# Adaptive Covariance Estimation with model selection 

Rolando Biscay, Hélène Lescornel and Jean-Michel Loubes

#### Abstract

We provide in this paper a fully adaptive penalized procedure to select a covariance among a collection of models observing i.i.d replications of the process at fixed observation points. For this we generalize the results of [3] and propose to use a data driven penalty to obtain an oracle inequality for the estimator. We prove that this method is an extension to the matricial regression model of the work by Baraud in [1].

Keywords: covariance estimation, model selection, adaptive procedure.

## 1 Introduction

Estimating the covariance function of stochastic processes is a fundamental issue in statistics with many applications, ranging from geostatistics, financial series or epidemiology for instance (we refer to [10], [8] or [5] for general references). While parametric methods have been extensively studied in the statistical literature (see [5] for a review), nonparametric procedures have only recently received attention, see for instance [6, 3, 4, 2, and references therein.

In [3], a model selection procedure is proposed to construct a non parametric estimator of the covariance function of a stochastic process under mild assumptions. However their method heavily relies on a prior knowledge of the variance. In this paper, we extend this procedure and propose a fully data driven penalty which leads to select the best covariance among a collection of models. This result constitutes a generalization to the matricial regression model of the selection methodology provided in [1].

Consider a stochastic process $(X(t))_{t \in T}$ taking its values in $\mathbb{R}$ and indexed by $T \subset \mathbb{R}^{d}$, $d \in \mathbb{N}$. We assume that $\mathbb{E}[X(t)]=0 \forall t \in T$ and we aim at estimating its covariance function $\sigma(s, t)=\mathbb{E}[X(s) X(t)]<\infty$ for all $t, s \in T$. We assume we observe $X_{i}\left(t_{j}\right)$ where $i \in\{1 \ldots n\}$ and $j \in\{1 \ldots p\}$. Note that the observation points $t_{j}$ are fixed and that the $X_{i}$ 's are independent copies of the process $X$. Set $x_{i}=\left(X_{i}\left(t_{1}\right), \ldots, X_{i}\left(t_{p}\right)\right) \forall i \in\{1 \ldots n\}$ and denote by $\Sigma$ the covariance matrix of $X$ at the observations points $\Sigma=\mathbb{E}\left(x_{i} x_{i}^{\top}\right)=$ $\left(\sigma\left(t_{j}, t_{k}\right)\right)_{1 \leq j \leq p, 1 \leq k \leq p}$.

Following the methodology presented in [3], we approximate the process $X$ by its projection onto some finite dimensional model. For this, consider a countable set of functions $\left(g_{\lambda}\right)_{\lambda \in \Lambda}$ which may be for instance a basis of $L^{2}(T)$ and choose a collection of models $\mathcal{M} \subset \mathcal{P}(\Lambda)$. For $m \subset \mathcal{M}$, a finite number of indices, the process can be
approximated by

$$
X(t) \approx \sum_{\lambda \in m} a_{\lambda} g_{\lambda}(t)
$$

Such an approximation leads to an estimator which depends on the collection of functions $m$, denoted by $\hat{\Sigma}_{m}$. Our objective is to select in a data driven way, the best model, i.e. the one close to an oracle $m_{0}$ defined as the minimizer of the quadratic risk, namely

$$
m_{0} \in \underset{m \in \mathcal{M}}{\arg \min } R(m)=\underset{m \in \mathcal{M}}{\arg \min } \mathbb{E}\left[\left\|\Sigma-\hat{\Sigma}_{m}\right\|^{2}\right]
$$

This result is achieved using a model selection procedure.
The paper falls into the following parts. The description of the statistical framework of the matrix regression is given in Section 2. Section 3 is devoted to the main statistical results. Namely we recall the results of the estimate given in [3] and prove an oracle inequality with a fully data driven penalty. Section 4 states technical results which are used in all the paper, while the proofs are postponed to the Appendix.

## 2 Statistical model and notations

We consider an $\mathbb{R}$-valued process $X(t)$ indexed by $T$ a subset of $\mathbb{R}^{d}$ with expectation equal to 0 . We are interested in its covariance function denoted by $\sigma(s, t)=\mathbb{E}[X(s) X(t)]$.

We have at hand the observations $x_{i}=\left(X_{i}\left(t_{1}\right), \ldots, X_{i}\left(t_{p}\right)\right)$ for $1 \leqslant i \leqslant n$ where $X_{i}$ are independent copies of the process and $t_{j}$ are deterministic points. We note $\Sigma \in \mathbb{R}^{p \times p}$ the covariance matrix of the vector $x_{i}$.

Hence we observe

$$
\begin{equation*}
x_{i} x_{i}^{\top}=\Sigma+U_{i}, \quad 1 \leqslant i \leqslant n \tag{1}
\end{equation*}
$$

where $U_{i}$ are i.i.d. error matrices with expectation 0 . We denote by $S$ the empirical covariance of the sample : $S=\frac{1}{n} \sum_{i=1}^{n} x_{i} x_{i}^{\top}$.

We use the Frobenius norm \| \| defined by $\|A\|^{2}=\operatorname{Tr}\left(A A^{\top}\right)$ for all matrix $A$. Recall that for a given matrix $A \in \mathbb{R}^{p \times q}$, $\operatorname{vec}(A)$ is the vector in $\in \mathbb{R}^{p q}$ obtained by stacking the columns of $A$ on top of one another. We denote by $A^{-}$the reflexive generalized inverse of the matrix $A$, see for instance in [9] or [7].

The idea is to consider that we have a quite good approximation of the process in the following form

$$
\begin{equation*}
X(t) \approx \sum_{\lambda \in m} a_{\lambda} g_{\lambda}(t) \tag{2}
\end{equation*}
$$

where $m$ is a finite subset of a countable set $\Lambda,\left(a_{\lambda}\right)_{\lambda \in \Lambda}$ are random coefficients in $\mathbb{R}$ and $\left(g_{\lambda}\right)_{\lambda \in \Lambda}$ are real valued functions. We will consider models $m$ among a finite collection denoted by $\mathcal{M}$.

We note $G_{m} \in \mathbb{R}^{p \times|m|}$ where $\left(G_{m}\right)_{j \lambda}=g_{\lambda}\left(t_{j}\right)$ and $a_{m}$ the random vector of $\mathbb{R}^{|m|}$ with coefficients $\left(a_{\lambda}\right)_{\lambda \in m}$.

Hence, we obtain the following approximations :

$$
x=\left(X\left(t_{1}\right), . ., X\left(t_{p}\right)\right)^{\top} \approx G_{m} a_{m}
$$

$$
\begin{gathered}
x x^{\top} \approx G_{m} a_{m} a_{m}^{\top} G_{m}^{\top} \\
\Sigma \approx G_{m} \mathbb{E}\left[a_{m} a_{m}^{\top}\right] G_{m}^{\top}
\end{gathered}
$$

Thus, this point of view leads us to approximate $\Sigma$ by a matrix in the subset

$$
\begin{equation*}
\mathcal{S}\left(G_{m}\right)=\left\{G_{m} \Psi G_{m}^{\top} / \Psi \text { symmetric in } \mathbb{R}^{|m| \times|m|}\right\} \subset \mathbb{R}^{p \times p} \tag{3}
\end{equation*}
$$

Hence, for a model $m$, a natural estimator for $\Sigma$ is given by the projection of $S$ onto $\mathcal{S}\left(G_{m}\right)$. We can prove using standard algebra (see in [3] for a general proof) that it has the following form :

$$
\begin{equation*}
\widehat{\Sigma}_{m}=\Pi_{m} S \Pi_{m} \quad m \in \mathcal{M} \quad \in \mathbb{R}^{p \times p} \tag{4}
\end{equation*}
$$

where

$$
\begin{equation*}
\Pi_{m}=G_{m}\left(G_{m}^{\top} G_{m}\right)^{-} G_{m}^{\top} \quad \in \mathbb{R}^{p \times p} \tag{5}
\end{equation*}
$$

are orthogonal projection matrices. Set

$$
D_{m}=\operatorname{Tr}\left(\Pi_{m} \otimes \Pi_{m}\right)
$$

which is the dimension of $\mathcal{S}\left(G_{m}\right)$ assumed to be positive, and $\Sigma_{m}=\Pi_{m} \Sigma \Pi_{m}$ the projection of $\Sigma$ onto this subspace.

