Abstract

Bayesian implementation concerns decision making problems when agents have incomplete information. A recent work [Wu, Quantum mechanism helps agents combat “bad” social choice rules. *Intl. J. of Quantum Information* 9 (2011) 615-623] generalized the implementation theory with complete information to a quantum domain. In this paper, we propose a quantum Bayesian mechanism and an algorithmic Bayesian mechanism, which amend the traditional results for Bayesian implementation.

Key words: Algorithmic mechanism design; Bayesian implementation.

1 Introduction

Mechanism design is an important branch of economics. Compared with game theory, it concerns a reverse question: given some desirable outcomes, can we design a game that produces them? Nash implementation and Bayesian implementation are two key topics of the mechanism design theory. The former assumes complete information among the agents, whereas the latter concerns incomplete information. Maskin [1] provided an almost complete characterization of social choice rules that are Nash implementable when the number of agents is at least three. Postlewaite and Schmeidler [2], Palfrey and Srivastava [3], and Jackson [4] together constructed a framework for Bayesian implementation.

In 2011, Wu [5] claimed that the sufficient conditions for Nash implementation shall be amended by virtue of a quantum mechanism. Furthermore, this amendment holds in the macro world by virtue of an algorithmic mechanism [6]. Given these accomplishments in the field of Nash implementation, this paper aims to investigate what will happen if the quantum mechanism is applied to Bayesian implementation.

The rest of this paper is organized as follows: Section 2 recalls preliminaries of Bayesian implementation given by Serrano [7]. In Section 3, a novel condition, multi-Bayesian monotonicity, is defined. Section 4 and 5 are the main parts of this paper, in which we will propose quantum and algorithmic Bayesian mechanisms respectively. The last section draws the conclusions.
2 Preliminaries

Let \( N = \{1, \cdots, n\} \) be a finite set of agents with \( n \geq 2 \), \( A = \{a_1, \cdots, a_k\} \) be a finite set of social outcomes. Let \( T_i \) be the finite set of agent \( i \)'s types, and the private information possessed by agent \( i \) is denoted as \( t_i \in T_i \). We refer to a profile of types \( t = (t_1, \cdots, t_n) \) as a state. Consider environments in which the state \( t = (t_1, \cdots, t_n) \) is not common knowledge among the \( n \) agents. We denote by \( T \) the set of states compatible with an environment, i.e., a set of states that is common knowledge among the agents. Let \( T = \prod_{i \in N} T_i \). Each agent \( i \in N \) knows his type \( t_i \in T_i \), but not necessarily the types of the others. We will use the notation \( t_{-i} \) to denote \( (t_j)_{j \neq i} \). Similarly, \( T_{-i} = \prod_{j \neq i} T_j \).

Each agent has a prior belief, probability distribution, \( q_i \) defined on \( T \). We make an assumption of nonredundant types: for every \( i \in N \) and \( t_i \in T_i \), there exists \( t_{-i} \in T_{-i} \) such that \( q_i(t) > 0 \). For each \( i \in N \) and \( t_i \in T_i \), the conditional probability of \( t_{-i} \in T_{-i} \), given \( t_i \), is the posterior belief of type \( t_i \) and it is denoted \( q_i(t_{-i}|t_i) \). For simplicity, we shall consider only single-valued rules, i.e., an SCF \( f \) is a mapping \( f : T \mapsto A \). Let \( \mathcal{F} \) denote the set of SCFs. Given agent \( i \)'s state \( t_i \) and utility function \( u_i(\cdot, t): \Delta \times T \mapsto \mathbb{R} \), the conditional expected utility of agent \( i \) of type \( t_i \) corresponding to a social choice function (SCF) \( f : T \mapsto \Delta \) is defined as:

\[
U_i(f|t_i) = \sum_{t'_i \in T_i} q_i(t'_i|t_i)u_i(f(t'_i, t_i), (t'_i, t_i)).
\]

An environment with incomplete information is a list \( E = \langle N, A, (u_i, T_i, q_i)_{i \in N} \rangle \). An environment is economic if, as part of the social outcomes, there exists a private good (e.g., money) over which all agents have a strictly positive preference. Two SCFs \( f \) and \( h \) are equivalent (\( f \approx h \)) if \( f(t) = h(t) \) for every \( t \in T \).

