DIAMETER CONTROLS AND SMOOTH CONVERGENCE AWAY FROM SINGULAR SETS

SAJJAD LAKZIAN

Abstract. We prove that if a family of metrics, $g_i$, on a compact Riemannian manifold, $M^n$, have a uniform lower Ricci curvature bound and converge to $g_\infty$ smoothly away from a singular set, $S$, with Hausdorff measure, $H^{n-1}(S) = 0$, and if there exists connected precompact exhaustion, $W_j$, of $M^n \setminus S$ satisfying $\text{diam}_g(M^n) \leq D_0$, $\text{Vol}_g(\partial W_j) \leq A_0$ and $\text{Vol}_g(M^n \setminus W_j) \leq V_j$ where $\lim_{j \to \infty} V_j = 0$ then the Gromov-Hausdorff limit exists and agrees with the metric completion of $(M^n \setminus S, g_\infty)$. This is a strong improvement over prior work of the author with Sormani that had the additional assumption that the singular set had to be a smooth submanifold of codimension two. We have a second main theorem in which the Hausdorff measure condition on $S$ is replaced by diameter estimates on the connected components of the boundary of the exhaustion, $\partial W_j$. This second theorem allows for singular sets which are open subregions of the manifold. In addition, we show that the uniform lower Ricci curvature bounds in these theorems can be replaced by the existence of a uniform linear contractibility function. If this condition is removed altogether, then we prove that $\lim_{j \to \infty} d_F(M_j', N_j') = 0$, in which $M_j'$ and $N_j'$ are the settled completions of $(M_i, g_i)$ and $(M_\infty \setminus S, g_\infty)$ respectively and $d_F$ is the Sormani-Wenger Intrinsic Flat distance. We present examples demonstrating the necessity of many of the hypotheses in our theorems. Finally, as an application, we will prove the Candella-de la Ossa's conjecture for Calabi-Yau conifolds.

1. Introduction

In this paper, we will prove results concerning the smooth convergence of Riemannian metrics away from a singular set $S$ and will provide some important application of our results. One definition of smooth convergence away from singularities is as follows:

**Definition 1.1.** We will say that a sequence of Riemannian metrics $g_i$ on a compact manifold $M^n$ converges smoothly away from $S \subset M^n$ to a Riemannian metric $g_\infty$ on $M^n \setminus S$ if for every compact set $K \subset M^n \setminus S$, $g_i$ converge $C^{k, \alpha}$ smoothly to $g_\infty$ as tensors.

Right away from the definition, it is apparent that the global geometry is not well controlled under such convergence. It is natural to ask under what additional conditions the original sequence of manifolds, $M_i = (M^n, g_i)$ have the expected Gromov-Hausdorff (GH) and Sormani-Wenger Intrinsic Flat (SWIF) limits [10] [22]. Recall that there are examples of sequences of metrics on spheres which

Lakzian was partially supported by NSF DMS #1006059.
converge smoothly away from a point singularity which have no subsequence converging in the GH or the SWIF sense, so additional conditions are necessary (c.f. [13]).

Many results concerning GH limits of the $M_i$ have appeared in the literature. For example, Anderson in [2] studies the convergence of Einstein metrics to orbifolds. Bando-Kasue-Nakajima in [4] studies the singularities of the Einstein ALF manifolds. Eyssidieux-Guedj-Zeriahi in [7] prove similar results for the solutions to the complex Monge-Ampere equation. Also Huang in [11], Ruan-Zhong in [18], Sesum in [19], Tian in [23] and Tosatti in [25] study the convergence of Kahler-Einstein metrics and Kahler-Einstein orbifolds. However, even in this setting, the relationship is not completely clear and the limits need not agree (see [3].) In Tian-Viaclovsky [24], compactness results for various classes Riemannian metrics in dimension four were obtained in particular for anti-self-dual metrics, Kahler metrics with constant scalar curvature, and metrics with harmonic curvature. Also the relation between different notions of convergence for Ricci flow is studied in [12].

Here we first study SWIF limits of sequences of manifolds which converge away from a singular set and then prove the SWIF and GH limits agree using techniques developed in prior work of the author with Sormani in [LS]. All necessary background on these techniques and on SWIF convergence is reviewed in Section 2.

**Theorem 1.2.** Let $M_i = (M^n, g_i)$ be a sequence of compact oriented Riemannian manifolds such that there is a subset, $S$, with $H^{n-1}(S) = 0$ and connected precompact exhaustion, $W_j$, of $M \setminus S$ satisfying (5) with $g_i$ converge smoothly to $g_\infty$ on each $W_j$:

1. $\text{diam}_{M_i}(W_j) \leq D_0 \quad \forall i \geq j$,
2. $\text{Vol}_{g_i}(\partial W_j) \leq A_0$,

and

3. $\text{Vol}_{g_i}(M \setminus W_j) \leq V_j$ where $\lim_{j \to \infty} V_j = 0$.

Then

4. $\lim_{j \to \infty} d_{\mathcal{F}}(M'_i, N') = 0$.

where $M'_i$ and $N'$ are the settled completion of $(M, g_i)$ and $(M \setminus S, g_\infty)$ respectively.

Here $\text{diam}_M(W)$ is the extrinsic diameter found by

5. $\text{diam}_M(W) = \sup \{d_M(x, y) : x, y \in W\}$

where $d_M$ is the extrinsic distance measured in $M$ rather than $W$:

6. $d_M(x, y) = \inf \{L(C) : C : [0, 1] \to M, \, C(0) = x, \, C(1) = y\}$.

We write $M_i = (M, g_i)$. The intrinsic diameter of $W$ is then $\text{diam}_W(W)$. See Remark 3.3 for the necessity of the hypotheses in Theorem 1.2.

Under the conditions of Theorem 1.2, if we assume in addition that the manifolds in the sequence have a uniform lower bound on Ricci curvature, then the
SWIF and GH limits agree, so we obtain the following new theorem relating the GH limit to the metric completion of the smooth limit away from the singularity:

**Theorem 1.3.** Let \( M_i = (M, g_i) \) be a sequence of oriented compact Riemannian manifolds with uniform lower Ricci curvature bounds,

\[
\text{Ricci}_{g_i}(V, V) \geq (n - 1)H_{g_i}(V, V) \quad \forall V \in T M_i ,
\]

which converges smoothly away from a singular set, \( S \), with \( H^{n-1}(S) = 0 \). If there is a connected precompact exhaustion, \( W_j \), of \( M \setminus S \),

\[
\bar{W}_j \subset W_{j+1} \quad \text{with} \quad \bigcup_{j=1}^{\infty} W_j = M \setminus S ,
\]

satisfying

\[
diam(M_i) \leq D_0 ,
\]

\[
Vol_{g_i}(\partial W_j) \leq A_0 ,
\]

and

\[
Vol_{g_i}(M \setminus W_j) \leq V_j \quad \text{where} \quad \lim_{j \to \infty} V_j = 0 ,
\]

then

\[
\lim_{j \to \infty} d_{GH}(M_j, N) = 0 ,
\]

where \( N \) is the metric completion of \( (M \setminus S, g_\infty) \).

See Remark 3.3 for the necessity of our hypotheses in Theorem 1.3. We may replace the Ricci condition by a condition on contractibility (see Theorem 3.6.) For the necessity of the hypotheses in this theorem see [13, Remark 6.8].

Theorems 1.2-1.3 improve upon a prior result of the author and Sormani in [LS] because we no longer require the singular set to be a smooth submanifold of codimension 2 as was required there. In fact, we may even allow the singular set to be an open domain as long as we have sufficiently strong controls on the diameters of the exhaustion’s boundaries as seen in the following theorem:

**Theorem 1.4.** Let \( M_i = (M, g_i) \) be a sequence of Riemannian manifolds such that there is a closed subset, \( S \), and a connected precompact exhaustion, \( W_j \), of \( M \setminus S \)

satisfying (8) such that \( g_i \) converge smoothly to \( g_\infty \) on each \( W_j \).

