Abstract

We propose a new relation between quark mixing matrix and lepton mixing matrix. Since the parameters in the quark sector are well determined, we employ them to describe the mixing of leptons. Phenomenologically, we study the neutrino oscillation probabilities for different channels, which can be measured precisely in forthcoming reactor and accelerator experiments. As an example of the applicability of our assumption, CP violation in the lepton sector is also discussed. In the latest T2K experiment, the range of the mixing angle θ_{13} is measured, and our prediction of θ_{13} is compatible with their result.

Key words: neutrino oscillation; lepton mixing; quark-lepton complementarity; quark mixing

PACS: 14.60.Pq, 14.60.Lm, 12.15.Ff

The results of many neutrino oscillation experiments in the last decade have demonstrated that there exist physics beyond standard model in neutrino sector. It is commonly accepted that neutrinos are massive and mixing [1]. Neutrino oscillation is governed by two mass square differences Δm_{21}^2 , Δm_{31}^2 and the lepton mixing matrix proposed by Pontecorvo, Maki, Nakawaga and Sakata (PMNS) [2]

$$U_{\text{PMNS}} = \begin{pmatrix} U_{e1} & U_{e2} & U_{e3} \\ U_{\mu1} & U_{\mu2} & U_{\mu3} \\ U_{\tau1} & U_{\tau2} & U_{\tau3} \end{pmatrix}. \quad (1)$$

If neutrinos are of the Majorana type, there should be an additional diagonal matrix with two Majorana phases $P = \text{diag}(e^{i\alpha_1/2}, e^{i\alpha_2/2}, 1)$ multiplied to Eq. (1) from the right. But the two Majorana phases do not affect neutrino oscillations, thus we do not include them in our calculations.

Before more underlying theory of the origin of the mixing is found, parametrizing the mixing matrix properly is helpful in understanding the mixing pattern and analyzing experimental results. A commonly used form is the standard parametrization proposed by Chau and Keung (CK) [3]

$$U_{\text{CK}} = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{pmatrix}, \quad (2)$$

where $s_{ij} = \sin \theta_{ij}$ and $c_{ij} = \cos \theta_{ij}$ ($i, j = 1, 2, 3$) are the mixing angles, and δ is the CP-violating phase. The current global fits of the neutrino mixing parameters are given at the $1(3)\sigma$ level by [4]

$$\theta_{12} = 34.4 \pm 1.0 \text{ } (^{+3.2}_{-2.9})^\circ, \quad \theta_{23} = 42.8^{+4.7}_{-2.9} \text{ } (^{+10.7}_{-7.3})^\circ, \quad \theta_{13} = 5.6^{+3.0}_{-2.7} \text{ } (\leq 12.5)^\circ; \quad (3)$$

$$\Delta m_{21}^2 = 7.59 \pm 0.20 \text{ } (^{+0.61}_{-0.69}) \times 10^{-5} \text{eV}^2, \quad \Delta m_{31}^2 = \begin{cases} -2.36 \pm 0.11 \text{ } (\pm 0.37) \times 10^{-3} \text{eV}^2, \\ +2.46 \pm 0.12 \text{ } (\pm 0.37) \times 10^{-3} \text{eV}^2. \end{cases} \quad (4)$$

These results for angles are compatible with the tri-bimaximal (TB) matrix [5]

$$U_{\text{TB}} = \begin{pmatrix} 2/\sqrt{6} & 1/\sqrt{3} & 0 \\ -1/\sqrt{6} & 1/\sqrt{3} & 1/\sqrt{2} \\ 1/\sqrt{6} & -1/\sqrt{3} & 1/\sqrt{2} \end{pmatrix}. \quad (5)$$

Therefore, it is widely accepted that U_{TB} is a good approximation to reality [6].

