# A simple proof of the Fundamental Theorem of Calculus for the Lebesgue integral 

March, 2012

Rodrigo López Pouso<br>Departamento de Análise Matemática<br>Facultade de Matemáticas, Universidade de Santiago de Compostela, Campus Sur 15782 Santiago de Compostela, Spain.

#### Abstract

This paper contains a new elementary proof of the Fundamental Theorem of Calculus for the Lebesgue integral. The hardest part of our proof simply concerns the convergence in $L^{1}$ of a certain sequence of step functions, and we prove it using only basic elements from Lebesgue integration theory.

## 1 Introduction

Let $f:[a, b] \longrightarrow \mathbb{R}$ be absolutely continuous on $[a, b]$, i.e., for every $\varepsilon>0$ there exists $\delta>0$ such that if $\left\{\left(a_{j}, b_{j}\right)\right\}_{j=1}^{n}$ is a family of pairwise disjoint subintervals of $[a, b]$ satisfying

$$
\sum_{j=1}^{n}\left(b_{j}-a_{j}\right)<\delta
$$

then

$$
\sum_{j=1}^{n}\left|f\left(b_{j}\right)-f\left(a_{j}\right)\right|<\varepsilon .
$$

Classical results ensure that $f$ has a finite derivative almost everywhere in $I=[a, b]$, and that $f^{\prime} \in \mathrm{L}^{1}(I)$, see [3] or [8, Corollary 6.83]. These results, which we shall use in this paper, are the first steps in the proof of the main connection between absolute continuity and Lebesgue integration: the Fundamental Theorem of Calculus for the Lebesgue integral.

Theorem 1.1 If $f: I=[a, b] \longrightarrow \mathbb{R}$ is absolutely continuous on $I$ then

$$
f(b)-f(a)=\int_{a}^{b} f^{\prime}(x) d x \quad \text { in Lebesgue's sense. }
$$

In this note we present a new elementary proof to Theorem 1.1 which seems more natural and easy than the existing ones. Indeed, our proof can be sketched simply as follows:

1. We consider a well-known sequence of step functions $\left\{h_{n}\right\}_{n \in \mathbb{N}}$ which tends to $f^{\prime}$ almost everywhere in $I$ and, moreover,

$$
\int_{a}^{b} h_{n}(x) d x=f(b)-f(a) \quad \text { for all } n \in \mathbb{N} \text {. }
$$

2. We prove, by means of elementary arguments, that

$$
\lim _{n \rightarrow \infty} \int_{a}^{b} h_{n}(x) d x=\int_{a}^{b} f^{\prime}(x) d x
$$

More precise comparison with the literature on Theorem 1.1 and its several proofs will be given in Section 3.

In the sequel $m$ stands for the Lebesgue measure in $\mathbb{R}$.

## 2 Proof of Theorem 1.1

For each $n \in \mathbb{N}$ we consider the partition of the interval $I=[a, b]$ which divides it into $2^{n}$ subintervals of length $(b-a) 2^{-n}$, namely

$$
x_{n, 0}<x_{n, 1}<x_{n, 2}<\cdots<x_{n, 2^{n}},
$$

where $x_{n, i}=a+i(b-a) 2^{-n}$ for $i=0,1,2, \ldots, 2^{n}$.
Now we construct a step function $h_{n}:[a, b) \longrightarrow \mathbb{R}$ as follows: for each $x \in[a, b)$ there is a unique $i \in\left\{0,1,2, \ldots, 2^{n}-1\right\}$ such that

$$
x \in\left[x_{n, i}, x_{n, i+1}\right),
$$

and we define

$$
h_{n}(x)=\frac{f\left(x_{n, i+1}\right)-f\left(x_{n, i}\right)}{x_{n, i+1}-x_{n, i}}=\frac{2^{n}}{b-a}\left[f\left(x_{n, i+1}\right)-f\left(x_{n, i}\right)\right] .
$$

