset \mathbb{H}_\Gamma$ there exists a finite set $F \subset \Gamma$ such that $K \subset F\overline{D} = \bigcup_{\gamma \in F} \gamma \overline{D}$.

Now we extend the hyperbolic measure to $\mathbb{H}_\Gamma$ in such a way that the boundary $\partial \mathbb{H}_\Gamma = \mathbb{H}_\Gamma \setminus \mathbb{H}$ is a nullset. Let $L^2_{\text{loc}}(\mathbb{H}_\Gamma)$ be the space of local $L^2$-functions on $\mathbb{H}_\Gamma$. Then $\Gamma$ acts on $L^2_{\text{loc}}(\mathbb{H}_\Gamma)$. Since $\Gamma$ acts discontinuously with compact quotient on $\mathbb{H}_\Gamma$, one has $L^2_{\text{loc}}(\mathbb{H}_\Gamma) = L^2(\Gamma \backslash \mathbb{H})$.

Define the space $L^2_q(\Gamma \backslash \mathbb{H})$ as the space of all $f \in L^2_{\text{loc}}(\mathbb{H}_\Gamma)$ such that $J_q f = 0$, so in other words,

$$L^2_q(\Gamma \backslash \mathbb{H}) = H^0_{q, \text{par}}(\Gamma, L^2_{\text{loc}}(\mathbb{H}_\Gamma)).$$

Then $L^2_1(\Gamma \backslash \mathbb{H}) = L^2(\Gamma \backslash \mathbb{H})$ is a Hilbert space in a natural way. We want to install Hilbert space structures on the spaces $L^2_q(\Gamma \backslash \mathbb{H})$ for $q \geq 2$ as well. For this purpose we introduce the space $F_q$ of all measurable functions $f : \mathbb{H} \to \mathbb{C}$ such that $J_q f = 0$ modulo nullfunctions. Then $L^2_q(\Gamma \backslash \mathbb{H})$ is a subset of $F_q$.

**Lemma 2.1** Let $S \subset \Gamma$ be a finite set of generators which is assumed to be symmetric and to contain the unit element. Let $D \subset \mathbb{H}$ be a closed fundamental domain of $\Gamma$ which has finitely many geodesic sides.

Any $f \in F_q$ is uniquely determined by its restriction to

$$S^{q-1}D = \bigcup_{s_1, \ldots, s_{q-1} \in S} s_1 \ldots s_{q-1}D.$$ 

One has

$$F_q \cap L^2(S^{q-1}D) = L^2_q(\Gamma \backslash \mathbb{H}),$$

where on both sides we mean the restriction to $S^qD$, which is unambiguous by the first assertion. In this way the space $L^2_q(\Gamma \backslash \mathbb{H})$ is a closed subspace of the Hilbert space $L^2(S^{q-1}D)$. The induced Hilbert space topology on $L^2_q(\Gamma \backslash \mathbb{H})$ is independent of the choices of $S$ and $D$, although the inner product is not. The action of the group $\Gamma(1)$ on $L^2_q(\Gamma \backslash \mathbb{H})$ is continuous, but not unitary unless $q = 1$. 
Proof: We have to show that any \( f \in L_q = L^2_q(\Gamma \setminus \mathbb{H}) \) which vanishes on \( S^{q-1}D \), is zero. We use induction on \( q \). The case \( q = 1 \) is clear. Let \( q \geq 2 \) and write \( \bar{L}_q = L_q/L_{q-1} \). Consider the order lowering operator

\[
\Lambda : L_q \to \text{Hom}(\Gamma, \bar{L}_{q-1}) \cong \text{Hom}(\Gamma, \mathbb{C}) \otimes \bar{L}_{q-1},
\]

given by

\[
\Lambda(f)(\gamma) = (\gamma - 1)f.
\]

The kernel of \( \Lambda \) is \( L_{q-1} \). Now assume \( f(S^{q-1}D) = 0 \). Then for every \( s \in S \) we have \( (s-1)f(S^{q-2}D) = 0 \) and hence, by induction hypothesis, we conclude \( (s-1)f = 0 \). But as \( S \) generates \( \Gamma \) this means that \( \Lambda(f) = 0 \) and so \( f \in L_{q-1} \), so, again by induction hypothesis, we get \( f = 0 \).