In contrast to the large mixing in lepton sector, the observed Cabibbo-Kobayashi-Maskawa [7](CKM) quark mixing matrix V_{CKM} is close to the unit matrix. Although it seems that the mixing of quarks and leptons are unrelated with each other, there indeed exist phenomenological relations between mixing angles called quark-lepton complementarity (QLC) [8], given by

$$\theta_{12}^Q + \theta_{12} = \pi/4, \quad \theta_{23}^Q + \theta_{23} = \pi/4, \quad \theta_{13}^Q \sim \theta_{13} \sim 0. \quad (6)$$

We pointed out in previous works [9] that the unit matrix pattern for quark mixing is connected with the bimaximal matrix pattern [10] for lepton mixing

through QLC relations. But present data imply that the tri-bimaximal matrix U_{TB} is closer to reality than bimaximal matrix. Therefore, a natural idea is to connect the unit matrix in quark sector with the tri-bimaximal matrix in lepton sector. Based on this consideration, we propose here a simple relation between the lepton and quark mixing matrices

$$V_{\text{CKM}}^\dagger U_{\text{PMNS}} V_{\text{CKM}} = U_{\text{TB}}, \quad (7)$$

under an Ansatz that U_{PMNS} becomes an exact tri-bimaximal mixing U_{TB} in a limit $V_{\text{CKM}} = 1$ [11]. Such a relation maybe comes from certain flavor symmetries, and the corresponding symmetry breaking effects may induce the deviations of the observed V_{CKM} and U_{PMNS} from the exact unit matrix and tri-bimaximal matrix. By assuming Eq. (7), we can employ one set of parameters to describe both quark and lepton mixing matrices, thus Eq. (7) can be regarded as the quark-lepton complementarity in matrix form.

Currently, the quark mixing matrix is well determined. For the Wolfenstein parametrization [12]

$$V_{\text{CKM}} = \begin{pmatrix} 1 - \frac{1}{2}\lambda^2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \frac{1}{2}\lambda^2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4), \quad (8)$$

the up-to-date fit gives [13]

$$\begin{aligned} \lambda &= 0.2253 \pm 0.0007, & A &= 0.808_{-0.015}^{+0.022}, \\ \rho(1 - \lambda^2/2 + \dots) &= 0.132_{-0.014}^{+0.022}, & \eta(1 - \lambda^2/2 + \dots) &= 0.341 \pm 0.013. \end{aligned} \quad (9)$$

By inserting Eq. (8) into Eq. (7), one can easily get the PMNS matrix in terms

of λ , A , ρ and η , given by¹

$$\begin{aligned}
U_{\text{PMNS}} &= V_{\text{CKM}} U_{\text{TB}} V_{\text{CKM}}^\dagger \\
&= U_{\text{TB}} + \lambda \begin{pmatrix} \frac{1}{\sqrt{3}} - \frac{1}{\sqrt{6}} & -\frac{-1+\sqrt{2}}{\sqrt{3}} & \frac{1}{\sqrt{2}} \\ -\frac{-1+\sqrt{2}}{\sqrt{3}} & -\frac{1}{\sqrt{3}} + \frac{1}{\sqrt{6}} & 0 \\ -\frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{6}} & 0 \end{pmatrix} \\
&+ \lambda^2 \begin{pmatrix} -\frac{-1+\sqrt{2}}{\sqrt{3}} & -\frac{1}{\sqrt{3}} + \frac{1}{\sqrt{6}} & -\frac{A}{\sqrt{3}} \\ \frac{A}{\sqrt{6}} + \frac{1}{\sqrt{6}} - \frac{1}{\sqrt{3}} & \left(\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{3}}\right) A + \frac{-1+\sqrt{2}}{\sqrt{3}} & \left(\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{3}}\right) A - \frac{1}{2\sqrt{2}} \\ \frac{2A-1}{2\sqrt{6}} & \frac{1}{6}(-2\sqrt{3}A + 3\sqrt{2}A + \sqrt{3}) & \left(-\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}}\right) A \end{pmatrix} + \mathcal{O}(\lambda^3).
\end{aligned} \tag{10}$$

Clearly, we describe the deviations of V_{CKM} from the unit matrix and U_{PMNS} from the tri-bimaximal matrix with the same set of parameters. In other words, relation Eq. (7) provides a unified way of parametrizing both quark and lepton mixing matrices.

