# A REMARK ON THE OMORI-YAU MAXIMUM PRINCIPLE 

Albert Borbély

#### Abstract

A Riemannian manifold $M$ is said to satisfy the Omori-Yau maximum principle if for any $C^{2}$ bounded function $g: M \rightarrow \mathbb{R}$ there is a sequence $x_{n} \in M$, such that $\lim _{n \rightarrow \infty} g\left(x_{n}\right)=\sup _{M} g, \lim _{n \rightarrow \infty}\left|\nabla g\left(x_{n}\right)\right|=0$ and $\lim \sup _{n \rightarrow \infty} \Delta g\left(x_{n}\right) \leq 0$. It is shown that if the Ricci curvature does not approach $-\infty$ too fast the manifold satisfies the Omori-Yau maximum principle. This improves earlier necessary conditions. The given condition is quite optimal.

## 0. Introduction

Definition. A Riemannian manifold $M$ is said to satisfy the Omori-Yau maximum principle if for any $C^{2}$ function $g: M \rightarrow \mathbb{R}$ which is bounded from above and for any $\epsilon>0$ there is a point $x_{\epsilon} \in M$, such that $\left|g\left(x_{\epsilon}\right)-\sup _{M} g\right|<\epsilon,\left|\nabla g\left(x_{\epsilon}\right)\right|<\epsilon$ and $\Delta g\left(x_{n}\right)<\epsilon$.

This principle has turned out to be very useful in differential geometry and received considerable attention recently. A necessary condition in terms of the Ricci curvature for a manifold to satisfy this principle was first proved by Omori in $[\mathrm{O}]$ and later generalized by Yau $[\mathrm{Y}]$. It states that if the Ricci curvature is bounded from below then the manifold satisfies the Omori-Yau maximum principle.

This was improved upon by Ratto, Rigoli and Setti in [RRS, Theorem 2.3].
Theorem (Ratto-Rigoli-Setti). Let $M^{n}$ be a complete Riemannian manifold, $p \in M^{n}$ be a fixed point and $r(x)$ be the distance function from $p$. Let us assume that away from the cut locus of $p$ we have

$$
\operatorname{Ricc}(\nabla r, \nabla r) \geq-(n-1) B G^{2}(r)
$$

where $B>0$ is some constant and $G(t)$ has the following properties:

$$
\begin{aligned}
& \text { (i) } G(0)=1, \quad G^{\prime} \geq 0 \\
& \text { (ii) } \int_{0}^{\infty} \frac{d t}{G(t)}=\infty \\
& \text { (iii) } \frac{d^{2 k+1}}{d t^{2 k+1}} \sqrt{G}(0)=0 \quad \text { for all } \quad k \in \mathbb{N} \\
& \text { (iv) } \quad \limsup _{t \rightarrow \infty} \frac{t \sqrt{G(\sqrt{t})}}{\sqrt{G(t)}}<\infty .
\end{aligned}
$$

[^0]Then $M^{n}$ satisfies the Omori-Yau maximum principle.
The goal of the present note is to improve the necessary condition given in [RRS]. The actual statement is given as a Corollary. Basically we remove the last two conditions on the function $G(t)$, which turned out not to be essential.

Another interesting necessary condition, requiring the existence of an exhaustion function with certain properties, was given by Kim and Lee in [KL]. Interestingly there is an alternative proof by Kim and Lee of the Ratto-Rigoli-Setti result in [KL] which is still using these extra conditions.

The proof uses the same method we used in an earlier paper [B].
Theorem. Let $M^{n}$ be a complete Riemannian manifold, $p \in M^{n}$ be a fixed point and $r(x)$ be the distance function from $p$. Let us assume that

$$
\Delta r(x) \leq G(r(x))
$$

for all $x \in M^{n}$ where $r$ is smooth and $r(x)>1$, where $G(t)$ has the following properties:

$$
G \geq 1, \quad G^{\prime} \geq 0, \quad \text { and } \quad \int_{0}^{\infty} \frac{d t}{G(t)}=\infty
$$