Consider a mechanism \( \Gamma = ((M_i)_{i \in N}, g) \) imposed on an incomplete information environment \( E, g : M \mapsto \mathcal{F} \). A Bayesian Nash equilibrium of \( \Gamma \) is a profile of strategies \( \sigma^* = (\sigma^*_i)_{i \in N} \) where \( \sigma^*_i : T_i \mapsto M_i \) such that for all \( i \in N \) and for all \( t_i \in T_i \),

\[
U_i(g(\sigma^*))(t_i) \geq U_i(g(\sigma_{-i}^*, \sigma'_i))(t_i), \quad \forall \sigma'_i : T_i \mapsto M_i.
\]

Denote by \( \mathcal{B}(\Gamma) \) the set of Bayesian equilibria of the mechanism \( \Gamma \). Let \( g(\mathcal{B}(\Gamma)) \) be the corresponding set of equilibrium outcomes. An SCF \( f \) is Bayesian implementable if there exists a mechanism \( \Gamma = ((M_i)_{i \in N}, g) \) such that \( g(\mathcal{B}(\Gamma)) \approx f \). An SCF \( f \) is incentive compatible if truth-telling is a Bayesian equilibrium of the direct mechanism associated with \( f \), i.e., if for every \( i \in N \) and for every \( t_i \in T_i \),

\[
\sum_{t'_i \in T_{-i}} q_i(t'_i|t_i)u_i(f(t'_i, t_i), (t'_i, t_i)) \geq \sum_{t'_i \in T_{-i}} q_i(t'_i|t_i)u_i(f(t'_i, t'_i), (t'_i, t_i)),
\]

\( \forall t'_i \in T_i \).
Consider a strategy in a direct mechanism for agent $i$, i.e., a mapping $\alpha_i = (\alpha_i(t_i))_{t_i \in T_i} : T_i \mapsto T_i$. A deception $\alpha = (\alpha_i)_{i \in N}$ is a collection of such mappings where at least one differs from the identity mapping. Given an SCF $f$ and a deception $\alpha$, let $[f \circ \alpha]$ denote the following SCF: $[f \circ \alpha](t) = f(\alpha(t))$ for every $t \in T$. For a type $t_i \in T_i$, an SCF $f$, and a deception $\alpha$, let $f_{\alpha(t)}(t') = f(t', \alpha(t_i))$ for all $t' \in T$. An SCF $f$ is **Bayesian monotonic** if for any deception $\alpha$, whenever $f \circ \alpha \neq f$, there exist $i \in N$, $t_i \in T_i$, and an SCF $y$ such that

$$U_i(y \circ \alpha|t_i) > U_i(f \circ \alpha|t_i), \quad \text{while} \quad U_i(y_{\alpha(t)}|t'_i) \leq U_i(f|t'_i), \quad \forall t'_i \in T_i. \quad (*)$$

In economic environments, the sufficient and necessary conditions for full Bayesian implementation are incentive compatibility and Bayesian monotonicity. To facilitate the following discussion, here we cite the Bayesian mechanism (Page 404, line 4, [7]) as follows: Consider a mechanism $\Gamma = ((M_i)_{i \in N}, g)$, where $M_i = T_i \times F \times \mathbb{Z}_\alpha$, and $\mathbb{Z}_\alpha$ is the set of nonnegative integers. Each agent is asked to report his type $t_i$, an SCF $f_i$ and a nonnegative integer $z_i$, i.e., $m_i = (t_i, f_i, z_i)$. The outcome function $g$ is as follows:

(i) If for all $i \in N$, $m_i = (t_i, f, 0)$, then $g(m) = f(t)$, where $t = (t_1, \ldots, t_n)$.

(ii) If for all $j \neq i$, $m_j = (t_j, f, 0)$ and $m_i = (t'_i, y, z_i) \neq (t'_i, f, 0)$, we can have two cases:

(a) If for all $t_i$, $U_i(y_t|t_i) \leq U_i(f|t_i)$, then $g(m) = y(t'_i, t_{-i})$;

(b) Otherwise, $g(m) = f(t'_i, t_{-i})$.