The lepton mixing angles are given by

$$\begin{aligned}
\sin^2 \theta_{13} &= \frac{\lambda^2}{2} - \sqrt{\frac{2}{3}} A \lambda^3 + \mathcal{O}(\lambda^4), \\
\sin^2 \theta_{23} &= \frac{1}{2} - \frac{1}{12} (4(\sqrt{6} - 3)A + 3) \lambda^2 + \frac{A}{2\sqrt{3}} (2\rho + \sqrt{2} - 2) \lambda^3 + \mathcal{O}(\lambda^4), \\
\sin^2 \theta_{12} &= \frac{1}{3} - \frac{2}{3}(\sqrt{2} - 1)\lambda + \frac{1}{6}(3 - 2\sqrt{2})\lambda^2 + \frac{1}{9} (2A(\sqrt{6} - 3\rho) + 9\sqrt{2} - 12) \lambda^3 + \mathcal{O}(\lambda^4).
\end{aligned} \tag{11}$$

With the central values in Eq. (9), we get numerically

$$\theta_{12} \cong 31.80^\circ, \quad \theta_{23} \cong 44.66^\circ, \quad \theta_{13} \cong 7.67^\circ, \tag{12}$$

which are compatible with the fit results in Eq. (3). Comparing with the exact tri-bimaximal mixing angles

$$\theta_{12} = \arcsin \frac{1}{\sqrt{3}}, \quad \theta_{23} = \pi/4, \quad \theta_{13} = 0, \tag{13}$$

our result for θ_{12} is more closer to the prediction of QLC since the 1σ range for the corresponding quark mixing angle reads [14] $\theta_{12}^Q = 13.03(\pm 0.05)^\circ$.

¹ For simplicity, we present expressions to the second order of λ here, but all the results below result from U_{PMNS} to $\mathcal{O}(\lambda^3)$.

Denoting ϵ_{ij} the deviations from the exact tri-bimaximal angles, we have

$$\epsilon_{12} \equiv \theta_{12} - \arcsin \frac{1}{\sqrt{3}} \cong -3.46^\circ, \quad \epsilon_{23} \equiv \theta_{23} - \frac{\pi}{4} \cong -0.34^\circ, \quad \epsilon_{13} \equiv \theta_{13} \cong 7.67^\circ. \quad (14)$$

As it shows, a relatively large θ_{13} is predicted from our assumption, and such a prediction can be tested precisely in future reactor and accelerator experiments.

An important property of the relation in Eq. (7) is that different phase conventions of V_{CKM} give different predictions on lepton mixing angles. We give a brief argument here. If V_{CKM} is rephased by taking

$$V'_{\text{CKM}} = \Psi_1 V_{\text{CKM}} \Psi_2^\dagger, \quad (15)$$

in which $\Psi_1 \equiv \text{diag}(e^{iu}, e^{ic}, e^{it})$ and $\Psi_2 \equiv \text{diag}(e^{id}, e^{is}, e^{ib})$ consist of arbitrary phases and can be absorbed into the redefinition of quark phases, Eq. (7) turns into

$$U = V'_{\text{CKM}} U_{\text{TB}} V'_{\text{CKM}}{}^\dagger = \Psi_1 V_{\text{CKM}} \Psi_2^\dagger U_{\text{TB}} \Psi_2 V_{\text{CKM}}{}^\dagger \Psi_1^\dagger. \quad (16)$$

Because V_{CKM} (V_{CKM}^\dagger) does not commute with Ψ_2^\dagger (Ψ_2), it is generally impossible to absorb the phases in Ψ_2 (Ψ_2^\dagger) into the redefinition of lepton phases. As a result, the magnitudes of elements in U_{PMNS} and consequently lepton mixing angles depend on the rephasing matrix Ψ_2 (Ψ_2^\dagger), which does not bring any difference in V_{CKM} . Therefore, predictions on lepton mixing resulting from Eq. (7) will be changed if we change the parametrization of quark mixing matrix. Similar arguments can be applied for assumptions discussed in Ref. [11]. For generality, detailed discussion concerning the behavior of mixing angles on phases in Ψ_2^\dagger (Ψ_2) is given in the Appendix of this letter. As an instance, another parametrization [15] for V_{CKM} is also employed to determine leptonic mixing angles in the Appendix.

We now turn to the application of the assumption Eq. (7) to neutrino oscillations. Let us denote $P_{\alpha\beta} = P(\nu_\alpha \rightarrow \nu_\beta)$ the probability of transition from a neutrino flavor α to a neutrino flavor β . Similar to the discussion in Ref. [16], the probability can be found as $P_{\alpha\beta} = |S_{\beta\alpha}(t, t_0)|^2$, in which $S(t, t_0)$ is the evolution matrix such that

$$|\nu(t)\rangle = S(t, t_0)|\nu(t_0)\rangle, \quad S(t_0, t_0) = 1. \quad (17)$$

For simplicity, we neglect the effects due to interactions between neutrinos and matters in which the neutrino beam propagates and only deal with oscillation

probabilities in vacuum, the evolution matrix can be given by

$$S_{\beta\alpha}(t, t_0) = \sum_{i=1}^3 (U_{\alpha i})^* U_{\beta i} e^{-iE_i L}, \quad \alpha, \beta = e, \mu, \tau, \quad (18)$$

where $L = t - t_0$ is the length of the baseline in neutrino experiment and E_i are the eigenvalue of the effective hamiltonian

$$H \simeq \frac{1}{2E} U \text{diag}(0, \Delta m_{21}^2, \Delta m_{31}^2) U^\dagger, \quad (19)$$

in which E is the average energy of the neutrino beam.