We next show that

\[
F_q \cap L^2(S^{q-1}D) = F_q \cap L^2(S^{q-1}+jD)
\]

for every \( j \geq 0 \). The inclusion "\( \supset \)" is clear. We show the other inclusion by induction on \( q \) and \( j \). For \( q = 1 \) or \( j = 0 \) there is no problem. So assume the claim proven for \( q \). Let \( f \in F_{q+1} \cap L^2(S^{q+j}D) \) and let \( s \in S \). Then \( f(sz) = f(z) + f(sz) - f(z) \), the function \( f(z) \) in in \( L^2(S^{q+j}D) \) and the function \( f(sz) - f(z) \) is in \( F_q \cap L^2(S^{q+j-1}D) = L^2(S^{q+j}D) \) by induction hypothesis. It follows that \( f \in L^2(s^{-1}S^{q+j}D) \) and since this holds for every \( s \) we get \( f \in L^2(S^{q+j+1}D) \) as claimed.

We now come to

\[
F_q \cap L^2(S^{q-1}D) = L^2_q(\Gamma \setminus \mathbb{H}).
\]

Let \( f \in F_q \cap L^2(S^{q-1}D) \). For every compact subset \( K \) of \( \mathbb{H}_\Gamma \) there exists \( j \geq 0 \) such that \( K \subset S^{q-1+j}D \). Therefore, \( f \) is in \( L^2(K) \) for every compact subset \( K \) of \( H_\Gamma \). As the latter space is locally compact, \( f \) is in \( L^2_{\text{loc}}(\mathbb{H}_\Gamma) \). Since \( I^2_\Gamma f = 0 \) we get \( f \in L^2(\Gamma \setminus \mathbb{H}) \). For the other inclusion let \( f \in L^2_{\text{loc}}(\Gamma \setminus \mathbb{H}) \). As \( S^{q-1}D \) is relatively compact in \( \mathbb{H}_\Gamma \) it follows that \( f \in L^2(S^{q-1}D) \) as claimed.

We next show independence of the topology of \( S \). So let \( S' \) be another set of generators. Then there exists \( l \in \mathbb{N} \) such that \( S' \subset S^l \). Hence it suffices to show that the topology from the inclusion \( L^2_q(\Gamma \setminus \mathbb{H}) \subset L^2(S^{q-1}D) \) coincides with the topology from the inclusion \( L^2_q(\Gamma \setminus \mathbb{H}) \subset L^2(S^{q+j}D) \) for every \( j \geq 0 \). If a sequence tends to zero in the latter, it clearly tends to zero in the first. The other way round is proven by induction on \( j \) similar to the above. In particular, the continuity of the \( \Gamma(1) \)-action follows.
Finally, we show the independence of $D$. Let $D'$ be another closed fundamental domain with finitely many geodesic sides. Then there exists $l \in \mathbb{N}$ such that $D' \subset S^l D$ and the claim follows along the same lines as above.

We define the space $\mathcal{M}_{\nu,q} = \mathcal{M}_{\nu,q}(\Gamma)$ of Maaß-wave forms of order $q$ to be the space of all $u \in L^2_q(\Gamma \backslash \mathbb{H})$ which are twice continuously differentiable and satisfy
\[
\Delta u = \left(\frac{1}{4} - \nu^2\right) u.
\]

Fix a finite dimensional representation $(\eta, V_\eta)$ of $\Gamma(1)$, which is $\Gamma_{\text{par}}$-trivial and becomes a unipotent length $q$ representation on restriction to $\Gamma$.

We set $\mathcal{M}_{\nu,q,\eta} = (V_\eta \otimes \mathcal{M}_{\nu,q})^{\Gamma(1)}$. Likewise we define $\tilde{\mathcal{M}}_{\nu,q} = (V_\eta \otimes \tilde{\mathcal{M}}_{\nu,q})^{\Gamma(1)}$.

\begin{lemma}
Let $D'_\nu$ be the space of all distributions $u$ on $\mathbb{H}$ with $\Delta u = \left(\frac{1}{4} - \nu^2\right) u$. Then
\[
\tilde{\mathcal{M}}_{\nu,q,\eta} = (V_\eta \otimes \tilde{\mathcal{M}}_{\nu,q})^{\Gamma(1)} = (V_\eta \otimes D'_\nu)^{\Gamma(1)}
\]
and
\[
\mathcal{M}_{\nu,q,\eta} = (V_\eta \otimes \mathcal{M}_{\nu,q})^{\Gamma(1)} = (V_\eta \otimes (D'_\nu \cap L^2_{\text{loc}}(\mathbb{H}_\Gamma)))^{\Gamma(1)}.
\]
\end{lemma}