(iii) In all other cases, the total endowment of the economy is awarded to the agent of smallest index among those who announce the largest integer.

### 3 Multi-Bayesian monotonicity

**Definition 1:** An SCF $f$ is **multi-Bayesian monotonic** if there exist a deception $\alpha$, $f \circ \alpha \neq f$, and a set of agents $N^\alpha = \{i^1, i^2, \ldots\} \subseteq N$, $2 \leq |N^\alpha| \leq n$, such that for every $i \in N^\alpha$, there exist $t_i \in T_i$ and an SCF $y^i \in F$ that satisfy:

$$U_i(y^i \circ \alpha|t_i) > U_i(f \circ \alpha|t_i), \quad \text{while} \quad U_i(y^j_{\alpha(t)}|t'_i) \leq U_i(f|t'_i), \quad \forall t'_i \in T_i. \quad (**).$$

Let $l = |N^\alpha|$. Without loss of generality, let these $l$ agents be the last $l$ agents among $n$ agents.

In 1993, Matsushima [9] claimed that Bayesian monotonicity is a very weak condition when utility functions are quasi-linear and lotteries are available. Consider an SCF $f$ that satisfies Bayesian monotonicity, if there is a deception $\alpha$ such that its corresponding agent $i$ has another symmetric agent $j$ (i.e., $i \neq j$, $u_i = u_j$, $T_i = T_j$, the prior belief and posterior belief hold by them are the same), then $f$ is multi-Bayesian monotonic.

**Example 1:** Similar to Example 23.B.5 in Ref. [8], here we consider an auction
setting with one seller (i.e., agent 0) and three buyers (i.e., agent 1, 2 and 3). All buyers’ privately observed valuations $t_i$ are drawn independently from the uniform distribution on $[0, 1]$ and this fact is common knowledge among the agents. Each buyer submits a sealed bid, $b_i \geq 0$ ($i = 1, 2, 3$). The sealed bids are examined and the buyer with the highest bid is declared the winner. If there is a tie, the winner is chosen randomly. The winning buyer pays an amount equal to his bid to the seller. The losing buyer does not pay anything.

Consider the social choice function $f(t) = (x_0(t), x_1(t), x_2(t), x_3(t), p_0(t), p_1(t), p_2(t), p_3(t))$, in which

$$
x_1(t) = 1, \quad \text{if } t_1 \geq t_2 \text{ and } t_1 \geq t_3; \quad = 0 \text{ otherwise;}
$$

$$
x_2(t) = 1, \quad \text{if } t_2 > t_1 \text{ and } t_2 \geq t_3; \quad = 0 \text{ otherwise;}
$$

$$
x_3(t) = 1, \quad \text{if } t_3 > t_1 \text{ and } t_3 > t_2; \quad = 0 \text{ otherwise;}
$$

$$
x_0(t) = 0, \quad \text{for all } t;
$$

$$
p_1(t) = -\frac{2}{3} \theta_1 x_1(t);
$$

$$
p_2(t) = -\frac{2}{3} \theta_2 x_2(t);
$$

$$
p_3(t) = -\frac{2}{3} \theta_3 x_3(t);
$$

$$
p_0(t) = -[p_1(t) + p_2(t) + p_3(t)].
$$

It can be easily checked that the strategies $b_i(t_i) = \frac{2}{3} t_i$ (for $i = 1, 2, 3$) constitute a Bayesian Nash equilibrium of this auction that indirectly yields the outcomes specified by $f(t)$. Thus, according to Theorem 1 [4], $f$ is incentive compatible and Bayesian monotonic. Since the three buyers are symmetric, then according to the definition of multi-Bayesian monotonicity, $f$ is multi-Bayesian monotonic.

**Proposition 1**: In economic environments, consider an SCF $f$ that is incentive compatible and Bayesian monotonic, if $f$ is multi-Bayesian monotonic, then $f \circ \alpha$ is not Bayesian implementable by using the traditional Bayesian mechanism, where $\alpha$ is specified in the definition of multi-Bayesian monotonicity.

