The dynam ics of $N$ point vortices in a uid is described by the $H$ elm holtz-K irchho (HK) equations which lead to a com pletely integrable H am iltonian system for $\mathrm{N}=2$ or 3 but chaotic dynam ics for $N>3$. H ere we consider a generalization of the $H K$ equations to describe the dynam ics ofm agnetic vortices within a collective-coordinate approxim ation. In particular, we analyze in detail the dynam ics of a system of three $m$ agnetic vortioes by a suitable generalization of the solution for three point vortices in an ordinary uid obtained by $G$ roblim ore than a century ago. The signi cance of our results for the dynam ics of ferrom agnetic elem ents is brie y discussed.

## I. INTRODUCTION

Ferrom agnetic $m$ edia are described by the density of $m$ agnetic $m$ om ent or $m$ agnetization $m=m(r ; t)$ which is a vector eld of constant length that satis es the highly nonlinear LandauLifshitz (LL) equation. M agnetic bubbles and vortiges are special solutions of the LL equation characterized by a topological invariant som etim es called the P ontryagin index or skym ion num ber. U pon suitable norm alization, the skym ion num ber is integer form agnetic bubbles occuring in $m$ agnetic m s w ith perpendicular easy-axis an isotropy [1] and half integer for $m$ agnetic vortioes that $m$ ay be realized in the case of $m$ agnetic $\mathrm{m} s \mathrm{~s}$ ith easy-plane anistotropy [2].

M ost of the early studies were carried out on $m$ agnetic $\mathrm{lm} s$ of in nite extent where vortioes and bubbles occur as excited states above a uniform ground state. M ore recently it has been realized that the ground state of a disc-shaped $m$ agnetic elem ent, with a diam eter of a few hundred nanom eters, is itself a vortex con guration. H ence the vortex is a nontrivialm agnetic state that can be spontaneously created on $m$ agnetic elem ents of nite extent. Such a possibility is of obvious signi cance for devioe applications and explains the current interest on this sub ject [3, 4, 5].

T he dynam ics ofm agnetic vortioes is greatly a ected by the underlying topologicalstructure 6 , 7]. Th is is described by a topological vorticity which gives the skym ion num ber upon integration over the plane of the $m$ agnetic m . A s a result, the essential features of $m$ agnetic vortex dynam ics are sim ilar to those displayed by ordinary vortices in uid dynam ics. A single vortex or antivortex is spontaneously pinned and thus cannot $m$ ove freely $w$ ithin the ferrom agnetic $m$ edium. H ow ever, vortex $m$ otion relative to the $m$ edium is possible in the presence of other vortioes, or extemally applied magnetic eld gradients, and displays characteristics analogous to those of two-dim ensional (2D) motion of electric charges in a uniform magnetic eld. In particular, tw o like vortices onbit around each other while a vortex-antivortex pair undergoes K elvin $m$ otion. A recent review of tw $o$-vortex $m$ agnetic system $s$ together $w$ ith som e progress in the study of three-vortex dynam ics $m$ ay be found in Refs. [8, [9].

In the present paper we study the dynam ics of a system consisting of N interacting $m$ agnetic vortioes within a collective-coordinate approxim ation which evades the com plexities of the com plete LL equation but retains im portant dynam ical features due to the underly ing topology. T he relevant equations are a generalization of the $H \mathrm{~K}$ equations encountered in the study of N point vortioes in ordinary uids [10, 11]. The latter equations were solved explicitly by H em holtz him self for the two-vortex $(\mathbb{N}=2$ ) system, while $K$ irchho concluded that the three-vortex $(\mathbb{N}=3)$ system is com pletely integrable. But a complete solution for $\mathrm{N}=3 \mathrm{was}$ given in the 1877 dissertation of G robli [12] recently review ed by A ref et al [13] (see also [14]). For N > 3, the system is not com pletely integrable and thus leads to chaotic dynam ics.

In Section II, we state the appropriate modi cations of the HK equations to account for $N$ interacting $m$ agnetic vortices, derive the corresponding conservation law S , and provide a rst dem onstration w th an explicit solution for tw o-vortex system s . T he generalization of G robli's solution to three $m$ agnetic vortioes is given in Section III and is illustrated in detail in Section IV for im portant special cases such as scattering of a vortex-antivortex pair o a target vortex initially at rest, three-vortex collapse, bounded three-vortex $m$ otion, etc. O ur $m$ ain conclusions are sum $m$ arized in Section $V$.
II. GENERALIZATION OF THE HELMHOLTZKIRCHHOFFEQUATIONS

W e consider a system of N magnetic vortioes labeled by $=1 ; 2 ;::: \mathrm{N}$. Each vortex is characterized by a pair of indices ( ; ) where is the vortex num ber and the polarity, which take the values = 1 and $=1$ in any combination. W e also de ne the skym ion num ber

$$
\begin{equation*}
s= \tag{1}
\end{equation*}
$$

which also takes the distinct values $s=1$ (in any combination for varying =1;2;:: :N ) and di ers from the standard de nition of the P ontryagin index by an overall norm alization $\left(\mathbb{N}=\frac{1}{2} \mathrm{~s}\right)$ [8, 9 ].

N ow , in a collective-coordinate approxim ation [15, 16, 17], the position ofeach vortex is labeled by a vector $r=(x ; y)$ in the $2 D$ plane and the energy functional is given by

$$
E=\begin{array}{ll}
X & \ln j x \quad r j  \tag{2}\\
< &
\end{array}
$$

in suitable units. N ote that the energy is a fiunction of the vortex num ber but not the polarities
. The equations of m otion are then wrilten in H am iltonian form as

$$
\begin{equation*}
s \frac{d x}{d t}=\frac{@ E}{@ y} ; \quad s \quad \frac{d y}{d t}=\frac{@ E}{@ x} ; \quad=1 ; 2 ;::: N ; \tag{3}
\end{equation*}
$$

or, m ore explicitly, as
$T$ hese di er from the $H K$ equations for $N$ point vortices in an ordinary uid by the presence of the polarities (or the skym ion num bers s) in addition to the vortex num bers. . Equations (4) reduce to the $H K$ equations in the special lim it where all polarities are taken to be equal $(1=2=:::=N$ ). A lso note that the vortex num ber $m$ ay assum e any continuous value for a uid vortex but takes the quantized values 1 for a m agnetic vortex.

In addition to the conserved energy of Eq. (2), the H am iltonian system (3) or (4) possesses conservation law s which originate in translational and rotational invariance; i.e., the analog of linear $m$ om entum $P=\left(P_{x} ; P_{y}\right) w$ th

$$
\begin{equation*}
P_{x}=X^{X} \text { s } y ; \quad P_{y}={ }^{X} \quad s x ; \tag{5}
\end{equation*}
$$

and angular $m$ om entum

$$
\begin{equation*}
L=\frac{1}{2}^{X} \quad s \quad\left(x^{2}+y^{2}\right) \tag{6}
\end{equation*}
$$

both de ned in convenient units. A ctually, the physical signi cance of these conservation law s depends crucially on whether or not the total skym ion num ber

$$
\begin{equation*}
S={ }^{X} \quad s={ }^{X} \tag{7}
\end{equation*}
$$

vanishes. The linear $m$ om entum (5) assum es its custom ary m eaning only when $S=0$. For $S \in 0$, one $m$ ay instead de ne the conserved guiding center $R=\left(R_{x} ; R_{y}\right) w$ ith

$$
\begin{equation*}
R_{X}=\frac{1}{S}^{X} \quad s x ; \quad R_{Y}=\frac{1}{S}^{X} \quad s y \text {; } \tag{8}
\end{equation*}
$$

$w$ hich is a $m$ easure of position rather than linear $m$ om entum. The inherent transm utation of m om entum into position occurs also w ithin the com plete LL equation and hasbeen the sub ject of several investigations [6, 7, []]. To com plete the discussion of conservation law s w e note that the linear $m$ om entum (5) and the angular $m$ om entum (6) $m$ ay be com bined to yield the derivative conserved quantity

$$
\begin{equation*}
\frac{1}{2}^{X} \sin (r \quad r)^{2} \tag{9}
\end{equation*}
$$

which depends only on the relative distances jr r jand will play an im portant role in the follow ing.