If each connected component of \( M \setminus W_j \) has a connected boundary,

\[
\limsup_{i \to \infty} \left\{ \sum_{\beta} \text{diam}(\Omega^\beta_{j,0})(\Omega^\beta_j) : \Omega^\beta_j \text{ connected component of } \partial W_j \right\} \leq B_j ,
\]

where \( \lim_{j \to \infty} B_j = 0 \), and if we have

\[
diam_{(W_j, g)}(W_j) \leq D_{int} ,
\]

\[
Vol_{g}(\partial W_j) \leq A_0 ,
\]

then

\[
\lim_{j \to \infty} d_{GH}(M_j, N) = 0 ,
\]

where \( N \) is the metric completion of \( (M \setminus S, g_\infty) \).
\[ \text{Vol}_g(M \setminus W_j) \leq V_j \text{ where } \lim_{j \to \infty} V_j = 0, \]

then

\[ \lim_{j \to \infty} d_F(M'_j, N') = 0. \]

where \( N' \) is the settled completion of \((M \setminus S, g_{\infty})\).

See Remark 4.2 for the necessity of our hypotheses in Theorem 1.4.

In presence of a uniform lower Ricci curvature bound, Theorem 1.4 can be applied to prove the following theorem:

**Theorem 1.5.** Let \( M_i = (M_i, g_i) \) be a sequence of oriented Riemannian manifolds with uniform lower Ricci curvature bounds,

\[ \text{Ricci}_{g_i}(V, V) \geq (n - 1)H_{g_i}(V, V) \quad \forall V \in TM_i, \]

which converges smoothly away from a closed singular set, \( S \).

If there is a connected precompact exhaustion, \( W_j \), of \( M \setminus S \), satisfying (8) such that each connected component of \( M \setminus W_j \) has a connected boundary,

\[ \limsup_{i \to \infty} \sum_{\beta} \text{diam}_{(\Omega_{\beta}^j, g_i)}(\Omega_{\beta}^j) : \Omega_{\beta}^j \text{ connected component of } \partial W_j \leq B_j, \]

where \( \lim_{j \to \infty} B_j = 0 \), and if we have

\[ \text{diam}(M_i) \leq D_0, \]

\[ \text{diam}_{(W_j, g_i)}(W_j) \leq D_{\text{int}}, \]

and volume controls:

\[ \text{Vol}_{g_i}(\partial W_j) \leq A_0, \]

\[ \text{Vol}_{g_i}(M \setminus W_j) \leq V_j \text{ such that } \lim_{j \to \infty} V_j = 0, \]

then

\[ \lim_{j \to \infty} d_{\text{GH}}(M_j, N) = 0. \]

where \( N \) is the metric completion of \((M \setminus S, g_{\infty})\).

In Theorems 1.3 and 1.5, the diameter hypothesis \( \text{diam}(M_i) \leq D_0 \) is not necessary when the Ricci curvature is nonnegative (see Lemma 2.14).

The Ricci curvature condition in Theorems 1.3 and 1.5 may be replaced by a requirement that the sequence of manifolds have a uniform linear contractibility function (see Theorem 4.5 and Theorem 3.6). See Definition 2.4 for the definition of a contractibility function. Recall that Greene-Petersen have a compactness theorem for sequences of manifolds with uniform contractibility functions and upper bounds on their volume [9].

Subsequently, as an application of our Theorems and relying on diameter bounds and convergence results obtained by Rong-Zhang [17] and Tossati [25], we will
prove the following Theorem which is known in the literature as the Candella-de la Ossa’s conjecture, for Calabi-Yau conifolds.

**Theorem 1.6.** Let $M_0$ be a singular $n-$dimensional normal variety with isolated conifold singularities then,

(i) Extremal transitions $\tilde{M} \to M_0 \to M_t \ (t \neq 0)$ are continuous with respect to the Gromov-Hausdorff distance i.e. there exist families of Ricci-flat Kähler metrics $\tilde{g}_s$ on $\tilde{M}$ and $g_t$ on $M_t$ and compact metric space $(X, d_X)$ such that

\[
(\tilde{M}, \tilde{g}_s) \xrightarrow{G-H} (X, d_X) \xleftarrow{G-H} (M_t, g_t)
\]

(ii) Flops $\tilde{M}_1 \to M_0 \to \tilde{M}_2$ are continuous with respect to the Gromov-Hausdorff distance i.e. there families of Ricci-flat Kähler metrics $\tilde{g}_{1,s}$ and a compact metric space $(X, d_X)$ such that

\[
(\tilde{M}_1, \tilde{g}_{1,s}) \xrightarrow{G-H} (X, d_X) \xleftarrow{G-H} (\tilde{M}_2, \tilde{g}_{2,s})
\]

**Remark 1.7.** Different proofs of Candella-de la Ossa’s conjecture in various settings has been given in Rong-Zhang [17] and Song [20]. Our proof is a more coarse geometric proof and to a great deal avoids the advanced PDE techniques used in other proofs.

The paper is organized as follows: In Section 2 we will briefly review all the notions and theorems that we have used in this paper; In Section 3 we give a proof of our theorems which assume $H^{n−1}(S) = 0$ [Theorem 1.2, Theorem 1.3, and Theorem 3.6]; Section 4 is devoted to the proof of our theorems which replace the Hausdorff measure hypothesis with diameter bounds [Theorem 1.4, Theorem 1.5, and Theorem 4.5]; Section 5 discusses a few interesting examples to illustrate the underlying phenomena and also to prove the necessity of some our hypotheses and finally, In Section 6 we present a proof of Theorem 1.6.

**Acknowledgements**

The author would like to thank Christina Sormani for her constant encouragement, assistance with exposition and particularly for sketching ideas towards Examples 5.5 and 5.6. Also many thanks go to Xiaochun Rong for teaching the author about the Candella-de la Ossa’s conjecture. He would like to thank Dimitri Burago specifically for drawing Example 5.7 in conversations with his advisor that were then related to him. The author also would like to express his gratitude to Jeff Cheeger and Fanghua Lin for teaching him advanced Riemannian Geometry and Geometric Measure Theory. The author is very grateful to Karl-Theodor Sturm for his interest in the author’s research and for the opportunity to work with him as a postdoctoral fellow at the Hausdorff Center for Mathematics in Bonn.
2. Background

2.1. Metric Completion and Settled Completion. We give a very brief review of the definitions of metric completion and settled completion of a metric space:

**Definition 2.1.** Given a precompact metric space, \( X \), the metric completion, \( \bar{X} \) of \( X \) is the space of Cauchy sequences, \( \{x_j\} \), in \( X \) with the metric

\[
d((x_j), (y_j)) = \lim_{j \to \infty} d_X(x_j, y_j),
\]

and where two Cauchy sequences are identified if the distance between them is 0. There is an isometric embedding, \( \varphi : X \to \bar{X} \), defined by \( \varphi(x) = \{x\} \) where \( \{x\} \) is a constant sequence. Lipschitz functions, \( F : X \to Y \), extend to \( F : \bar{X} \to Y \) via \( F(\{x_j\}) = \lim_{j \to \infty} F(x_j) \) as long as \( Y \) is complete.

The definition of the settled completion which is essential in studying the Intrinsic Flat convergence of metric spaces is as follows

**Definition 2.2 (Sormani-Wenger [22]).** The settled completion, \( X' \), of a metric space \( X \) with a measure \( \mu \) is the collection of points \( x \) in the metric completion \( \bar{X} \) which have positive lower density

\[
\liminf_{r \to 0} \frac{\mu(B_p(r))}{r^m} > 0.
\]

The resulting space is then “completely settled”.

2.2. GH and SWIF Distances. The Gromov-Hausdorff (GH) distance was defined by Gromov as

\[
d_{GH}(X_1, X_2) = \inf \left\{ d_H^Z(\varphi_1(X_1), \varphi_2(X_2)) : \varphi_i : X_i \to Z \right\}
\]

where the infimum is taken over all common metric spaces, \( Z \), and all isometric embeddings, \( \varphi_i : X_i \to Z \). Limit spaces obtained from the Gromov-Hausdorff convergence are compact metric spaces [10].