**Proof**: According to Serrano’s proof (Page 404, line 33, [7]), all equilibrium strategies fall under rule (i), i.e., $f$ is unanimously announced and all agents announce the integer 0. Consider the deception $\alpha$ specified in the definition of multi-Bayesian monotonicity. At first sight, if every agent $i \in N$ submits $(\alpha_i(t_i), f, 0)$, then $f \circ \alpha$ may be generated as the equilibrium outcome by rule (i). However, For each agent $i \in N^\alpha$, he has incentives to unilaterally deviate from $(\alpha_i(t_i), f, 0)$ to $(\alpha_i(t_i), y^i, 0)$ in order to obtain $y^i \circ \alpha$ by rule (ii.a). This is a profitable deviation for each agent $i \in N^\alpha$. Therefore, $f \circ \alpha$ is not Bayesian implementable. □
4 A quantum Bayesian mechanism

Following Ref. [5], here we will propose a quantum Bayesian mechanism to modify the sufficient conditions for Bayesian implementation. According to Eq (4) in Ref. [10], two-parameter quantum strategies are drawn from the set:

$$\hat{\omega}(\theta, \phi) = \begin{bmatrix} e^{i\phi} \cos(\theta/2) & i \sin(\theta/2) \\ i \sin(\theta/2) & e^{-i\phi} \cos(\theta/2) \end{bmatrix},$$

\(\hat{\Omega} = \{\hat{\omega}(\theta, \phi) : \theta \in [0, \pi], \phi \in [0, \pi/2]\}, \hat{J} \equiv \cos(\gamma/2)\hat{I}^\otimes n + i \sin(\gamma/2)\sigma_\gamma^\otimes n\) (where \(\gamma \in [0, \pi/2]\) is an entanglement measure, \(\sigma_\gamma\) is Pauli matrix), \(\hat{I} \equiv \hat{\omega}(0, 0), \hat{D}_n \equiv \hat{\omega}(\pi, \pi/n), \hat{C}_n \equiv \hat{\omega}(0, \pi/n)\).

Without loss of generality, we assume that:

1) Each agent \(i\) has a quantum coin \((\text{qubit})\) and a classical card \(i\). The basis vectors \(|C\rangle = (1, 0)^T\), \(|D\rangle = (0, 1)^T\) of a quantum coin denote head up and tail up respectively.

2) Each agent \(i\) independently performs a local unitary operation on his/her own quantum coin. The set of agent \(i\)’s operation is \(\hat{\Omega}_i \equiv \hat{\Omega}\). A strategic operation chosen by agent \(i\) is denoted as \(\hat{\omega}_i \in \hat{\Omega}_i\). If \(\hat{\omega}_i = \hat{I}\), then \(\hat{\omega}_i(|C\rangle) = |C\rangle, \hat{\omega}_i(|D\rangle) = |D\rangle\); If \(\hat{\omega}_i = \hat{D}_n\), then \(\hat{\omega}_i(|C\rangle) = |D\rangle, \hat{\omega}_i(|D\rangle) = |C\rangle\). \(\hat{I}\) denotes “Not flip”, \(\hat{D}_n\) denotes “Flip”.

3) The two sides of a card are denoted as Side 0 and Side 1. The information written on the Side 0 (or Side 1) of card \(i\) is denoted as \(\text{card}(i, 0)\) (or \(\text{card}(i, 1)\)). A typical card written by agent \(i\) is described as \(c_i = (\text{card}(i, 0), \text{card}(i, 1))\), where \(\text{card}(i, 0), \text{card}(i, 1) \in \mathcal{T}_i \times \mathcal{F} \times \mathbb{Z}_+\). The set of \(c_i\) is denoted as \(C_i\).

4) There is a device that can measure the state of \(n\) coins and send messages to the designer.