This section is concluded with a simple application of the general form alism to the case of tw o-vortex system $s(\mathbb{N}=2)$. Equations (4) then read

$$
\begin{align*}
& { }_{1} \frac{\mathrm{dx}_{1}}{\mathrm{dt}}=\quad{ }_{2} \frac{\mathrm{Y}_{1} \mathrm{Y}_{2}}{\mathrm{~d}^{2}} ; \quad 2 \frac{\mathrm{dx}_{2}}{\mathrm{dt}}=\quad{ }_{1} \frac{\mathrm{Y}_{2}}{\mathrm{~d}^{2}} \text {; } \\
& { }_{1} \frac{d y_{1}}{d t}=2 \frac{x_{1}}{d^{2}} ; \quad 2 \frac{d y_{2}}{d t}=1 \frac{x_{2} x_{1}}{d^{2}} ; \tag{10}
\end{align*}
$$

where $d^{2} \quad\left(\begin{array}{ll}x_{2} & x_{1}\end{array}\right)^{2}+\left(\begin{array}{ll}y_{2} & y_{1}\end{array}\right)^{2}$ is the squared relative distance betw een the tw 0 vortices $w h i c h$ is conserved by virtue of the conservation of the energy E of Eq. (2) restricted to $\mathrm{N}=2$ for any choice of vortex num bers and polarities. But the details of the $m$ otion depend on the speci c choice of 's and 's as dem onstrated below with two representative exam ples.
$F$ irst, we consider a vortex-antivortex pair w ith equal polarities:

$$
\begin{equation*}
(1 ; 1)=(1 ; 1) ; \quad(2 ; 2)=(1 ; 1) ; \tag{11}
\end{equation*}
$$

hence opposite skym ion num bers $s_{1}=1 ; s_{2}=1$ and total skym ion num ber $S=s_{1}+s_{2}=0$. A straightforw ard solution of Eqs. (10) then leads to K elvin $m$ otion where the vortex and the antivortex $m$ ove in form ation at constant relative distance $d$, along parallel tra jectories that are perpendicular to the line connecting the vortex and the antivortex, with speed

$$
\begin{equation*}
\mathrm{V}=\frac{1}{\mathrm{~d}} \tag{1}
\end{equation*}
$$

and linear $m$ om entum (5) that is parallel to the velocity.
In contrast, a vortex-antivortex pair w th opposite polarities:

$$
\begin{equation*}
(1 ; 1)=(1 ; 1) ; \quad(2 ; 2)=(1 ; 1) ; \tag{13}
\end{equation*}
$$

hence $s_{1}=s_{2}=1$ and nonvanishing total skym ion num ber $S=s_{1}+s_{2}=2$, undergoes rotationalm otion at constant diam eter $d$, around a xed guiding center (8) which $m$ ay be taken to be the origin of the coordinate system $\left(x_{1}+x_{2}=0=y_{1}+y_{2}\right)$, with angular frequency

$$
\begin{equation*}
!=\frac{2}{\mathrm{~d}^{2}}: \tag{14}
\end{equation*}
$$

A detailed study ofK elvin and rotationalm otion w as carried out w ithin the com plete LL equation in Refs. [18] and [19], respectively, the results of which were recently review ed in Ref. [8]. In particular, their results con m the validity of Eqs. (12) and (14) for su ciently large relative distance d, as expected for the collective-coordinate approxim ation adopted in the present paper.

F inally we note the the $m$ otion of a tw o-vortex system is $K$ elvin-like when the total skymm ion num ber vanishes $\left(S=s_{1}+s_{2}=1_{1}+2_{2}=0\right)$ and rotational otherw ise ( $S=s_{1}+S_{2}=$ $1_{1}+2_{2}=2$ ) irrespectively of the detailed con guration of the vortex num bers $1 ; 2$ and polarities 1; 2 .

## III. THREEMAGNETIC VORTICES

C onsider a system of three interacting $m$ agnetic vortioes $w$ ith vortex num bers and polarities given by the three pairs of indioes $(1 ; 1) ;(2 ; 2) ;(3 ; 3)$. The three vortioes form a triangle whose vertices are located at $r_{1}=\left(x_{1} ; y_{1}\right) ; r_{2}=\left(x_{2} ; y_{2}\right) ; r_{3}=\left(x_{3} ; y_{3}\right)$ and $m$ ove about the 2 D plane according to Eqs. (4) w ritten here explicitly as

$$
\begin{align*}
& 1 \frac{d x_{1}}{d t}={ }_{2} \frac{y_{1} y_{2}}{C_{3}^{2}}+{ }_{3} \frac{y_{3} y_{1}}{C_{2}^{2}} ; \quad 1 \frac{d y_{1}}{d t}={ }_{2} \frac{x_{1} x_{2}}{C_{3}^{2}} \quad 3 \frac{x_{3}}{C_{2}^{2}} ; \\
& 2 \frac{d x_{2}}{d t}=\quad \frac{y_{2} Y_{3}}{C_{1}^{2}}+{ }_{1} \frac{y_{1} y_{2}}{C_{3}^{2}} ; \quad{ }_{2} \frac{d y_{2}}{d t}={ }_{3} \frac{x_{2} x_{3}}{C_{1}^{2}} \quad{ }_{1} \frac{x_{1}}{C_{3}^{2}} ;  \tag{15}\\
& 3 \frac{d x_{3}}{d t}=\quad{ }_{1} \frac{Y_{3} Y_{1}}{C_{2}^{2}}+{ }_{2} \frac{Y_{2} Y_{3}}{C_{1}^{2}} ; \quad 3 \frac{d y_{3}}{d t}=\quad{ }_{1} \frac{x_{3} x_{1}}{C_{2}^{2}} \quad{ }_{2} \frac{x_{2} x_{3}}{C_{1}^{2}} ;
\end{align*}
$$

where

$$
\begin{equation*}
C_{1}=\dot{j} r_{2} \quad r_{3} \dot{j} \quad C_{2}=\dot{r}_{3} \quad r_{1} \dot{j} \quad C_{3}=\dot{r}_{1} \quad r_{2} j \tag{16}
\end{equation*}
$$

are the lengths of the triangle sides.
Our task is to solve the initial-value problem de ned by Eqs. (15) w ith intial conditions fumished by the $t=0$ con guration of the three vortices. Needless to say, a num erical solution is straightforw ard and has indeed been used to con $m$ our $m$ ain analytical results obtained in the follow ing by a generalization of $G$ robli's original solution for ordinary uid vortices [12].

The key observation is that the scalar quantities $\mathrm{C}_{1} ; \mathrm{C}_{2}$ and $\mathrm{C}_{3}$ satisfy a closed system of equations of their ow $n$, which $m$ ay be em ployed to determ ine the tim e evolution of the shape and size of the vortex triangle, irrespectively of its relative orientation and $m$ otion in the plane. Speci cally, as a consequence of Eqs. [15),

$$
\begin{array}{llll}
\frac{d}{d t}\left(\mathrm{C}_{1}^{2}\right)=4 & { }_{1} \mathrm{~A} & \frac{1}{{ }_{3} \mathrm{C}_{2}^{2}} & \frac{1}{{ }_{2} \mathrm{C}_{3}^{2}} \\
\frac{\mathrm{~d}}{\mathrm{dt}}\left(\mathrm{C}_{2}^{2}\right)=4{ }_{2} \mathrm{~A} & \frac{1}{{ }_{1} \mathrm{C}_{3}^{2}} & \frac{1}{{ }_{3} \mathrm{C}_{1}^{2}}  \tag{17}\\
\frac{\mathrm{~d}}{\mathrm{dt}}\left(\mathrm{C}_{3}^{2}\right)=4 & { }_{3} \mathrm{~A} & \frac{1}{{ }_{2} \mathrm{C}_{1}^{2}} & \frac{1}{{ }_{1} \mathrm{C}_{2}^{2}}
\end{array}:
$$

Here $A=\left\{\begin{array}{l}\text { A } \\ j \\ w h e r e \\ =1\end{array}\right.$ or 1 when the vortioes $(1 ; 2 ; 3)$ appear in the counterclockw ise or clockw ise sense in the plane, and $\overline{7} j \mathrm{j}$ is the area of the vortex triangle which $m$ ay be expressed entirely in term S of $\mathrm{C}_{1} ; \mathrm{C}_{2}$ and $\mathrm{C}_{3}$ :

$$
\mathfrak{Z} j=\left[\begin{array}{lll}
C  \tag{18}\\
(C & C_{1}
\end{array}\right)\left(C \quad C_{2}\right)\left(\begin{array}{ll}
C & C_{3}
\end{array}\right]^{1=2} ; \quad C \quad \frac{1}{2}\left(C_{1}+C_{2}+C_{3}\right):
$$