The Sormani Wenger Intrinsic Flat (SWIF) distance is defined similarly by replacing the Hausdorff distance by the flat distance, viewing \( \varphi_i(M_i) \) as integral current spaces in the sense of [1]. The limit spaces obtained under intrinsic flat convergence are “integral current spaces”: completely settled metric spaces with an integral current structure that defines a notion of integration over \( m \)-forms. When the limit is the settled completion of an open manifold, this the integral current structure is simply defined by integration over that open manifold (see [22] for more details.)

The SWIF distance, \( d_F(M_1, M_2) \), is estimated by explicitly constructing a filling manifold, \( B^{m+1} \), between the two given manifolds, finding the excess boundary manifold \( A^m \) satisfying

\[
\int_{\varphi_1(M_1)} \omega - \int_{\varphi_2(M_2)} \omega = \int_B d\omega + \int_A \omega,
\]

and summing their volumes

\[
d_F(M_1^m, M_2^m) \leq \text{Vol}_m(A^m) + \text{Vol}_{m+1}(B^{m+1}).
\]
In the next subsection we present review a theorem which clarifies the concept of the intrinsic flat distance while proving a means of estimating it.

2.3. Estimating the Gromov Hausdorff and Intrinsic Flat Distance. We can estimate both of these distances by applying the following theorem which was proven in prior work of the author with Sormani [13] by constructing an explicit space $Z$ and isometric embeddings $\varphi_i$. Here we have cut and pasted the exact theorem statement along with the corresponding figure from that paper:

**Theorem 2.3.** Suppose $M_1 = (M, g_1)$ and $M_2 = (M, g_2)$ are oriented precompact Riemannian manifolds with diffeomorphic subregions $U_i \subset M_i$ and diffeomorphisms $\psi_i : U \rightarrow U_i$ such that

(32) $\psi_i^*g_1(V, V) < (1 + \varepsilon)^2\psi_i^*g_2(V, V) \quad \forall V \in TU,$

and

(33) $\psi_i^*g_2(V, V) < (1 + \varepsilon)^2\psi_i^*g_1(V, V) \quad \forall V \in TU.$

Taking the extrinsic diameters,

(34) $D_{U_i} = \sup\{\text{diam}_M(W) : W \text{ is a connected component of } U_i\} \leq \text{diam}(M_i).$

we define a hemispherical width,

(35) $a > \frac{\arccos(1 + \varepsilon)^{-1}}{\pi} \max\{D_{U_1}, D_{U_2}\}.$

Taking the difference in distances with respect to the outside manifolds,

(36) $\lambda = \sup_{x,y \in U} |d_{M_1}(\psi_1(x), \psi_1(y)) - d_{M_2}(\psi_2(x), \psi_2(y))|,$

we define heights,

(37) $h = \sqrt{\lambda(\max\{D_{U_1}, D_{U_2}\} + \lambda/4)},$

and

(38) $\bar{h} = \max\{h, \sqrt{\varepsilon^2 + 2\varepsilon D_{U_1}}, \sqrt{\varepsilon^2 + 2\varepsilon D_{U_2}}\}.$

Then the Gromov-Hausdorff distance the metric completions is bounded,

(39) $d_{GH}(\bar{M}_1, \bar{M}_2) \leq a + 2\bar{h} + \max\{d^{M_1}_H(U_1, M_1), d^{M_2}_H(U_2, M_2)\},$

and the intrinsic flat distance between the emphsettled completions is bounded,

$d_F(M_1', M_2') \leq (2\bar{h} + a) \left( \text{Vol}_m(U_1) + \text{Vol}_m(U_2) + \text{Vol}_{m-1}(\partial U_1) + \text{Vol}_{m-1}(\partial U_2) \right) + \text{Vol}_m(M_1 \setminus U_1) + \text{Vol}_m(M_2 \setminus U_2).$

Note that permission to reprint this figure along with the statement of Theorem 2.3 has been granted by the author and Christina Sormani who own the copyright to this figure that first appeared in [13].
2.4. Review of Compactness Theorems.

**Definition 2.4.** A function $\rho : [0, r_0] \rightarrow [0, \infty)$ is a contractibility function for a manifold $M$ with metric $g$ if every ball $B_p(r)$ is contractible within $B_p(\rho(r))$.

**Theorem 2.5** (Gromov [10]). A sequence of compact Riemannian manifolds, $(M_j, g_j)$, such that $\text{diam}(M_j) \leq D$ and $\text{Ricci}_{M_j} \geq -H$, has a subsequence converging in the Gromov-Hausdorff sense to a metric space $(X, d)$.

**Theorem 2.6** (Greene-Petersen [9]). A sequence of compact Riemannian manifolds, $(M_j, g_j)$, such that $\text{Vol}(M_j) \leq V$ and such that there is a uniform contractibility function, $\rho : [0, r_0] \rightarrow [0, \infty)$, for all the $M_j$, has a subsequence converging in the Gromov-Hausdorff sense to a metric space $(X, d)$.

In [21] the following theorems were proven which can be applied to deduce information about the Gromov-Hausdorff limit of a sequence.

**Theorem 2.7** (Sormani-Wenger [22]). If a sequence of oriented compact Riemannian manifolds, $(M_j, g_j)$, with a uniform linear contractibility function, $\rho : [0, \infty) \rightarrow [0, \infty)$ and a uniform upper bound on volume, $\text{Vol}(M_j) \leq V$, converges in the Gromov-Hausdorff sense to $(X, d)$, then it converges in the intrinsic flat Sense to $(X, d, T)$ (see Theorem 4.14 of [22]).

Recall that, in general, the intrinsic flat limits and Gromov-Hausdorff limits need not agree [13] Examples 2.3 and 2.3] because intrinsic flat limits do not include points with 0 density as in [28]. In fact intrinsic flat limits may exist when Gromov-Hausdorff limits do not [Example 5.11].

**Theorem 2.8** (Sormani-Wenger). If a sequence of oriented compact Riemannian manifolds, $(M_j, g_j)$, such that $\text{diam}(M_j) \leq D$ and $\text{Ricci}_{M_j} \geq 0$ and $\text{vol}(M_j) \geq V_0$ converges in the Gromov-Hausdorff sense to $(X, d)$, then it converges in the intrinsic flat Sense to $(X, d, T)$ (see Theorem 4.16 of [22]).

This theorem is conjectured to hold with uniform lower bounds on Ricci curvature [22].
2.5. **Review of Smooth Convergence away from Singular Sets.** Here we review results from our prior work with Sormani in [13]. We need the following key definition (a bound on the metric distortions) in order to state the results. Recall the definition of the extrinsic distance in (6).

**Definition 2.9.** Given a sequence of Riemannian manifolds \( M_i = (M, g_i) \) and an open subset, \( U \subset M \), a connected precompact exhaustion, \( W_j \), of \( U \) satisfying (8) is uniformly well embedded if there exist a \( \lambda_0 \) such that

\[
\limsup_{j \to \infty} \limsup_{k \to \infty} \limsup_{i \to \infty} \lambda_{i,j,k} \leq \lambda_0,
\]

and

\[
\limsup_{k \to \infty} \lambda_{i,j,k} = \lambda_{i,j} \text{ where } \limsup_{i \to \infty} \lambda_{i,j} = \lambda_j \text{ and } \lim_{j \to \infty} \lambda_j = 0.
\]

where,

\[
\lambda_{i,j,k} = \sup_{x,y \in W_j} |d_{(W_k,g_i)}(x,y) - d_{(M,g_i)}(x,y)|.
\]

The author and Sormani in [13] have proven:

**Theorem 2.10.** Let \( M_i = (M, g_i) \) be a sequence of Riemannian manifolds such that there is a closed subset, \( S \), and a uniformly well embedded connected precompact exhaustion, \( W_j \), of \( M \setminus S \) satisfying (8) such that \( g_i \) converge smoothly to \( g_\infty \) on each \( W_j \) with

\[
\text{diam}_{M_i}(W_j) \leq D_0 \quad \forall i \geq j,
\]

\[
\text{Vol}_{g_i}(\partial W_j) \leq A_0,
\]

and

\[
\text{Vol}_{g_i}(M \setminus W_j) \leq V_j \text{ where } \lim_{j \to \infty} V_j = 0,
\]

Then

\[
\lim_{j \to \infty} d_F(M'_j, N') = 0.
\]

where \( N' \) is the settled completion of \((M \setminus S, g_\infty)\).