Then $M^{n}$ satisfies the Omori-Yau maximum principle.
As a consequence we have the following.
Corollary. Let $M^{n}$ be a complete Riemannian manifold, $p \in M^{n}$ be a fixed point and $r(x)$ be the distance function from $p$. Let us assume that away from the cut locus of $p$ we have

$$
\operatorname{Ricc}(\nabla r, \nabla r) \geq-G^{2}(r)
$$

where $G(t)$ has the following properties:

$$
G \geq 1, \quad G^{\prime} \geq 0, \quad \text { and } \quad \int_{0}^{\infty} \frac{d t}{G(t)}=\infty
$$

Then $M^{n}$ satisfies the Omori-Yau maximum principle.
The main condition on the function $G(t)$ in the Corollary and in the Ratto-Rigoli-Setti Theorem is the same $\left(\int 1 / G(t)=\infty\right)$ but there are additional technical conditions imposed on the function $G(t)$ in the later Theorem. In this respect Corollary can be considered as a refinement of the Ratto-Rigoli-Setti Theorem.

Let us mention that this condition is quite optimal. If $\int_{0}^{\infty} 1 / G(t) d t<\infty$, there are manifolds with $\Delta r \leq G(r)$ for which the Omori-Yau maximum principle does not apply. The details can be found in Section 3.

## 1. Proof of the Theorem

Proof of the Theorem. Set $L=\sup g$ and let us assume that $g<L$ at every point of $M$. Otherwise $g$ assumes its maximum at some point and that point trivially satisfies the conditions of the Definition for all $\epsilon>0$.

Define the function $F(t)$ as

$$
F(t)=e^{\int_{0}^{t} \frac{1}{G(s)} d s}
$$

Then clearly: $F \geq 1, \quad F$ is strictly increasing and $\lim _{t \rightarrow \infty} F(t)=\infty$.
For any $\epsilon<\min \{1, L-\sup \{g(x): r(x)<1\}\}$ define the function $h_{\lambda}: M \rightarrow \mathbb{R}$ as

$$
h_{\lambda}(x)=\lambda F(r(x))+L-\epsilon .
$$

Since $F(r(x)) \geq 1$, for $\lambda>\epsilon$ we have

$$
h_{\lambda}(x)>L>g(x) \quad \text { for all } \quad x \in M
$$

Define $\lambda_{0}$ as

$$
\lambda_{0}=\inf \left\{\lambda: h_{\lambda}(x)>g(x) \quad \text { for all } \quad x \in M\right\}
$$

Since $\sup g=L$ it is easy to see that $\lambda_{0}>0$ and $h_{\lambda_{0}}(x) \geq g(x)$ for all $x \in M$.
We claim that there is a point $x_{\epsilon} \in M$ such that $h_{\lambda_{0}}\left(x_{\epsilon}\right)=g\left(x_{\epsilon}\right)$.
This will follow from the observation that if $h_{\lambda}(x)>g(x)$ for all $x \in M$, then there is a $\lambda^{\prime}<\lambda$ such that $h_{\lambda^{\prime}}(x)>g(x)$ for all $x \in M$. To show this we argue as follows.

Let $r_{0}$ be large enough such that $h_{\lambda}(x)>L+1$ for $r(x)>r_{0}$. Since $\lim _{r \rightarrow \infty} F(r)=$ $\infty$ such $r_{0}$ must exists. The set $\left\{x \in M: r(x) \leq r_{0}\right\}$ is compact, therefore $h_{\lambda}(x)>g(x)$ for all $x \in M$ implies that there is a $\lambda^{\prime}<\lambda$ such that $h_{\lambda^{\prime}}(x)>g(x)$ for all $\left.x \in M: r(x) \leq r_{0}\right\}$. Choosing $\lambda^{\prime}$ sufficiently close to $\lambda$ we can achieve that $h_{\lambda^{\prime}}(x)>L$ for $r(x)=r_{0}$. Since $F$ is increasing we obtain that $h_{\lambda^{\prime}}(x)>L$ for $r(x) \geq r_{0}$. Combining this with the previous remark we have $h_{\lambda^{\prime}}(x)>g(x)$ for all $x \in M$.