Eqs. (17) constistute a reduced dynam ical system that is com pletely integrable because it possesses tw o conservation law s; nam ely

$$
\begin{equation*}
\mathrm{B}=\mathrm{C}_{1}^{1=}{ }_{1}^{1} \mathrm{C}_{2}^{1=}{ }_{2} \mathrm{C}_{3}^{1={ }_{3}} ; \quad=\frac{\mathrm{s}_{2} \mathrm{~S}_{3} \mathrm{C}_{1}^{2}+\mathrm{s}_{3} \mathrm{~s}_{1} \mathrm{C}_{2}^{2}+\mathrm{s}_{1} \mathrm{~S}_{2} \mathrm{C}_{3}^{2}}{\mathrm{~s}_{1}+\mathrm{s}_{2}+\mathrm{s}_{3}} ; \tag{19}
\end{equation*}
$$

where the conservation of $B$ follow sfrom the conservation of the energy of Eq. (2), and from the conservation of the quantity de ned in Eq. 9), both restricted to the three-vortex system and norm alized in a $m$ anner suitable for subsequent analysis. The conservation of $B$ and $m$ ay be con m ed directly from Eqs. (17). Thus, having determ ined $B$ and from the initial ( $t=0$ ) values of $C_{1} ; \mathrm{C}_{2}$ and $\mathrm{C}_{3}$, one m ay use $\mathrm{Eqs}$. (19) to elim inate tw of these variables, say, $\mathrm{C}_{2}$ and $C_{3}$ in favor of $C_{1}$ and thereby reduce $E$ qs. (17) to a single equation for $C_{1}$ that $m$ ay be integrated by a sim ple quadrature.

In order to com plete the solution we $m$ ust also determ ine the relative orientation and $m$ otion of the vortex triangle in the plane and thus solve for the actual vortex tra jectories. The latter $m$ ay be conveniently described in polar coordinates (r ; ); = 1;2;3. U sing these coordinates H am ilton's equations (3) read

$$
\begin{equation*}
s r \frac{d r}{d t}=\frac{@ E}{@} \quad s r \frac{d}{d t}=\frac{@ E}{@ r}: \tag{20}
\end{equation*}
$$

W e write explicitly the three equations for the polar angles:

$$
\begin{align*}
& \left.\left.{ }_{1} r_{1} \frac{d}{d t}={ }_{2} \frac{r_{1} \quad r_{2} \cos (1}{} C_{3}^{2}\right)+{ }_{3} \frac{r_{1} r_{3} \cos (3}{} C_{1}^{2}\right) ; \\
& \left.{ }_{2} r_{2} \frac{d 2}{d t}={ }_{3} \frac{r_{2} r_{3} \cos (2 \quad 3)}{C_{1}^{2}}+{ }_{1} \frac{r_{2} r_{1} \cos (1}{} \quad 2\right) \text { C }  \tag{21}\\
& \left.{ }_{3} r_{3} \frac{d d_{3}}{d t}={ }_{1} \frac{r_{3} r_{1} \cos (3 \quad 1)}{C_{2}^{2}}+{ }_{2} \frac{r_{3} r_{2} \cos (2}{}{ }_{3}\right) \text { C }
\end{align*}
$$

A crucial step for sim plifying the latter equations is to set the guiding center (8) at the origin, i.e., $\mathrm{R}_{\mathrm{x}}=0=\mathrm{R}_{\mathrm{Y}}$. In polar coordinates this constraint reads:

$$
\begin{align*}
s_{1} r_{1} \cos s_{1}+s_{2} r_{2} \cos s_{2}+s_{3} r_{3} \cos 3 & =0 \\
s_{1} r_{1} \sin { }_{1}+s_{2} r_{2} \sin 2+s_{3} r_{3} \sin 3 & =0: \tag{22}
\end{align*}
$$

Simple com binations of Eqs. (22) yield

$$
\begin{array}{ll}
2 s_{2} s_{3} r_{2} r_{3} \cos \left(~_{2}\right. & 3)=s_{1}^{2} r_{1}^{2} \quad s_{2}^{2} r_{2}^{2} \\
2 s_{3} s_{1} r_{3} r_{1} \cos \left(s_{3}^{2} r_{3}^{2}\right. & 1)=s_{1}^{2} r_{1}^{2}+s_{2}^{2} r_{2}^{2}  \tag{23}\\
2 s_{1} s_{2} r_{1} r_{2} \cos \left(s_{3}^{2} r_{3}^{2}\right. & 2)=s_{1}^{2} r_{1}^{2} \\
s_{2}^{2} r_{2}^{2}+s_{3}^{2} r_{3}^{2}:
\end{array}
$$

Further, we w rite the sides of the triangle using polar coordinates:

$$
\begin{array}{lll}
C_{1}^{2}=r_{2}^{2}+r_{3}^{2} & 2 r_{2} r_{3} \cos (2 & 3) \\
C_{2}^{2}=r_{3}^{2}+r_{1}^{2} & 2 r_{3} r_{1} \cos (3 & 1)  \tag{24}\\
C_{3}^{2}=r_{1}^{2}+r_{2}^{2} & 2 r_{1} r_{2} \cos (1 & 2) ;
\end{array}
$$

and we can now use Eqs. (23) and (24) to obtain explicit relations betw een the radialcoordinates $r$ and the sides of the triangle $C$ :

$$
\begin{array}{ll}
s_{2} s_{3} C_{1}^{2}=\left(s_{2}+s_{3}\right) & s_{1}\left(s_{1}+s_{2}+s_{3}\right) r_{1}^{2} \\
s_{3} s_{1} C_{2}^{2}=\left(s_{3}+s_{1}\right) & s_{2}\left(s_{1}+s_{2}+s_{3}\right) r_{2}^{2}  \tag{25}\\
s_{1} s_{2} C_{3}^{2}=\left(s_{1}+s_{2}\right) & s_{3}\left(s_{1}+s_{2}+s_{3}\right) r_{3}^{2} ;
\end{array}
$$

where is the conserved quantity already de ned in Eq. (19).
W e are now ready to write Eqs. (21) in a form where the radialcoordinates r are elim inated and only the variables C and appear. W e use Eqs. (24) to elim inate the cosines and E qs. (25) to express the radial coordinates in term s of the C 's in Eqs. (21), to obtain

$$
\begin{align*}
21_{1} 3_{3}\left(s_{1}+s_{2}+s_{3}\right) r_{1}^{2} C_{2}^{2} C_{3}^{2} \frac{d_{1}}{d t} & ={ }_{3} C_{2}^{2}\left[s_{2} s_{3}\left(C_{1}^{2}+C_{2}^{2}+C_{3}^{2}\right)+2 s_{2}^{2} C_{3}^{2}\right] \\
& +{ }_{2} C_{3}^{2}\left[s_{2} s_{3}\left(C_{1}^{2}+C_{2}^{2}+C_{3}^{2}\right)+2 s_{3}^{2} C_{2}^{2}\right] \\
21_{12} 3\left(s_{1}+s_{2}+s_{3}\right) r_{2}^{2} C_{3}^{2} C_{1}^{2} \frac{d_{2}}{d t} & ={ }_{1} C_{3}^{2}\left[s _ { 3 } s _ { 1 } \left(C_{1}^{2}\right.\right.  \tag{26}\\
+ & \left.\left.C_{2}^{2}+C_{3}^{2}\right)+2 s_{3}^{2} C_{1}^{2}\right] \\
2 C_{1}^{2}\left[s _ { 3 } s _ { 1 } \left(C_{1}^{2}\right.\right. & \left.\left.C_{2}^{2}+C_{3}^{2}\right)+2 s_{1}^{2} C_{3}^{2}\right] \\
21_{3}\left(s_{1}+s_{2}+s_{3}\right) r_{3}^{2} C_{1}^{2} C_{2}^{2} \frac{d_{3}}{d t}= & { }_{2} C_{1}^{2}\left[s _ { 1 } s _ { 2 } \left(C_{1}^{2}+C_{2}^{2}\right.\right. \\
& \left.\left.C_{3}^{2}\right)+2 s_{1}^{2} C_{2}^{2}\right]
\end{align*}
$$

where it is understood that the $r$ 's are given through Eqs. (25) in term s of the C 's. Explicit applications of the preceding general results are given in Section $\mathbb{I V}$.

```
IV . AN INTERESTING THREE-VORTEX SYSTEM
```