**Remark 2.11.** Example [5.6] demonstrates the necessity of well-embeddedness condition in Theorem 2.10.

**Lemma 2.12.** Let \( M_i = (M, g_i) \) be a sequence of Riemannian manifolds such that there is a closed subset, \( S \), and a connected precompact exhaustion, \( W_j \), of \( M \setminus S \) satisfying (8) such that \( g_i \) converge smoothly to \( g_\infty \) on each \( W_j \). If \( \text{Vol}_{g_\infty}(M \setminus S) < \infty \) and

\[
\text{Vol}_{g_i}(M \setminus W_j) \leq V_j \text{ where } \lim_{j \to \infty} V_j = 0,
\]

then there exists a uniform \( V_0 > 0 \) such that

\[
\text{Vol}_{g_i}(M) < V_0.
\]
Proposition 2.13. Suppose we have a sequence of manifolds, \( M_j = (M, g_j) \) with a uniform lower bound on Ricci curvature and
\[
\text{Vol}(M_j) \leq V_0,
\]
converging smoothly away from a singular set to \((M \setminus S, g_\infty)\). Suppose also that \((M, g_j)\) converge in the intrinsic flat sense to \(N'\) where \(N'\) is the settled completion of \((M \setminus S, g_\infty)\). Then
\[
d_{GH}(\bar{M}_j, \bar{N}) \to 0,
\]
and \(\bar{N} = N'\).

Lemma 2.14. Suppose we have a sequence of manifolds, \( M_j = (M, g_j) \) with non-negative Ricci curvature and
\[
\text{Vol}(M_j) \leq V_0,
\]
converging smoothly away from a singular set to \((M \setminus S, g_\infty)\) then
\[
diam(M_i(W_j)) \leq diam(M_i) \leq D_0 \quad \forall i \geq j.
\]

Theorem 2.15. Let \( M_i = (M, g_i) \) be a sequence of compact oriented Riemannian manifolds with a uniform linear contractibility function, \( \rho \), which converges smoothly away from a singular set, \( S \). If there is a uniformly well embedded connected precompact exhaustion of \( M \setminus S \) as in (8) satisfying the volume conditions (101) and (102) then
\[
\lim_{j \to \infty} d_{GH}(M_j, N) = 0,
\]
where \( N \) is the settled and metric completion of \((M \setminus S, g_\infty)\).

Proof. By Lemma 2.12 we have
\[
\text{Vol}(M_i) \leq V_0.
\]
This combined with the uniform contractibility function allows us to apply the Greene-Petersen Compactness Theorem. In particular we have a uniform upper bound on diameter:
\[
diam(M_i) \leq D_0.
\]
We may now apply Theorem 2.10 to obtain
\[
\lim_{j \to \infty} d_F(M_j, N') = 0
\]
We then apply Theorem 2.7 to see that the flat limit and Gromov-Hausdorff limits agree due to the existence of the uniform linear contractibility function and the fact that the volume is bounded below uniformly by the smooth limit. In particular the metric completion and the settled completion agree.

\[\square\]
3. Hausdorff Measure Estimates $\implies$ Well-Embeddedness.

We now prove Theorems 1.2, 1.3 and its counterpart (with Ricci condition replaced by contractibility condition) stated in the introduction. First we must prove the following two lemmas:

**Lemma 3.1.** Let $M^n$ be compact Riemannian manifold, $S$ a subset of $M$ with $H^{n-1}(S) = 0$, and let $\gamma : [0, L] \rightarrow M$ be a shortest geodesic parametrized by arclength with endpoints $x, y \in M \setminus S$. Then, for any small enough $\epsilon > 0$, there exists a path $\gamma_\epsilon$ joining $x, y$ such that $\gamma_\epsilon \cap S = \emptyset$ and

\begin{equation}
L(\gamma_\epsilon) \leq L(\gamma) + \epsilon.
\end{equation}

**Proof.** Let $\Gamma : [-\sigma, \sigma]^{n-1} \times [0, L] \subset \mathbb{R}^n \rightarrow M$ be the $(n-1)$-th variation of $\gamma$ given by

\begin{equation}
\Gamma(t_1, t_2, \ldots, t_{n-1}, s) = \exp_{\gamma(s)} F(t_1, t_2, \ldots, t_{n-1}, s)
\end{equation}

where

\begin{equation}
F(t_1, t_2, \ldots, t_{n-1}, s) = \sin \left( \frac{\pi s}{L} \right) \left( \sum_i t_i e_i(s) \right),
\end{equation}

in which $\{e_i(s)\}$ is a parallel orthonormal frame along $\gamma$ and $e_0(s)$ is the unit tangent to $\gamma$.

For any $\bar{t} = (t_1, \ldots, t_{n-1})$, the curve $\gamma_{\bar{t}}(s) := \Gamma(t_1, t_2, \ldots, t_{n-1}, s)$ is a curve from $x$ to $y$. If we choose $\sigma$ sufficiently small then,

\begin{equation}
L(\gamma) \leq L(\gamma_{\bar{t}}) \leq L(\gamma) + \epsilon,
\end{equation}

therefore, to prove the lemma, we need to find a $\bar{t}$ such that

\begin{equation}
\gamma_{\bar{t}} \cap S = \emptyset.
\end{equation}

**Claim:** There exists some $\sigma > 0$ such that after restricting the domain of $\Gamma$ accordingly, for any small $\delta > 0$, $\Gamma$ is bi-Lipschitz on

\begin{equation}
\Lambda_\delta = [-\sigma, \sigma]^{n-1} \times [\delta, L - \delta].
\end{equation}

To see this, we need to compute the derivative of $\Gamma$. Let

\begin{equation}
x(u, s, t_1, \ldots, t_{n-1}) = \exp_{\gamma(s)} \left( u F(s, t_1, \ldots, t_{n-1}) \right),
\end{equation}

for fixed $s, t_1, \ldots, t_{n-1}$, as $u$ ranges from 0 to 1, the curve $x(u, s, t_1, \ldots, t_{n-1})$ is a geodesic segment from $\gamma(s)$ to $\Gamma(s, t_1, \ldots, t_{n-1})$. As $s$ varies, $x$ is a variation through geodesics therefore,

\begin{equation}
D(\Gamma) \left( \frac{\partial}{\partial s} \right)(s, t_1, \ldots, t_{n-1}) = J(1),
\end{equation}

where, $J$ is the Jacobi field along this geodesic segment, with the initial conditions $J(0) = e_0(s)$, $\nabla_{\partial s} J(0) = \frac{\pi}{L} \cos \left( \frac{\pi s}{L} \right) \sum_i t_i e_i(s)$ since,
\[ \nabla_{\partial s} J(0) = \nabla_{\partial s} \frac{\partial x}{\partial s}(0, s, t_1, \ldots, t_{n-1}) \]
\[ = \nabla_{\partial u} \frac{\partial x}{\partial u}(0, s, t_1, \ldots, t_{n-1}) \]
\[ = \nabla_{\partial s} F(0, s, t_1, \ldots, t_{n-1}) \]
\[ = \frac{\pi}{L} \cos \left( \frac{\pi s}{L} \right) \sum_i t_i e_i(s). \]

Also for any \( 1 \leq i \leq n-1 \) we have:

\[ D(\Gamma) \left( \frac{\partial}{\partial t_i} \right)(s, t_1, \ldots, t_{n-1}) = \left( \exp_{\gamma(s)} \right)_{F(s, t_1, \ldots, t_{n-1})} \sin \left( \frac{\pi s}{L} \right) e_i(s). \]

For \( t_1 = \ldots, t_{n-1} = 0 \), and \( V = \alpha_0 \frac{\partial}{\partial s} + \sum_i \alpha_i \frac{\partial}{\partial t_i} \) with \( \|V\| = 1 \) we compute:

\[ \|D(\Gamma)V\| = \left\| D(\Gamma) \left( \alpha_0 \frac{\partial}{\partial s} + \sum_i \alpha_i \frac{\partial}{\partial t_i} \right) \right\| \]
\[ = \left\| \alpha_0 e_0(s) + \sin \left( \frac{\pi s}{L} \right) \sum_i \alpha_i e_i(s) \right\|. \]

Therefore, for any \( \delta > 0 \), there exist \( c(\delta) > 0 \) such that on \( \gamma \),

\[ 0 < c(\delta) \leq \|D(\Gamma)V\| \leq 1. \]

By continuity, for a small enough \( \sigma \), we will have

\[ 0 < \frac{c(\delta)}{2} \leq \|D(\Gamma)V\| \leq 3/2, \]

on \([-\sigma, \sigma]^{n-1} \times [\delta, L-\delta]\).