Inspecting the values of the mass square difference in Eq. (4), one can find Δm_{21}^2 is much less than Δm_{31}^2 , thus can be neglected to a good precision. The calculation of $P_{\alpha\beta}$ is now straightforward, such that by combining Eq. (7), Eq. (8) and Eq. (18), we get the evolution matrix $S_{\beta\alpha}$ and consequently the oscillation probability $P_{\alpha\beta}$. Expanded to λ^3 , oscillation probabilities can be expressed in a matrix form as

$$P = \begin{pmatrix} 1 - 2\lambda^2\Delta + 4\sqrt{\frac{2}{3}}A\lambda^3\Delta & \lambda^2\Delta - 2\sqrt{\frac{2}{3}}A\lambda^3\Delta & \lambda^2\Delta - 2\sqrt{\frac{2}{3}}A\lambda^3\Delta \\ \lambda^2\Delta - 2\sqrt{\frac{2}{3}}A\lambda^3\Delta & 1 - \Delta & \Delta - \lambda^2\Delta + 2\sqrt{\frac{2}{3}}A\lambda^3\Delta \\ \lambda^2\Delta - 2\sqrt{\frac{2}{3}}A\lambda^3\Delta & \Delta - \lambda^2\Delta + 2\sqrt{\frac{2}{3}}A\lambda^3\Delta & 1 - \Delta \end{pmatrix} + \mathcal{O}(\lambda^4), \quad (20)$$

where we have defined $\Delta \equiv \sin^2\left(\frac{L\Delta m_{31}^2}{4E}\right)$.

Let us have a first look at the oscillation probability matrix in Eq. (20). Apparently, it exhibits a hierarchical structure among different channels of neutrino oscillation. The diagonal elements P_{ee} , $P_{\mu\mu}$ and $P_{\tau\tau}$ which measure the disappearance probabilities for ν_e , ν_μ and ν_τ beams are of $\mathcal{O}(1)$. It is also not difficult to understand that the $\nu_\mu \leftrightarrow \nu_\tau$ probabilities $P_{\mu\tau}$ and $P_{\tau\mu}$ are of $\mathcal{O}(1)$, since ν_μ and ν_τ are maximally mixing implied by data. Other terms measuring probabilities of $\nu_e \leftrightarrow \nu_\mu$ and $\nu_e \leftrightarrow \nu_\tau$ are of $\mathcal{O}(\lambda^2)$. Interestingly, there are no terms proportional to λ , that is because such terms are suppressed by Δm_{21}^2 , which we neglect here.

To get the anti-neutrino oscillation probabilities $P_{\bar{\alpha}\bar{\beta}}$, one needs to take the replacement $U_{\text{PMNS}} \rightarrow U_{\text{PMNS}}^*$, which, in our case, is equivalent to reverse the sign of η , i.e.

$$P_{\bar{\alpha}\bar{\beta}} = P_{\alpha\beta}(\eta \rightarrow -\eta). \quad (21)$$

However, the CP-violating parameter η is missing in Eq. (20), meaning that

to this approximation, we have

$$P_{\bar{\alpha}\bar{\beta}} = P_{\alpha\beta}. \quad (22)$$

Therefore, CP symmetry is preserved, and resulting from the CPT theorem, time reversal symmetry is also preserved, i.e., $P_{\alpha\beta} = P_{\beta\alpha}$. Consistently, Eq. (20) is a symmetric matrix.