For an explicit dem onstration we consider a three-vortex system with vortex numbers and polarities given by

$$
\begin{equation*}
(1 ; 1)=(1 ; 1) ; \quad(2 ; 2)=(1 ; 1) ; \quad(3 ; 3)=(1 ; 1) \tag{27}
\end{equation*}
$$

and corresponding skym ion numbers $s_{1}=1 ; s_{2}=1=s_{3}$. The pair ( $1 ; 2$ ) is the vortex -antivortex pair of Eq. (11) which would undergo K elvin $m$ otion in the absence of vortex 3 . In contrast, the pair $(2 ; 3)$ w ould undergo rotationalm otion in the absence of vortex 1 , as discussed in Sec. II follow ing Eq. (13). T hus them otion of the three vortices is expected to be a com bination of $K$ elvin and rotationalm otion. Since the total skym ion num ber $S=s_{1}+s_{2}+s_{3}=1$ is di erent from zero, the guiding center for the three-vortex system de ned from Eq. 88), i.e.,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{x}}=\mathrm{x}_{1}+\mathrm{x}_{2}+\mathrm{x}_{3} ; \quad \mathrm{R}_{\mathrm{y}}=\mathrm{y}_{1}+\mathrm{y}_{2}+\mathrm{y}_{3} ; \tag{28}
\end{equation*}
$$

is conserved and thus rem ains xed during the $m$ otion.
W e now retum to the reduced system (17) applied for the speci c choice (27):

$$
\begin{align*}
& \frac{d}{d t}\left(\mathrm{C}_{1}^{2}\right)=4 \mathrm{~A} \frac{1}{\mathrm{C}_{2}^{2}}+\frac{1}{\mathrm{C}_{3}^{2}} \\
& \frac{\mathrm{~d}}{\mathrm{dt}}\left(\mathrm{C}_{2}^{2}\right)=4 \mathrm{~A} \frac{1}{\mathrm{C}_{3}^{2}}+\frac{1}{\mathrm{C}_{1}^{2}}  \tag{29}\\
& \frac{d}{d t}\left(\mathrm{C}_{3}^{2}\right)=4 \mathrm{~A} \frac{1}{\mathrm{C}_{1}^{2}} \frac{1}{\mathrm{C}_{2}^{2}} ;
\end{align*}
$$

while the conservation law s de ned from Eq. (19) are given by

$$
\begin{equation*}
\mathrm{B}=\frac{\mathrm{C}_{1} \mathrm{C}_{3}}{\mathrm{C}_{2}} ; \quad=\mathrm{C}_{1}^{2}+\mathrm{C}_{2}^{2}+\mathrm{C}_{3}^{2}: \tag{30}
\end{equation*}
$$

O ne $m$ ay then express $C_{2}$ and $C_{3}$ in term $s$ of $C_{1}$ as

$$
\begin{equation*}
\mathrm{C}_{2}^{2}=\frac{\mathrm{C}_{1}^{2}+}{\mathrm{C}_{1}^{2}+\mathrm{B}^{2}} \mathrm{C}_{1}^{2} ; \quad \mathrm{C}_{3}^{2}=\frac{\mathrm{C}_{1}^{2}+}{\mathrm{C}_{1}^{2}+\mathrm{B}^{2}} \mathrm{~B}^{2} \tag{31}
\end{equation*}
$$

and the area of the triangle de ned earlier in Eq. (18) as

$$
\begin{equation*}
4 A=\quad q \overline{4 C_{2}^{2} C_{3}^{2} \quad 2}={\frac{C}{C_{1}^{2}+B^{2}}}_{q \overline{4 B^{2} C_{1}^{2}\left(C_{1}^{2}+\right)^{2}{ }^{2}\left(C_{1}^{2}+B^{2}\right)^{2}}: ~}^{\text {a }} \tag{32}
\end{equation*}
$$

Then the system of Eqs. (29) reduces to the single equation

$$
\begin{equation*}
\frac{d}{d t}\left(C_{1}^{2}\right)=\frac{1}{C_{1}^{2}+} \frac{1}{C_{1}^{2}}+\frac{1}{B^{2}} \quad q \overline{4 B^{2} C_{1}^{2}\left(C_{1}^{2}+\right)^{2}{ }^{2}\left(C_{1}^{2}+B^{2}\right)^{2}} ; \tag{33}
\end{equation*}
$$

which $m$ ay readily be integrated to yield $C_{1}=C_{1}(t)$, as well as $C_{2}=C_{2}(t)$ and $C_{3}=C_{3}(t)$ from Eq. (31), for any speci c values of the conserved quantities B and calculated from the initial three-vortex con guration.

In order to com plete the solution we $m$ ust also determ ine the relative orientation and $m$ otion of the vortex triangle in the plane and thus solve for the actual vortex trajectories. W e w ill follow the derivation given in Section III and quote only im portant results that will allow us to provide a detailed illustration of the three-vortex $m$ otion for the special case of vortex num bers and polarities given by Eq. (27).

It is convenient to specify a reference fram e such that its origin coincides w ith the conserved guiding center of Eq. (28):

$$
\begin{equation*}
\mathrm{x}_{1}+\mathrm{x}_{2}+\mathrm{x}_{3}=0 ; \quad \mathrm{y}_{1}+\mathrm{y}_{2}+\mathrm{y}_{3}=0: \tag{34}
\end{equation*}
$$

In this fram e the radial distances $r_{1} ; r_{2}$ and $r_{3}$ are related to the triangle sides $C_{1} ; C_{2}$ and $C_{3}$ by Eq. (25) applied for $s_{1}=1 ; s_{2}=1=s_{3}$ :

$$
\begin{equation*}
\mathrm{r}_{1}^{2}=2\left(\mathrm{C}_{2}^{2}+\mathrm{C}_{3}^{2}\right) \quad \mathrm{C}_{1}^{2} ; \quad \mathrm{r}_{2}^{2}=\mathrm{C}_{2}^{2} ; \quad \mathrm{r}_{3}^{2}=\mathrm{C}_{3}^{2} ; \tag{35}
\end{equation*}
$$

while the angular variables satisfy Eqs. (26) now reduced to

$$
\begin{align*}
\frac{\mathrm{d}_{1}}{\mathrm{dt}} & =\frac{1}{2\left(\mathrm{C}_{1}^{2}+2\right)} \quad \frac{1}{\mathrm{C}_{2}^{2}} \quad \frac{1}{\mathrm{C}_{3}^{2}} \\
\frac{\mathrm{~d}_{2}}{\mathrm{dt}} & =\frac{1}{2 \mathrm{C}_{2}^{2}} \quad \frac{1}{\mathrm{C}_{1}^{2}}+\frac{1}{\mathrm{C}_{3}^{2}}+\frac{1}{\mathrm{C}_{1}^{2}}  \tag{36}\\
\frac{\mathrm{~d}_{3}}{\mathrm{dt}} & =\frac{1}{2 \mathrm{C}_{3}^{2}} \frac{1}{\mathrm{C}_{2}^{2}} \quad \frac{1}{\mathrm{C}_{1}^{2}}+\frac{1}{\mathrm{C}_{1}^{2}}:
\end{align*}
$$

To sum $m$ arize, for the speci c choige of vortex num bers and polarities given by Eq. (27), the radialvariables $r_{1} ; r_{2}$ and $r_{3}$ are expressed in term $\operatorname{sofC}_{1} ; C_{2}$ and $C_{3}$ from $E$ qs. (35) and ultim ately in term $s$ of $C_{1}$ alone using the conservation law sas in Eqs. (31) ; while the tim e evolution of $\mathrm{C}_{1}$ is determ ined from Eq. (33) by a straightforw ard integration. Sim ilarly, we $m$ ay use Eqs. (31) to express the right-hand sides of Eq. (36) in term $s$ of $C_{1}$ and thus the tim e evolution of the angular variables 1 ; 2 and 3 is also reduced to sim ple quadratures.