Also by making \( \sigma \) smaller, we can assume that

\[ \sigma < \frac{r_{focal}}{n}, \]

in which, \( r_{focal} \) is the focal radius of the geodesic \( \gamma \). This guarantees that \( \Gamma \) is injective on \([-\sigma, \sigma]^{n-1} \times [\delta, L-\delta]\) which is compact, therefore \( \Gamma \) is a homeomorphism with the derivative bounded away from zero on its domain. By applying the inverse function theorem, we deduce that \( \Gamma \) is a diffeomorphism on \([-\sigma, \sigma]^{n-1} \times [\delta, L-\delta]\) onto its image. As a result, \( \Gamma \) is bi-Lipschitz on \( \Lambda_\delta \).

It is rather straightforward to see that for a Lipschitz function \( f : \mathbb{R}^n \to \mathbb{R}^m \), any subset \( A \subset \mathbb{R}^n \) and \( 0 \leq s < \infty \), we have

\[ H^s(f(A)) \leq [\text{Lip} f]^t H^t(A) \]
(see [15, Theorem 3.1.2]). Therefore, bi-Lipschitz preimages of sets of 0 Hausdorff measure, have 0 Hausdorff measure. Since \( \Gamma \) is bi-Lipschitz on \( \Lambda_\delta \), we get:

\[ H^{n-1} \left( \Gamma^{-1}(S) \cap \Lambda_\delta \right) = 0. \]
Now we can compute:
\[
H^{n-1}\left(\Gamma^{-1}(S)\right) \leq H^{n-1}\left(\bigcup_i \left(\Gamma^{-1}(S) \cap \Lambda_{1/i}\right)\right)
+ H^{n-1}\left(\Gamma^{-1}(S) \cap [-\sigma, \sigma]^{n-1} \times \{0\}\right)
+ H^{n-1}\left(\Gamma^{-1}(S) \cap [-\sigma, \sigma]^{n-1} \times \{L\}\right)
= 0.
\]

Since any orthogonal projection \(\Pr : \mathbb{R}^n \to \mathbb{R}^k\) is distance decreasing, we have \(\text{Lip}(\Pr) \leq 1\). By \((71)\) (see \([15\; \text{Theorem } 3.1.2]\)), for any \(A \subset \mathbb{R}^n\) and any \(0 \leq s < \infty\), we get
\[
(73) \quad H^s(\Pr(A)) \leq H^s(A)
\]

Thus for any orthogonal projection \(\Pr\) onto an \((n-1)\)-dimensional face of \([-\sigma, \sigma]^{n-1} \times \{0, L\}\) we have
\[
(74) \quad H^{n-1}\left(\Pr\left(\Gamma^{-1}(S)\right)\right) = 0.
\]

Let \(\Pr_1\) and \(\Pr_2\) be the projections onto the faces \([-\sigma, \sigma]^{n-1} \times \{0\}\) and \([-\sigma, \sigma]^{n-1} \times \{L\}\) respectively. Setting \(E_1 = \Pr_1 \left(\Gamma^{-1}(S)\right)\) and \(E_2 = \Pr_2 \left(\Gamma^{-1}(S)\right)\), then,
\[
(75) \quad H^{n-1}(E_i) = 0 \quad \text{for } i = 1, 2
\]
and so,
\[
(76) \quad H^{n-1}(\{-\sigma, \sigma\}^{n-1} \setminus E_i) = (2\sigma)^{n-1} \quad \text{for } i = 1, 2.
\]

Any countable union of null sets is a null set (see \([8\; \text{p. } 26]\)) hence, \(E_1 \cup E_2\) is a null set. This means that
\[
(77) \quad H^{n-1}\left(\{-\sigma, \sigma\}^{n-1} \setminus E_1 \cup \{-\sigma, \sigma\}^{n-1} \setminus E_2\right) = (2\sigma)^{n-1}.
\]

Let \(\bar{t} = (t_1, t_2, \ldots, t_{n-1}) \in (\{-\sigma, \sigma\}^{n-1} \setminus E_0) \cap (\{-\sigma, \sigma\}^{n-1} \setminus E_L)\), then the path
\[
(78) \quad \gamma_{\bar{t}}(s) = \Gamma(t_1, t_2, t_3, \ldots, s),
\]
is a path joining \(x, y\) and \(\gamma_{\bar{t}} \cap \Sigma = \emptyset\) which also satisfies
\[
(79) \quad |L(\gamma_s) - L(\gamma)| \leq \epsilon.
\]

\[\square\]

**Lemma 3.2.** Let \(M^n\) be a compact Riemannian manifold, \(S\) a set with \(H^{n-1}(S) = 0\) and \(\text{diam}_{g_0}(M \setminus S) < \infty\) then, any connected precompact exhaustion, \(W_j\) of \(M^n \setminus S\) is uniformly well embedded.

**Proof:** We claim for fixed \(i, j\),
\[
(80) \quad \lambda_{i,j} = \limsup_{k \to \infty} \lambda_{i,j,k} = 0.
\]

Suppose not. Let \(x_{i,j,k}, y_{i,j,k} \in W_j\) achieve to supremum in the definition of \(\lambda_{i,j}\).

Since \(\hat{W}_j\) is compact, a subsequence as \(k \to \infty\) converges to \(x_{i,j}, y_{i,j} \in \hat{W}_j\). Let \(\gamma_{i,j}\) be a minimizing geodesic between these points in \(M\) with respect to \(g_i\). Since
$S$ is a set of codimension strictly larger than than 1, by applying Lemma 3.1 we can find a curve $C_{i,j} : [0, 1] \to M \setminus S$ between these points such that

\[(81) \quad L_{g_i}(C_{i,j}) \leq d_{M,g_i}(x_{i,j}, y_{i,j}) + \lambda_{i,j}/5,\]

Let $k$ be chosen from the subsequence sufficiently large that

\[
\begin{align*}
C_{i,j}([0, 1]) &\subset W_k, \\
d((W_{j,k})(x_{i,j,k}, x_{i,j})) &< \lambda_{i,j}/10, \\
d((W_{j,k})(y_{i,j,k}, y_{i,j})) &< \lambda_{i,j}/10,
\end{align*}
\]

Thus

\[
d((W_{j,k})(x_{i,j,k}, y_{i,j,k}) \leq d((W_{j,k})(x_{i,j,k}, x_{i,j})) + d((W_{j,k})(x_{i,j}, y_{i,j})) + d((W_{j,k})(y_{i,j}, y_{i,j,k})) \\
\leq \lambda_{i,j}/10 + d_{M,g_i}(x_{i,j}, y_{i,j}) + \lambda_{i,j}/5 + \lambda_{i,j}/10 \\
\leq 2\lambda_{i,j}/5 + d_{M,g_i}(x_{i,j,k}, y_{i,j,k}) + d_{M,g_i}(x_{i,j,k}, y_{i,j}) + d_{M,g_i}(y_{i,j,k}, y_{i,j}) \\
\leq 3\lambda_{i,j}/5 + d_{W_{j,k}}(x_{i,j,k}, y_{i,j,k}) \\
\leq 3\lambda_{i,j}/5 + d_{W_{j,k}}(x_{i,j,k}, y_{i,j,k}) - \lambda_{i,j,k},
\]

by the choice of $x_{i,j,k}$ and $y_{i,j,k}$. This is a contradiction.