Next, we have to show that $h_{\lambda_{0}}$ is smooth at $x_{\epsilon}$. The argument is exactly the same as the argument in $[B]$, but we include it at the and of this proof for the convenience of the reader.

Once we established the smoothness of $h_{\lambda_{0}}$ at $x_{\epsilon}$, the rest of the argument is straight forward.

From the definition of $F$ and from the fact that $G^{\prime} \geq 0$ we have

$$
F^{\prime}=\frac{F}{G} \quad \text { and } \quad F^{\prime \prime}=\frac{F^{\prime}}{G}-\frac{F G^{\prime}}{G^{2}} \leq \frac{F}{G^{2}}
$$

From the fact that $g\left(x_{\epsilon}\right)=\lambda_{0} F\left(r\left(x_{\epsilon}\right)\right)+L-\epsilon<L$ we conclude that

$$
\begin{equation*}
L-g\left(x_{\epsilon}\right) \leq \epsilon, \tag{1.1}
\end{equation*}
$$

moreover

$$
\begin{equation*}
\lambda_{0} F\left(r\left(x_{\epsilon}\right)\right)<\epsilon \quad \text { hence } \quad \lambda_{0}<\frac{\epsilon}{F\left(r\left(x_{\epsilon}\right)\right)}<\epsilon . \tag{1.2}
\end{equation*}
$$

Since

$$
h_{\lambda_{0}}(x) \geq g(x), \quad \text { and } \quad h_{\lambda_{0}}\left(x_{\epsilon}\right)=g\left(x_{\epsilon}\right),
$$

we have

$$
\nabla g\left(x_{\epsilon}\right)=\nabla h_{\lambda_{0}}\left(x_{\epsilon}\right) \quad \text { and } \quad \Delta h_{\lambda_{0}}\left(x_{\epsilon}\right) \geq \Delta g\left(x_{\epsilon}\right)
$$

Taking into consideration (1.2), the definition of $F$, the fact that $|\nabla r|=1$ and the assumption that $G(r) \geq 1$, the first equality above yields

$$
\begin{equation*}
\left|\nabla g\left(x_{\epsilon}\right)\right|=\left|\lambda_{0} F^{\prime}\left(r\left(x_{\epsilon}\right)\right) \nabla r\left(x_{\epsilon}\right)\right|=\frac{\epsilon}{F(r)} \cdot \frac{F(r)}{G(r)}<\epsilon \tag{1.3}
\end{equation*}
$$

For the Laplace of $h_{\lambda_{0}}$ we have

$$
\begin{align*}
\Delta g\left(x_{\epsilon}\right) & \leq \Delta h_{\lambda_{0}}\left(x_{\epsilon}\right)=\lambda_{0}\left(F^{\prime}\left(r\left(x_{\epsilon}\right)\right) \Delta r\left(x_{\epsilon}\right)+F^{\prime \prime}\left(r\left(x_{\epsilon}\right)\right)\left|\nabla r\left(x_{\epsilon}\right)\right|^{2}\right) \leq  \tag{1.4}\\
& \leq \frac{\epsilon}{F}\left(\frac{F}{G} \Delta r+\frac{F}{G^{2}}\right) \leq 2 \epsilon
\end{align*}
$$

The inequalities (1.1), (1.3) and (1.4) show that the point $x_{\epsilon}$ satisfies the conditions in the Definition.

Finally, we have to show that $h_{\lambda_{0}}$ is smooth at $x_{\epsilon}$. Since $h_{\lambda}(x)=\lambda F(r(x))+L-\epsilon$ it is enough to show that $r$ is smooth at $x_{\epsilon}$. If not, then $x_{\epsilon}$ must be on the cut locus of $p$. In this case we have two possibilities. Either there are two distinct minimizing geodesic segments $\gamma_{1}, \gamma_{2}:\left[0, t_{0}\right] \rightarrow M$ joining $p$ to $x_{\epsilon}$, or there is a geodesic segment $\gamma:\left[0, t_{0}\right] \rightarrow M$ from $p$ to $x_{\epsilon}$ along which $x_{\epsilon}$ is conjugate to $p$.