Hence we obtain the model selection procedure defined in [3]. The estimation error for a model $m \in \mathcal{M}$ is given by

$$
\begin{equation*}
\mathbb{E}\left(\left\|\Sigma-\widehat{\Sigma}_{m}\right\|^{2}\right)=\left\|\Sigma-\Pi_{m} \Sigma \Pi_{m}\right\|^{2}+\frac{\delta_{m}^{2} D_{m}}{n} \tag{6}
\end{equation*}
$$

where

$$
\begin{aligned}
& \delta_{m}^{2}=\frac{\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)}{D_{m}}, \\
& \Phi=V\left(\operatorname{vec}\left(x_{1} x_{1}^{\top}\right)\right) .
\end{aligned}
$$

Given $\theta>0$, it is thus natural to define the penalized covariance estimator $\widehat{\Sigma}=\widehat{\Sigma}_{\widehat{m}}$ by

$$
\widehat{m}=\arg \min _{m \in \mathcal{M}}\left\{\frac{1}{n} \sum_{i=1}^{n}\left\|x_{i} x_{i}^{\top}-\widehat{\Sigma}_{m}\right\|^{2}+\operatorname{pen}(m)\right\}
$$

where

$$
\begin{equation*}
\operatorname{pen}(m)=(1+\theta) \frac{\delta_{m}^{2} D_{m}}{n} . \tag{7}
\end{equation*}
$$

The following result proved in [3] states an oracle inequality for the estimator $\widehat{\Sigma}$.
Theorem 2.1. Let $q>0$ be given such that there exists $\kappa>2(1+q)$ satisfying $\mathbb{E}\left\|x_{1} x_{1}^{\top}\right\|^{\kappa}<$ $\infty$. Then, for some constants $K(\theta)>1$ and $C^{\prime}(\theta, \kappa, q)>0$ we have that

$$
\left(\mathbb{E}\|\Sigma-\widehat{\Sigma}\|^{2 q}\right)^{1 / q} \leq 2^{\left(q^{-1}-1\right)_{+}}\left[K(\theta) \inf _{m \in \mathcal{M}}\left(\left\|\Sigma-\Pi_{m} \Sigma \Pi_{m}\right\|^{2}+\frac{\delta_{m}^{2} D_{m}}{n}\right)+\frac{\Delta_{\kappa}}{n} \delta_{\text {sup }}^{2}\right]
$$

where

$$
\Delta_{\kappa}^{q}=C^{\prime}(\theta, \kappa, q) \mathbb{E}\left\|x_{1} x_{1}^{\top}\right\|^{\kappa}\left(\sum_{m \in \mathcal{M}} \delta_{m}^{-\kappa} D_{m}^{-(\kappa / 2-1-q)}\right)
$$

and

$$
\delta_{\text {sup }}^{2}=\max \left\{\delta_{m}^{2}: m \in \mathcal{M}\right\}
$$

However the penalty defined here depends on the quantity $\delta_{m}$ which is unknown in practice since it relies on the matrix $\Phi=V\left(v e c\left(x x^{\top}\right)\right)$. Our objective is to study a covariance estimator built with a new penalty involving an estimator of $\Phi$.

More precisely, we will replace pen $(m)$ by an empirical version $\widehat{p e n}(m)$, where

$$
\begin{equation*}
\widehat{p e n}(m)=(1+\theta) \frac{\widehat{\delta}_{m}^{2} D_{m}}{n} \tag{8}
\end{equation*}
$$

and

$$
\widehat{\delta}_{m}^{2}=\frac{\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \widehat{\Phi}\right)}{D_{m}},
$$

with $\widehat{\Phi}$ an estimator of $\Phi$.
The objective is to generalize Theorem 2.1 and to construct a fully adaptive penalized procedure to estimate the covariance function.

## 3 Main result : adaptive penalized covariance estimation

Here we state the oracle inequality obtained for the new covariance estimator introduced previously.

Set

$$
y_{i}=\operatorname{vec}\left(x_{i} x_{i}^{\top}\right), 1 \leqslant i \leqslant n,
$$

which are vectors in $\mathbb{R}^{p^{2}}$ and denote by $S_{v e c}=\frac{1}{n} \sum_{i=1}^{n} y_{i}$ their empirical mean. Consider the following constant $C_{i n f}=\inf _{m \in \mathcal{M}} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)$, and assume that the collection of models is chosen such that $C_{i n f}>0$. Set

$$
\begin{aligned}
\widehat{\Phi} & =\frac{1}{n} \sum_{i=1}^{n}\left(y_{i} y_{i}^{\top}-S_{v e c} S_{v e c}^{\top}\right), \\
\widehat{\delta}_{m}^{2} & =\frac{\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \widehat{\Phi}\right)}{D_{m}}
\end{aligned}
$$

Given $\theta>0$, we consider the covariance estimator $\widetilde{\Sigma}=\widehat{\Sigma}_{\widetilde{m}}$ with

$$
\widetilde{m}=\arg \min _{m \in \mathcal{M}}\left\{\frac{1}{n} \sum_{i=1}^{n}\left\|x_{i} x_{i}^{\top}-\widehat{\Sigma}_{m}\right\|^{2}+\widehat{p e n}(m)\right\}
$$

where

$$
\begin{equation*}
\widehat{p e n}(m)=(1+\theta) \frac{\widehat{\delta}_{m}^{2} D_{m}}{n} . \tag{9}
\end{equation*}
$$

Theorem 3.1. Let $1 \geqslant q>0$ be given such that there exists $\beta>\max (2(1+2 q), 3+2 q)$ satisfying $\mathbb{E}\left\|x x^{\top}\right\|^{\beta}<\infty$.

Then, for a constant $C$ depending on $\theta, \beta$ and $q$, we have for $n \geqslant n\left(\beta, \theta, C_{\text {inf }}, \Sigma\right)$, and $\forall \kappa \in] 2(1+2 q) ; \min (\beta, 2 \beta-4)[:$

$$
\begin{align*}
\left(\mathbb{E}\left[\|\Sigma-\widetilde{\Sigma}\|^{2 q}\right]\right)^{1 / q} & \leqslant C \inf _{m \in \mathcal{M}}\left(\left\|\Sigma-\Sigma_{m}\right\|^{2}+\frac{\delta_{m}^{2} D_{m}}{n}\right)  \tag{10}\\
& +\frac{C}{n}\left[\widetilde{\Delta}_{\beta}\left[\mathbb{E}\left[\left\|x x^{\top}\right\|^{\beta}\right]^{\frac{2}{\beta}}+\|\Sigma\|^{2}\right]+\delta_{\text {sup }}^{2} \Delta_{\kappa}\right] \tag{11}
\end{align*}
$$

where

$$
\begin{aligned}
& \widetilde{\Delta}_{\beta}^{q}=c(\theta, \beta, q)\left(\mathbb{E}\left[\left\|x x^{\top}\right\|^{\beta}\right] \sum_{m \in \mathcal{M}} \delta_{m}^{-\beta} D_{m}^{-\beta / 2}\right)^{1-\frac{2 q}{\kappa}} \\
& \Delta_{\kappa}^{q}=C(\theta, \kappa, q) \mathbb{E}\left\|x x^{\top}\right\|^{\kappa}\left(\sum_{m \in \mathcal{M}} \delta_{m}^{-\kappa} D_{m}^{-(\kappa / 2-1-q)}\right)
\end{aligned}
$$

and

$$
\delta_{\mathrm{sup}}^{2}=\max \left\{\delta_{m}^{2}: m \in \mathcal{M}\right\}
$$

We have obtained in Theorem 3.1 an oracle inequality since the estimator $\widetilde{\Sigma}$ has the same quadratic risk as the "oracle" estimator except for an additive term of order $O\left(\frac{1}{n}\right)$ and a constant factor. Hence, the selection procedure is optimal in the sense that it behaves as if the true model were at hand.

The proof of this theorem is divided into two parts. First, as in the of Theorem 2.1 proved in [3], we will consider a vectorized version of the model (1). In this technical part we will obtain an oracle inequality under some particular assumptions for a general penalty. In a second part, we will prove that our particular penalty verifies these assumptions by using properties of the estimator $\widehat{\Phi}$.

## 4 Technical results

### 4.1 Vectorized model

Here we consider the vectorized version of model (1). In this case, we observe the following vectors in $\mathbb{R}^{p^{2}}$ :

$$
\begin{equation*}
y_{i}=f_{i}+\varepsilon_{i} \quad 1 \leqslant i \leqslant n . \tag{12}
\end{equation*}
$$

Here $y_{i}$ corresponds to vec $\left(x_{i} x_{i}^{\top}\right)$ in the model (1), $f_{i}$ to vect $(\Sigma)$ and $\varepsilon_{i}$ to vec $\left(U_{i}\right)$. We set $f=\left(f_{1}^{\top}, \ldots, f_{n}^{\top}\right)^{\top}, y=\left(y_{1}^{\top}, \ldots, y_{n}^{\top}\right)^{\top}$ and $\varepsilon=\left(\varepsilon_{1}^{\top}, \ldots, \varepsilon_{n}^{\top}\right)^{\top}$, which are vectors in $\mathbb{R}^{n p^{2}}$.

We estimate $f$ by an estimator of the form

$$
\widehat{f}_{m}=P_{m} y \quad m \in \mathcal{M},
$$

where $P_{m}$ is the orthogonal projection onto a subspace $\mathcal{S}_{m}$ of dimension $D_{m}$. We note $f_{m}=$ $P_{m} f$ and we consider the empirical norm $\|f\|_{n}^{2}=\frac{1}{n} \sum_{i=1}^{n} f_{i}^{\top} f_{i}$ with the corresponding scalar product $\langle\cdot, \cdot\rangle_{n}$.