W ithout loss of generality, the in itial three-vortex con guration is shown in Fig . 1 . In particular, $b$ is the initial length of the base $(1 ; 2)$ of the triangle and $h$ the corresponding height. $T$ he im pact param eter $a$ is de ned as the distance of vortex 2 from the $y$-axis and is taken to be negative when vortex 2 is located to the left of the $y$-axis and positive otherw ise. A lso note that

F IG . 1: In itial con guration of three $m$ agnetic vortices $(1,2,3)$ w ith vortex num bers and polarities given by Eq. (27). The origin of the coordinate fram e is taken to coincide $w$ ith the conserved guiding center of the three-vortex system. The im pact param eter $a$ is taken to be negative when vortex 2 lies to the left of the $y$-axis and positive otherw ise.
vortex 3 is initially located on the negative $x$-axis at a distance $b$ from the origin, thus enforcing Eqs. (34). H ence, the initial values of the triangle sides are $C_{1}^{2}=h^{2}+(a+b)^{2} ; C_{2}^{2}=h^{2}+a^{2}$, and $C_{3}^{2}=b^{2}$, and the conserved quantities of Eq. (30) are given by

$$
\begin{equation*}
\mathrm{B}^{2}=\frac{\mathrm{h}^{2}+(\mathrm{a}+\mathrm{b})^{2}}{\mathrm{~h}^{2}+\mathrm{a}^{2}} \mathrm{~b}^{2} ; \quad=2 \mathrm{ab} \tag{37}
\end{equation*}
$$

where is positive for left im pact $(a<0)$ and negative for right im pact $(a>0)$. This com pletes the description of the general procedure which is explicitly im plem ented in the continuation of this section using exam ples of increasing com plexity.

> A. Special case
$F$ irst we em ploy the general form alism developed in the present paper to recover a special solution already given in the Appendix of our earlier paper [9]. The initial con guration is taken to be an isosceles triangle de ned by choosing the im pact param eter $\mathrm{a}=\mathrm{b}=2$ in F ig. 1 . $T$ he vortex-antivortex pair $(1 ; 2)$ would then $m$ ove upw ard with initial velocity $V \quad 1=b$ ( $K$ elvin $m$ otion) and eventually collide against the target vortex 3. A fter collision the vortex-antivortex pair m oves o to in nity at som e scattering angle while the target vortex com es to rest at a new location. O ur aim in the follow ing is to calculate the scattering angle as well as the nalposition of the target vortex.

N ow, inserting $a=b=2$ in Eq. (37), we nd that the values of the conserved quantities are given by

$$
\begin{equation*}
B^{2}=b^{2}= \tag{38}
\end{equation*}
$$

and are independent of the initial triangle height $h$. T hen Eqs. (31) read

$$
\begin{equation*}
\mathrm{C}_{1}(\mathrm{t})=\mathrm{C}_{2}(\mathrm{t}) ; \quad \mathrm{C}_{3}(\mathrm{t})=\mathrm{b} \tag{39}
\end{equation*}
$$

which establish that the triangle rem ains isosceles ( $C_{1}=C_{2}$ ) and the length of its base rem ains constant $\left(C_{3}=\mathrm{b}\right)$ at alltim est> 0 . But $C_{1}$ itselfundergoes a nontrivialtim e evolution govemed
by Eq. (33) :

$$
\begin{equation*}
\frac{d}{d t}\left(C_{1}^{2}\right)=\quad b \frac{1}{C_{1}^{2}}+\frac{1}{b^{2}} \quad q \overline{4 C_{1}^{2} \quad 1}: \tag{40}
\end{equation*}
$$

A m ore convenient param etrization is obtained by

$$
\begin{equation*}
C_{1}=\frac{r}{H^{2}+\frac{1}{4} b^{2}}=C_{2} ; \quad C_{3}=b ; \tag{41}
\end{equation*}
$$

where $H=H(t)$ is the instantaneous height of the triangle. Eq. (40) then reads

$$
\begin{equation*}
\frac{d H}{d t}=\quad \frac{H^{2}+\frac{5}{4} b^{2}}{b} \frac{H^{2}+\frac{1}{4} b^{2}}{} \tag{42}
\end{equation*}
$$

and $m$ ust be solved $w$ ith initial condition $H(t=0)=h$.
D uring the initial stages of the evolution the three vortioes $(1 ; 2 ; 3)$ appear in the plane in a counterclockw ise sense and thus $=1$. Eq. (42) is then integrated to yield

$$
\begin{align*}
& \frac{\mathrm{H}}{\mathrm{~b}} \frac{4}{5} \arctan \frac{\mathrm{H}}{\mathrm{~b}}=\frac{\mathrm{t}_{0} \mathrm{t}}{\mathrm{~b}^{2}} ; \quad 0 \quad \mathrm{t}  \tag{43}\\
& \frac{t_{0}}{2} ; \mathrm{t}_{0} \quad \mathrm{~b}^{2} \quad \frac{h}{b} \quad \frac{4}{5} \arctan \frac{h}{b} \quad:
\end{align*}
$$

A stapproaches to, height $H$ approaches zero and the triangle reduces to a straight line elem ent $(1 ; 3 ; 2)$ at $t=t_{0} w$ ith vortex 3 located at the center of the line elem ent (1;2). A lso recalling that the length of the line elem ent $(1 ; 2)$ rem ains constant (equal to b) we conclude that to is the instance of the closest encounter of the three vortices. For $t>t_{0}$, vortex 3 em erges from the other side and thus Eq. (42) m ust be integrated w ith $=1$ and initialcondition $\mathrm{H}\left(\mathrm{t}=\mathrm{t}_{0}\right)=0$ :

$$
\begin{equation*}
\frac{\mathrm{H}}{\mathrm{~b}} \frac{4}{5} \arctan \frac{\mathrm{H}}{\mathrm{~b}}=\frac{\mathrm{t} \quad \mathrm{t}_{0}}{\mathrm{~b}^{2}} ; \quad \mathrm{t}>\mathrm{t}_{0}: \tag{44}
\end{equation*}
$$

In the far future ( $t$ ! 1 ) H ! $t=b$ which is consistent $w$ ith a vortex-antivortex pair $(1,2) \mathrm{m}$ oving aw ay from the target vortex 3 w ith asym ptotic speed $\mathrm{V}=1=\mathrm{b}$, in agreem ent w ith Eq. (12)

The preceding results already suggest a process in which the vortex-antivortex pair $(1,2)$ initially approaches the target vortex 3 but eventually $m$ oves $o$ to in nity at a scattering angle that rem ains to be calculated. O ne m ust also ascertain the fate of the target vortex 3 well after collision. B oth of these questions are answ ered below by applying Eqs. (35) and (36) to the special case treated in this subsection.

First, we note that E qs. (35) suggest that the three vortioes $(1,2,3)$ together w ith the origin of the coordinate system $O$ (i.e., the guiding center of the three-vortex system ) form a parallelogram 1203 at all tim es during the collision. In particular, the third equation (35) establishes that $r_{3}=C_{3}=\mathrm{b}$ is tim e independent, or, vortex 3 m oves on a circle whose center coincides w ith the guiding center and its radius is a constant b equal to the constant length of the base of the triangle. Furtherm ore, the polar angle 3 changes during collision by the sam e am ount as the base of the triangle $(1,2)$ rotates in the 2D plane. Therefore, the total change 3 is equal to the scattering angle of the vortex-antivortex pair ( 1,2 ) and also speci es the nallocation of the target vortex 3.