In both cases we have

$$
t_{0}=r\left(x_{\epsilon}\right)
$$

Let us start with the first case. Let $w=\gamma_{1}^{\prime}\left(t_{0}\right)$ and $v=\gamma_{2}^{\prime}\left(t_{0}\right)$. Since $\gamma_{1}$ and $\gamma_{2}$ are distinct segments we have $w \neq v$. The functions $t \rightarrow r\left(\gamma_{i}(t)\right)$ are differentiable on $\left(0, t_{0}\right)$ (for $\left.i=1,2\right)$ and they have a left-derivative at $t_{0}$.

From the fact that $h_{\lambda_{0}} \geq g$ and $h_{\lambda_{0}}\left(x_{\epsilon}\right)=g\left(x_{\epsilon}\right)$ we have

$$
\liminf _{s \rightarrow 0^{+}} \frac{h_{\lambda_{0}}\left(\gamma_{2}\left(t_{0}+s\right)\right)-h_{\lambda_{0}}\left(\gamma_{2}\left(t_{0}\right)\right)}{s} \geq D_{v} g\left(x_{\epsilon}\right)
$$

where $D_{v} g\left(x_{\epsilon}\right)$ denotes the directional derivative of $g$ at the point $x_{\epsilon}$ in the direction of $v$. Moreover since $g$ is smooth and $h_{\lambda_{0}}$ has a directional derivative at $x_{\epsilon}$ in the direction of $-v$, we also have

$$
-\lambda_{0} F^{\prime}\left(r\left(x_{\epsilon}\right)\right)=D_{-v} h_{\lambda_{0}}\left(x_{\epsilon}\right) \geq D_{-v} g\left(x_{\epsilon}\right)=-D_{v} g\left(x_{\epsilon}\right)
$$

This yields

$$
\begin{equation*}
D_{v} g\left(x_{\epsilon}\right) \geq \lambda_{0} F^{\prime}\left(r\left(x_{\epsilon}\right)\right) \tag{1.5}
\end{equation*}
$$

Combining this with the above inequality we obtain

$$
\liminf _{s \rightarrow 0^{+}} \frac{h_{\lambda_{0}}\left(\gamma_{2}\left(t_{0}+s\right)\right)-h_{\lambda_{0}}\left(\gamma_{2}\left(t_{0}\right)\right)}{s} \geq \lambda_{0} F^{\prime}\left(r\left(x_{\epsilon}\right)\right) .
$$

Taking into account the special form of $h_{\lambda_{0}}$ we have

$$
\begin{equation*}
\liminf _{s \rightarrow 0^{+}} \frac{r\left(\gamma_{2}\left(t_{0}+s\right)\right)-r\left(\gamma_{2}\left(t_{0}\right)\right)}{s} \geq 1 \tag{1.6}
\end{equation*}
$$

This will lead to a contradiction. Since $v \neq w$, there is a $0<c<1$ depending only on the angle of $v$ and $w$, such that

$$
\begin{equation*}
r\left(\gamma_{2}\left(t_{0}+s\right)\right)<t_{0}+c s \tag{1.7}
\end{equation*}
$$

for a small enough $s>0$.

One can see this by connecting the point $\gamma_{1}\left(t_{0}-s\right)$ to $\gamma_{2}\left(t_{0}+s\right)$ by a geodesic segment. Since $\gamma_{1}$ and $\gamma_{2}$ are different there is a $0<c_{1}<1$ such that for a small enough $s>0$ we have $\operatorname{dist}\left(\gamma_{1}\left(t_{0}-s\right), \gamma_{2}\left(t_{0}+s\right)\right)<c_{1} 2 s$ and this implies (1.7). Since $r\left(x_{\epsilon}\right)=r\left(\gamma_{2}\left(t_{0}\right)\right)=t_{0}$ it is easy to see that (1.6) and (1.7) are in direct contradiction.