On the one hand, the construction of $\left\{h_{n}\right\}_{n \in \mathbb{N}}$ implies that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} h_{n}(x)=f^{\prime}(x) \quad \text { for all } x \in[a, b) \backslash N, \tag{2.1}
\end{equation*}
$$

where $N \subset I$ is a null-measure set such that $f^{\prime}(x)$ exists for all $x \in I \backslash N$.
On the other hand, for each $n \in \mathbb{N}$ we compute
$\int_{a}^{b} h_{n}(x) d x=\sum_{i=0}^{2^{n}-1} \int_{x_{n, i}}^{x_{n, i+1}} h_{n}(x) d x=\sum_{i=0}^{2^{n}-1}\left[f\left(x_{n, i+1}\right)-f\left(x_{n, i}\right)\right]=f(b)-f(a)$,
and therefore it only remains to prove that

$$
\lim _{n \rightarrow \infty} \int_{a}^{b} h_{n}(x) d x=\int_{a}^{b} f^{\prime}(x) d x
$$

Let us prove that, in fact, we have convergence in $\mathrm{L}^{1}(I)$, i.e.,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{a}^{b}\left|h_{n}(x)-f^{\prime}(x)\right| d x=0 \tag{2.2}
\end{equation*}
$$

Let $\varepsilon>0$ be fixed and let $\delta>0$ be one of the values corresponding to $\varepsilon / 4$ in the definition of absolute continuity of $f$.

Since $f^{\prime} \in \mathrm{L}^{1}(I)$ we can find $\rho>0$ such that for any measurable set $E \subset I$ we have

$$
\begin{equation*}
\int_{E}\left|f^{\prime}(x)\right| d x<\frac{\varepsilon}{4} \quad \text { whenever } m(E)<\rho . \tag{2.3}
\end{equation*}
$$

The following lemma will give us fine estimates for the integrals when $\left|h_{n}\right|$ is "small". We postpone its proof for better readability.

Lemma 2.1 For each $\varepsilon>0$ there exist $k, n_{k} \in \mathbb{N}$ such that

$$
k \cdot m\left(\left\{x \in I: \sup _{n \geq n_{k}}\left|h_{n}(x)\right|>k\right\}\right)<\varepsilon .
$$

Lemma 2.1 guarantees that there exist $k, n_{k} \in \mathbb{N}$ such that

$$
\begin{equation*}
k \cdot m\left(\left\{x \in I: \sup _{n \geq n_{k}}\left|h_{n}(x)\right|>k\right\}\right)<\min \left\{\delta, \frac{\varepsilon}{4}, \rho\right\} . \tag{2.4}
\end{equation*}
$$

Let us denote

$$
A=\left\{x \in I: \sup _{n \geq n_{k}}\left|h_{n}(x)\right|>k\right\},
$$

which, by virtue of (2.4) and (2.3), satisfies the following properties:

$$
\begin{align*}
m(A) & <\delta,  \tag{2.5}\\
k \cdot m(A) & <\frac{\varepsilon}{4},  \tag{2.6}\\
\int_{A}\left|f^{\prime}(x)\right| d x & <\frac{\varepsilon}{4} . \tag{2.7}
\end{align*}
$$

We are now in a position to prove that the integrals in (2.2) are smaller than $\varepsilon$ for all sufficiently large values of $n \in \mathbb{N}$. We start by noticing that (2.7) guarantees that for all $n \in \mathbb{N}$ we have

$$
\begin{align*}
\int_{I}\left|h_{n}(x)-f^{\prime}(x)\right| d x & =\int_{I \backslash A}\left|h_{n}(x)-f^{\prime}(x)\right| d x+\int_{A}\left|h_{n}(x)-f^{\prime}(x)\right| d x \\
& <\int_{I \backslash A}\left|h_{n}(x)-f^{\prime}(x)\right| d x+\int_{A}\left|h_{n}(x)\right| d x+\frac{\varepsilon}{4} . \tag{2.8}
\end{align*}
$$

The definition of the set $A$ implies that for all $n \in \mathbb{N}, n \geq n_{k}$, we have

$$
\left|h_{n}(x)-f^{\prime}(x)\right| \leq k+\left|f^{\prime}(x)\right| \quad \text { for almost all } x \in I \backslash A,
$$

so the Dominated Convergence Theorem yields

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int_{I \backslash A}\left|h_{n}(x)-f^{\prime}(x)\right| d x=0 . \tag{2.9}
\end{equation*}
$$