A quantum Bayesian mechanism \(Q_B = (\hat{\Sigma}_i)_{i \in N}, \hat{g})\) describes a strategy set \(\hat{\Sigma}_i = \{\hat{\sigma}_i : \mathcal{T}_i \mapsto \hat{\Omega}_i \times C_i\}\) for each agent \(i\) and an outcome function \(\hat{g} : \otimes_{i \in N} \hat{\Omega}_i \times \prod_{i \in N} C_i \mapsto \mathcal{F}\). A strategy profile is \(\hat{\sigma} = (\hat{\sigma}_1, \cdots, \hat{\sigma}_n)\), where \(\hat{\sigma}_{-i} : \mathcal{T}_{-i} \mapsto \otimes_{j \neq i} \hat{\Omega}_j \times \prod_{j \neq i} C_j\). A Bayesian Nash equilibrium of \(Q_B\) is a strategy profile \(\hat{\sigma}^* = (\hat{\sigma}_1^*, \cdots, \hat{\sigma}_n^*)\) such that for every \(i \in N\) and for every \(t_i \in \mathcal{T}_i\),

$$U_i(\hat{g}(\hat{\sigma}^*)|t_i) \geq U_i(\hat{g}(\hat{\sigma}_{-i}^*, \hat{\sigma}_i^*)|t_i), \quad \forall \hat{\sigma}_i : \mathcal{T}_i \mapsto \hat{\Omega}_i \times C_i.$$

The setup of the quantum Bayesian mechanism \(Q_B = (\hat{\Sigma}_i)_{i \in N}, \hat{g})\) is depicted in Fig. 1. The working steps of \(Q_B\) are given as follows:

Step 1: Nature selects a state \(t \in \mathcal{T}\) and assigns \(t\) to the agents. Each agent \(i\) knows \(t_i\) and \(q_i(t)|t_i\). The state of each quantum coin is set as \(|C\rangle\). The initial state of the \(n\) quantum coins is \(|\psi_0\rangle = \underbrace{|C \cdots C \rangle}_n\).

Step 2: If \(f\) is multi-Bayesian monotonic, then go to Step 4.
Given $n \geq 3$ agents and an SCF $f$, suppose $f$ satisfies multi-Bayesian monotonicity. For each $i \in N^\alpha$, let $\text{card}(i, 0) = (\alpha_i(t_i), f, 0)$, $\text{card}(i, 1) = (\alpha_i(t_i), y', 0)$; for each $i \notin N^\alpha$, let $\text{card}(i, 0) = (\alpha_i(t_i), f, 0)$, $\text{card}(i, 1) = (t_i, f_i, z_i)$ (where $\alpha, N^\alpha, y'$ are specified in the definition of multi-Bayesian monotonicity). We define the payoff to the $n$-th agent as follows: $\$_{C-CC}$ represents the payoff to the $n$-th agent when the measured state of $n$ quantum coins in Step 7 of $\Gamma_B^D$ is $|C \cdots CC\rangle$; $\$_{C-CD}$ represents the payoff to the $n$-th agent when the measured state of $n$ quantum coins is $|C \cdots C D\rangle$. $\$_{D-DE}$ and $\$_{D-DC}$ are defined similarly.

**Definition 2:** Given an SCF $f$ satisfying multi-Bayesian monotonicity, define condition $\lambda^B$ as follows:
1) $\lambda^B_1$: Consider the payoff to the $n$-th agent, $\$_{C-CC} > \$_{D-DE}$, i.e., he/she prefers the expected payoff of a certain outcome (generated by rule (i)) to the expected payoff of an uncertain outcome (generated by rule (iii)).
2) $\lambda^B_2$: Consider the payoff to the $n$-th agent, $\$_{C-CC} > \$_{C-CD}[1 - \sin^2 \gamma \sin^2(\pi/l)] + \$_{D-DC} \sin^2 \gamma \sin^2(\pi/l)$.
Proposition 2: In economic environments, consider an SCF $f$ that is incentive compatible and Bayesian monotonic, if $f$ is multi-Bayesian monotonic and condition $\lambda^B$ is satisfied, then $f \circ \alpha$ is Bayesian implementable by using the quantum Bayesian mechanism.