In order to actually calculate 3 in the present special case, we apply Eq. (36) with $\mathrm{C}_{1}=\mathrm{C}_{2}$ :

$$
\begin{equation*}
\frac{d_{3}}{d t}=\frac{1}{C_{1}^{2}}=\frac{1}{H^{2}+\frac{1}{4} b^{2}} \tag{45}
\end{equation*}
$$

FIG.2: Tim e evolution of $C_{1} ; C_{2}$ and $C_{3}$ for an in itial three-vortex triangle given by $F$ ig. 1 with $a=$ $0 ; b=1 ; h=5 . N$ ote that all three lengths sim ultaneously collapse to zero at a nite tim e to calculated from Eq. (53).
where we may insert $H=H(t)$ from Eqs. (43) and (44) to obtain $3=3(t)$ by a further integration. In fact, a m ore direct calculation of the total scattering angle 3 is obtained by com bining Eqs. (42) and (45) to w rite

$$
\begin{equation*}
\frac{d_{3}}{d H}=\quad \frac{b}{H^{2}+\frac{5}{4} b^{2}} \tag{46}
\end{equation*}
$$

and

$$
\begin{equation*}
{ }_{3}=b_{0}^{Z_{h}} \frac{d H}{H^{2}+\frac{5}{4} b^{2}}+b_{0}^{Z_{1}} \frac{d H}{H^{2}+\frac{5}{4} b^{2}} ; \tag{47}
\end{equation*}
$$

where the two term smay be intenpreted as the scattering angles before and after collision and correspond to the two branches of the solution $H=H$ ( $t$ ) given by Eqs. (43) and (44). In particular, for pure scattering where the vortex-antivortex pair originates very far from the target vortex (h! 1):

$$
\begin{equation*}
3=2 b_{0}^{Z_{1}} \frac{d H}{H^{2}+\frac{5}{4} b^{2}}=\frac{2}{5} ; \tag{48}
\end{equation*}
$$

which reproduces the special result given in the A ppendix of $R$ ef. [g]. A detailed illustration of the actual vortex tra jectories $m$ ay be found in $F$ ig. A 1 of the above reference (using a di erent convention for the origin of the coordinate system) and in F ig. 5 of the present paper (w here the origin of the coordinate system coincides with the guiding center).

B . Three-vortex collapse

At rst sight, the special exam ple treated in the preceding subsection would seem to correspond to a head-on collision of a vortex-antivortex pair o a target vortex. H owever, such an interpretation seem $s$ to be unjusti ed in view of the peculiar scattering angle calculated in Eq. (48). Indeed, an exam ple that is closer to head-on collision is obtained by choosing vanishing im pact param eter $(a=0)$ in the initial vortex con guration shown in Fig. 1 .

The in itial yortex triangle is then orthogonal, with intial values of the length of its sides $C_{1}(t=0)=\frac{h^{2}+b^{2}}{h^{2}} C_{2}(t=0)=h$ and $C_{3}(t=0)=b$. The two conserved quantities of Eq. (30) now read

$$
\begin{equation*}
\mathrm{B}=\frac{\mathrm{C}_{1} \mathrm{C}_{3}}{\mathrm{C}_{2}}=\frac{\mathrm{b}}{\mathrm{~h}} \overline{\mathrm{~h}^{2}+\mathrm{b}^{2}} ; \quad=\mathrm{C}_{1}^{2}+\mathrm{C}_{2}^{2}+\mathrm{C}_{3}^{2}=0: \tag{49}
\end{equation*}
$$

A notable consequence of the conservation of $=0$ is that the vortex triangle rem ains orthogonal at all tim es, even though the length of its sides $\mathrm{C}_{1} ; \mathrm{C}_{2}$, and $\mathrm{C}_{3}$, as w ell as its relative orientation in the 2D plane, undergo a nontrivial tim e evolution.

In particular, the evolution of $\mathrm{C}_{1}$ is govemed by Eq. (33) applied with $=0$ and B given by Eq. (49) :

$$
\begin{equation*}
\frac{\mathrm{dC}_{1}}{\mathrm{dt}}=\frac{\mathrm{C}_{1}^{2}+\mathrm{B}^{2}}{\mathrm{BC} \mathrm{C}_{1}^{2}} \tag{50}
\end{equation*}
$$

while $C_{2}$, and $C_{3}$ obtained from Eq. (31) are now given by

$$
\begin{equation*}
C_{2}=\frac{C_{1}^{2}}{\mathrm{C}_{1}^{2}+\mathrm{B}^{2}} ; \quad C_{3}=\frac{\mathrm{B} \mathrm{C}_{1}}{\mathrm{C}_{1}^{2}+\mathrm{B}^{2}}: \tag{51}
\end{equation*}
$$

Eq. (50) $m$ ay easily be integrated to yield

$$
\begin{equation*}
\frac{\mathrm{C}_{1}}{\mathrm{~B}} \arctan \frac{\mathrm{C}_{1}}{\mathrm{~B}}=\frac{\mathrm{t}_{0} \mathrm{t}}{\mathrm{~B}^{2}} \tag{52}
\end{equation*}
$$

where the integration constant $t_{0}$ is calculated from the initial condition $C_{1}(t=0)=p \overline{h^{2}+b^{2}}$, or

$$
\begin{equation*}
t_{0}=\frac{b^{2}}{h^{2}}\left(h^{2}+b^{2}\right) \frac{h}{b} \quad \arctan \frac{h}{b}: \tag{53}
\end{equation*}
$$

The physical signi cance of $t_{0}$ becom es apparent by applying Eq. (52) in the lim it $t!t_{0}$ :

$$
\begin{equation*}
\mathrm{C}_{1}\left(\mathrm{t}!\mathrm{t}_{0}\right) \quad\left[3 \mathrm{~B}\left(\mathrm{t}_{0} \quad \mathrm{t}\right)\right]^{1=3} ; \tag{54}
\end{equation*}
$$

and Eqs. (51) in the sam e lim it to yield

$$
C_{2}\left(t!t_{0}\right) \quad \frac{1}{B}\left[3 B\left(\begin{array}{ll}
t_{0} & t \tag{55}
\end{array}\right)\right]^{2=3} ; \quad C_{3}\left(t!t_{0}\right) \quad\left[3 B\left(t_{0} \quad t\right)\right]^{1=3}:
$$

Therefore, $t_{0}$ calculated explicitly from Eq. (53) is the instance at which all three $\mathrm{C}_{1} ; \mathrm{C}_{2}$ and $\mathrm{C}_{3}$ vanish sim ultaneously, or, the vortex triangle collapses to a point. A lso taking into account Eq. (35), we conclude that the vortex triangle collapses to the guiding center ( $r_{1}=r_{2}=r_{3}=0$ ) of the three-vortex system in a nite time interval $t_{0}$. The exact tim e dependence of $C_{1} ; C_{2}$ and $\mathrm{C}_{3}$ calculated from Eqs. (52) and (51) over the entire tim e interval 0 t $t_{0}$ is depicted in Fig. 2.

F IG . 3: Trajectories of the three vortices 1,2 and 3 em anating form an initialthree-vortex con guration given by $F$ ig. 1 with $a=0 ; b=1 ; h=5$. N ote that the three trajectories $m$ erge at the origin of the coordinate fram e which is taken to coincide with the guiding center of the three-vortex system.

C om plete inform ation about the vortex tra jectories $m$ ay be obtained by further utilizing the results of Eqs. (35) and (36) or by a direct num erical integration of Eqs. (15). The actual trajectories are illustrated in $F$ ig. 3 which explicitly dem onstrates the predicted three-vortex collap.se. A notable feature of Fig . 3 is that vortex 1 m oves on a straight line that connects its originalposition $w$ ith the guiding center of the three-vortex system .

A though this special case of vanishing im pact param eter $(a=0)$ is clearly singular from the point of view of scattering theory, it is still possible to calculate the scattering angle 3 before collapse. F irst, we apply the third of Eqs. (36) w ith $=0$ :

$$
\begin{equation*}
\frac{d_{3}}{d t}=\frac{1}{C_{1}^{2}} \tag{56}
\end{equation*}
$$

and com bine this result w ith Eq. (50) to obtain

$$
\begin{equation*}
d_{3}=\frac{\mathrm{B} \mathrm{dC}_{1}}{\mathrm{~B}^{2}+\mathrm{C}_{1}^{2}}: \tag{57}
\end{equation*}
$$

T he scattering angle before collapse is then obtained by integrating Eq. (57) betw een the values $C_{1}(t=0)=\frac{h^{2}+b^{2}}{}$ and $C_{1}(t=0)=0:$

$$
\begin{equation*}
\text { 3 Bंefore }=Z_{0}^{Z^{p} \overline{h^{2}+b^{2}}} \frac{B d C_{1}}{B^{2}+C_{1}^{2}}=\arctan \frac{h}{b}: \tag{58}
\end{equation*}
$$

In the lim it where the vortex-antivortex pair originates at a large distance $h$ ! 1 from the target vortex, we nd 3 方efore $=2$ and, by convention, 3 立otal $=2(=2)=$. This result agrees w ith the interpretation of this special case as a head-on collision whose singular nature w ill also becom e apparent in the discussion of the follow ing subsection.

```
C . Scattering in the general case
```

O ur aim in this subsection is to determ ine the scattering angle as a function of im pact param eter $a$. The general strategy is suggested by the special exam ples treated in the preceding tw o subsections. Thus we retum to the initial con guration depicted in $F$ ig. ⿴囗 arbitraty $a$, which yields values for the conserved quantities B and as given in Eq. 37). In particular, we shall be interested in the lim it h! 1 :

$$
\begin{equation*}
\mathrm{B}^{2}=\mathrm{b}^{2} ; \quad=2 \mathrm{ab} ; \tag{59}
\end{equation*}
$$

which corresponds to pure (asym ptotic) scattering where the vortex-antivortex pair is initially located very far from the target vortex and also diverges to in nity after collision.