Next we must show

\[(82) \quad \lim_{j \to \infty} \lim_{k \to \infty} \lim_{i \to \infty} \lambda_{i,j,k} \leq \lambda_0.\]

Observe that

\[(83) \quad \lambda_{i,j,k} \leq \bar{\lambda}_{i,j,k} = \text{diam}(W_{j,k})(W_j).\]

Since $g_i \to g_\infty$ on $W_k$ we know

\[(84) \lim_{i \to \infty} \lambda_{i,j,k} \leq \text{diam}(W_{k,g_\infty})(W_j).\]

Claim:

\[(85) \quad \lim_{k \to \infty} \text{diam}(W_{k,g_\infty})(W_j) \leq \text{diam}_{M \setminus S,g_\infty}(W_j).\]

Suppose not; then, there exists $s > 0$ and a subsequence $k \to \infty$ such that

\[(86) \quad \lim_{k \to \infty} \text{diam}(W_{k,g_\infty})(W_j) = L > \text{diam}_{M \setminus S,g_\infty}(W_j) + 5\delta.\]

Pick $x_k, y_k \in W_j$ so that

\[(87) \quad \text{diam}(W_{k,g_\infty})(W_j) \leq d(W_{k,g_\infty})(x_k, y_k) + \delta.\]

$W_j$ is compact therefore, after passing to a subsequence,

\[(88) \quad x_k \to x \in \tilde{W}_j\]

\[(89) \quad y_k \to y \in \tilde{W}_j.\]
Therefore, there exists a curve \( c : [0, 1] \rightarrow M \setminus S \) such that,

\[
L_{g_\infty}(c) < d_{(M \setminus S, g_\infty)}(x, y) + \delta
\]

(90)

\[
< \operatorname{diam}_{(M \setminus S, g_\infty)}(W_j) + \delta
\]

(91)

\[
\leq \operatorname{diam}_{(M \setminus S, g_\infty)}(W_j) + \delta
\]

(92)

\[
< L - 4\delta.
\]

(93)

For \( k \) sufficiently large, we have

\[
c([0, 1]) \subset W_k,
\]

(94)

so

\[
L - 4\delta > L_{g_\infty}(c) > d_{(W_k, g_\infty)}(x, y)
\]

(95)

\[
> d_{(W_k, g_\infty)}(x_k, y_k) - 2\delta
\]

(96)

\[
\geq \operatorname{diam}_{(W_k, g_\infty)}(W_j) - 3\delta.
\]

(97)

Taking the limit as \( k \to \infty \), we get:

\[
L - 4\delta \geq L.
\]

(98)

which is a contradiction hence, the claim is proved and we have

\[
\limsup_{k \to \infty} \limsup_{i \to \infty} \lambda_{i, j, k} \leq \operatorname{diam}_{(M \setminus S, g_\infty)}(W_j),
\]

(99)

and so

\[
\limsup_{j \to \infty} \limsup_{k \to \infty} \limsup_{i \to \infty} \lambda_{i, j, k} \leq \operatorname{diam}_{g_\infty}(M \setminus S).
\]

(100)

Proof of Theorem \textbf{1.2}:

Proof. The lemmas \textbf{3.1} and \textbf{3.2} prove the well-embeddedness and then applying the Theorem \textbf{2.10} completes the proof of Theorem \textbf{1.2}.

\(\square\)

Remark 3.3. Example \textbf{5.5} demonstrates that the connectivity of the exhaustion in Theorems \textbf{1.2} hence, in Theorems \textbf{1.3} and \textbf{3.6} is a necessary condition. The excess volume bound in (234) is shown to be necessary in \textbf{[13, Example 3.7]}. All these examples satisfy the uniform embeddedness hypothesis of Theorem \textbf{2.10} and demonstrate the necessity of these conditions in that theorem as well. By Lemma \textbf{2.14} the diameter hypothesis is not necessary when the Ricci curvature is nonnegative although the volume condition is still necessary as seen in \textbf{[13, Example 3.8]}. Otherwise we see this is a necessary condition in Example \textbf{5.3}. We were unable to find an example proving the necessity of the uniform bound on the boundary volumes, (233), and suggest this as an open question in \textbf{[13, Remark 3.15]}. The Hausdorff measure condition \( H^{n-1}(S) = 0 \) of Theorem \textbf{1.2} and the uniform embeddedness hypothesis of Theorem \textbf{2.10} are seen to be necessary for their respective theorems in \textbf{5.6}.

Proof of Theorem \textbf{1.3}.
Proof. The assumption $H^{n-1}(S) = 0$ along with the hypotheses (52), (233) and (234), allows us to apply Theorem 1.2. Therefore, $(M_i, g_i)$ has an intrinsic flat limit and this limit coincides with the settled completion of $(M \setminus S, g_\infty)$. Now by proposition 2.13, the Gromov-Hausdorff and Intrinsic Flat limits agree. □

Remark 3.4. Example 5.3 proves the necessity of the condition (52) in Theorem 1.3.

Remark 3.5. From [6], Ricci bounded below and $d_{GH}(M_i, M) \to 0$ imply $\text{Vol}(M_i) \to \text{Vol}(M)$ (conjectured by Anderson-Cheeger) and $M_i$ are homeomorphic to $M$ for $i$ sufficiently large (later proved diffeomorphic in [15].) This means that (234) in Theorem 1.3 is a necessary condition.

Theorem 3.6. Let $M_i = (M, g_i)$ be a sequence of oriented compact Riemannian manifolds with a uniform linear contractibility function, $\rho$, which converges smoothly away from a closed singular subset, $S$, with $H^{n-1}(S) = 0$. If there is a connected precompact exhaustion of $M \setminus S$ as in (8) satisfying the volume conditions
\begin{align}
(101) \quad \text{Vol}_{g_i}(\partial W_j) &\leq A_0 \\
(102) \quad \text{Vol}_{g_i}(M \setminus W_j) &\leq V_j \text{ where } \lim_{j \to \infty} V_j = 0,
\end{align}
then
\begin{equation}
(103) \quad \lim_{j \to \infty} d_{GH}(M_j, N) = 0,
\end{equation}
where $N$ is the settled and metric completion of $(M \setminus S, g_\infty)$.

Proof. By the proof of Theorem 2.15 we see that
\begin{equation}
(104) \quad \text{diam}(M_i) \leq D_0,
\end{equation}
This along with $H^{n-1}(S) = 0$, (101) and (102), allows us to apply the Lemma 3.2 to get the well-embeddedness of the exhaustion $\{W_j\}$. Then, we can fully apply Theorem 2.15 and that finishes the proof. □

4. Diameter Controls $\implies$ Well-embeddedness.

In this section we prove Theorems 1.4, 1.5 and its counterpart (with Ricci condition replaced with contractibility condition.) In the theorems of this section, there is no co-dimension condition on the singular set $S$. We first need to prove the following lemma:

Lemma 4.1. Suppose $W_j$ is a connected precompact exhaustion of $M \setminus S$ with boundaries $\partial W_j$ such that any connected component of $M \setminus W_j$ has a connected boundary. If the intrinsic diameters satisfy
\begin{equation}
(105) \quad \text{diam}_{(W_j, g_i)}(W_j) \leq D_{\text{int}},
\end{equation}
and

\[\limsup_{i \to \infty} \left\{ \sum_{\beta} \text{diam}_{(\Omega_{j}^{\beta},\beta)}(\Omega_{j}^{\beta}) : \Omega_{j}^{\beta} \text{ connected component of } \partial W_{j} \right\} \leq B_{j}\]

satisfies \(\lim_{j \to \infty} B_{j} = 0\) then \(W_{j}\) is uniformly well embedded.

