#### Abstract

Ag-sheathed SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta}$  (Sm-1111) superconducting wires were prepared by a one-step solid state reaction at temperatures as low as 850~900 °C, instead of commonly used temperatures of 1150~1250°C. The X-ray diffraction pattern of the as-sintered samples is well indexed on the basis of tetragonal ZrCuSiAs-type structure. We characterized transport critical current density  $J_c$  of the SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta$ </sub> wires in increasing and subsequently decreasing fields, by a resistive four-probe method. A transport  $J_c$  as high as ~1300 A/cm<sup>2</sup> at 4.2 K and self field has been observed for the first time in Sm-1111 type polycrystalline superconductors. The  $J_c$  also shows a rapid depression in small applied fields as well as a magnetic-history dependence, indicating weak-linked grain boundaries. The low-temperature synthesis method can be very beneficial to fabricating the RE-1111 iron oxynictides in a convenient and safe way.</sub>

## Introduction

The recent discovery of superconductivity in LaFeAsO<sub>1-x</sub>F<sub>x</sub> (La-1111) and related compounds, with a highest  $T_c$  of ~55 K [1, 2], has triggered worldwide research efforts in both theoretical and experimental aspects for the purpose of understanding the high- $T_c$  mechanism, discovering new superconductors, and investigating magnetic and electronic properties of the new superconductors [3-14]. In particular, the fluorine doped RE-1111 (RE = Sm, Pr and Nd) oxypnictides have drawn great interest, because of their high critical transition temperatures  $T_c$  (>50 K), high local critical current density  $J_c$  and high upper critical field  $H_{c2}$  [15].

Initially, the RE-1111 oxypnictides were synthesized in sealed quartz tubes at temperatures as high as 1150-1250 °C [1, 16], but the synthesis process is non-ideal due to volatility of some components (F and As) and explosion accident. Another method, high pressure synthesis, was done in boron nitride crucibles under high pressure (up to ~5 GPa) and high temperatures (~1200 °C). This method can be used to make fluorine free RE-1111 oxypnictides with a high density, but it is restrict to small sample dimensions [2, 17]. Based on the conventional powder-in-tube method, we have proposed a metal-tube sealed one-step method, which avoid the explosion accident and is versatile for the fabrication of FeAs-based oxypnictides [6]. However, the sintering temperatures are still as high as ~1180 °C [18].

In this paper, we report first synthesis of fluorine doped Sm-1111 wires at temperatures as low as  $850\sim900^{\circ}$ C. Transport critical current density of the SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta$ </sub> was characterized in increasing and subsequently decreasing fields, by a resistive four-probe method, and evidence for weak-link behavior were demonstrated.

#### **Experimental details**

Fluorine doped Sm-1111 polycrystalline were prepared by the one-step method and the details of fabrication process are described elsewhere [19]. Sm filings, Fe powder, Fe<sub>2</sub>O<sub>3</sub> powder, As pieces and SmF<sub>3</sub> powder, with a ratio Sm : Fe : As : O : F = 1 : 1 : 1 : 0.7 : 0.3, were well ground in Ar atmosphere, with the aim to achieve a uniform distribution. The final powder was filled in a silver tube (OD: 8 mm, ID: 6.4 mm). The composite were filled in an iron tube (OD: 11.6 mm, ID: 8.2 mm). The filled tube was swaged and drawn down to a wire of 1.95 mm in diameter. Short samples were cut from the as-drawn wires for sintering. The short wires were sintered at 500 °C for 15 hours, heated to 850-900 °C for 40 hours in Ar atmosphere.

Phase identification was characterized by powder X-ray diffraction (XRD) analysis with Cu-K $\alpha$  radiation from 20 to 70°. Resistivity measurements were carried out by the standard four-probe method using a PPMS system. Dc magnetization measurements were performed with a superconducting quantum interference device SQUID magnetometer. The transport critical currents  $I_c$  at 4.2 K and its magnetic dependence were evaluated at the High Field Laboratory for Superconducting Materials (HFLSM) in Sendai, Japan, by a standard four-probe resistive method, with a criterion of 1  $\mu$ V cm<sup>-1</sup>. The  $I_c$  measurement was performed for 2-3 samples to check reproducibility.

#### **Results and discussion**

X-ray diffraction pattern of the SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta}$  wire samples taken after heat-treatment is shown in Fig. 1. As is seen from the figure, most of peaks as noted can be indexed on the basis of tetragonal ZrCuSiAs-type structure, with a small amount of impurity phases, ensuring the Sm-1111 phase can be synthesized at 850-900 °C, about 300 °C lower than those (1150~1200 °C) reported previously [16-18]. In the present study, we adopted 0.3- $\delta$  for the fluorine concentration because fluorine evaporated during the heat-treatment process. The lattice parameters were derived from the X-ray diffraction pattern using a X'Pert Plus program, and the resultant values are *a* = 0.3933 nm and *c* = 0.8477 nm, respectively. Compared to the undoped SmFeAsO (*a* = 0.3940 nm, *c* = 0.8450 nm), both a- and c- axis were reduced, indicating fluorine was successfully adopted into Sm-1111 lattice [20].</sub>

Figure 2 shows normalized resistivity versus temperature measurement of the SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta$ </sub> specimens. In agreement with previous reports, SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta$ </sub> is characterized by a nearly linear decrease of resistivity with temperature. The onset of superconductivity occurs at 41 K, and zero resistivity is achieved at 31 K (upper inset). The *T<sub>c</sub>* is consistent with the value reported by Chen's group, for which the sintering

temperatures are 1160~1200 °C [16]. In addition, a slight drop of resistivity was observed above 48 K. Since the critical transition temperature  $T_c$  of SmFeAsO<sub>1-x</sub>F<sub>x</sub> is strongly dependent on fluorine concentration, we suggest that Sm-1111 phase with higher  $T_c$  can be synthesized at such low temperatures by depressing fluorine volatility.

