(Dated: February 15, 2022)

On Archimedean lattices, the Ising model exhibits spontaneous ordering. Three examples of these lattices of the majority-vote model with noise are considered and studied through extensive Monte Carlo simulations. The order/disorder phase transition is observed in this system. The calculated values of the critical noise parameter are $q_c = 0.089(5)$, $q_c = 0.078(3)$, and $q_c = 0.114(2)$ for honeycomb, Kagomé and triangular lattices, respectively. The critical exponents β/ν , γ/ν and $1/\nu$ for this model are 0.15(5), 1.64(5), and 0.87(5); 0.14(3), 1.64(3), and 0.86(6); 0.12(4), 1.59(5), and 1.08(6) for honeycomb, Kagomé and triangular lattices, respectively. These results differs from the usual Ising model results and the majority-vote model on so-far studied regular lattices or complex networks. The effective dimensionalities of the system $D_{\text{eff}} = 1.96(5)$ (honeycomb), $D_{\text{eff}} = 1.92(4)$ (Kagomé), and $D_{\text{eff}} = 1.83(5)$ (triangular) for these networks are just compatible to the embedding dimension two.

I. INTRODUCTION

The majority-vote model (MVM) [1] defined on two-dimensional regular lattices shows second-order phase transition with critical exponents β , γ , ν — which characterize the system in the vicinity of the phase transition — identical [1–3] with those of equilibrium Ising model [4, 5].

On the other hand MVM on the complex networks exhibit different behavior [6–12]. Campos *et al.* investigated MVM on *undirected* small-world network [6]. This network was constructed using the square lattice (SL) by the rewiring procedure. Campos *et al.* found that the critical exponents γ/ν and β/ν are different from those of the Ising model [5] and depend on the rewiring probability. Luz and Lima studied MVM on *directed* small-world network [7] constructed using the same process described by Sánchez *et al.* [13]. They also found that the critical exponents γ/ν and β/ν are different from these of the Ising model on square lattice, but contrary to results of Campos *et al.* [6] for MVM the exponents do not depend on the rewiring probability. Pereira *et al.* [8] studied MVM on *undirected* Erdős–Rényi’s (ERU) classical random graphs [14], and Lima *et al.* [9] also studied this model on *directed* Erdős–Rényi’s (ERD) and their results obtained for critical exponents agree with the results of Pereira *et al.* [8], within the error bars. Lima *et al.* [10] also studied this model on random Voronoy–Delaunay lattice [15] with periodic boundary conditions. Lima also [11] studied the MVM on *directed* Albert–Barabási

(ABD) network [16] and contrary to the Ising model on these networks [17], the order/disorder phase transition *was* observed in this system. However, the calculated β/ν and γ/ν exponents for MVM on ABD and ABU networks are different from those for the Ising model [5] and depend on the mean value of connectivity \bar{z} of ABD and ABU network. Lima and Malarz [18] studied the MVM on $(3, 4, 6, 4)$ and $(3^4, 6)$ Archimedean lattices (AL). They remark that the critical exponents γ/ν , β/ν and $1/\nu$ for MVM on $(3, 4, 6, 4)$ AL are *different* from the Ising model [5] and *differ* from those for so-far studied regular two-dimensional lattices [1, 2], but for $(3^4, 6)$ AL, the critical exponents are much closer to those known analytically for SL Ising model.

The results presented in Refs. [6–12] show that the MVM on various complex topologies belongs to different universality classes. Moreover, contrary for MVM on regular lattices [1, 2], the obtained critical exponents are different from those of the equilibrium Ising model [5]. Very recently, Yang and Kim [19] showed that also for d -dimensional hypercube lattices ($3 \leq d \leq 6$) critical exponents for MVM differ from those for SL Ising model. The same situation occurs on hyperbolic lattices [20].

In this paper we study the MVM on three AL, namely on triangular (3^6), honeycomb (6^3), and Kagomé ($3, 6, 3, 6$) lattices.

The AL are vertex transitive graphs that can be embedded in a plane such that every face is a regular polygon. The AL are labeled according to the sizes of faces incident to a given vertex. The face sizes are sorted, starting from the face for which the list is the smallest in lexicographical order. In this way, the triangular lattice gets the name $(3, 3, 3, 3, 3, 3)$, abbreviated to (3^6) , honeycomb lattice is called (6^3) and Kagomé lattice is $(3, 6, 3, 6)$. Critical properties of these lattices were investigated in terms of site percolation [21] and Ising model

[22].