First we state the vectorized form of Theorem 2.1. Write

$$
\begin{aligned}
\delta_{m}^{2} & =\frac{\operatorname{Tr}\left(P_{m}\left(I_{n} \otimes \Phi\right)\right)}{D_{m}} \\
\delta_{\text {sup }}^{2} & =\max \left\{\delta_{m}^{2}: m \in \mathcal{M}\right\} .
\end{aligned}
$$

Given $\theta>0$, define the penalized estimator $\widehat{f}=\widehat{f}_{\widehat{m}}$, where

$$
\widehat{m}=\arg \min _{m \in \mathcal{M}}\left\{\left\|y-\widehat{f}_{m}\right\|_{n}^{2}+\operatorname{pen}(m)\right\},
$$

with

$$
\text { pen }(m)=(1+\theta) \frac{\delta_{m}^{2} D_{m}}{n} \text {. }
$$

Then, the proof of Theorem 2.1 relies on the following proposition proved in [3):
Proposition 4.1.: Let $q>0$ be given such that there exists $\kappa>2(1+q)$ satisfying $\mathbb{E}\left\|\varepsilon_{1}\right\|^{\kappa}<\infty$. Then, for some constants $K(\theta)>1$ and $C(\theta, \kappa, q)>0$ we have that

$$
\begin{equation*}
\left(\mathbb{E}\|f-\widehat{f}\|_{n}^{2 q}\right)^{1 / q} \leq 2^{\left(q^{-1}-1\right)}+\left[K(\theta) \inf _{m \in \mathcal{M}}\left(\left\|f-P_{m} f\right\|_{n}^{2}+\frac{\delta_{m}^{2} D_{m}}{n}\right)+\frac{\Delta_{\kappa}}{n} \delta_{\text {sup }}^{2}\right], \tag{13}
\end{equation*}
$$

where

$$
\Delta_{\kappa}^{q}=C(\theta, \kappa, q) \mathbb{E}\left\|\varepsilon_{1}\right\|^{\kappa}\left(\sum_{m \in \mathcal{M}} \delta_{m}^{-\kappa} D_{m}^{-(\kappa / 2-1-q)}\right) .
$$

The new estimator $\widetilde{\Sigma}$ defined previously corresponds here to the estimator $\widetilde{f}=\widehat{f}_{\widetilde{m}}$, where

$$
\widetilde{m}=\arg \min _{m \in \mathcal{M}}\left\{\left\|y-\widehat{f_{m}}\right\|_{n}^{2}+\widehat{p e n}(m)\right\},
$$

with

$$
\widehat{p e n}(m)=(1+\theta) \frac{\widehat{\delta}_{m}^{2} D_{m}}{n},
$$

and $\hat{\delta}_{m}^{2}$ is some estimator of $\delta_{m}^{2}$.
Next Proposition gives an oracle inequality for this estimator under new assumptions on the model. As Proposition 4.1, it is inspired by the paper [1].

Proposition 4.2. Let $1 \geqslant q>0$ be given such that there exists $\kappa>2(1+2 q)$ satisfying $\mathbb{E}\left\|\varepsilon_{1}\right\|^{\kappa}<\infty$.

For $\alpha \in] 0 ; 1\left[\right.$, set $\Omega=\cap_{m \in \mathcal{M}}\left\{\widehat{\delta}_{m}^{2} \geqslant(1-\alpha) \delta_{m}^{2}\right\}$.
Assume that
A1. $\mathbb{E}\left[\widehat{\delta}_{m}^{2}\right] \leqslant \delta_{m}^{2}$.
A2. $\mathbb{P}\left(\Omega^{c}\right) \leqslant \tilde{C}(\alpha) \frac{1}{n^{\gamma}}$ for some $\gamma \geqslant \frac{q}{1-2 q / \kappa}$.
Then, for a constant $C$ depending on $\kappa, \theta$ and $q$, and we have

$$
\begin{align*}
\left(\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q}\right]\right)^{1 / q} & \leqslant C \inf _{m \in \mathcal{M}}\left(\left\|f-P_{m} f\right\|_{n}^{2}+\frac{\delta_{m}^{2} D_{m}}{n}\right)  \tag{14}\\
& +\frac{C}{n}\left[\widetilde{\Delta}_{\kappa}\left[\mathbb{E}\left[\left\|\varepsilon_{1}\right\|^{\kappa}\right]^{\frac{2}{\kappa}}+\|f\|_{n}^{2}\right]+\delta_{\text {sup }}^{2} \Delta_{\kappa}\right] \tag{15}
\end{align*}
$$

where

$$
\left.\widetilde{\Delta}_{\kappa}^{q}=(\tilde{C}(\alpha))^{\left(1-\frac{2 q}{\kappa}\right)} \text { with } \alpha=\alpha(\theta) \text { is fixed in }\right] 0 ; 1[
$$

and

$$
\Delta_{\kappa}^{q}=C(\theta, \kappa, q) \mathbb{E}\left\|\varepsilon_{1}\right\|^{\kappa}\left(\sum_{m \in \mathcal{M}} \delta_{m}^{-\kappa} D_{m}^{-(\kappa / 2-1-q)}\right)
$$

Theorem 3.1 is thus a direct application of Proposition 4.2. Hence only remain to be checked the two assumptions A1 and A2.

### 4.2 Auxiliary concentration type lemmas

Here we state some propositions required in the proofs of the previous results.
To our knowledge, the first is due to von Bahr and Esseen in [11].
Lemma 4.3. Let $U_{1}, \ldots, U_{n}$ independent centred variables with values in $\mathbb{R}$. For any $1 \leqslant \kappa \leqslant 2$ we have :

$$
\mathbb{E}\left[\left|\sum_{i=1}^{n} U_{i}\right|^{\kappa}\right] \leqslant 8 \sum_{i=1}^{n} \mathbb{E}\left[\left|U_{i}\right|^{\kappa}\right]
$$

The next proposition is proved in [3].
Proposition 4.4. Given $N, k \in \mathbb{N}$, let $\widetilde{A} \in \mathbb{R}^{N k \times N k} \backslash\{0\}$ be a non-negative definite and symmetric matrix and $\varepsilon_{1}, \ldots, \varepsilon_{N}$ i.i.d random vectors in $\mathbb{R}^{k}$ with $\mathbb{E}\left(\varepsilon_{1}\right)=0$ and $V\left(\varepsilon_{1}\right)=\Phi$. Write $\varepsilon=\left(\varepsilon_{1}^{\top}, \ldots, \varepsilon_{N}^{\top}\right)^{\top}, \zeta(\varepsilon)=\sqrt{\varepsilon^{\top} \widetilde{A} \varepsilon}$, and $\delta^{2}=\frac{\operatorname{Tr}\left(\widetilde{A}\left(I_{N} \otimes \Phi\right)\right)}{\operatorname{Tr}(\widetilde{A})}$. For all $\beta \geq 2$ such that $\mathbb{E}\left\|\varepsilon_{1}\right\|^{\beta}<\infty$ it holds that, for all $x>0$,

$$
\begin{equation*}
\mathbb{P}\left(\zeta^{2}(\varepsilon) \geq \delta^{2} \operatorname{Tr}(\widetilde{A})+2 \delta^{2} \sqrt{\operatorname{Tr}(\widetilde{A}) \rho(\widetilde{A}) x}+\delta^{2} \rho(\widetilde{A}) x\right) \leq C_{2}(\beta) \frac{\mathbb{E}\left\|\varepsilon_{1}\right\|^{\beta} \operatorname{Tr}(\widetilde{A})}{\delta^{\beta} \rho(\widetilde{A}) x^{\beta / 2}}, \tag{16}
\end{equation*}
$$

where the constant $C_{2}(\beta)$ depends only on $\beta$.

## 5 Appendix

### 5.1 Proof of Proposition 4.2

This proof follows the guidelines of the proof of Theorem 6.1 in [1]. The following lemma will be helpful for the proof of this proposition

Lemma 5.1. Choose $\eta=\eta(\theta)>0$ and $\alpha=\alpha(\theta) \in] 0 ; 1[$ such that $(1+\theta)(1-\alpha) \geqslant$ $(1+2 \eta)$. Set $H_{m}(f)=\left\{\|f-\widetilde{f}\|_{n}^{2}-\tilde{\kappa}(\theta)\left[\left\|f-f_{m}\right\|_{n}^{2}+\frac{D_{m}}{n} \widehat{\delta}_{m}^{2}\right]\right\}_{+}$where $\tilde{\kappa}(\theta)=\left(2+\frac{4}{\eta}\right)(1+\theta)$. Then, for $m_{0}$ minimizing $m \mapsto\left\|f-f_{m}\right\|_{n}^{2}+\frac{D_{m}}{n} \delta_{m}^{2}$ in $m \in \mathcal{M}$

$$
\begin{equation*}
\mathbb{E}\left[H_{m_{0}}(f)^{q} \mathbf{1}_{\Omega}\right] \leqslant \Delta_{\kappa}^{q} \delta_{\text {sup }}^{2 q} \frac{1}{n^{q}} \tag{17}
\end{equation*}
$$

where $\Delta_{\kappa}$ was defined in Proposition 4.2.