We now turn our attention to the second case. Since $\gamma$ is distance minimizing between $p$ and $x_{\epsilon}$ the distance function $r$ is smooth at $\gamma(t)$ for $0<t<t_{0}$. Set $m(t)=\Delta r(\gamma(t))$. Then $m(t)$ is also smooth on the interval $\left(0, t_{0}\right)$ and since $\gamma\left(t_{0}\right)$ is conjugate to $p=\gamma(0)$ along $\gamma$ we have

$$
\begin{equation*}
\lim _{t \rightarrow t_{0}^{-}} m(t)=-\infty \tag{1.8}
\end{equation*}
$$

Since $\lambda_{0}>0$, from (1.5) we conclude that $D_{v} g\left(x_{\epsilon}\right)>0$, that is $\nabla g\left(x_{\epsilon}\right) \neq 0$. This implies that the level surface $H=\left\{x \in M: g(x)=g\left(x_{\epsilon}\right)\right\}$ is a smooth hypersurface near $x_{\epsilon}$. Denote by $H_{s}$ the surface parallel to $H$ and passing through the point $\gamma\left(t_{0}-s\right)$ for some $s>0$. Again, since $H$ is smooth near $x_{\epsilon}$ the surface $H_{s}$ will also be smooth near $\gamma\left(t_{0}-s\right)$ for a small enough $s>0$.

It is now clear from (1.8) that for some small $s>0$ we have

$$
m\left(t_{0}-s\right)<\text { trace of the } 2 \text { nd fundamental form of } H_{s} \text { at } \gamma\left(t_{0}-s\right)
$$

where the second fundamental form of $H_{s}$ at $\gamma\left(t_{0}-s\right)$ is taken in the direction of $\gamma^{\prime}\left(t_{0}-s\right)$.

Taking into account that $m\left(t_{0}-s\right)$ is the trace of the 2 nd fundamental form of the geodesic ball $B_{p}\left(t_{0}-s\right)$ around $p$ at the point $\gamma\left(t_{0}-s\right)$ (with respect to the same normal vector $\gamma^{\prime}\left(t_{0}-s\right)$ ) we conclude that there has to be a point $q_{s} \in H_{s}$, sufficiently close to $\gamma\left(t_{0}-s\right)$, that lies inside $B_{p}\left(t_{0}-s\right)$. This means that

$$
r\left(q_{s}\right)<t_{0}-s
$$

Since $H_{s}$ is parallel to $H$ we have a point on $q \in F$ such that $\operatorname{dist}\left(q_{s}, q\right)=s$. Combining this with the above inequality we have

$$
r(q)<t_{0}=r\left(x_{\epsilon}\right)
$$

Taking into account that $F$ is strictly increasing we obtain

$$
h_{\lambda_{0}}(q)=\lambda_{0} F(r(q))+L-\epsilon<\lambda_{0} F\left(r\left(x_{\epsilon}\right)\right)+L-\epsilon=h_{\lambda_{0}}\left(x_{\epsilon}\right)=g\left(x_{\epsilon}\right)=g(q) .
$$

This leads to a contradiction since $h_{\lambda_{0}} \geq g$ on $M$.

## 2. Proof of the Corollary

Let $q \in M$ be a point away from the cut locus of $p$ and $\gamma$ be a geodesic segment parameterized by arc length connecting $p$ to $q$. Set $m(t)=\Delta r(\gamma(t))$ and $R(t)=$ $\operatorname{Ricc}\left(\gamma^{\prime}(t), \gamma^{\prime}(t)\right)$. Then it is well known that $m(t)$ satisfies the Riccati inequality along $\gamma$. Taking into consideration the condition on the Ricci curvature we have

$$
m^{\prime}(t) \leq-R(t)-\frac{m^{2}(t)}{n-1} \leq G^{2}(t)-\frac{m^{2}(t)}{n-1}
$$

This implies that $m$ is decreasing as long as $m>\sqrt{n-1} G$ and a simple argument shows that

$$
m(t)<(\sqrt{n-1}+1) G
$$

for all $t>t_{0}$, where $t_{0}$ is a sufficiently large constant, independent of $G$.
This yields

$$
\Delta r<(\sqrt{n-1}+1) G \quad \text { if } \quad r>t_{0}
$$

for points that are not on the cut locus of $p$. Since $(\sqrt{n-1}+1) G$ satisfies the conditions in the Theorem the proof of the corollary is complete.