Defining the asymmetries in neutrino oscillations as

$$A_{\alpha\beta}^{\text{CP}} = P_{\alpha\beta} - P_{\bar{\alpha}\bar{\beta}}, \quad (23)$$

the probabilities in Eq. (20) imply $A_{\alpha\beta}^{\text{CP}} = 0$. The reason for the vanishing of $A_{\alpha\beta}^{\text{CP}}$ is that we neglect the contribution of the smaller mass square difference Δm_{21}^2 . Now taking this into account, we get nonzero values for CP asymmetries as

$$A^{\text{CP}} = \begin{pmatrix} 0 & a & -a \\ -a & 0 & a \\ a & -a & 0 \end{pmatrix}, \quad (24)$$

in which

$$a = \frac{2}{9}(2\sqrt{3} - 3)A\eta\lambda^3 \left(\sin\left(\frac{L\Delta m_{31}^2}{2E}\right) - \sin\left(\frac{L(\Delta m_{31}^2 - \Delta m_{21}^2)}{2E}\right) - \sin\left(\frac{L\Delta m_{21}^2}{2E}\right) \right) + \mathcal{O}(\lambda^4). \quad (25)$$

The structure of asymmetries in Eq. (24) comes from the unitarity of PMNS matrix and the conservation of probability. One also has [17]

$$A_{\mu e}^{\text{CP}} = -A_{\tau e}^{\text{CP}} = A_{\tau\mu}^{\text{CP}} = 4J_{\text{CP}} \left(\sin\left(\frac{L\Delta m_{13}^2}{2E}\right) + \sin\left(\frac{L\Delta m_{32}^2}{2E}\right) + \sin\left(\frac{L\Delta m_{21}^2}{2E}\right) \right), \quad (26)$$

in which

$$J_{\text{CP}} \equiv \text{Im}(U_{\mu 3}U_{e 2}U_{e 3}^*U_{\mu 2}^*) \quad (27)$$

is the rephasing invariant [18]. Combining Eq. (24), Eq. (25) and Eq. (26), we get

$$J_{\text{CP}} = -\frac{1}{18}(2\sqrt{3} - 3)A\eta\lambda^3 + \mathcal{O}(\lambda^4). \quad (28)$$

Compared with the results in Ref. [11], where they arrive at $J_{\text{CP}} \sim \mathcal{O}(\lambda)$ by assuming $V_{\text{CKM}}U_{\text{PMNS}} = U_{\text{TB}}$ or $V_{\text{CKM}}^\dagger U_{\text{PMNS}} = U_{\text{TB}}$, prediction of J_{CP} here

is quite smaller. This is because that the exact U_{TB} implies $J_{\text{CP}} = 0$, thus J_{CP} only depends on the deviation of U_{PMNS} from U_{TB} (which we denote by D below). Since V_{CKM} is close to the unit matrix, it can be regarded as the measurement of D . Then it is not difficult to understand the smallness of J_{CP} in Eq. (28) as one has

$$D \sim \mathcal{O}(V_{\text{CKM}}) \quad \text{and} \quad J_{\text{CP}} \sim \mathcal{O}(\lambda) \quad (29)$$

in Ref. [11], while

$$D \sim \mathcal{O}(V_{\text{CKM}}^2) \quad \text{and} \quad J_{\text{CP}} \sim \mathcal{O}(\lambda^3) \quad (30)$$

in this letter.

We emphasize that in the very recent T2K experiment [19], observations of $\nu_\mu \rightarrow \nu_e$ oscillation indicate that at 90% C.L., the data are consistent with

$$0.03(0.04) < \sin^2 2\theta_{13} < 0.28(0.34) \quad (31)$$

for $\delta = 0$ and normal (inverted) hierarchy. Such a result implies an apparent deviation from U_{TB} and is important in the establishment of lepton mixing pattern, in which new symmetries among leptons may hide. If θ_{13} is really large, the test of CP violation in the lepton sector is possible for future neutrino experiments since δ is always multiplied by θ_{13} in U_{PMNS} . With Eq. (31), straightforward calculations give

$$4.99^\circ(5.77^\circ) < \theta_{13} < 15.97^\circ(17.83^\circ) \quad (32)$$

at 90% C.L., for $\delta = 0$ and normal (inverted) hierarchy. We find that our prediction, i.e., $\theta_{13} \cong 7.67$ is compatible with the T2K result. Thus the relation Eq. (7) may serve as a good description of the deviation of U_{PMNS} from U_{TB} .