## Proof. Lemma 5.1

First, remark that on the set $\Omega$, for all $m \in \mathcal{M}$

$$
\widehat{p e n}(m) \geqslant(1-\alpha)(1+\theta) \frac{\delta_{m}^{2} D_{m}}{n} \geqslant(1+2 \eta) \frac{\delta_{m}^{2} D_{m}}{n}
$$

Set $\operatorname{pen}(m)=(1+2 \eta) \frac{\delta_{m}^{2} D_{m}}{n}$, which corresponds to the penalty of Proposition 4.1.
The proof of this lemma is based on the proof of Proposition 4.1 in [3]. In fact, it is sufficient to prove that for each $x>0$ and $\kappa \geq 2$

$$
\begin{equation*}
\mathbb{P}\left(\mathcal{H}(f) \mathbf{1}_{\Omega} \geq\left(1+\frac{2}{\eta}\right) \frac{x}{n} \delta_{m}^{2}\right) \leq c(\kappa, \eta) \mathbb{E}\left\|\varepsilon_{1}\right\|^{\kappa} \sum_{m \in \mathcal{M}} \frac{1}{\delta_{m}^{\kappa}} \frac{D_{m} \vee 1}{\left(\eta D_{m}+x\right)^{\kappa / 2}}, \tag{18}
\end{equation*}
$$

where we have set

$$
\mathcal{H}(f)=\left[\|f-\widetilde{f}\|_{n}^{2}-\left(2+\frac{4}{\eta}\right)\left\{\left\|f-f_{m_{0}}\right\|_{n}^{2}+\widehat{p e n}\left(m_{0}\right)\right\}\right]_{+} .
$$

Indeed, for each $m \in \mathcal{M}$,

$$
\begin{aligned}
\left\|f-f_{m_{0}}\right\|_{n}^{2}+\widehat{p e n}\left(m_{0}\right) & =\left\|f-f_{m_{0}}\right\|_{n}^{2}+(1+\theta) \frac{\widehat{\delta}_{m_{0}}^{2}}{n} D_{m_{0}} \\
& \leq(1+\theta)\left(\left\|f-f_{m_{0}}\right\|_{n}^{2}+\frac{\widehat{\delta}_{m_{0}}^{2}}{n} D_{m_{0}}\right)
\end{aligned}
$$

then we get that for all $q>0$,

$$
\begin{equation*}
\mathcal{H}^{q}(f) \mathbf{1}_{\Omega} \geq H_{m_{0}}^{q}(f) \mathbf{1}_{\Omega} \tag{19}
\end{equation*}
$$

Using the equality

$$
\mathbb{E}\left[\mathcal{H}^{q}(f) \mathbf{1}_{\Omega}\right]=\int_{0}^{\infty} q u^{q-1} \mathbb{P}\left(\mathcal{H}^{q}(f) \mathbf{1}_{\Omega}>u\right) d u
$$

and following the proof of Propositon 4.1 in [3] we obtain the upper bound (17) of Lemma 5.1 .

Now we turn to the proof of (18). For any $g \in \mathbb{R}^{n p^{2}}$ we define the empirical quadratic loss function by

$$
\gamma_{n}(g)=\|y-g\|_{n}^{2}
$$

Using the definition of $\gamma_{n}$ we have that for all $g \in \mathbb{R}^{n p^{2}}$,

$$
\|f-g\|_{n}^{2}=\gamma_{n}(g)+2\langle g-y, \varepsilon\rangle_{n}+\|\varepsilon\|_{n}^{2}
$$

and therefore

$$
\begin{equation*}
\|f-\widetilde{f}\|_{n}^{2}-\left\|f-P_{m_{0}} f\right\|_{n}^{2}=\gamma_{n}(\widetilde{f})-\gamma_{n}\left(P_{m_{0}} f\right)+2\left\langle\tilde{f}-P_{m_{0}} f, \varepsilon\right\rangle_{n} \tag{20}
\end{equation*}
$$

Using the definition of $\widetilde{f}$, we know that

$$
\gamma_{n}(\widetilde{f})+\widehat{p e n}(\widetilde{m}) \leq \gamma_{n}(g)+\widehat{p e n}\left(m_{0}\right)
$$

for all $g \in \mathcal{S}_{m_{0}}$. Then

$$
\begin{equation*}
\gamma_{n}(\widetilde{f})-\gamma_{n}\left(P_{m_{0}} f\right) \leq \widehat{p e n}\left(m_{0}\right)-\widehat{p e n}(\widetilde{m}) . \tag{21}
\end{equation*}
$$

So we get from (20) and (21) that

$$
\begin{align*}
\|f-\widetilde{f}\|_{n}^{2} \leq & \left\|f-P_{m_{0}} f\right\|_{n}^{2}+\widehat{p e n}\left(m_{0}\right)-\widehat{p e n}(\widetilde{m}) \\
& +2\left\langle f-P_{m_{0}} f, \varepsilon\right\rangle_{n}+2\left\langle P_{\widetilde{m}} f-f, \varepsilon\right\rangle_{n}+2\left\langle\widetilde{f}-P_{\widetilde{m}} f, \varepsilon\right\rangle_{n} \tag{22}
\end{align*}
$$

In the following we set for each $m^{\prime} \in \mathcal{M}$,

$$
\begin{aligned}
& \mathcal{B}_{m^{\prime}}=\left\{g \in \mathcal{S}_{m^{\prime}}:\|g\|_{n} \leq 1\right\} \\
& G_{m^{\prime}}=\sup _{t \in \mathcal{B}_{m^{\prime}}}\langle g, \varepsilon\rangle_{n}=\left\|P_{m^{\prime}} \varepsilon\right\|_{n} \\
& \quad u_{m^{\prime}}= \begin{cases}\frac{P_{m^{\prime}} f-f}{\left\|P_{m^{\prime}} f-f\right\|_{n}} & \text { if }\left\|P_{m^{\prime}} f-f\right\|_{n} \neq 0 \\
0 & \text { otherwise }\end{cases}
\end{aligned}
$$

Since $\widetilde{f}=P_{\widetilde{m}} f+P_{\widetilde{m}} \varepsilon$, gives

$$
\begin{gather*}
\|f-\widetilde{f}\|_{n}^{2} \leq\left\|f-P_{m_{0}} f\right\|_{n}^{2}+\widehat{p e n}\left(m_{0}\right)-\widehat{p e n}(\widetilde{m}) \\
+2\left\|f-P_{m_{0}} f\right\|_{n}\left|\left\langle u_{m_{0}}, \varepsilon\right\rangle_{n}\right|+2\left\|f-P_{\widetilde{m}} f\right\|_{n}\left|\left\langle u_{\widetilde{m}}, \varepsilon\right\rangle_{n}\right|+2 G_{\widetilde{m}}^{2} . \tag{23}
\end{gather*}
$$

Using repeatedly the following elementary inequality that holds for all positive numbers $\nu, x, z$

$$
\begin{equation*}
2 x z \leq \nu x^{2}+\frac{1}{\nu} z^{2} \tag{24}
\end{equation*}
$$

we get for any $m^{\prime} \in \mathcal{M}$

$$
\begin{equation*}
2\left\|f-P_{m^{\prime}} f\right\|_{n}\left|\left\langle u_{m^{\prime}}, \varepsilon\right\rangle_{n}\right| \leq \nu\left\|f-P_{m^{\prime}} f\right\|_{n}^{2}+\frac{1}{\nu}\left|\left\langle u_{m^{\prime}}, \varepsilon\right\rangle_{n}\right|^{2} . \tag{25}
\end{equation*}
$$

By Pythagora's Theorem we have

$$
\begin{align*}
\|f-\widetilde{f}\|_{n}^{2} & =\left\|f-P_{\widetilde{m}} f\right\|_{n}^{2}+\left\|P_{\widetilde{m}} f-\widetilde{f}\right\|_{n}^{2} \\
& =\left\|f-P_{\widetilde{m}} f\right\|_{n}^{2}+G_{\widetilde{m}}^{2} \tag{26}
\end{align*}
$$

We derive from (23) and (25) that for any $\nu>0$

$$
\begin{gathered}
\|f-\widetilde{f}\|_{n}^{2} \leq\left\|f-P_{m_{0}} f\right\|_{n}^{2}+\nu\left\|f-P_{m_{0}} f\right\|_{n}^{2}+\frac{1}{\nu}\left\langle u_{m_{0}}, \varepsilon\right\rangle_{n}^{2} \\
+\nu\left\|f-P_{\widetilde{m}} f\right\|_{n}^{2}+\frac{1}{\nu}\left\langle u_{\widetilde{m}}, \varepsilon\right\rangle_{n}^{2}+2 G_{\widetilde{m}}^{2}+\widehat{p e n}\left(m_{0}\right)-\widehat{p e n}(\widetilde{m}) .
\end{gathered}
$$

Now taking into account that by equation $26\left\|f-P_{\widetilde{m}} f\right\|_{n}^{2}=\|f-\widetilde{f}\|_{n}^{2}-G_{\widetilde{m}}^{2}$ the above inequality is equivalent to

$$
\begin{gather*}
(1-\nu)\|f-\widetilde{f}\|_{n}^{2} \leq(1+\nu)\left\|f-P_{m_{0}} f\right\|_{n}^{2}+\frac{1}{\nu}\left\langle u_{m_{0}}, \varepsilon\right\rangle_{n}^{2} \\
\quad+\frac{1}{\nu}\left\langle u_{\widetilde{m}}, \varepsilon\right\rangle_{n}^{2}+(2-\nu) G_{\widetilde{m}}^{2}+\widehat{p e n}\left(m_{0}\right)-\widehat{p e n}(\widetilde{m}) \tag{27}
\end{gather*}
$$