Proof: Since $f$ is multi-Bayesian monotonic, then there exist a deception $\alpha$, $f \circ \alpha \neq f$, and $2 \leq l \leq n$ agents that satisfy Eq (**), i.e., for each agent $i \in N^\alpha$, there exist $t_i \in T_i$ and an SCF $y^i \in F$ such that:

$$U_i(y^i \circ \alpha|t_i) > U_i(f \circ \alpha|t_i), \text{ while } U_i(y^i_{\alpha}(t_i)|t'_i) \leq U_i(f|t'_i), \quad \forall t'_i \in T_i.$$ 

Hence, the quantum Bayesian mechanism will enter Step 4. Each agent $i \in N$ sets $c_i = ((\alpha_i(t_i), f, 0), (t_i, f, z_i))$. Let $c = (c_1, \cdots, c_n)$. Since condition $\lambda^B$ is satisfied, then similar to the proof of Proposition 2 in Ref. [5], if the $n$ agents choose $\hat{\sigma}^* = (\hat{\omega}^*, c)$, where $\hat{\omega}^* = (\hat{\lambda}_{1}, \cdots, \hat{\lambda}_{l}, \hat{C}_i, \cdots, \hat{C}_i)$, then $\hat{\sigma}^* \in B(\Gamma^0_B)$. In Step 7, the corresponding measured state of $n$ quantum coins is $|C \cdots C\rangle$. Hence, for each agent $i \in N$, $m_i = (\alpha_i(t_i), f, 0)$. In Step 8, $\hat{g}(\hat{\sigma}^*) = f \circ \alpha \neq f$.

Therefore, $f \circ \alpha$ is implemented by $\Gamma^0_B$ in Bayesian Nash equilibrium. $\square$

5 An algorithmic Bayesian mechanism

Following Ref. [6], in this section we will propose an algorithmic Bayesian mechanism to help agents benefit from the quantum Bayesian mechanism in the macro world. In the beginning, we cite matrix representations of quantum states from Ref. [6].

5.1 Matrix representations of quantum states

In quantum mechanics, a quantum state can be described as a vector. For a two-level system, there are two basis vectors: $(1, 0)^T$ and $(0, 1)^T$. In the beginning, we define:

$$|C\rangle = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad \hat{I} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad \hat{\sigma}_x = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad |\psi_0\rangle = |C \cdots C\rangle = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \in \mathbb{R}^{2^n \times 1}$$
\[
\hat{f} = \cos(\gamma/2)\hat{\theta}_{i}^n + i \sin(\gamma/2)\hat{\phi}_{i}^n
\]

\[
\begin{bmatrix}
\cos(\gamma/2) & i \sin(\gamma/2) \\
\vdots & \vdots \\
\cos(\gamma/2) & i \sin(\gamma/2) \\
i \sin(\gamma/2) & \cos(\gamma/2)
\end{bmatrix}_{2^n \times 2^n}
\]

For \(\gamma = \pi/2\),

\[
\hat{f}_{\pi/2} = \frac{1}{\sqrt{2}}
\begin{bmatrix}
1 & i \\
\vdots & \vdots \\
i & 1
\end{bmatrix}_{2^n \times 2^n},
\]

\[
\hat{f}^*_{\pi/2} = \frac{1}{\sqrt{2}}
\begin{bmatrix}
1 & -i \\
\vdots & \vdots \\
-i & 1
\end{bmatrix}_{2^n \times 2^n}
\]

5.2 A simulating algorithm

Similar to Ref. [6], in the following we will propose a simulating algorithm that simulates the quantum operations and measurements in Steps 4-7 of the quantum Bayesian mechanism given in Section 4. The inputs and outputs of the algorithm are adjusted to the case of Bayesian implementation. The factor \(\gamma\) is also set as its maximum \(\pi/2\). For \(n\) agents, the inputs and outputs of the algorithm are illustrated in Fig. 2. The Matlab program is given in Fig. 3, which is cited from Ref. [6].

**Inputs:**
1) \(\theta_i, \phi_i, i = 1, \ldots, n\): the parameters of agent \(i\)'s local operation \(\hat{\omega}_i, \theta_i \in [0, \pi], \phi_i \in [0, \pi/2]\).
2) \(\text{card}(i, 0), \text{card}(i, 1), i = 1, \ldots, n\): the information written on the two sides of agent \(i\)'s card, where \(\text{card}(i, 0), \text{card}(i, 1) \in T_i \times \mathcal{F} \times \mathbb{Z}_+\).