In summary, we propose a new relation between quark mixing matrix V_{CKM} and lepton mixing matrix U_{PMNS} given by Eq. (7) as the quark-lepton complementarity in matrix form. Based on this relation, we parametrize U_{PMNS} with the quark mixing parameters in Eq. (10), and determine the deviations of mixing angles from the exact tri-bimaximal angles. Especially, our prediction of the mixing angle θ_{13} agrees with the latest T2K result. For neutrino oscillations, we derive oscillation probabilities for different channels given by Eq. (20). As we can see, to a good precision, the expressions for each probability are quite simple. Furthermore, the CP violation in neutrino flavor transitions are discussed.

Appendix : Dependence of lepton mixing angles on the phase convention of CKM matrix

With discussions concerning Eq. (16), we have pointed out that the predicted lepton mixing angles are dependent on the phase convention of V_{CKM} , i.e., Ψ_2 (Ψ_2^\dagger) in our notation. By substituting the Wolfenstein matrix Eq. (8) into Eq. (16), we arrive at the general expression of U_{PMNS} , which includes explicitly the phases in Ψ_1 and Ψ_2 . Since phases in Ψ_1 (Ψ_1^\dagger) can be absorbed into the redefinition of lepton fields, the physical mixing angles are thus dependent only on phase parameters d , s and b . To a good accuracy, mixing angles are determined by

$$\begin{aligned}\sin^2 \theta_{12} &= \frac{1}{3} - \frac{2}{3}\lambda \left(\sqrt{2} \cos \alpha - \cos \alpha \right) + \frac{1}{6}\lambda^2 \left(2\sqrt{2} \cos 2\alpha - 4\sqrt{2} + 3 \right) + \mathcal{O}(\lambda^3), \\ \sin^2 \theta_{23} &= \frac{1}{2} + \lambda^2 \left(-\sqrt{\frac{2}{3}} A \cos \beta + A \cos \beta - \frac{1}{4} \right) + \mathcal{O}(\lambda^3), \\ \sin^2 \theta_{13} &= \frac{\lambda^2}{2} - \sqrt{\frac{2}{3}} A \lambda^3 \cos \gamma + \mathcal{O}(\lambda^4),\end{aligned}$$

where we define $\alpha \equiv d - s$, $\beta \equiv b - s$ and $\gamma \equiv b + d - 2s$, and the last equation is to $\mathcal{O}(\lambda^3)$ because of the smallness of θ_{13} . It is easy to see that the sensitivities to phases of $\sin^2 \theta_{12}$, $\sin^2 \theta_{23}$ and $\sin^2 \theta_{13}$ are of $\mathcal{O}(\lambda)$, $\mathcal{O}(\lambda^2)$ and $\mathcal{O}(\lambda^3)$ respectively. With the best fit values in Eq. (9), the dependence of each mixing angle is illustrated in Fig. 1 and Fig. 2, which show that, the prediction of θ_{12} is strongly dependent on the phase, such that some areas of α are excluded by data and, the result in Eq. (12) can be improved by choose a particular value for α . However, the dependence of the predicted θ_{23} and θ_{13} on phases is negligibly small compared with current data.

Fig. 1. Behavior of $\sin^2 \theta_{12}$ versus $\alpha \equiv d - s$ (left) and $\sin^2 \theta_{23}$ versus $\beta \equiv b - s$ (right), both from $-\pi$ to π . The solid horizontal lines denote the 3σ ranges calculated from Eq. (3), while the dashed lines denote the best fit values.

In order to demonstrate that our predictions of U_{PMNS} and mixing angles depend on the parametrization of V_{CKM} , we here employ another Wolfenstein-

Fig. 2. Behavior of $\sin^2 \theta_{13}$ versus $\gamma \equiv b + d - 2s$ from $-\pi$ to π . The solid (dashed) horizontal lines denote 90% C.L. ranges of the newest T2K result with normal (invertd) hierarchy.

like parametrization [15], given by

$$V_{\text{CKM}} = \begin{pmatrix} 1 - \frac{\lambda^2}{2} & \lambda & e^{-i\delta} h \lambda^3 \\ -\lambda & 1 - \frac{\lambda^2}{2} & (f + e^{-i\delta} h) \lambda^2 \\ f \lambda^3 & -(f + e^{i\delta} h) \lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda),$$

to deduce the form of U_{PMNS} . The ranges for the parameters are

$$\lambda = 0.2253 \pm 0.0007, \quad h = 0.303_{-0.010}^{+0.014}, \quad f = 0.754_{-0.018}^{+0.022}, \quad \delta^Q = 90.97^\circ_{-4.44^\circ}^{+2.77^\circ}.$$