We choose $\left.\nu=\frac{2}{2+\eta} \in\right] 0,1[$, but for sake of simplicity we keep using the notation $\nu$. Let $\widetilde{p}_{1}$ and $\widetilde{p}_{2}$ be two functions depending on $\nu$ mapping $\mathcal{M}$ into $\mathbb{R}_{+}$. They will be specified as in [3] to satisfy

$$
\begin{equation*}
\operatorname{pen}\left(m^{\prime}\right) \geq(2-\nu) \widetilde{p}_{1}\left(m^{\prime}\right)+\frac{1}{\nu} \widetilde{p}_{2}\left(m^{\prime}\right) \forall\left(m^{\prime}\right) \in \mathcal{M} \tag{28}
\end{equation*}
$$

Remember that on $\Omega$, $\widehat{p e n}(m) \geqslant \operatorname{pen}(m) \forall m \in \mathcal{M}$. Since $\frac{1}{\nu} \widetilde{p}_{2}\left(m^{\prime}\right) \leq \operatorname{pen}\left(m^{\prime}\right)$ and $1+\nu \leq 2$, we get from (27) and (28) that on the set $\Omega$

$$
\begin{align*}
(1-\nu)\|f-\widetilde{f}\|_{n}^{2} & \leq(1+\nu)\left\|f-P_{m_{0}} f\right\|_{n}^{2}+\widehat{p e n}\left(m_{0}\right)+\frac{1}{\nu} \widetilde{p}_{2}\left(m_{0}\right)+(2-\nu)\left(G_{\widetilde{m}}^{2}-\widetilde{p}_{1}(\widetilde{m})\right) \\
& +\frac{1}{\nu}\left(\left\langle u_{\widetilde{m}}, \varepsilon\right\rangle_{n}^{2}-\widetilde{p}_{2}(\widetilde{m})\right)+\frac{1}{\nu}\left(\left\langle u_{m_{0}}, \varepsilon\right\rangle_{n}^{2}-\widetilde{p}_{2}\left(m_{0}\right)\right) \\
& \leq 2\left(\left\|f-P_{m_{0}} f\right\|_{n}^{2}+\widehat{p e n}\left(m_{0}\right)\right)+(2-\nu)\left(G_{\widetilde{m}}^{2}-\widetilde{p}_{1}(\widetilde{m})\right) \\
& +\frac{1}{\nu}\left(\left\langle u_{\widetilde{m}}, \varepsilon\right\rangle_{n}^{2}-\widetilde{p}_{2}(\widetilde{m})\right)+\frac{1}{\nu}\left(\left\langle u_{m_{0}}, \varepsilon\right\rangle_{n}^{2}-\widetilde{p}_{2}\left(m_{0}\right)\right) \tag{29}
\end{align*}
$$

As $\frac{2}{1-\nu}=2+\frac{4}{\eta}$ we obtain that

$$
\begin{aligned}
(1-\nu) \mathcal{H}(f) \mathbf{1}_{\Omega} & =\left\{(1-\nu)\|f-\widetilde{f}\|_{n}^{2}-(1-\nu)\left(2+\frac{4}{\eta}\right)\left(\left\|f-P_{m_{0}} f\right\|_{n}^{2}+\widehat{p e n}\left(m_{0}\right)\right)\right\}_{+} \mathbf{1}_{\Omega} \\
& =\left\{(1-\nu)\|f-\widetilde{f}\|_{n}^{2}-2\left(\left\|f-P_{m_{0}} f\right\|_{n}^{2}+\widehat{p e n}\left(m_{0}\right)\right)\right\}_{+} \mathbf{1}_{\Omega} \\
& \leq\left\{(2-\nu)\left(G_{\widetilde{m}}^{2}-\widetilde{p}_{1}(\widetilde{m})\right)+\frac{1}{\nu}\left(\left\langle u_{\widetilde{m}}, \varepsilon\right\rangle_{n}^{2}-\widetilde{p}_{2}(\widetilde{m})\right)+\frac{1}{\nu}\left(\left\langle u_{m}, \varepsilon\right\rangle_{n}^{2}-\widetilde{p}_{2}\left(m_{0}\right)\right)\right\}_{+}
\end{aligned}
$$

For any $x>0$,

$$
\begin{align*}
\mathbb{P}\left((1-\nu) \mathcal{H}(f) \mathbf{1}_{\Omega} \geq \frac{x \delta_{m}^{2}}{n}\right) & \leq \mathbb{P}\left(\exists m^{\prime} \in \mathcal{M}:(2-\nu)\left(G_{m^{\prime}}^{2}-\widetilde{p}_{1}\left(m^{\prime}\right)\right) \geq \frac{x \delta_{m^{\prime}}^{2}}{3 n}\right) \\
& +\mathbb{P}\left(\exists m^{\prime} \in \mathcal{M}: \frac{1}{\nu}\left(\left\langle u_{m^{\prime}}, \varepsilon\right\rangle_{n}^{2}-\widetilde{p}_{2}\left(m^{\prime}\right)\right) \geq \frac{x \delta_{m^{\prime}}^{2}}{3 n}\right) \\
& \leq \sum_{m^{\prime} \in \mathcal{M}} \mathbb{P}\left((2-\nu)\left(\left\|P_{m^{\prime}} \varepsilon\right\|_{n}^{2}-\widetilde{p}_{1}\left(m^{\prime}\right)\right) \geq \frac{x \delta_{m^{\prime}}^{2}}{3 n}\right) \\
& +\sum_{m^{\prime} \in \mathcal{M}} \mathbb{P}\left(\frac{1}{\nu}\left(\left\langle u_{m^{\prime}}, \varepsilon\right\rangle_{n}^{2}-\widetilde{p}_{2}\left(m^{\prime}\right)\right) \geq \frac{x \delta_{m^{\prime}}^{2}}{3 n}\right) \\
& :=\sum_{m^{\prime} \in \mathcal{M}} P_{1, m^{\prime}}(x)+\sum_{m^{\prime} \in \mathcal{M}} P_{2, m^{\prime}}(x) . \tag{30}
\end{align*}
$$

From now on, the proof of Lemma 5.1 is exactly the same as the end of the proof of Proposition 4.1 in [3] with $L_{m}=\nu$.

## Proof. Proposition 4.2

We first provide an upper bound for $\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega}\right]$, where the set $\Omega$ depends on $\alpha$ chose as in Lemma 5.1.

As $q \leqslant 1$, we have $(a+b)^{q} \leqslant a^{q}+b^{q}$. Together with Lemma 5.1 we deduce that

$$
\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega}\right] \leqslant \Delta_{\kappa}^{q} \delta_{s u p}^{2 q} \frac{1}{n^{q}}+\mathbb{E}\left[\tilde{\kappa}(\theta)^{q}\left[\left\|f-f_{m_{0}}\right\|_{n}^{2}+\frac{D_{m_{0}}}{n} \widehat{\delta}_{m_{0}}^{2}\right]^{q}\right] .
$$

Using the convexity of $x \mapsto x^{\frac{1}{q}}$ together with the Jensen inequality, we obtain

$$
\left(\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega}\right]\right)^{\frac{1}{q}} \leqslant 2^{1 / q-1} \Delta_{\kappa} \delta_{s u p}^{2} \frac{1}{n}+2^{1 / q-1} \mathbb{E}\left[\tilde{\kappa}(\theta)\left[\left\|f-f_{m_{0}}\right\|_{n}^{2}+\frac{D_{m_{0}}}{n} \widehat{\delta}_{m_{0}}^{2}\right]\right]
$$

and by using the assumption A1 we have that

$$
\begin{equation*}
\left(\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega}\right]\right)^{\frac{1}{q}} \leqslant 2^{1 / q-1} \Delta_{\kappa} \delta_{\text {sup }}^{2} \frac{1}{n}+2^{1 / q-1} \tilde{\kappa}(\theta)\left[\left\|f-f_{m_{0}}\right\|_{n}^{2}+\frac{D_{m_{0}}}{n} \delta_{m_{0}}^{2}\right] . \tag{31}
\end{equation*}
$$

Now we need to find an upper bound for the quantity $\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega^{c}}\right]$.
First, remark that

$$
\begin{gathered}
\|f-\widetilde{f}\|_{n}^{2}=\left\|f-P_{\widetilde{m}} y\right\|_{n}^{2}=\left\|f-P_{\widetilde{m}} f\right\|_{n}^{2}+\left\|P_{\widetilde{m}}(f-y)\right\|_{n}^{2} \\
\leqslant\left\|f-P_{\widetilde{m}} f\right\|_{n}^{2}+\|\varepsilon\|_{n}^{2}=\|f\|_{n}^{2}-\left\|P_{\widetilde{m}} f\right\|_{n}^{2}+\|\varepsilon\|_{n}^{2}
\end{gathered}
$$

And thus

$$
\|f-\widetilde{f}\|_{n}^{2} \leqslant\|f\|_{n}^{2}+\|\varepsilon\|_{n}^{2}
$$

So we have

$$
\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega^{c}}\right] \leqslant\|f\|_{n}^{2 q} \mathbb{P}\left(\Omega^{c}\right)+\mathbb{E}\left[\|\varepsilon\|_{n}^{2 q} \mathbf{1}_{\Omega^{c}}\right] .
$$

Using Hölder's inequality with $\frac{\kappa}{2 q}>1$ we obtain

$$
\mathbb{E}\left[\|\varepsilon\|_{n}^{2 q} \mathbf{1}_{\Omega^{c}}\right] \leqslant \mathbb{E}\left[\|\varepsilon\|_{n}^{\kappa}\right]^{\frac{2 q}{\kappa}} \mathbb{P}\left(\Omega^{c}\right)^{\left(1-\frac{2 q}{\kappa}\right)}
$$