\textbf{Proof:} The inclusion "$\subset$" is obvious in both cases. We show "$\supset$". In the first case, the space on the left can be described as the space of all smooth functions $u : \mathbb{H} \to V_\eta$ satisfying $\Delta u = \left(\frac{1}{4} - \nu^2\right) u$ as well as $J_{q+1} u = 0$ and $u(\gamma z) = \eta(\gamma) u(z)$ for every $\gamma \in \Gamma(1)$. Now let $u \in (V_\eta \otimes D'_\nu)^{\Gamma(1)}$. As $u$ satisfies an elliptic differential equation with smooth coefficients, $u$ is a smooth function with $\Delta u = \left(\frac{1}{4} - \nu^2\right) u$. The condition $u(\gamma z) = \eta(\gamma) u(z)$ is clear. Finally, the condition $J_{q+1} u = 0$ follows from that, as $\eta|_\Gamma$, being $\Gamma_{\text{par}}$-trivial and unipotent of length $q$, satisfies $\eta(J_{q+1}) = 0$. Hence the first claim is proven. The second is similar. \qed

As in the holomorphic case, every Maaß-form $f \in \mathcal{M}_{\nu,q}(\Gamma)$ has a Fourier expansion at every cusp $c$,
\[
f(\sigma_c z) = \sum_{n=0}^{\infty} a_{c,n}(y) e^{2\pi i \frac{c}{h} z},
\]
THE LEWIS CORRESPONDENCE...

with smooth functions $a_{c,n}(y)$.

We define the space $S_{\nu,q}$ of Maaß cusp forms to be the space of all $f \in M_{\nu,q}$ with $a_{c,0}(y) = 0$ for every cusp $c$. We also set $S_{\nu,q,\eta} = (V_\eta \otimes S_{\nu,q})^{\Gamma(1)}$.

Note that since $\eta$ is unipotent of length $q$ on $\Gamma$, we have

$$S_{\nu,q,\eta} = (V_\eta \otimes S_{\nu,q})^{\Gamma(1)}$$

for every $q' \geq q$.

### 3 Setting up the transform

It is the aim of this note to extend the Lewis Correspondence [4, 12, 13, 14] to the case of higher order forms. We will explain the approach in the case of cusp forms first.

Throughout, let $(\eta, V_\eta)$ be a finite dimensional representation of $\Gamma(1)$ which becomes $\Gamma_{\text{par}}$-trivial and unipotent of length $q$ when restricted to $\Gamma$.

We fix the following notation for the canonical generators of $\Gamma(1)$:

$$S = \pm \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \text{and} \quad T = \pm \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}.$$  

Then $S^2 = 1 = (ST)^3$, and $T$ is of infinite order. Note that there exists $N \in \mathbb{N}$ such that $T^N \in \Gamma$ as $\Gamma(1)/\Gamma$ is a finite group. Let $N$ be minimal with this property, then $N = N_\infty$ is the width of the cusp $\infty$ of $\Gamma$. We then have $\eta(T)^N = \eta(T^N) = 1$, as $\eta$ is trivial on parabolic elements of $\Gamma$.

Let $\Psi_{\nu,\eta}$ be the space of all holomorphic functions $\psi: \mathbb{C} \setminus (-\infty, 0] \to V_\eta$ satisfying the Lewis equation

$$\eta(T)\psi(z) = \psi(z + 1) + (z + 1)^{-2\nu-1}\eta(ST^{-1})\psi \left( \frac{z}{z+1} \right)$$  \hspace{1cm} (1)

and the asymptotic formula

$$0 = e^{+\pi i \nu} \lim_{\text{Im}(z) \to \infty} \left( \psi(z) + z^{-2\nu-1}\eta(S)\psi \left( \frac{-1}{z} \right) \right) + e^{-\pi i \nu} \lim_{\text{Im}(z) \to -\infty} \left( \psi(z) + z^{-2\nu-1}\eta(S)\psi \left( \frac{-1}{z} \right) \right),$$  \hspace{1cm} (2)
where both limits are supposed to exist.

Let $A$ denote the subgroup of $G$ consisting of diagonal matrices and let $N$ be the subgroup of upper triangular matrices with $\pm 1$ on the diagonal. The group $G$ then as a manifold is a direct product $G = ANK$. For $\nu \in \mathbb{C}$ and $a = \pm \text{diag}(t, t^{-1}) \in A$, $t > 0$, let $a^\nu = t^{2\nu}$. We insert the factor 2 for compatibility reasons.