**Outputs:**
\(m_i, i = 1, \ldots, n\): the agent \(i\)'s message that is sent to the designer, \(m_i \in T_i \times \mathcal{F} \times \mathbb{Z}_+\).

**Procedures of the algorithm:**
Step 1: Reading parameters \(\theta_i\) and \(\phi_i\) from each agent \(i \in N\) (See Fig. 3(a)).
Step 2: Computing the leftmost and rightmost columns of \(\hat{\omega}_1 \otimes \cdots \otimes \hat{\omega}_n\) (See Fig.
describes a strategy set \( \Gamma \). In Section 5.2, these parts are replaced by a simulating algorithm which operates and measurements, which are restricted by current experimental technologies. In the quantum Bayesian mechanism \( \Gamma \)

5.3 An algorithmic version of the quantum Bayesian mechanism

In the quantum Bayesian mechanism \( \Gamma_B^Q = ((\hat{\Sigma}_i)_{i \in N}, \hat{g}) \), the key parts are quantum operations and measurements, which are restricted by current experimental technologies. In Section 5.2, these parts are replaced by a simulating algorithm which can be easily run in a computer. Now we update the quantum Bayesian mechanism \( \Gamma_B^Q = ((\hat{\Sigma}_i)_{i \in N}, \hat{g}) \) to an algorithmic Bayesian mechanism \( \bar{\Gamma}_B = ((\bar{\Sigma}_i)_{i \in N}, \bar{g}) \), which describes a strategy set \( \bar{\Sigma}_i = \{\bar{\sigma}_i : T_i \mapsto [0, \pi] \times [0, \pi/2] \times C_i\} \) for each agent \( i \) and an outcome function \( \bar{g} : [0, \pi]^n \times [0, \pi/2]^n \times \prod_{i \in N} C_i \rightarrow \mathcal{F} \), where \( n \geq 3 \), \( C_i \) is the set of agent \( i \)'s card \( c_i = (\text{card}(i, 0), \text{card}(i, 1)) \). A typical message sent by agent \( i \) is denoted by \((\theta_i, \phi_i, t_i, f_i, z_i, t'_i, f'_i, z'_i)\).

A strategy profile is \( \bar{\sigma} = (\bar{\sigma}_i, \bar{\sigma}_{-i}) \) where \( \bar{\sigma}_{-i} : T_{-i} \mapsto [0, \pi]^{n-1} \times [0, \pi/2]^{n-1} \times \prod_{j \neq i} C_j \). A Bayesian Nash equilibrium of \( \bar{\Gamma}_B \) is a strategy profile \( \bar{\sigma}_i^* = (\bar{\sigma}_1^*, \ldots, \bar{\sigma}_n^*) \) such that for any agent \( i \in N \) and for all \( t_i \in T_i \),

\[
U_i(\bar{g}(\bar{\sigma}^*)|t_i) \geq U_i(\bar{g}(\bar{\sigma}_{-i}^*, \bar{\sigma}_i^')|t_i), \quad \forall \bar{\sigma}_i^* : T_i \mapsto [0, \pi] \times [0, \pi/2] \times C_i.
\]

Fig. 2. The inputs and outputs of the algorithm.
Since the factor $\gamma$ is set as its maximum $\pi/2$, the condition $\lambda^B$ in the quantum Bayesian mechanism shall be updated as $\lambda^{Bn/2}$. $\lambda^{Bn/2}_t$ is the same as $\lambda^B_t$, $\lambda^{Bn/2}_t$ is revised as follows: Consider the payoff to the $n$-th agent, $\$\text{C--CC} > \$\text{C--CD} \cos^2(\pi/l) + \$\text{D--DC} \sin^2(\pi/l)$.