But

$$
\mathbb{E}\left[\|\varepsilon\|_{n}^{\kappa}\right]=\frac{1}{n^{\frac{\kappa}{2}}} \mathbb{E}\left[\left(\sum_{i=1}^{n}\left\|\varepsilon_{i}\right\|^{2}\right)^{\frac{\kappa}{2}}\right]
$$

and as $\kappa \geqslant 2$, we can use Minkowsky's inequality to obtain

$$
\mathbb{E}\left[\|\varepsilon\|_{n}^{\kappa}\right] \leqslant \frac{1}{n^{\frac{\kappa}{2}}}\left(\sum_{i=1}^{n}\left(E\left[\left\|\varepsilon_{i}\right\|^{\kappa}\right]\right)^{\frac{2}{\kappa}}\right)^{\frac{\kappa}{2}}=\frac{1}{n^{\frac{\kappa}{2}}}\left(n\left(E\left[\left\|\varepsilon_{1}\right\|^{\kappa}\right]\right)^{\frac{2}{\kappa}}\right)^{\frac{\kappa}{2}}
$$

that is

$$
\mathbb{E}\left[\|\varepsilon\|_{n}^{\kappa}\right] \leqslant \mathbb{E}\left[\left\|\varepsilon_{1}\right\|^{\kappa}\right] .
$$

So we have

$$
\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega^{c}}\right] \leqslant\left[\mathbb{E}\left[\left\|\varepsilon_{1}\right\|^{\kappa}\right]^{\frac{2 q}{\kappa}}+\|f\|_{n}^{2 q}\right] \mathbb{P}\left(\Omega^{c}\right)^{\left(1-\frac{2 q}{\kappa}\right)},
$$

and with assumption A2

$$
\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega^{c}}\right] \leqslant\left[\mathbb{E}\left[\left\|\varepsilon_{1}\right\|^{\kappa}\right]^{\frac{2 q}{\kappa}}+\|f\|_{n}^{2 q}\right]\left(\tilde{C}(\alpha) \frac{1}{n^{\gamma}}\right)^{\left(1-\frac{2 q}{\kappa}\right)} .
$$

As $\gamma \geqslant \frac{q}{1-2 q / \kappa}$, we deduce that

$$
\begin{equation*}
\left(\mathbb{E}\left[\|f-\widetilde{f}\|_{n}^{2 q} \mathbf{1}_{\Omega^{c}}\right]\right)^{\frac{1}{q}} \leqslant 2^{\frac{1}{q}-1}\left[\mathbb{E}\left[\left\|\varepsilon_{1}\right\|^{\kappa}\right]^{\frac{2}{\kappa}}+\|f\|_{n}^{2}\right] \tilde{C}(\alpha)^{\frac{1-\frac{2 q}{q}}{q}} \frac{1}{n} \tag{32}
\end{equation*}
$$

To conclude, we use again the convexity of $x \mapsto x^{\frac{1}{q}}$ and the inequality (31) to get

$$
\begin{gathered}
\left(\mathbb{E}\left[\|f-\tilde{f}\|_{n}^{2 q}\right]\right)^{\frac{1}{q}} \leqslant 4^{\frac{1}{q}-1}\left[\mathbb{E}\left[\left\|\varepsilon_{1}\right\|^{\kappa}\right]^{\frac{2}{\kappa}}+\|f\|_{n}^{2}\right] \tilde{C}(\alpha)^{\frac{1-\frac{2 q}{\kappa}}{q}} \frac{1}{n} \\
+4^{1 / q-1} \Delta_{\kappa} \delta_{\text {sup }}^{2} \frac{1}{n} \\
+4^{1 / q-1} \tilde{\kappa}(\theta)\left[\left\|f-f_{m_{0}}\right\|_{n}^{2}+\frac{D_{m_{0}}}{n} \delta_{m_{0}}^{2}\right]
\end{gathered}
$$

### 5.2 Proof of Theorem 3.1

Recall that $\beta>\max (2(1+2 q), 3+2 q)$ and $\kappa \in] 2(1+2 q) ; \min (\beta, 2 \beta-4)[$. In order to use Proposition 4.2, we need to prove the following inequalities :
A1. $\mathbb{E}\left[\widehat{\delta}_{m}^{2}\right] \leqslant \delta_{m}^{2}$
A2. $\mathbb{P}\left(\Omega^{c}\right) \leqslant \tilde{C}(\alpha) \frac{1}{n^{\gamma}}$ for $\gamma \geqslant \frac{q}{1-2 q / \kappa}$.
First we prove A1.
Remember that $\widehat{\delta}_{m}^{2}=\frac{\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \widehat{\Phi}\right)}{D_{m}}$. By using the linearity of the trace and the equality $\mathbb{E}[\widehat{\Phi}]=\frac{n-1}{n} \Phi$, we obtain that $\mathbb{E}\left[\widehat{\delta}_{m}^{2}\right]=\frac{n-1}{n} \delta_{m}^{2}$ which proves the result.

For the second, write $\Omega^{c}=\cup_{m \in \mathcal{M}}\left\{\widehat{\delta}_{m}^{2} \leqslant(1-\alpha) \delta_{m}^{2}\right\}$. We bound up the quantity $\mathbb{P}\left(\widehat{\delta}_{m}^{2} \leqslant(1-\alpha) \delta_{m}^{2}\right)$ in the following Proposition.

Proposition 5.2. For all $m \in \mathcal{M}, \alpha \in] 0 ; 1\left[\right.$ and $n \geqslant n\left(\kappa, \beta, \alpha, C_{\text {inf }}, \Sigma\right)$ we have for some constants $C_{1}(\beta), C_{2}(\beta)$ :

$$
\mathbb{P}\left(\widehat{\delta}_{m}^{2} \leqslant(1-\alpha) \delta_{m}^{2}\right) \leqslant \frac{1}{n^{\gamma}}\left(C_{2}(\beta) 2^{\beta+1}+C_{1}(\beta) \frac{1}{\alpha^{\frac{\beta}{2}}}\right) \mathbb{E}\left[\left\|x x^{\top}\right\|^{\beta}\right] \delta_{m}^{-\beta} D_{m}^{-\frac{\beta}{2}},
$$

for $\gamma \geqslant \frac{q}{1-2 q / \kappa}$.
This Proposition concludes the proof of A2 with

$$
\tilde{C}(\alpha)=\left(C_{2}(\beta) 2^{\beta+1}+C_{1}(\beta) \frac{1}{\alpha^{\frac{\beta}{2}}}\right) \mathbb{E}\left[\left\|x x^{\top}\right\|^{\beta}\right] \sum_{m \in \mathcal{M}} \delta_{m}^{-\beta} D_{m}^{-\frac{\beta}{2}}
$$

## Proof. Proposition 5.2

We start by dividing $\mathcal{P}_{m}=\mathbb{P}\left(\widehat{\delta}_{m}^{2} \leqslant(1-\alpha) \delta_{m}^{2}\right)$ into two parts with one of them involving a sum of independent variables with expectation equal to 0 .

$$
\begin{gathered}
\mathcal{P}_{m}=\mathbb{P}\left(\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \widehat{\Phi}\right) \leqslant(1-\alpha) \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right) \\
\mathcal{P}_{m}=\mathbb{P}\left(\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\widehat{\Phi}-\left(\Phi+\mu \mu^{\top}\right)+\mu \mu^{\top}\right)\right) \leqslant-\alpha \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right) \\
\mathcal{P}_{m} \leqslant \mathbb{P}\left(\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\frac{1}{n} \sum_{i=1}^{n}\left(y_{i} y_{i}^{T}-\Phi-\mu \mu^{\top}\right)+\mu \mu^{\top}-S_{v e c} S_{\text {vec }}^{\top}\right)\right)\right| \geqslant \alpha \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right) \\
\mathcal{P}_{m} \leqslant \mathbb{P}\left(\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\frac{1}{n} \sum_{i=1}^{n}\left(y_{i} y_{i}^{T}-\Phi-\mu \mu^{\top}\right)\right)\right)\right| \geqslant \frac{\alpha}{2} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right)
\end{gathered}
$$

$$
+\mathbb{P}\left(\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu \mu^{\top}-S_{v e c} S_{v e c}^{\top}\right)\right)\right| \geqslant \frac{\alpha}{2} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right)
$$

Set

$$
Q 1=\mathbb{P}\left(\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\frac{1}{n} \sum_{i=1}^{n}\left(y_{i} y_{i}^{T}-\Phi-\mu \mu^{\top}\right)\right)\right)\right| \geqslant \frac{\alpha}{2} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right)
$$

and

$$
Q 2=\mathbb{P}\left(\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu \mu^{\top}-S_{\text {vec }} S_{\text {vec }}^{\top}\right)\right)\right| \geqslant \frac{\alpha}{2} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right)
$$

## Study of Q1

First we use Markov's inequality to obtain

$$
A 1 \leqslant \frac{2^{\frac{\beta}{2}} \mathbb{E}\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\frac{1}{n} \sum_{i=1}^{n}\left(y_{i} y_{i}^{T}-\Phi-\mu \mu^{\top}\right)\right)\right)\right|^{\frac{\beta}{2}}\right]}{\left(\alpha \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right)^{\frac{\beta}{2}}}
$$