Our main goal is to check the hypothesis of Grinstein *et al.* [23] — i.e., that non-equilibrium stochastic spin systems with up-down symmetry fall in the universality class of the equilibrium Ising model — for systems in-between ordinary, regular lattices (like SL [1]) and complex spin systems (like spins on ERU and ERD [8, 9] or ABU and ABD [11, 12]).

With extensive Monte Carlo simulation we show that MVM on 6^3 , $(3, 6, 3, 6)$ and 3^6 AL exhibits second-order phase transitions with effective dimensionality $D_{\text{eff}} \approx 1.96$, 1.92 and 1.83 and has critical exponents that *do not* fall into universality class of the equilibrium Ising model.

II. MODEL AND SIMULATION

We consider the MVM [1] defined by a set of “voters” or spin variables σ taking the values $+1$ or -1 , situated on every node of the 6^3 , $(3, 6, 3, 6)$ and 3^6 AL with $N = L^2$ sites for 6^3 and 3^6 , and $N = 3L^2$ sites for $(3, 6, 3, 6)$. The evolution is governed by single spin-flip like dynamics with a probability w_i of i -th spin to flip is given by

$$w_i = \frac{1}{2} \left[1 - (1 - 2q)\sigma_i \cdot \text{sign} \left(\sum_{j=1}^z \sigma_j \right) \right], \quad (1)$$

and the sum runs over the number $z = 3$ (for $(3, 6, 3, 6)$ and (6^3) lattices) and $z = 6$ (for (3^6) lattice) of nearest neighbors of i -th spin. The control parameter $0 \leq q \leq 1$ plays the role of the temperature in equilibrium systems and measures the probability of aligning against the majority of neighbors. It means, that a given spin i adopts the majority sign of its neighbors with probability $(1 - q)$ and the minority sign with probability q [1, 8–12].

To study the critical behavior of the model we define the variable $m \equiv \sum_{i=1}^N \sigma_i / N$. In particular, we are interested in the magnetization M , susceptibility χ and the reduced fourth-order cumulant U

$$M(q) \equiv \langle |m| \rangle, \quad (2a)$$

$$\chi(q) \equiv N (\langle m^2 \rangle - \langle m \rangle^2), \quad (2b)$$

$$U(q) \equiv 1 - \frac{\langle m^4 \rangle}{3\langle m^2 \rangle^2}, \quad (2c)$$

where $\langle \dots \rangle$ stands for a thermodynamics average. The results are averaged over the N_{run} independent simulations.

These quantities are functions of the noise parameter q and obey the finite-size scaling relations

$$M = L^{-\beta/\nu} f_m(x), \quad (3a)$$

$$\chi = L^{\gamma/\nu} f_\chi(x), \quad (3b)$$

$$\frac{dU}{dq} = L^{1/\nu} f_U(x), \quad (3c)$$

where ν , β , and γ are the usual critical exponents, $f_{m,\chi,U}(x)$ are the finite size scaling functions with

$$x = (q - q_c)L^{1/\nu} \quad (3d)$$

being the scaling variable. Therefore, from the size dependence of M and χ we obtained the exponents β/ν and γ/ν , respectively. The maximum value of susceptibility also scales as $L^{\gamma/\nu}$. Moreover, the value of q^* for which χ has a maximum is expected to scale with the system size as

$$q^* = q_c + bL^{-1/\nu} \text{ with } b \approx 1. \quad (4)$$

Therefore, the relations (3c) and (4) may be used to get the exponent $1/\nu$. We evaluate also the effective dimensionality, D_{eff} , from the hyper-scaling hypothesis

$$2\beta/\nu + \gamma/\nu = D_{\text{eff}}. \quad (5)$$

We performed Monte Carlo simulation on the 6^3 , $(3, 6, 3, 6)$ and 3^6 AL with various systems of size $N = 64$, 256 , 1024 , 4096 , 16384 , and 65536 for 6^3 and $(3, 6, 3, 6)$ AL and $N = 192$, 768 , 3072 , 12288 , 49152 , and 196608 for 3^6 . It takes 2×10^5 Monte Carlo steps (MCS) to make the system reach the steady state, and then the time averages are estimated over the next 2×10^5 MCS. One MCS is accomplished after all the N spins are investigated whether they flip or not. The results are averaged over N_{run} ($20 \leq N_{\text{run}} \leq 50$) independent simulation runs for each lattice and for given set of parameters (q, N) .