In order to calculate the scattering angle we retum to Eq. (36) and express its right-hand side entirely in term sof $C_{1}$ using Eq. (31) to elim inate $C_{2}$ and $C_{3} . W$ e then com bine the resulting equation with Eq. (33) to w rite

$$
\begin{equation*}
\frac{\mathrm{d}_{3}}{\mathrm{dC}_{1}^{2}}=\frac{1}{-p} \frac{\frac{\mathrm{~B}^{2}}{\mathrm{C}_{1}^{2}+}+\frac{\mathrm{C}_{1}^{2}+}{\mathrm{C}_{1}^{2}+\mathrm{B}^{2}} \mathrm{~B}^{2}}{4 \mathrm{~B}^{2} \mathrm{C}_{1}^{2}\left(\mathrm{C}_{1}^{2}+\right)^{2}{ }^{2}\left(\mathrm{C}_{1}^{2}+\mathrm{B}^{2}\right)^{2}}: \tag{60}
\end{equation*}
$$

Sim ple inspection of this equation suggests using scaled variables u and from

$$
\begin{equation*}
\mathrm{u} \frac{\mathrm{C}_{1}^{2}}{\mathrm{~B}^{2}} ; \quad \quad \overline{\mathrm{B}^{2}}=\frac{2 \mathrm{a}}{\mathrm{~b}} \tag{61}
\end{equation*}
$$

to obtain

$$
\begin{equation*}
\frac{d_{3}}{d u}=\frac{1}{p} \frac{\frac{(1)}{2(u+)}+\frac{u+}{u+1}}{4 u(u+)^{2} r^{2}(u+1)^{2}}: \tag{62}
\end{equation*}
$$

B ased on this equation the total scattering angle is calculated as a function of the param eter alone by a procedure sim ilar to that em ployed in the special exam ple treated in subsection A :

$$
\begin{equation*}
3=2 \sum_{u_{0}}^{Z_{1}} \frac{\frac{(1)}{2(u+)}+\frac{u+}{u+1}}{4 u(u+)^{2} r^{2}(u+1)^{2}} d u \tag{63}
\end{equation*}
$$

where the factor oftw o and the upper lim it of integration are dictated by the fact that the vortexantivortex pair is located very far from the target vortex wellbefore and after the collision. The low er lim it $u_{0}$ is a speci $c$ value of $u=C_{1}^{2}=B^{2}$ for $w$ hich the area of the vortex triangle vanishes. $T$ herefore, $u_{0} m$ ust be chosen am ong the three roots of the cubic equation

$$
\begin{equation*}
4 u(u+)^{2} \quad{ }^{2}(u+1)^{2}=0: \tag{64}
\end{equation*}
$$

It is thus im portant to exam ine the behavior of the roots as functions of the param eter .
For $<0$ there exists a real and positive root $u_{1}$ and two com plex roots $u_{2}$ and $u_{3}$ such that $u_{2}=u_{3}$. In this region the lower lim it in the integral of Eq. (63) m ust be chosen as $u_{0}=u_{1}$. N ow, $=0$ is an exceptional point in that all three roots vanish ( $u_{1}=u_{2}=u_{3}=0$ ) and thus the lower lim it $m$ ust be chosen as $u_{0}=0$. A pplying Eq. (63) for $=0$ and $u_{0}=0$ yields

$$
\begin{equation*}
3=\int_{0}^{\mathrm{Z}_{1}} \frac{\mathrm{du}}{(\mathrm{u}+1)^{\mathrm{p}} \overline{\mathrm{u}}}= \tag{65}
\end{equation*}
$$

in agreem entwith the conclusion ofSubsection $B$. Indeed, $=0$ corresponds to vanishing im pact param eter $(a=0)$ which is the special case discussed in Subsection B (three-vortex collapse).

N ext we consider the region $0 \ll 1$ where the cubic equation again possesses a real and positive root $u_{1}$ and two com plex roots $u_{2}=u_{3}$. Thus the low er lim it $m$ ust again be chosen as $u_{0}=u_{1}$. Now, $=1$ is another exceptional point in that all three roots becom e real ( $u_{1}=\frac{1}{4} ; u_{2}=1=u_{3}$ ) and the lower lim it $m$ ust be chosen to coincide $w$ ith the positive root $\mathrm{u}_{0}=\mathrm{u}_{1}=\frac{1}{4}$. Applying Eq. (63) for $=1$ and $\mathrm{u}_{0}=\frac{1}{4}$ yields

$$
\begin{equation*}
3=2_{\frac{1}{4}}^{Z_{1}} \frac{d u}{(u+1)^{P}} \overline{4 u \quad 1}=\stackrel{2}{P_{5}} ; \tag{66}
\end{equation*}
$$

which coincides with the result of Eq. (48). This is not surprising because $=2 a=b=1$ leads to an im pact param eter $\mathrm{a}=\mathrm{b}=2$ which is indeed the special case discussed in Subsection A.

For $>1$, the cubic equation again possesses a real and positive root $u_{1}$ and two com plex roots $u_{2}=u_{3}$, thus we must choose $u_{0}=u_{1}$. This generic picture continues to hold until reaches the critical value

$$
\begin{equation*}
c=\frac{27}{2} \tag{67}
\end{equation*}
$$

where all three roots becom e real ( $u_{1}=0: 5625 ; u_{2}=9=u_{3}$ ) and rem ain real and positive for
$>{ }_{c}$. In this range of , the three roots $m$ ay be ordered as $u_{1}<u_{2}<u_{3}$ and the lower lim it of integration in Eq. (63) m ust now be chosen as $u_{0}=u_{3}$.

F IG . 4: Scattering angle during collision of a vortex-antivortex (K elvin) pair ( 1,2 ) with a target vortex 3 , as a function of im pact param eter $a$. N ote the crossover behavior at the critical values $a=b=0$ and $\mathrm{a}=\mathrm{b}=\quad 27=4$ discussed in the text. The results depicted in this gure should be read modulo 2 .

In all cases the denom inator in Eq. (63) does not possess singularities in the dom ain of integration $\left[u_{0} ; 1\right.$ ) except for an integrable square root singularity at the low er end. It can also be show $n$ that the num erator in Eq. (63) does not exhibit singularities in the integration dom ain. Thus we have provided a com plete prescription for the calculation of the scattering angle, which entails locating the appropriate root $u_{0}=u_{0}()$ of the cubic equation and an elem entary num erical integration of the integral in Eq. (63) for any value of $=2 \mathrm{a}=\mathrm{b}$. The calculated scattering angle as a function of im pact param eter a $m$ easured in units ofb is depicted in $F$ ig. 44.

Thus the scattering angle displays critical (crossover) behavior at two characteristic values of the im pact param eter; nam ely, $\mathrm{a}=\mathrm{b}=0$, which corresponds to the three-vortex collapse discussed
in subsection $B$, and $a=b=27=4$, which corresponds to the critical coupling $=2 a=b=27=2$ of Eq. (67) .

F IG . 5: V ortex trajectories for six characteristic values of the im pact param eter a. In all cases a vortexantivortex (K elvin) pair (1,2) collides with a target vortex 3 and is de ected by a scattering angle in agreem ent with the results of F ig. 4. T he target vortex 3 is at rest well before collision and also com es to rest well after collision, as expected for an isolated vortex which is alw ays spontaneously pinned.

In F ig. 5 w e display the actual vortex tra jectories calculated num erically from Eqs. (15) for a set of six characteristic values of $a=b$. T he change of pattem becom es clear as one crosses the tw o critical values $\mathrm{a}=\mathrm{b}=0$ and $\mathrm{a}=\mathrm{b}=27=4$. The nature of the criticalparam eter cofEq. (67) is further illum inated in the follow ing subsection.