**Proof.** Recall from Definition 2.9 that we have

\[\lambda_{i,j,k} = \sup_{x,y \in \bar{W}_{j}}|d_{(W_{k},\mathbb{S})}(x,y) - d_{(M,\mathbb{S})}(x,y)| \leq \text{diam}_{(W_{k},\mathbb{S})}(W_{j}).\]

Since

\[\text{diam}_{(W_{k},\mathbb{S})}(W_{j}) \leq \text{diam}_{(W_{k},\mathbb{S})}(W_{k}),\]

and \(g_{i}\) converges smoothly on \(W_{k}\) we have,

\[\lim_{i \to \infty} \text{diam}_{(W_{k},\mathbb{S})}(W_{k}) = \text{diam}_{(W_{k},\mathbb{S})}(W_{k}) \leq D_{\text{int}}.\]

Therefore,

\[\limsup_{j \to \infty} \limsup_{k \to \infty} \lambda_{i,j,k} \leq \limsup_{j \to \infty} \limsup_{k \to \infty} \text{diam}_{(W_{k},\mathbb{S})}(W_{k}) \leq D_{\text{int}}.\]

Now suppose \(x_{i,j,k}, y_{i,j} \in \partial W_{j}\) give the supremum in the definition of \(\lambda_{i,j,k}\). Let \(\gamma_{i,j,k}\) and \(C_{i,j,k}\) be shortest paths between \(x_{i,j,k}\) and \(y_{i,j,k}\) in \(\bar{W}_{k}\) and \(M\) respectively. Letting \(k \to \infty\) and passing to a subsequence if necessary, \(x_{i,j,k} \to x_{i,j} \in \bar{W}_{j}\) and \(y_{i,j,k} \to y_{i,j} \in \bar{W}_{j}\). Passing to a subsequence again if necessary, \(C_{i,j,k}\) converges to \(C_{i,j}\) which is a shortest path between \(x_{i,j}\) and \(y_{i,j}\) in \(M\) (c.f. [5][Prop 2.5.17]). And let \(y_{i,j}^{k}\) be the shortest path between \(x_{i,j}\) and \(y_{i,j}\) in \(\bar{W}_{k}\).

We will estimate \(C_{i,j}\) by curves in \(\partial W_{j}\) with controlled increase in the length. Denote the curve obtained in \(n\)th step by \(C_{i,j}^{n}\) and let \(C_{i,j}^{0} = C_{i,j}\). To obtain \(C_{i,j}^{n+1}\) from \(C_{i,j}^{n}\) we proceed as follows: Suppose \(\{\Omega_{j}^{\beta}\}_{n \in \mathbb{N}}\) are the connected components met by \(C_{i,j}\) (in more than one point). If \(C_{i,j}^{n}\) does not intersect \(\Omega_{j}^{n+1}\), then we let \(C_{i,j}^{n+1} = C_{i,j}^{n}\). If \(C_{i,j}^{n}\) intersects \(\Omega_{j}^{n+1}\) then define

\[t_{1} = \inf \left\{ t : C_{i,j}^{n}(t) \in \Omega_{j}^{n+1} \right\},\]

and

\[t_{2} = \sup \left\{ t : C_{i,j}^{n}(t) \in \Omega_{j}^{n+1} \right\}.\]

Since \(\Omega_{j}^{n+1}\) is connected, we can replace the segment \(C_{i,j}^{n}[t_{1},t_{2}]\) with a shortest path in \(\Omega_{j}^{n+1}\). The curve obtained in this way is our \(C_{i,j}^{n+1}\). Note that connectivity of the boundary components of \(M \setminus W_{j}\) implies that if \(C_{i,j}^{n}\) enters \(M \setminus W_{j}\) through \(\Omega_{j}^{n+1}\) at time \(t\), then it has to intersect \(\Omega_{j}^{n+1}\) again at time \(t' > t\) in order to enter \(W_{j}\).

This construction implies that for all \(n\),

\[L(C_{i,j}^{n}) \leq L(C_{i,j}^{0}) + B_{j},\]

hence, the sequence \(\{C_{i,j}^{n}\}_{n \in \mathbb{N}}\) obtained in this way have uniform bounded length and as a result, we can apply the Arzela-Ascoli’s theorem to obtain, after possibly
passing to a subsequence, a limit $C'_{ij}$ i.e. $C'_{ij}$ is a curve with end points $x_{ij}, y_{ij}$ and there are parametrizations of $\{C^n_{ij}\}_{n \in \mathbb{N}}$ and $C'_{ij}$ on the same domain such that $\{C^n_{ij}\}_{n \in \mathbb{N}}$ uniformly converges to $C'_{ij}$. We claim that $C'_{ij}$ is contained in $\bar{W}_j$. For any $t$, tracing the curve $C_0^{ij}$ back and forth from the point $C_0^{ij}(t)$, we reach two immediate components $\Omega_l^{ij}$ and $\Omega_m^{ij}$ and this means that for $n \geq \max\{l, m\}$, $C^n_{ij}(t) \in \bar{W}_j$ and since $C^n_{ij}(t) \to C'_{ij}(t)$ we must have $C'_{ij}(t) \in \bar{W}_j$. Furthermore, for $i$ large enough (depending on $j$)

$$\limsup_{i \to \infty} \left( L(\gamma^{ij}_0) - L(C_{ij}) \right) \leq \limsup_{i \to \infty} \left( L(C'_0^{ij}) - L(C_{ij}) \right) \leq \limsup_{i \to \infty} \sum_\beta \text{diam}^0(\Omega^{0}_j) < B_j.$$  

(114)

Also

$$\lim_{k \to \infty} \lambda_{ijk} = \lim_{k \to \infty} \left( d(W_k, \mathcal{S}_0) \left( x_{ijk}, y_{ijk} \right) - d(M, \mathcal{S}_0) \left( x_{ijk}, y_{ijk} \right) \right) \leq \lim_{k \to \infty} \left( d(W_k, \mathcal{S}_0) \left( x_{ijk}, y_{ijk} \right) - d(M, \mathcal{S}_0) \left( x_{ijk}, y_{ijk} \right) \right) = L(\gamma^{ij}_0) - L(C_{ij}).$$

(115)

Therefore, combining (114) and (115) we have

$$\lambda_j = \limsup_{i \to \infty} \lim_{k \to \infty} \lambda_{ijk} \leq B_j,$$

(116)

hence,

$$\limsup_{j \to \infty} \lambda_j \leq \lim_{j \to \infty} B_j = 0.$$

(117)

Proof of Theorem 1.4:

Proof. The Lemma 4.1 combined with Theorem 2.10 completes the proof of Theorem 1.4. Recall Definition 2.9.

Remark 4.2. Example 5.5 demonstrates that the connectivity of the exhaustion in Theorem 1.4, hence in Theorems 1.5 and 4.5 is a necessary condition. Example 5.7 demonstrates that in Theorem 1.4, hence, in Theorems 1.5, 4.5 and 1.6 the condition on the intrinsic diameter cannot be replaced by the same condition on the extrinsic diameter. The necessity of other conditions follow as in Remark 3.3.

Proof of Theorem 1.5:

Proof. The hypothesis $\text{diam}(M_j) \leq D_0$ combined with the hypothesis including (233) and (234), allows us to apply Theorem 1.4. So $(M_i, g_i)$ has an intrinsic flat limit and this intrinsic flat limit is the settled completion of $(M \setminus S, g_\infty)$. Thus by Proposition 2.13, the Gromov-Hausdorff and Intrinsic Flat limits agree.

Remark 4.3. Example 5.3 proves the necessity of the condition (20) in Theorem 1.5.
Remark 4.4. From [6], Ricci bounded below and \( d_{GH}(M_i, M) \to 0 \) imply \( \text{Vol}(M_i) \to \text{Vol}(M) \) (conjectured by Anderson-Cheeger) and \( M_i \) are homeomorphic to \( M \) for \( i \) sufficiently large (later proved diffeomorphic in [16].) This means that (234) in Theorem 1.5 is a necessary condition.