We must consider the two following cases :

- If $\frac{\beta}{2} \geqslant 2$, Rosenthal's inequality gives

$$
\begin{gathered}
\mathbb{E}\left[\left|\frac{1}{n} \sum_{i=1}^{n} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\left(y_{i} y_{i}^{T}-\Phi-\mu \mu^{\top}\right)\right)\right)\right|^{\frac{\beta}{2}}\right] \\
\leqslant C\left(\frac{\beta}{2}\right) \frac{1}{n^{\frac{\beta}{2}-1}} \mathbb{E}\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}-\Phi-\mu \mu^{\top}\right)\right)\right|^{\frac{\beta}{2}}\right] \\
+C\left(\frac{\beta}{2}\right)\left(\frac{1}{n} \mathbb{E}\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}-\Phi-\mu \mu^{\top}\right)\right)\right|^{2}\right]\right)^{\frac{\beta}{4}} .
\end{gathered}
$$

As $\frac{\beta}{2} \geqslant 2, \frac{1}{n^{\frac{\beta}{2}-1}} \leqslant \frac{1}{n^{\frac{\beta}{4}}}$ and we can use Jensen's inequality on the second term to obtain

$$
\begin{aligned}
& \mathbb{E}\left[\left|\frac{1}{n} \sum_{i=1}^{n} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\left(y_{i} y_{i}^{T}-\Phi-\mu \mu^{\top}\right)\right)\right)\right|^{\frac{\beta}{2}}\right] \\
\leqslant & C\left(\frac{\beta}{2}\right) \mathbb{E}\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}-\Phi-\mu \mu^{\top}\right)\right)\right|^{\frac{\beta}{2}}\right] \frac{2}{n^{\frac{\beta}{4}}} .
\end{aligned}
$$

- If $1 \leqslant \frac{\beta}{2} \leqslant 2$, we use Lemma 4.3 of subsection 4.2 to get

$$
\begin{aligned}
& \mathbb{E}\left[\left|\frac{1}{n} \sum_{i=1}^{n} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\left(y_{i} y_{i}^{T}-\Phi-\mu \mu^{\top}\right)\right)\right)\right|^{\frac{\beta}{2}}\right] \\
& \leqslant \frac{8}{n^{\frac{\beta}{2}-1}} \mathbb{E}\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}-\Phi-\mu \mu^{\top}\right)\right)\right|^{\frac{\beta}{2}}\right]
\end{aligned}
$$

In both cases, we can use the fact that $x \mapsto x^{\frac{\beta}{2}}$ is a convex and increasing function to obtain

$$
\begin{gathered}
\mathbb{E}\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}-\Phi-\mu \mu^{\top}\right)\right)\right|^{\frac{\beta}{2}}\right] \\
\leqslant 2^{\frac{\beta}{2}-1}\left[\mathbb{E}\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}\right)\right)\right|^{\frac{\beta}{2}}\right]+\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\Phi+\mu \mu^{\top}\right)\right)\right|^{\frac{\beta}{2}}\right]
\end{gathered}
$$

And by using the Jensen's inequality on the second term we have that

$$
\begin{aligned}
\mathbb{E} & {\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}-\Phi-\mu \mu^{\top}\right)\right)\right|^{\frac{\beta}{2}}\right] } \\
& \leqslant 2^{\frac{\beta}{2}} \mathbb{E}\left[\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}\right)\right)\right|^{\frac{\beta}{2}}\right] .
\end{aligned}
$$

Now consider the following lemma.
Lemma 5.3. If $\Psi$ is symmetric non-negative definite, then

$$
\begin{equation*}
\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Psi\right) \in[0 ; \operatorname{Tr}(\Psi)] \tag{33}
\end{equation*}
$$

From this fact we get that

$$
\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(y_{1} y_{1}^{\top}\right)\right)\right|^{\frac{\beta}{2}} \leqslant \operatorname{Tr}\left(y_{1} y_{1}^{\top}\right)^{\frac{\beta}{2}}=\left\|y_{1}\right\|^{\beta}=\left\|x x^{\top}\right\|^{\beta}
$$

In conclusion, we have

$$
\begin{equation*}
Q 1 \leqslant C_{1}(\beta) \frac{\mathbb{E}\left[\left\|x x^{\top}\right\|^{\beta}\right]}{\alpha^{\frac{\beta}{2}} \delta_{m}^{\beta} D_{m}^{\frac{\beta}{2}}} \frac{1}{n^{\gamma}}, \tag{34}
\end{equation*}
$$

with $\gamma=\min \left(\frac{\beta}{4}, \frac{\beta}{2}-1\right)$ and $C_{1}(\beta)=2 C\left(\frac{\beta}{2}\right)$ if $\beta \geqslant 4$ where $C\left(\frac{\beta}{2}\right)$ is the constant in Rosenthal's inequality and $C_{1}(\beta)=8$ if $2 \leqslant \beta \leqslant 4$. Remark that $\frac{\beta}{4} \geqslant \frac{\kappa}{4}$ and $\frac{\beta}{2}-1 \geqslant \frac{\kappa}{4}$, so $\gamma \geqslant \frac{\kappa}{4}$.

## Study of Q2

Recall that

$$
Q 2=\mathbb{P}\left(\left|\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu \mu^{\top}-S_{\text {vec }} S_{\text {vec }}^{\top}\right)\right)\right| \geqslant \frac{\alpha}{2} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right)
$$

Set

$$
B 2=\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu \mu^{\top}-S_{\text {vec }} S_{\text {vec }}^{\top}\right)\right)
$$

Using the properties of the trace, we can write

$$
\begin{aligned}
B 2 & =\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu \mu^{\top}\right)\right)-\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(S_{\text {vec }} S_{\text {vec }}^{\top}\right)\right) \\
& =\operatorname{Tr}\left(\mu^{\top}\left(\Pi_{m} \otimes \Pi_{m}\right) \mu\right)-\operatorname{Tr}\left(S_{\text {vec }}^{\top}\left(\Pi_{m} \otimes \Pi_{m}\right) S_{\text {vec }}\right)
\end{aligned}
$$

But $\Pi_{m} \otimes \Pi_{m}$ is an orthogonal projection matrix, then

$$
\begin{gathered}
B 2=\operatorname{Tr}\left(\mu^{\top}\left(\Pi_{m} \otimes \Pi_{m}\right)^{\top}\left(\Pi_{m} \otimes \Pi_{m}\right) \mu\right)-\operatorname{Tr}\left(S_{\text {vec }}^{\top}\left(\Pi_{m} \otimes \Pi_{m}\right)^{\top}\left(\Pi_{m} \otimes \Pi_{m}\right) S_{v e c}\right) \\
B 2=\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) \mu\right\|^{2}-\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) S_{v e c}\right\|^{2} \\
B 2=\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) \mu\right\|-\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) S_{v e c}\right\|\right)\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) \mu\right\|+\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) S_{v e c}\right\|\right)
\end{gathered}
$$

Hence

$$
\begin{gathered}
|B 2| \leqslant\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{v e c}\right)\right\|\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) \mu\right\|+\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) S_{v e c}\right\|\right) \\
|B 2| \leqslant\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{v e c}\right)\right\|^{2}+2\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{v e c}\right)\right\|\left\|\left(\Pi_{m} \otimes \Pi_{m}\right) \mu\right\| \\
|B 2| \leqslant\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{v e c}\right)\right\|^{2}+2\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{v e c}\right)\right\|\|\mu\|
\end{gathered}
$$

Finally

$$
\begin{align*}
Q 2 & \leqslant \mathbb{P}\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{v e c}\right)\right\|^{2} \geqslant \frac{\alpha}{4} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right)  \tag{35}\\
& +\mathbb{P}\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{\text {vec }}\right)\right\| \geqslant \frac{\alpha}{8\|\mu\|} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right)
\end{align*}
$$

Now we need to provide an upper bound for the quantities

$$
\mathbb{P}\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{\text {vec }}\right)\right\|^{2} \geqslant t\right)
$$

For this we will use the deviation bound provided by Proposition 4.4 stated in subsection 4.2 .