Let $\left( \pi_\nu, V_{\pi_\nu} \right)$ denote the principal series representation of $G$ with parameter $\nu$. The representation space $V_{\pi_\nu}$ is the Hilbert space of all functions $\varphi : G \to \mathbb{C}$ with $\varphi(\text{an}x) = a^{\nu + \frac{t}{2}} \varphi(x)$ for $a \in A, n \in N, x \in G$, and $\int_K |\varphi(k)|^2 \, dk < \infty$ modulo nullfunctions. The representation is $\pi_\nu(x) \varphi(y) = \varphi(yx)$. There is a special vector $\varphi_0$ in $V_{\pi_\nu}$ given by

$$\varphi_0(\text{an}k) = a^{\nu + \frac{t}{2}}.$$  

This vector is called the basic spherical function with parameter $\nu$.

For a continuous $G$-representation $(\pi, V_\pi)$ on a topological vector space $V_\pi$ let $\left( \pi^\omega \right)$ denote the subrepresentation on the space of analytic vectors, i.e. $V_{\pi^\omega}$ consists of all vectors $v$ in $V_\pi$ such that for every continuous linear map $\alpha : V_{\pi} \to \mathbb{C}$ the map $g \mapsto \alpha(\pi(g)v)$ is real analytic on $G$. This space comes with a natural topology. Let $\left( \pi^{-\omega}_\nu \right)$ be its topological dual. In the case of $\pi = \pi_\nu$ it is known that $\pi^\omega_\nu$ and $\pi^{-\omega}_\nu$ are in perfect duality, i.e., they are each other’s topological duals. The vectors in $\pi^{-\omega}_\nu$ are called hyperfunction vectors of the representation $\pi_\nu$.

As a crucial tool we will use the space

$$A_{\nu, \eta}^{-\omega} = (\pi^{-\omega}_\nu \otimes \eta)^{\Gamma(1)} = H^0(\Gamma(1), \pi^{-\omega}_\nu \otimes \eta)$$

and call it the space of $\eta$-automorphic hyperfunctions.

For an automorphic hyperfunction $\alpha \in A_{\nu, \eta}^{-\omega}$ we consider the function $u : G \to V_\eta$ given by

$$u(g) \overset{\text{def}}{=} \langle \pi_{-\nu}(g)\varphi_0, \alpha \rangle.$$  

Here $\langle \cdot, \cdot \rangle$ is the canonical pairing $\pi^\omega_{-\nu} \times \pi^{-\omega}_{-\nu} \otimes \eta \to V_\eta$. Then $u$ is right $K$-invariant, hence can be viewed as a function on $\mathbb{H}$. As such it lies in $\tilde{\mathcal{M}}_{\nu, \eta}$ since $\alpha$ is $\Gamma$-equivariant and the Casimir operator on $G$, which induces $\Delta$, is scalar on $\pi_\nu$ with eigenvalue $\frac{1}{4} - \nu^2$. The transform $F : \alpha \mapsto u$ is
called the Poisson transform. It follows from [15], Theorem 5.4.3, that the Poisson transform

\[ P: A_{\nu, \eta}^{\omega} \rightarrow \tilde{M}_{\nu, \eta} \]

is an isomorphism for \( \nu \notin \frac{1}{2} + \mathbb{Z} \).

For \( \alpha \in A_{\nu, \eta}^{\omega} \) put

\[ \psi_\alpha(z) = f_\alpha(z) - z^{-2\nu-1}\eta(S)\left(\frac{-1}{z}\right), \]

with \( f_\alpha \) such that the function \( z \mapsto (1 + z^2)^{\nu+\frac{1}{2}}f_\alpha(z) \) represents the restriction \( \alpha|_R \). Then the Bruggeman transform \( B: \alpha \mapsto \psi_\alpha \) maps \( A_{\nu, \eta}^{\omega} \) to \( \Psi_{\nu, \eta} \). It is a bijection if \( \nu \notin \frac{1}{2} + \mathbb{Z} \), as can be seen similar to [4], Proposition 2.2.

For \( \nu \notin \frac{1}{2} + \mathbb{Z} \) we finally define the Lewis transform as the map \( \boxed{L}: \mathcal{M}_{\nu, \eta} \rightarrow \Psi_{\nu, \eta} \), given by

\[ L \overset{\text{def}}{=} B \circ P^{-1}. \]

**Theorem 3.1** (Lewis transform; cf. [14], Thm. 1.1) For \( \nu \notin \frac{1}{2} + \mathbb{Z} \) and \( \text{Re}(\nu) > -\frac{1}{2} \) the Lewis transform is a bijective linear map from the space of Maaß cusp forms \( S_{\nu, q, \eta} \) to the space \( \Psi_{\nu, \eta}^0 \) of period functions.

**Proof:** The proof runs, with small obvious changes, along the lines of the corresponding result [4], Theorem 3.3. \( \Box \)