## 3. An example

In this section we sketch an example, that shows that the condition in the Theorem is quite optimal. Let $M^{n}$ be a Hadamard manifold that is rotationally symmetric around $p \in M^{n}$.

Let $r$ be the distance function from $p$ and assume that $\Delta r(x)>G(r)$ for all $x \in M^{n}$, where $G$ satisfies the conditions:

$$
G \geq 1, \quad G^{\prime} \geq 0, \quad \text { and } \quad \int_{0}^{\infty} \frac{d t}{G(t)}<\infty
$$

Then there is a bounded function $h: M \rightarrow \mathbb{R}$ which shows that the manifold $M^{n}$ does not satisfy the Omori-Yau maximum principle. To construct $h$ we need the following lemma.

Lemma. Let $G:[0, \infty) \rightarrow \mathbb{R}$ be a function satisfying the conditions:

$$
G \geq 1, \quad G^{\prime} \geq 0, \quad \text { and } \quad \int_{0}^{\infty} \frac{d t}{G(t)}<\infty
$$

Then there is a function $H:[0, \infty) \rightarrow \mathbb{R}$ such that

$$
H \geq 1 / 2, \quad H^{\prime} \geq 0, \quad 2 H \leq G, \quad H^{\prime} \leq H^{2} \quad \text { and } \quad \int_{0}^{\infty} \frac{d t}{H(t)}<\infty
$$

First we construct the function $h: M^{n} \rightarrow \mathbb{R}$ and give the proof of the Lemma later.

Let

$$
h(x)=\int_{0}^{r(x)} \frac{d t}{H(t)}
$$

The last condition on $H$ in the Lemma implies that $h$ is bounded from above. A simple computation shows that

$$
\Delta h=\frac{\Delta r}{H}-\frac{H^{\prime}}{H^{2}}|\nabla r|^{2}
$$

Since $\Delta r>G(r) \geq 2 H(r),|\nabla r|=1$ and $H^{\prime} \leq H$ we have

$$
\Delta h>2-1=1 .
$$

This clearly shows that the manifold $M^{n}$ does not satisfy the Omori-Yau maximum principle.

All that remains is to prove the Lemma.
Proof of Lemma. Let $A \subset(0, \infty)$ be defined as

$$
A=\left\{t>0: \frac{G^{\prime}(t)}{2}>\left(\frac{G(t)}{2}\right)^{2}\right\}
$$

It is an open set therefore

$$
A=\cup I_{n},
$$

where $I_{n}=\left(t_{n}, s_{n}\right)$ are disjoint open intervals.
This is the set where $G / 2$ grows too fast. We obtain $H$ by modifying $G / 2$ on a slightly larger set so that it will never grow too fast, that is $H^{\prime} \leq H^{2}$.

For a given $n$ define the function $k_{n}(t)$ to be

$$
k_{n}(t)=\frac{1}{a_{n}-t},
$$

where $a_{n}$ is chosen such that $k_{n}\left(t_{n}\right)=G\left(t_{n}\right) / 2$. Then we have
$k_{n}\left(t_{n}\right)=\frac{G\left(t_{n}\right)}{2}, \quad k_{n}^{\prime}(t)=k_{n}^{2}(t) \quad$ and $\quad \frac{G^{\prime}(t)}{2}>\left(\frac{G(t)}{2}\right)^{2} \quad$ for $\quad t \in\left(t_{n}, \min \left\{s_{n}, a_{n}\right\}\right)$.
This implies that

$$
k_{n}(t)<\frac{G(t)}{2} \quad \text { for } \quad t \in\left(t_{n}, \min \left\{s_{n}, a_{n}\right\}\right)
$$

Let $v_{n}>t_{n}$ be the first point where $k_{n}\left(v_{n}\right)=G\left(v_{n}\right) / 2$. Such point must exists since $\lim _{t \rightarrow a_{n}} k_{n}(t)=\infty$. Therefore we have $t_{n}<s_{n}<v_{n}<a_{n}$ and as a result $J_{n}=\left(t_{n}, v_{n}\right) \supset I_{n}$.