From (2.8) and (2.9) we deduce that there exists $n_{\varepsilon} \in \mathbb{N}, n_{\varepsilon} \geq n_{k}$, such that for all $n \in \mathbb{N}, n \geq n_{\varepsilon}$, we have

$$
\begin{equation*}
\int_{I}\left|h_{n}(x)-f^{\prime}(x)\right| d x<\frac{\varepsilon}{2}+\int_{A}\left|h_{n}(x)\right| d x . \tag{2.10}
\end{equation*}
$$

Finally, we estimate $\int_{A}\left|h_{n}\right|$ for each fixed $n \in \mathbb{N}, n \geq n_{\varepsilon}$. First, we decompose $A=B \cup C$, where

$$
B=\left\{x \in A:\left|h_{n}(x)\right| \leq k\right\} \quad \text { and } \quad C=A \backslash B .
$$

We immediately have

$$
\begin{equation*}
\int_{B}\left|h_{n}(x)\right| d x \leq k \cdot m(B) \leq k \cdot m(A)<\frac{\varepsilon}{4} \quad \text { by (2.6). } \tag{2.11}
\end{equation*}
$$

Obviously, $\int_{C}\left|h_{n}\right|<\varepsilon / 4$ when $C=\varnothing$. Let us see that this inequality holds true when $C \neq \varnothing$. For every $x \in C=\left\{x \in A:\left|h_{n}(x)\right|>k\right\}$ there is a unique index $i \in\left\{0,1,2, \ldots, 2^{n}-1\right\}$ such that $x \in\left[x_{n, i}, x_{n, i+1}\right)$. Since $\left|h_{n}\right|$ is constant on $\left[x_{n, i}, x_{n, i+1}\right)$ we deduce that $\left[x_{n, i}, x_{n, i+1}\right) \subset C$. Thus there exist indexes $i_{l} \in\left\{0,1,2, \ldots, 2^{n}-1\right\}$, with $l=1,2, \ldots, p$ and $i_{l} \neq i_{\tilde{l}}$ if $l \neq \tilde{l}$, such that

$$
C=\bigcup_{l=1}^{p}\left[x_{n, i_{l}}, x_{n, i_{l}+1}\right)
$$

Therefore

$$
\sum_{l=1}^{p}\left(x_{n, i_{l}+1}-x_{n, i_{l}}\right)=m(C) \leq m(A)<\delta \quad \text { by (2.5) }
$$

and then the absolute continuity of $f$ finally comes into action:

$$
\begin{aligned}
\int_{C}\left|h_{n}(x)\right| d x & =\sum_{l=1}^{p} \int_{x_{n, i_{l}}}^{x_{n, i_{l}+1}}\left|h_{n}(x)\right| d x \\
& =\sum_{l=1}^{p}\left|f\left(x_{n, i_{l}+1}\right)-f\left(x_{n, i_{l}}\right)\right|<\frac{\varepsilon}{4}
\end{aligned}
$$

This inequality, along with (2.10) and (2.11), guarantee that for all $n \in$ $\mathbb{N}, n \geq n_{\varepsilon}$, we have

$$
\int_{I}\left|h_{n}(x)-f^{\prime}(x)\right| d x<\varepsilon
$$

thus proving (2.2) because $\varepsilon$ was arbitrary.
Proof of Lemma 2.1. Let $\varepsilon>0$ be fixed and let $\rho>0$ be such that for every measurable set $E \subset I$ with $m(E)<\rho$ we have

$$
\int_{E}\left|f^{\prime}(x)\right| d x<\frac{\varepsilon}{2}
$$

Let $N \subset I$ be as in (2.1) and let $k \in \mathbb{N}$ be sufficiently large so that

$$
m\left(\left\{x \in I \backslash N:\left|f^{\prime}(x)\right| \geq k\right\}\right)<\rho
$$

which implies that

$$
\begin{equation*}
k \cdot m\left(\left\{x \in I \backslash N:\left|f^{\prime}(x)\right| \geq k\right\}\right) \leq \int_{\left\{x \in I \backslash N:\left|f^{\prime}(x)\right| \geq k\right\}}\left|f^{\prime}(x)\right| d x<\frac{\varepsilon}{2} . \tag{2.12}
\end{equation*}
$$