III. RESULTS AND DISCUSSION

In Fig. 1 we show the dependence of the magnetization M , Binder cumulant U_4 , and the susceptibility χ on the noise parameter q , obtained from simulations on (6^3) , $(3, 6, 3, 6)$ and (3^6) AL with N ranging from $N = 64$ to 196608 sites. The shape of $M(q)$, U , and χ curve, for a given value of N , suggests the presence of the second-order phase transition in the system. The phase transition occurs at the value of the critical noise parameter q_c . The critical noise parameter q_c is estimated as the point where the curves for different system sizes N intercept each other [24]. Then, we obtain $q_c = 0.089(5)$ and $U_4^* = 0.578(3)$; $q_c = 0.078(3)$ and $U_4^* = 0.613(4)$; $q_c = 0.114(5)$ and $U_4^* = 0.601(5)$ for 6^3 , $(3, 6, 3, 6)$ and 3^6 AL, respectively.

In Fig. 3 we plot the dependence of the magnetization $M^* = M(q_c)$ vs. the linear system size L . The slopes of curves correspond to the exponent ratio β/ν according to Eq. (3a). The obtained exponents are $\beta/\nu = 0.15(5)$,

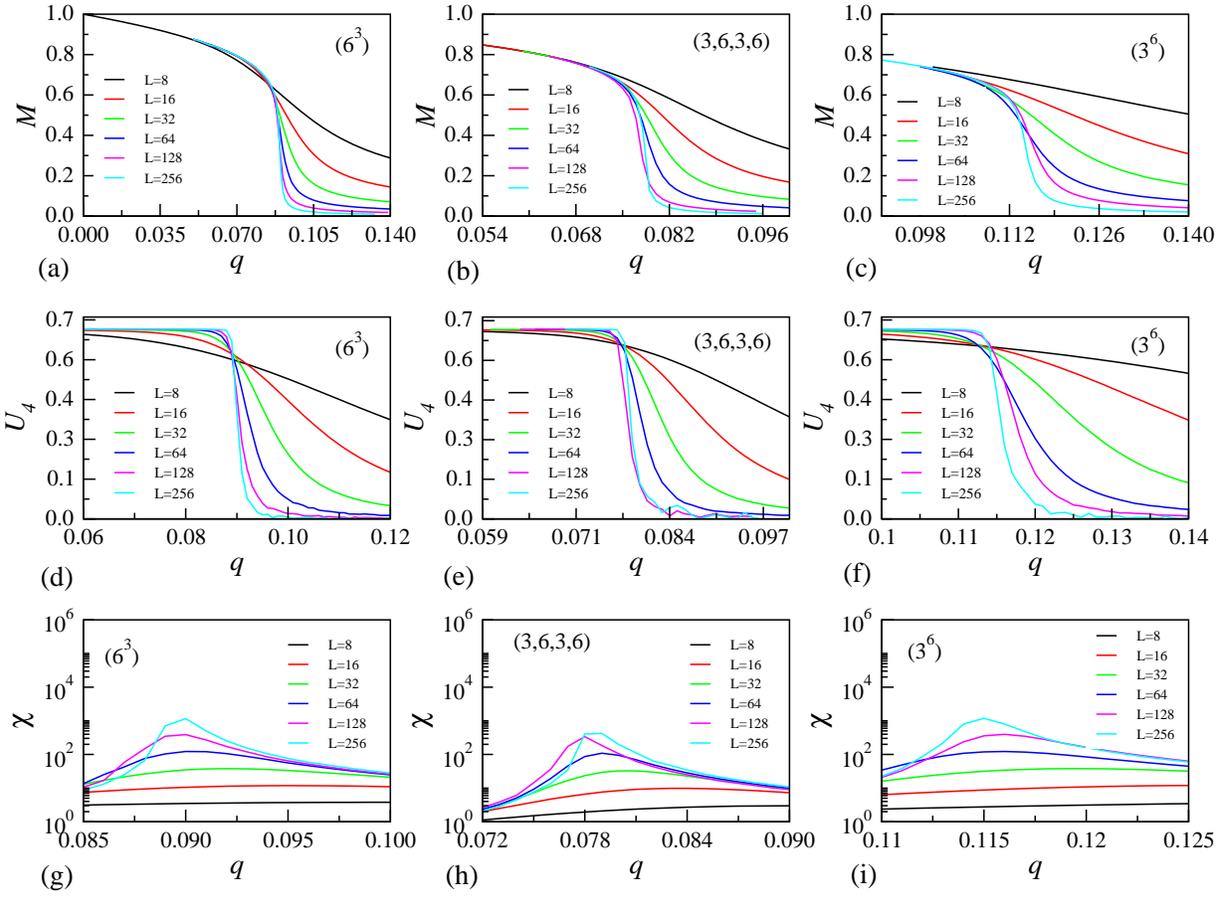