**Working steps of the algorithmic Bayesian mechanism $\bar{\Gamma}_B$:**

Step 1: Given an SCF $f$, if $f$ is multi-Bayesian monotonic, go to Step 3.
Step 2: Each agent $i$ sends $(t_i, f_i, z_i)$ as $m_i$ to the designer. Go to Step 5.
Step 3: Each agent $i \in N^a$ sets $\text{card}(i, 0) = (\alpha_i(t_i), f, 0)$, $\text{card}(i, 1) = (\alpha_i(t_i), y^i, 0)$; each agent $i \notin N^a$ sets $\text{card}(i, 0) = (\alpha_i(t_i), f, 0)$, $\text{card}(i, 1) = (t_i, f_i, z_i)$ (where $\alpha, N^a, y^i$ are specified in the definition of multi-Bayesian monotonicity). Then each agent $i$ submits $\theta_i, \phi_i$, $\text{card}(i, 0)$ and $\text{card}(i, 1)$ to the simulating algorithm.
Step 4: The simulating algorithm runs and outputs messages $m_1, \cdots, m_n$ to the designer.
Step 5: The designer receives the overall message $m = (m_1, \cdots, m_n)$ and let the final outcome be $g(m)$ using rules (i)-(iii) of the traditional Bayesian mechanism. END.

5.4 New results for Bayesian implementation

**Proposition 3:** In economic environments, given an SCF $f$ that is incentive compatible and Bayesian monotonic:
1) If $f$ is multi-Bayesian monotonic and condition $\lambda^{Bn/2}$ is satisfied, then $f \circ \alpha$ is Bayesian implementable by using the algorithmic Bayesian mechanism.
2) If $f$ is not multi-Bayesian monotonic, then $f$ is Bayesian implementable.

**Proof:** 1) Since $f$ is multi-Bayesian monotonic, then $\bar{\Gamma}_B$ enters Step 3.
Each agent $i \in N^a$ sets $\text{card}(i, 0) = (\alpha_i(t_i), f, 0)$, $\text{card}(i, 1) = (\alpha_i(t_i), y^i, 0)$; each agent $i \notin N^a$ sets $\text{card}(i, 0) = (\alpha_i(t_i), f, 0)$, $\text{card}(i, 1) = (t_i, f_i, z_i)$ (where $\alpha, N^a, y^i$ are specified in the definition of multi-Bayesian monotonicity). Then each agent $i$ submits $\theta_i, \phi_i$, $\text{card}(i, 0)$ and $\text{card}(i, 1)$ to the simulating algorithm. Since condition $\lambda^{Bn/2}$ is satisfied, then similar to the proof of Proposition 1 in Ref. [6], if the $n$ agents choose $\bar{\sigma}^* = (\bar{\sigma}_i^*)_{i \in N}$, where for $1 \leq i \leq (n - l)$, $\theta_i = \phi_i = 0$; for $(n - l + 1) \leq i \leq n$, $\theta_i = 0, \phi_i = \pi/l$, then $\bar{\sigma}^* \in \mathcal{B}(\bar{\Gamma}_B)$).
In Step 6 of the simulating algorithm, the corresponding measured state is $C_1 \cdots C_n$.

Hence, in Step 7 of the simulating algorithm, $m_i = \text{card}(i, 0) = (\alpha_i(t_i), f, 0)$ for each agent $i \in N$. Finally, in Step 5 of $\bar{\Gamma}_B$, $g(\bar{\sigma}^*) = g(m) = f \circ \alpha \neq f$.
Therefore, $f \circ \alpha$ is implemented by $\bar{\Gamma}_B$ in Bayesian Nash equilibrium.
2) If $f$ is not multi-Bayesian monotonic, then $\bar{\Gamma}_B$ is reduced to the traditional Bayesian mechanism. Since the SCF $f$ is incentive compatible and Bayesian monotonic, then it is Bayesian implementable. □
6 Conclusions

This paper follows the series of papers on quantum mechanisms [5,6], and generalizes the quantum and algorithmic mechanisms in Refs. [5,6] to Bayesian implementation. It can be seen that for \( n \) agents, the time complexity of quantum and algorithmic Bayesian mechanisms are \( O(n) \) and \( O(2^n) \) respectively. Although current experimental technologies restrict the quantum Bayesian mechanism to be commercially available, for small-scale cases (e.g., less than 20 agents [6]), the algorithmic Bayesian mechanism can help agents benefit from quantum Bayesian mechanism just in the macro world.