Let us define

$$
E_{j}=\left\{x \in I \backslash N: \sup _{n \geq j}\left|h_{n}(x)\right|>k\right\} \quad(j \in \mathbb{N}) .
$$

Notice that $E_{j+1} \subset E_{j}$ for every $j \in \mathbb{N}$, and $m\left(E_{1}\right)<\infty$, hence

$$
\begin{equation*}
\lim _{j \rightarrow \infty} m\left(E_{j}\right)=m\left(\bigcap_{j=1}^{\infty} E_{j}\right) . \tag{2.13}
\end{equation*}
$$

Clearly, $\cap_{j=1}^{\infty} E_{j} \subset\left\{x \in I \backslash N:\left|f^{\prime}(x)\right| \geq k\right\}$, so we deduce from (2.13) that we can find some $n_{k} \in \mathbb{N}$ such that

$$
m\left(E_{n_{k}}\right) \leq m\left(\left\{x \in I \backslash N:\left|f^{\prime}(x)\right| \geq k\right\}\right)+\frac{\varepsilon}{2 k},
$$

and then (2.12) yields $k \cdot m\left(E_{n_{k}}\right)<\varepsilon$.

## 3 Final remarks

The sequence $\left\{h_{n}\right\}_{n \in \mathbb{N}}$ is used in other proofs of Theorem 1.1, see [1] or [10. The novelty in this paper is our elementary and self-contained proof of (2.2). Incidentally, a revision of the proof of our Lemma 2.1]shows that it holds true for any sequence of measurable functions $\tilde{h}_{n}: E \subset \mathbb{R} \longrightarrow \mathbb{R}$ which converges pointwise almost everywhere to some $h \in \mathrm{~L}^{1}(E)$ and $m(E)<\infty$.

Our proof avoids somewhat technical results often invoked to prove Theorem [1.1. For instance, we do not use any sophisticated estimate for the measure of image sets such as [4, Theorem 7.20], [8, Lemma 6.88] or [10, Proposition 1.2], see also [6]. We do not use the following standard lemma either: an absolutely continuous function having zero derivative almost everywhere is constant, see [4, Theorem 7.16] or [8, Lemma 6.89]. It is worth having a look at [5] for a proof of that lemma using tagged partitions; see also 22 for a proof based on full covers (9]. Concise proofs of Theorem 1.1 follow from the Radon-Nikodym Theorem, see [1], 4] or [7, but this is far from being elementary.

Finally, it is interesting to note that (2.2) easily follows from the Dominated Convergence Theorem when $f$ is Lipschitz continuous on $I$. This fact made the author think about the following project for students in an introductory course to Lebesgue integration.

Project: Two important results for the price of one.

1. Let $f: I=[a, b] \longrightarrow \mathbb{R}$ be Lispchitz continuous on $I$. A deep result (worth to know without proof) guarantees that $f^{\prime}(x)$ exists for almost all $x \in I$, see [4, Theorem 7.8].
Consider the sequence $\left\{h_{n}\right\}_{n \in \mathbb{N}}$ as defined in Section 2 and prove
(a) $\left\{h_{n}(x)\right\}_{n \in \mathbb{N}}$ tends to $f^{\prime}(x)$ for almost all $x \in I$;
(b) $\int_{I} h_{n}(x) d x=f(b)-f(a)$ for all $n \in \mathbb{N}$;
(c) (Use the Dominated Convergence Theorem) $f^{\prime} \in L^{1}(I)$ and

$$
f(b)-f(a)=\int_{a}^{b} f^{\prime}(x) d x \quad \text { in Lebesgue's sense. }
$$

2. Let $g: I=[a, b] \longrightarrow \mathbb{R}$ be Riemann-integrable on $I$ and define

$$
f(x)=(R) \int_{a}^{x} g(s) d s \quad(x \in I),
$$

where $(R) \int$ stands for the Riemann integral.
Use the information in Exercise 1 to deduce that $g \in \mathrm{~L}^{1}(I)$ and

$$
(R) \int_{a}^{b} g(x) d x=\int_{a}^{b} g(x) d x \quad \text { in Lebesgue's sense. }
$$