D . B ounded three-vortex m otion
The analysis of the cubic equation (64) revealed the im portance of the critical param eter $c=27=2$ of Eq. (67) above which all three roots are real (and positive). W e m ay then order the roots as $u_{1}<u_{2}<u_{3}$ and note that the argum ent under the square root in, say, Eq. (62) is positive $w$ hen either $u>u_{3}$ or $u_{1}<u<u_{2}$. The form er case,

$$
\begin{equation*}
>\quad c=\frac{27}{2} ; \quad u>u_{3} \tag{68}
\end{equation*}
$$

corresponds to the scattering solution discussed in subsection $C$ where $u=C_{1}^{2}=B^{2}$ approaches in nity wellbefore or after the collision, while it reaches its $m$ in $m u m$ value $u_{3}$ at som e instance during collision. In contrast, the case

$$
\begin{equation*}
>\quad c=\frac{27}{2} ; \quad u_{1}<u<u_{2} ; \tag{69}
\end{equation*}
$$

$m$ ay lead to a $m$ otion where $u$ oscillates betw een the values $u_{1}$ and $u_{2}$. A lso taking into account Eq. (31) we conclude that all three $C_{1} ; C_{2}$ and $C_{3}$ would then rem ain bounded. The aim of th is subsection is to explicitly construct a special class of solutions that realize Eqs. (69) and thus lead to bounded (quasiperiodic) three-vortex motion. In order to achieve the two conditions displayed in Eqs. (69) we consider an initial con guration where the three vortioes $(1,2,3)$ lie on a straight line in the order indicated and thus the relative distances are such that $\mathrm{C}_{1}+\mathrm{C}_{3}=\mathrm{C}_{2}$. speci cally, we choose

$$
\begin{equation*}
\mathrm{C}_{1}=(2+) \mathrm{b} ; \quad \mathrm{C}_{2}=(3+) \mathrm{b} ; \quad \mathrm{C}_{3}=\mathrm{b} \tag{70}
\end{equation*}
$$

and initially place the three vortioes along the negative $x$-axis at points such that

$$
\begin{align*}
& \mathrm{x}_{1}=\mathrm{C}_{2} \quad \mathrm{C}_{3} ; \quad \mathrm{x}_{2}=\mathrm{C}_{2} ; \quad \mathrm{x}_{3}=\mathrm{C}_{3} ; \\
& \mathrm{y}_{1}=\mathrm{y}_{2}=\mathrm{y}_{3}=0: \tag{71}
\end{align*}
$$

T hen the origin of the coordinate system coincides $w$ ith the guiding center de ned by Eqs. (28). O ur aim is to calculate the vortex trajectories em anating from the initial con guration de ned by Eqs. (70) and (71).

W e rst consider the two conserved quantities calculated from such an initial con guration,

$$
\begin{equation*}
\mathrm{B}^{2}=\frac{\mathrm{C}_{1}^{2} \mathrm{C}_{3}^{2}}{\mathrm{C}_{2}^{2}}=\frac{2+\mathrm{b}^{2} ; \quad=\quad \mathrm{C}_{1}^{2}+\mathrm{C}_{2}^{2}+\mathrm{C}_{3}^{2}=2\left(3+\quad \mathrm{b}^{2} ; ~ ; ~\right.}{3+} \tag{72}
\end{equation*}
$$

and thus

$$
\begin{equation*}
=\frac{}{\mathrm{B}^{2}}=\frac{2(3+\quad)^{3}}{(2+)^{2}} \tag{73}
\end{equation*}
$$

is now the im portant dim ensionless quantity that controls the behavior of the roots of the cubic equation. N ote that $=0$ leads to the critical param eter $c=27=2$ of Eq. (67) while, interestingly, $>$ c for both positive and negative values of the param eter .

A num ericalsolution of the initial value problem reveals an interesting picture. For $>0$, we encouter a situation of the type described by Eq. (68) whidh corresponds to a scattering solution where the vortex-antivortex pair $(1,2) \mathrm{m}$ oves o to in nity leaving behind vortex 3 w hich relocates to a new nalposition. H ow ever, < 0 leads to a situation of the type anticipated by Eq. (69) . $T$ he resulting bounded (quasiperiodic) three-vortex $m$ otion is ilhustrated in F ig. 6 for $=1=4$.

FIG. 6: Trajectories of three vortices in bounded (quasiperiodic) motion em anating from an initial con guration speci ed by Eqs. (70) and (71) w ith $=\frac{1}{4}$.

A though the present calculation is perform ed in an in nite $m$ agnetic $l m$, this type ofbounded $m$ otion $m$ ay be relevant for the dynam ics in nite, disc-shaped ferrom agnetic elem ents.

In the special lim it ! 0 the three vortioes lie on a straight line for all tim es at constant relative distances:

$$
\begin{equation*}
\mathrm{C}_{1}=2 \mathrm{~b} ; \quad \mathrm{C}_{2}=3 \mathrm{~b} ; \quad \mathrm{C}_{3}=\mathrm{b}: \tag{74}
\end{equation*}
$$

Such a linear con guration rotates rigidly around a xed guiding center with constant angular frequency

$$
\begin{equation*}
!=\frac{d_{1}}{d t}=\frac{d_{2}}{d t}=\frac{d_{3}}{d t}=\frac{1}{6 b^{2}} \tag{75}
\end{equation*}
$$

a relation obtained by applying Eqs. (36) to the present degenerate case.

## V. CONCLUSIONS

$W$ e have studied the equations of $m$ otion for $m$ agnetic vortices $w$ hich are approxim ated as point vortioes. These are a generalization of the $H$ elm holtz $K$ irchho equations [10, 11] derived for ordinary uid vortioes. They di er from them in that $m$ agnetic vortioes have an additional characteristic, their polarity, which enters in the equations. The main body of the paper is devoted to the case of three $m$ agnetic vortices which constitute an integrable system. For the integration of this system we follow the steps of the sem inal paper of $G$ robli [12] m odi ed to include the vortex polarity.
$M$ agnetic vortioes are com $m$ only observed in $m$ agnetic elem ents $w$ ith typicaldim ensions of the order of a few microm eters or hundreds of nanom eters. A single vortex spontaneously created at the center of an elem ent can be driven by a $m$ agnetic eld or an electrical current to produce excitations in its vicinity. It has been observed in various num erical sim ulations that such
excitations often have the form of a hum of $m$ agnetization opposite to that of the original vortex. In som e cases the lum ps are am pli ed to becom e vortex-antivortex pairs with clearly distinct constituent vortices. Such a process was apparently observed in experim ents where the original vortex was driven by a magnetic eld [3, 4] or an electrical current [5]. The fact that the created vortex-antivortex pair has opposite polarity to the original vortex should most probably be attributed to the e ect of the $m$ agnetostatic (dipole-dipole) interaction which is the only $m$ agnetic interaction that prim arily favors dom ains of opposite $m$ agnetization. From these exam ples it follows that the three-vortex con guration, given in Eq. (27), on which we have $m$ ainly focused in this paper, is a particularly interesting one for the pupposes of understanding vortex dynam ics in $m$ agnetic elem ents.

In view of the above com $m$ ents it is interesting to com pare our results $w$ ith simulations of the Landau-Lifshitz equation. W e have used the Landau-Lifshitz equation with an exchange interaction and an on-site easy-plane anisotropy so that vortioes are the relevant excitations of the system. Som e results have been published in Refs. [8, [9]. For the case of vortex-antivortex pairs where the vortioes are well-separated the sim ulations show very good agreem ent w th the analytical solutions for the vortex trajectories. It is worth discussing separately the special case of three-vortex collapse of Subsection IV B which would appear to be speci c to the point vortex system. We have sim ulated the case of zero angular $m$ om entum $w$ ithin the LandauLifshitz equation and have observed vortex trajectories very sim ilar to those shown in $F$ ig. 3 . $T$ he original vortex and the antivortex are annihilated when the three-vortex system collapses to the origin and an isolated vortex 1 is the nal outcom e of the sim ulation. The results of the sim ulation are closer to the analytical solutions when the vortex-antivortex pair is large, i.e., the vortex and the antivortex are initially well separated.