FIG. 1: (Color on-line). The magnetization M , Binder cumulant U_4 , and susceptibility χ as a function of the noise parameter q , for $L = 8, 16, 32, 64, 128$, and 256 lattice sizes, and with $N = L^2$ sites for 6^3 (first column), 3^6 (second column) and $N = 3L^2$ sites for $(3, 6, 3, 6)$ AL (third column).

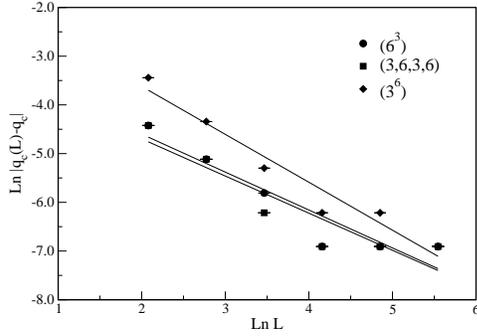

FIG. 2: Plot $\ln |q_c(L) - q_c|$ versus the linear system size L for 6^3 (circles), $(3, 6, 3, 6)$ (squares), 3^6 (diamonds).

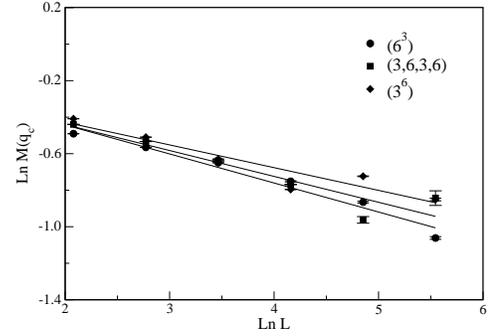

FIG. 3: Plot the dependence of the magnetization $M^* = M(q_c)$ vs. the linear system size L .

0.14(3), and 0.12(4), respectively for 6^3 , $(3, 6, 3, 6)$ and 3^6 AL.

The exponents ratio γ/ν at q_c are obtained from the slopes of the straight lines with $\gamma/\nu = 1.64(5)$ for 6^3 , $\gamma/\nu = 1.64(3)$ for $(3, 6, 3, 6)$, and $\gamma/\nu = 1.59(5)$ for 3^6 ,

as presented in Fig. 4. The exponents ratio γ/ν at $q_{\chi_{max}}(N)$ are $\gamma/\nu = 1.66(8)$ for 6^3 , $\gamma/\nu = 1.62(5)$ for $(3, 6, 3, 6)$, and $\gamma/\nu = 1.64(1)$ for 3^6 , as presented in Fig. 5.

To obtain the critical exponent $1/\nu$, we used the scal-

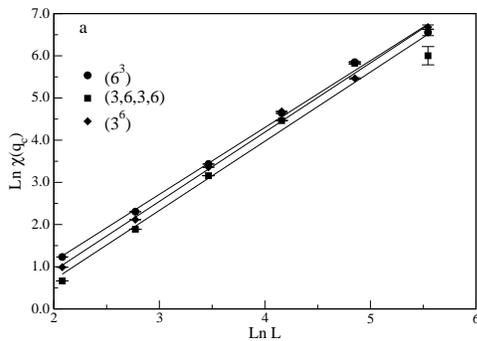

FIG. 4: Susceptibility at q_c versus L for (6^3) , $(3, 6, 3, 6)$ and (3^6) AL.