The lower inset of Fig. 2 displays temperature dependence of zero-field-cooled (ZFC) and field-cooled magnetization for the SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta$ </sub> specimen measured under 20 Oe. The diamagnetic signal on zero-field-cooling appears near 40 K, and significantly increases below 30 K, which is well consistent with the resistance result. The FC and ZFC measurements yield maximum signals of ~2% and ~80% of complete flux expulsion, respectively. The small diamagnetic signal on field-cooling indicates that the specimen shows strong pinning of trapped vortices.

Global critical current densities,  $J_c$ 's, of the polycrystalline FeAs-based superconductors, have been investigated by many groups, through remanent magnetization, magneto-optical imaging, Campbell's method and resistive four-probe method, and evidence for granular behavior were presented [7-12]. The global  $J_c$  have generally been restricted to values  $<10^4$  A/cm<sup>2</sup> at 4.2 K in self field, and a rapid depression was observed by applying small magnetic fields (~0.1 T) [10]. Recently, an experimental result showed that weak-link grain boundaries are characteristic of iron pnictides, and they ascribed this to competing orders, low carrier density and unconventional pairing symmetry [21]. Another study argued that the origin of low  $J_{cb}$ is the tensile strain generated by dislocations located along the boundary [22]. Further study on the features of transport critical current density in polycrystalline oxypnictides, especially by a standard four-probe method, could be much helpful for understanding the weak-link mechanism in iron-based superconductors.

We evaluated transport critical currents,  $I_c$ 's, of the SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta$ </sub> wires by a standard four-probe method in applied fields up to 14 T. Two typical original current-voltage plots were shown in the inset of Fig. 3, and the zero resistive currents of ~13 A and ~1 A, were clearly seen for self field and 14 T, respectively. A repeated measurement was carried out right after a virgin measurement at 0 T, and the resultant

plot was almost the same as the virgin one, suggesting that the transport property of the SmFeAsO<sub>0.7</sub> $F_{0.3-\delta}$  superconducting wires are not affect by current history.

Transport critical current density  $J_c$  as a function of field for Sm-1111 wires is presented in Fig. 3. A transport  $J_c$  as high as ~1300 A/cm<sup>2</sup> at 4.2 K and self field has been observed for the first time in 1111-type polycrystalline superconductors. The  $J_c$ values show a strong field dependence in low field region (e.g.  $J_c$  (0 T)  $\geq$  10  $J_c$  (0.5 T)), and this is in analogue to that of sintered YBCO, which shows an intrinsic weak-link behavior. In high field region, the  $J_c$  is almost field independent, constant at ~80 A/cm<sup>2</sup> between 0.5 T and 14 T. In Sr<sub>0.6</sub>K<sub>0.4</sub>Fe<sub>2</sub>As<sub>2</sub>, a similar field dependence of  $J_c$  was observed, but the  $J_c$  value is much lower [23]. The transport  $J_c$  in Sm- and Nd-1111 bulk superconductors, which were fabricated under 6 GPa at 1250 °C, have been evaluated previously, and it was reported that the defects at grain boundaries, such as impurity phases and cracks, produce a multiply connected current-blocking network [10]. Clearly, the impurity phases, peaks of which were observed in the XRD pattern, were thought to be harmful to the transport capability, and a higher transport  $J_c$  should be expected for SmFeAsO<sub>0.7</sub>F<sub>0.3- $\delta}</sub> superconductors with improved raw$ powder and sintering process.</sub>

After increasing the field monotonically to 14 T, transport  $J_c$  was also measured as a function of decreasing field until 0 T. An important point to note is the increased value of  $J_c$  in the region above 0.4 T, compared with the data for the virgin curve. The  $J_c$  is seen to peak on decreasing the field at 0.4 T, so that for 0 T, the  $J_c$  value is substantially reduced as compared to the virgin measurement. The hysteretic effects are supposed to be related to weak-linked grain boundaries as well as penetration of flux into strong pinning intra-granular regions, and that the presence of intra-granular critical currents enhances inter-granular critical currents when the applied field is reduced from higher values. The peak in the transport  $J_c$  for decreasing fields, is generally attributed to compensation of the applied field and by the effect of paramagnetic intra-granular currents generated in decreasing field [24].

Results confirm that synthesis of fluorine doped Sm-1111 iron oxypnictide can be achieved with a low temperature one-step method. Because of its high similarity with other RE-1111 oxypnictides, the low temperature synthesis can be extended to many different materials, such as Nd-, Pr-, Ce- and La- 1111. However, the main advance is that it is not necessary to afford high temperatures of ~1200 °C for synthesis iron oxypnictides. This becomes more important when one considers the high As vapour-pressure and the resultant explosion accident. Although the transport critical current density  $J_c$  in polycrystalline iron oxypnictides is limited by the weak links between grains, higher  $J_c$  values could be expected in pure and textured materials, which is the on-going research. This low-temperature synthesis would give further encouragement to the development of the RE-1111 FeAs-based superconductors, with a highest  $T_c$  of 55 K, for potential applications.

### Conclusions

We demonstrated a Sm-1111 synthesis temperature as low as ~900 °C. Such a temperature is far lower than those reported previously, and is comparable with the synthesis temperatures of 122 iron pnictides (850-900 °C). The low temperature synthesis method reported here can be applied to other RE-1111 oxypnictides, such as Nd-, Pr-, Ce- and La- 1111, to synthesize a variety of elemental polycrystalline superconductors and single crystals, using appropriate precursors and heat-treatment program.