Set

$$
G_{n}=\frac{1}{n}\left(\begin{array}{ccc}
I d_{p^{2}} & \ldots & I d_{p^{2}} \\
I d_{p^{2}} & \ldots & I d_{p^{2}} \\
\vdots & \ddots & \vdots \\
I d_{p^{2}} & \ldots & I d_{p^{2}}
\end{array}\right) \in \mathbb{R}^{p^{2} n \times p^{2} n}
$$

Then

$$
G_{n}(y-f)=\mathbf{1}_{\mathbf{n}} \otimes\left(S_{\text {vec }}-\mu\right)
$$

Now, if

$$
H_{m}=I d_{n} \otimes\left(\Pi_{m} \otimes \Pi_{m}\right)=\left(\begin{array}{cccc}
\Pi_{m} \otimes \Pi_{m} & 0 & \cdots & 0 \\
0 & \Pi_{m} \otimes \Pi_{m} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \ldots & \Pi_{m} \otimes \Pi_{m}
\end{array}\right) \in \mathbb{R}^{p^{2} n \times p^{2} n},
$$

we have

$$
H_{m}\left(\mathbf{1}_{n} \otimes\left(S_{v e c}-\mu\right)\right)=\mathbf{1}_{n} \otimes\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(S_{v e c}-\mu\right)\right)
$$

In conclusion, with

$$
A_{m}=H_{m} G_{n}=\frac{1}{n}\left(\begin{array}{ccc}
\Pi_{m} \otimes \Pi_{m} & \ldots & \Pi_{m} \otimes \Pi_{m} \\
\Pi_{m} \otimes \Pi_{m} & \ldots & \Pi_{m} \otimes \Pi_{m} \\
\vdots & \ddots & \vdots \\
\Pi_{m} \otimes \Pi_{m} & \ldots & \Pi_{m} \otimes \Pi_{m}
\end{array}\right) \in \mathbb{R}^{p^{2} n \times p^{2} n}
$$

we have that

$$
A_{m}(y-f)=\mathbf{1}_{n} \otimes\left(\left(\Pi_{m} \otimes \Pi_{m}\right)\left(S_{v e c}-\mu\right)\right)
$$

Moreover, $A_{m}$ is an orthogonal projection matrix and we have the following equalities

$$
\begin{gathered}
\left\|A_{m}(y-f)\right\|^{2}=n\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(S_{v e c}-\mu\right)\right\|^{2}=(y-f)^{\top} A_{m}(y-f) \\
\operatorname{Tr}\left(A_{m}\right)=\frac{n}{n} \operatorname{Tr}\left(\Pi_{m} \otimes \Pi_{m}\right)=D_{m} \\
\operatorname{Tr}\left(A_{m}\left(I d_{n} \otimes \Phi\right)\right)=\frac{n}{n} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)=\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)
\end{gathered}
$$

Now we can use Proposition 4.4 with $\widetilde{A}=A_{m}, \varepsilon_{i}=y_{i}-\mu, \operatorname{Tr}\left(A_{m}\right)=D_{m}, \rho\left(A_{m}\right)=1$, $\delta^{2}=\delta_{m}^{2}$ and $\beta \geqslant 2$.

This gives for all $x>0$
$\mathbb{P}\left((y-f)^{\top} A_{m}(y-f) \geqslant \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\left[1+\sqrt{\frac{x}{D_{m}}}\right]^{2}\right) \leqslant C_{2}(\beta) \frac{\mathbb{E}\left[\left\|y_{1}-\mu\right\|^{\beta}\right] D_{m}^{\frac{\beta}{2}+1}}{\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)^{\frac{\beta}{2}} x^{\frac{\beta}{2}}}$,
that is

$$
\mathbb{P}\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(S_{v e c}-\mu\right)\right\|^{2} \geqslant \frac{1}{n} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\left[1+\sqrt{\frac{x}{D_{m}}}\right]^{2}\right) \leqslant C_{2}(\beta) \frac{\mathbb{E}\left[\left\|y_{1}-\mu\right\|^{\beta}\right] D_{m}^{\frac{\beta}{2}+1}}{\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)^{\frac{\beta}{2}} x^{\frac{\beta}{2}}}
$$

In order to use this deviation bound to obtain the inequalities

$$
\mathbb{P}\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{v e c}\right)\right\|^{2} \geqslant \frac{\alpha}{4} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right) \leqslant \tilde{C} \frac{1}{n^{\gamma}}
$$

and

$$
\mathbb{P}\left(\left\|\left(\Pi_{m} \otimes \Pi_{m}\right)\left(\mu-S_{v e c}\right)\right\| \geqslant \frac{\alpha}{8\|\mu\|} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)\right) \leqslant \tilde{C} \frac{1}{n^{\gamma}}
$$

with $\gamma \geqslant \frac{q}{1-2 q / \kappa}$, we need to find $x>0$ satisfying the three following facts

$$
\begin{gather*}
\forall m \in \mathcal{M} \quad \frac{\alpha}{4} \geqslant \frac{1}{n}\left(1+\sqrt{\frac{x}{D_{m}}}\right)^{2}  \tag{36}\\
\forall m \in \mathcal{M} \quad\left(\frac{\alpha}{8\|\mu\|}\right)^{2} \operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right) \geqslant\left(\frac{\alpha}{8\|\mu\|}\right)^{2} C_{i n f} \geqslant \frac{1}{n}\left(1+\sqrt{\frac{x}{D_{m}}}\right)^{2}  \tag{37}\\
\frac{D_{m}^{\frac{\beta}{2}+1}}{\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Phi\right)^{\frac{\beta}{2}} x^{\frac{\beta}{2}}}=\frac{D_{m}}{\delta_{m}^{\beta} x^{\frac{\beta}{2}}} \leqslant C \frac{1}{n^{\gamma}} \tag{38}
\end{gather*}
$$

(36) and (37) hold for the choice $x=D_{m} n^{r}$ with $r<1$ and if $n$ is large enough to have

$$
\begin{equation*}
\frac{1}{n}\left(1+\sqrt{n^{r}}\right)^{2} \leqslant \frac{\alpha}{4} \tag{39}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{1}{n}\left(1+\sqrt{n^{r}}\right)^{2} \leqslant\left(\frac{\alpha}{8\|\mu\|}\right)^{2} C_{i n f} \tag{40}
\end{equation*}
$$

In order to obtain (38) with $x=D_{m} n^{r}$, we use the inequality $D_{m} \leqslant n$ which gives

$$
\frac{D_{m}}{\delta_{m}^{\beta} x^{\frac{\beta}{2}}} \leqslant \frac{1}{\delta_{m}^{\beta} D_{m}^{\frac{\beta}{2}} n^{r \beta / 2-1}}
$$

Moreover

$$
\mathbb{E}\left[\left\|y_{1}-\mu\right\|^{\beta}\right] \leqslant \mathbb{E}\left[\left(\left\|y_{1}\right\|+\|\mu\|\right)^{\beta}\right]
$$

and by using properties of convexity we obtain

$$
\mathbb{E}\left[\left\|y_{1}-\mu\right\|^{\beta}\right] \leqslant 2^{\beta-1}\left(\mathbb{E}\left[\left\|y_{1}\right\|^{\beta}\right]+\|\mu\|^{\beta}\right)
$$

With the Jensen's inequality we get:

$$
\mathbb{E}\left[\left\|y_{1}-\mu\right\|^{\beta}\right] \leqslant 2^{\beta} \mathbb{E}\left[\left\|y_{1}\right\|^{\beta}\right] .
$$

In conclusion, with $r=\frac{\frac{\kappa}{2}+2}{\beta}<1$ we obtain for $n \geqslant n\left(\kappa, \beta, \alpha, C_{\text {inf }}, \Sigma\right)$

$$
\begin{equation*}
Q 2 \leqslant 2^{\beta+1} C_{2}(\beta) \frac{\mathbb{E}\left[\left\|x x^{\top}\right\|^{\beta}\right]}{\delta_{m}^{\beta} D_{m}^{\frac{\beta}{2}}} \frac{1}{n^{\kappa / 4}} \tag{41}
\end{equation*}
$$

where $C_{2}(\beta)$ is the constant which appears in Proposition 4.4 .
In conclusion, combining (34) and (41)

$$
\mathbb{P}\left(\widehat{\delta}_{m}^{2} \leqslant(1-\alpha) \delta_{m}^{2}\right) \leqslant \frac{1}{n^{\kappa / 4}}\left(C_{2}(\beta) 2^{\beta+1}+C_{1}(\beta) \frac{1}{\alpha^{\frac{\beta}{2}}}\right) \mathbb{E}\left[\left\|x x^{\top}\right\|^{\beta}\right] \delta_{m}^{-\beta} D_{m}^{-\frac{\beta}{2}}
$$

for $n \geqslant n\left(\kappa, \beta, \alpha, C_{i n f}, \Sigma\right)$.
To conclude, remark that $\frac{\kappa}{4}(1-2 q / \kappa)=\frac{\kappa-2 q}{4}>\frac{2+2 q}{4} \geqslant q$ as $q \leqslant 1$.

## Proof. Lemma 5.3

Recall that $\Pi_{m} \otimes \Pi_{m}$ is an orthogonal projection matrix. Hence there exists an orthogonal matrix $P_{m}$ such that $P_{m}^{\top}\left(\Pi_{m} \otimes \Pi_{m}\right) P_{m}=D$, with $D$ a diagonal matrix with $D_{i i}=1$ if $i \leqslant D_{m}$, and $D_{i i}=0$ otherwise. Then if $\Psi$ is symmetric non-negative definite we have :

$$
\operatorname{Tr}\left(\left(\Pi_{m} \otimes \Pi_{m}\right) \Psi\right)=\operatorname{Tr}\left(D P_{m}^{\top} \Psi P_{m}\right)
$$

$$
\begin{gathered}
=\sum_{l=1}^{p^{2}} \sum_{k=1}^{p^{2}} D_{k l}\left(P_{m}^{\top} \Psi P_{m}\right)_{k l}=\sum_{l=1}^{p^{2}} D_{l l}\left(P_{m}^{\top} \Psi P_{m}\right)_{l l} \\
=\sum_{l=1}^{D_{m}}\left(P_{m}^{\top} \Psi P_{m}\right)_{l l} \in[0 ; \operatorname{Tr}(\Psi)]
\end{gathered}
$$

Indeed, $P_{m}^{\top} \Psi P_{m}$ is non-negative definite so all its diagonal entries are non-negative.