The intervals $I_{n}$ are all disjoint but $J_{n}$ are not necessarily disjoint intervals. However if $J_{n} \cap J_{m} \neq \emptyset$, then either $J_{n} \subset J_{m}$ or $J_{m} \subset J_{n}$. This follows simply from the way the intervals $J_{n}$ were constructed and from the fact that the graphs of the functions $1 /(a-t), t<a$ and $1 /(b-t), t<b$ are translates of each other.

Therefore we can select a pairwise disjoint family of intervals $J_{n_{l}}$ such that $B=\cup J_{n}=\cup J_{n_{l}}$. To simplify the notation without loss of generality we can assume that the intervals $J_{n}$ are already pairwise disjoint.

We can now define the function $H(t)$ as follows

$$
H(t)= \begin{cases}\frac{G(t)}{2} & \text { if } \quad t \notin B=\cup J_{n} \\ \frac{1}{a_{n}-t} & \text { if } t \in J_{n}\end{cases}
$$

It is clear from the construction that $H$ satisfies the first four properties in the Lemma. It remains to show that it will satisfy the remaining property

$$
\begin{equation*}
\int_{0}^{\infty} \frac{d t}{H(t)}<\infty \tag{3.1}
\end{equation*}
$$

We can write

$$
\int_{0}^{\infty} \frac{d t}{H(t)}=\int_{B} \frac{d t}{H(t)}+\int_{\mathbb{R}^{+}-B} \frac{d t}{H(t)}
$$

The second integral is clearly finite since

$$
\int_{\mathbb{R}^{+}-B} \frac{d t}{H(t)}=\int_{\mathbb{R}^{+}-B} \frac{2 d t}{G(t)}<\infty
$$

The first integral can be computed as follows

$$
\int_{B} \frac{d t}{H(t)}=\int_{\cup J_{n}} \frac{d t}{H(t)}=\sum_{n=1}^{\infty} \int_{t_{n}}^{v_{n}} a_{n}-t d t=\frac{1}{2} \sum_{n=1}^{\infty}\left(a_{n}-t_{n}\right)^{2}-\left(a_{n}-v_{n}\right)^{2}
$$

From the construction of the intervals $J_{n}$ and the function $H$ one obtains that

$$
a_{n}-t_{n}=\frac{2}{G\left(t_{n}\right)} \quad \text { and } \quad a_{n}-v_{n}=\frac{2}{G\left(v_{n}\right)} .
$$

To show that the infinite sum above is finite it is enough to show that any partial-sum is bounded by a fixed constant. For this reason consider the sum

$$
\sum_{n=1}^{m}\left(a_{n}-t_{n}\right)^{2}-\left(a_{n}-v_{n}\right)^{2}=\sum_{n=1}^{m}\left(\frac{2}{G\left(t_{n}\right)}\right)^{2}-\left(\frac{2}{G\left(v_{n}\right)}\right)^{2}
$$

By rearranging the terms if necessary, without loss of generality we can assume that

$$
t_{1}<v_{1}<t_{2}<v_{2}<\ldots .<t_{n}<v_{n}<t_{n+1}<v_{n+1}<\ldots<t_{m}<v_{m}
$$

Taking into consideration that $G(t)$ is an increasing function, we obtain that

$$
\sum_{n=1}^{m}\left(a_{n}-t_{n}\right)^{2}-\left(a_{n}-v_{n}\right)^{2}=\sum_{n=1}^{m}\left(\frac{2}{G\left(t_{n}\right)}\right)^{2}-\left(\frac{2}{G\left(v_{n}\right)}\right)^{2}<\left(\frac{2}{G\left(t_{1}\right)}\right)^{2}
$$

This shows that the above sum is finite, which in turn proves (3.1). This completes the proof of the lemma.