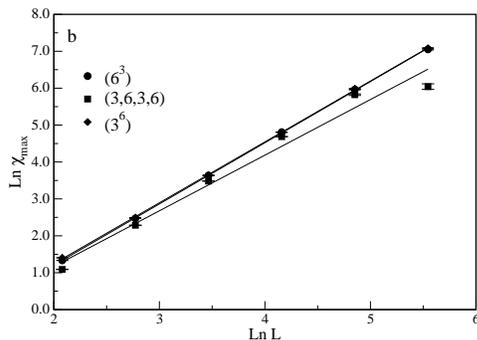

FIG. 5: Susceptibility at $q_{\chi_{max}}(N)$ versus L for 6^3 , $(3, 6, 3, 6)$ and 3^6 AL.

ing relation (4). The calculated values of the exponents $1/\nu$ are $1/\nu = 0.87(5)$ for 6^3 (circles), $1/\nu = 0.86(6)$ for $(3, 6, 3, 6)$ (squares), and $1/\nu = 1.08(6)$ for 3^6 (diamonds) (see Fig. 2). Eq. (5) yields effective dimensionality of systems $D_{\text{eff}} = 1.96(5)$ for 6^3 , $D_{\text{eff}} = 1.92(4)$ for $(3, 6, 3, 6)$, and $D_{\text{eff}} = 1.83(5)$ for 3^6 . The MVM on those three AL has the effective dimensionality close to two contrary to ER classical random graphs ($0.99 \leq D_{\text{eff}} \leq 1.02$) [8] or directed AB networks ($0.998 \leq D_{\text{eff}} \leq 1.018$) [12] with roughly the same nodes connectivity ($\bar{z} = 3$) as for (6^3) and $(3, 6, 3, 6)$, and ($\bar{z} = 6$) 3^6 AL.

The results of simulations are collected in Tab. I.

IV. CONCLUSION

We presented a very simple non-equilibrium MVM on 6^3 , $(3, 6, 3, 6)$ and 3^6 AL. On these lattices, the MVM shows a second-order phase transition. Our Monte Carlo

simulations demonstrate that the effective dimensionality D_{eff} is close to two, i.e. that hyper-scaling may be valid.

Finally, we remark that the critical exponents γ/ν , β/ν and $1/\nu$ for MVM on *regular* 6^3 , $(3, 6, 3, 6)$ and 3^6 AL are *similar* to the MVM model on *regular* $(3, 4, 6, 4)$ and $(3^4, 6)$ [18] and are *different* from the Ising model [5] and

TABLE I: Critical parameter, exponents and effective dimension for MVM model on 6^3 , $(3, 6, 3, 6)$ and 3^6 . For completeness we cite data for SL Ising model as well.

	6^3	$(3,6,3,6)$	3^6	SL Ising
q_c	0.089(5)	0.078(2)	0.114(5)	
β/ν	0.15(5)	0.14(3)	0.12(4)	0.125
γ/ν^a	1.64(5)	1.64(3)	1.59(5)	1.75
γ/ν^b	1.66(8)	1.62(5)	1.64(1)	1.75
$1/\nu$	0.87(5)	0.86(6)	1.08(6)	1
D_{eff}^c	1.96(5)	1.92(4)	1.83(5)	2

^aobtained using $\chi(N)$ at $q = q_c$

^bobtained using $\chi(N)$ at $q = q^*$

^cobtained using ratio γ/ν given by dependence $\chi(N)$ at $q = q_c$

differ from those for so-far studied regular lattices [1, 2] and for the *directed* and *undirected* ER random graphs [8, 9] and for the *directed* and *undirected* AB networks [11, 12]. However, in the latter cases [8, 9, 11, 12] the scaling relations (3) must involve the number of sites N instead of linear system size L as these networks in natural way do not possess such characteristic which allow for $N \propto L^d$ ($d \in \mathbb{Z}$) dependence [26]. For (6^3) , $(3, 6, 3, 6)$ and (3^6) AL some critical exponents are much closer to those known analytically for square lattice Ising model, i.e. $\beta = 1/8 = 0.125$, $\gamma = 7/4 = 1.75$ and $\nu = 1$, but except for ν they differ for more than three numerically estimated uncertainties.