Further detailed analysis and discussions concerning the relationship of this form of parametrization with others are given in Ref. [20]. By substituting this new Wolfenstein-like parametrization into Eq. (7), we get the expression for U_{PMNS} to $\mathcal{O}(\lambda^2)$ as

$$U_{\text{PMNS}} = V_{\text{CKM}} U_{\text{TB}} V_{\text{CKM}}^\dagger = U_{\text{TB}} + \lambda \begin{pmatrix} \frac{1}{\sqrt{3}} - \frac{1}{\sqrt{6}} & -\frac{-1+\sqrt{2}}{\sqrt{3}} & \frac{1}{\sqrt{2}} \\ -\frac{-1+\sqrt{2}}{\sqrt{3}} & -\frac{1}{\sqrt{3}} + \frac{1}{\sqrt{6}} & 0 \\ -\frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{6}} & 0 \end{pmatrix} + \lambda^2 \begin{pmatrix} -\sqrt{\frac{2}{3}} + \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{3}} + \frac{1}{\sqrt{6}} & -\frac{f}{\sqrt{3}} - \frac{e^{-i\delta}}{\sqrt{3}} \\ \frac{f}{\sqrt{6}} + \frac{e^{-i\delta} h}{\sqrt{6}} + \frac{1}{\sqrt{6}} - \frac{1}{\sqrt{3}} & -\frac{f}{\sqrt{3}} + \frac{f}{\sqrt{2}} - \frac{e^{-i\delta} h}{\sqrt{3}} + \frac{e^{i\delta} h}{\sqrt{2}} - \frac{1}{\sqrt{3}} + \sqrt{\frac{2}{3}} & -\frac{f}{\sqrt{3}} + \frac{f}{\sqrt{2}} - \frac{e^{-i\delta}}{\sqrt{3}} + \frac{e^{-i\delta} h}{\sqrt{2}} - \frac{1}{2\sqrt{2}} \\ \frac{f}{\sqrt{6}} + \frac{e^{i\delta}}{\sqrt{6}} - \frac{1}{2\sqrt{6}} & -\frac{f}{\sqrt{3}} + \frac{f}{\sqrt{2}} - \frac{e^{i\delta}}{\sqrt{3}} + \frac{e^{i\delta} h}{\sqrt{2}} + \frac{1}{2\sqrt{3}} & \frac{f}{\sqrt{3}} - \frac{f}{\sqrt{2}} + \frac{e^{-i\delta}}{\sqrt{3}} - \frac{e^{i\delta}}{\sqrt{2}} \end{pmatrix}.$$

Comparing with Eq. (10), one can easily find that differences begin to appear in terms of $\mathcal{O}(\lambda^2)$. To $\mathcal{O}(\lambda^3)$, mixing angles are given by

$$\begin{aligned} \sin^2 \theta_{13} &= \frac{\lambda^2}{2} - \sqrt{\frac{2}{3}} (f + \cos \delta) \lambda^3, \\ \sin^2 \theta_{23} &= \frac{1}{2} - \frac{1}{12} \left(4(\sqrt{6} - 3)f + 4(\sqrt{6} - 3h) \cos \delta + 3 \right) \lambda^2 + \frac{1}{2\sqrt{3}} \left((\sqrt{2} - 2)f + \sqrt{2} \cos \delta \right) \lambda^3, \\ \sin^2 \theta_{12} &= \frac{1}{3} - \frac{2}{3} (\sqrt{2} - 1) \lambda + \frac{1}{6} (3 - 2\sqrt{2}) \lambda^2 + \frac{1}{9} \left(2\sqrt{6} f + (3(\sqrt{6} - 2)h - \sqrt{6}) \cos \delta + 9\sqrt{2} - 12 \right) \lambda^3, \end{aligned}$$

in which $\sin^2 \theta_{13}$, $\sin^2 \theta_{12}$ differ from Eq. (11) only in terms proportional to λ^3 and the difference of $\sin^2 \theta_{23}$ is of $\mathcal{O}(\lambda^2)$. Therefore, the numerical results for mixing angles are very close to Eq. (12), as straightforward calculation gives

$$\theta_{12} \cong 31.84^\circ, \quad \theta_{23} \cong 44.61^\circ, \quad \theta_{13} \cong 7.82^\circ.$$