Theorem 4.5. Let \( M_i = (M, g_i) \) be a sequence of Riemannian manifolds with a uniform linear contractibility function, \( \rho \), which converges smoothly away from a closed singular set, \( S \), with

\[
\text{Vol}(M_i) \leq V_0. \tag{118}
\]

If there is a connected precompact exhaustion, \( W_j \), of \( M \setminus S \), satisfying (8) such that each connected component of \( M \setminus W_j \) has a connected boundary, satisfying (118)-(27), (2) and (16) then

\[
\lim_{j \to \infty} d_{GH}(M_j, N) = 0. \tag{119}
\]

where \( N \) is the metric completion of \((M \setminus S, g_{\infty})\).

Proof. By Lemma 2.12, we have

\[
\text{Vol}(M_i) \leq V_0. \tag{120}
\]

This combined with the uniform contractibility function allows us to apply the Greene-Petersen Compactness Theorem. In particular we have a uniform upper bound on diameter

\[
\text{diam}(M_i) \leq D_0, \tag{121}
\]

We may now apply Theorem 1.4 to obtain

\[
\lim_{j \to \infty} d_F(M_j, N') = 0. \tag{122}
\]

We then apply Theorem 2.7 to see that the flat limit and Gromov-Hausdorff limits agree due to the existence of the uniform linear contractibility function and the fact that the volume is bounded below uniformly by the smooth limit. In particular the metric completion and the settled completion agree. \( \square \)

5. Examples

In this section we present some examples which helps in understanding the notions we have mentioned so far. Some examples will prove the necessity of some conditions in Theorem 1.5.

5.1. Unbounded Limits. The following examples show why some sort of bounded geometry is necessary in this context.

Example 5.1. There are metrics \( g_j \) on the sphere \( M^3 \) with a uniform upper bound on volume such that \((M^3, g_j)\) converge smoothly away from a point singularity \( S = \{p_0\} \) to a complete noncompact manifold. There is no Gromov-Hausdorff limit in this case. The intrinsic flat limit is \((M \setminus S, g_{\infty})\).
Proof. Let
\[ g_0 = h^2(r)dr^2 + f^2(r)g_{S^2}, \]
be defined on \( M \setminus S \) as a complete metric such that
\[ \int_0^{\pi} h(r)dr = \infty, \]
and
\[ \int_0^{\pi} \omega_2 h(r) f^2(r)dr < \infty, \]
so that \( \text{diam}(M \setminus S, g_0) = \infty \) and \( \text{Vol}(M \setminus S, g_0) < \infty \).

We set
\[ g_j = h_j^2(r)dr^2 + f_j^2(r)g_{S^2}, \]
such that
\[ h_j(r) = h(r) \quad r \in [0, \pi - 1/j], \]
\[ f_j(r) = f(r) \quad r \in [0, \pi - 1/j], \]
and extend smoothly so that \( g_j \) is a metric on \( S^3 \).

Metrics \( g_j \) converge smoothly to \( g_0 \) away from \( S = \{p_0\} = r^{-1}(\pi) \) and, since \( (M \setminus S, g_0) \) is noncompact, \( (M, g_j) \) has no Gromov-Hausdorff limit. The intrinsic flat limit of \( (M, g_j) \) is the settled completion of \( (M \setminus S, g_0) \) by Theorem 1.2, taking \( W_j = r^{-1}[0, \pi - 1/j] \) since
\[ \int_{\pi - 1/k}^{\pi} \omega_2 h(r) f^2(r)dr = 0, \]
by the finiteness of \( (125) \) and we also have \( \text{Vol}_g(\partial(W_j)) \leq f^2(r) \). In this case the settled completion is just \( (M \setminus S, g_0) \) because it is already a complete metric space with positive density. \( \square \)

Example 5.2. There are metrics \( g_j \) on \( M^3 = S^3 \) converging smoothly away from a singular set \( S = \{p_0\} \) to a complete noncompact manifold of infinite volume. \( (M, g_j) \) have no intrinsic flat or Gromov-Hausdorff limit since, if such a limit existed it would have to contain the smooth limit and the smooth limit has infinite diameter and volume.

Proof. We define a metric \( g_0 \) on \( M \setminus S \) exactly as in Example 5.1 except that we replace \( (125) \) with
\[ \int_0^{\pi} \omega_2 h(r) f^2(r)dr = \infty, \]
so that \( \text{diam}(M \setminus S, g_0) = \infty \) and \( \text{Vol}(M \setminus S, g_0) = \infty \).

Selecting \( g_j \) also as in that example, we have \( (M, g_j) \) converge smoothly away from \( S \) to \( (M \setminus S, g_0) \). However there is no Gromov-Hausdorff limit because the diameter diverges to infinity \( [10] \) and there is no intrinsic flat limit because the volume diverges to infinity \( [22] \). \( \square \)
One may define pointed Gromov-Hausdorff and pointed intrinsic flat limits to deal with unboundedness. However even assuming boundedness, we see in [13, Example 3.11] that the Gromov-Hausdorff limit need not exist.

5.2. Ricci Example. This example shows that the mere uniform lower bound for Ricci curvature does not imply the existence of the Gromov-Hausdorff limit.

Example 5.3. There are metrics $g_j$ on $M^3 = S^3$ with negative uniform lower bound on Ricci curvature, converging smoothly away from a singular set $S = \{p_0\}$ to a complete noncompact manifold of finite volume.

Proof. Consider the metric $g_0$ on $S^3 \setminus \{p_0\} = \mathbb{R} \times S^2$ given by
\[
\bar{g}(t) = dt^2 + (\bar{f}(t))^2 g_{S^2},
\]
where, $\bar{f}$ is a nonzero smooth function such that
\[
\bar{f}(t) = \sin(t) \quad \text{for} \quad t \in [0, \pi/2],
\]
\[
\bar{f}(t) = \exp(-t) \quad \text{for} \quad t \in [\pi/2 + 1, \infty),
\]
with $\bar{f}''(t) < \bar{f}(t)$ elsewhere. Hence, $\bar{g}$ has Ricci curvature bounded below by
\[
-\Lambda = -2 \max \frac{\bar{f}''}{\bar{f}} > -\infty.
\]
We can extract warped metrics $\bar{g}_j$ on $[0, j + 1] \times S^2$
\[
\bar{g}(t) = dt^2 + \bar{f}_j(t)^2 g_{S^2},
\]
where $\bar{f}_j$ is a nonzero smooth function satisfying
\[
\bar{f}_j(t) = \bar{f}(t) \quad \text{for} \quad t \in [0, j - 1],
\]
\[
\bar{f}_j(t) = \exp(-j \sin(\exp(j(\pi + t - j - 1))) \quad \text{for} \quad t \in [j, j + 1],
\]
and
\[
-2 \max \frac{\bar{f}_j''}{\bar{f}_j} \geq -\Lambda.
\]
Note that in fact we are cutting off a part of $\bar{f}$ and replacing it with a less concave function which closes up like a sin function hence obtaining a metric on $S^3$, with lower bound on Ricci curvature.

It is clear that
\[
\text{Vol}(M, g_0) \leq \infty.
\]

Let $\phi : [0, \pi] \to [0, \infty)$ be a smooth increasing function such that
\[
\phi(r) = r \quad \text{for} \quad r \in [0, \pi/2],
\]
with
\[
\lim_{r \to \pi} \phi(r) = \infty.
\]
For $j > 2$, let $\phi_j(r) : [0, \pi] \to [0, L_j = j + \pi/2 + 1]$ be a smooth increasing function such that

$$\phi_j(r) = \phi(r) \quad \text{for} \quad r \in [0, \phi^{-1}(j + \pi/2)],$$

and

$$\phi_j(r) = j + r - \pi/2 + 1 \quad \text{for} \quad r \nearrow \pi.$$

we construct metrics

$$g_j(r) = \phi_j^*(\bar{g}),$$

with Ricci bounded below by $-\Lambda$ converging smoothly away from $\{p_0\}$ to $\phi^*(\bar{g})$. Taking $W_j = r^{-1}([0, \pi - 1/j])$ we observe that $W_j$ satisfies all the hypotheses in Theorem 1.5 except that $\text{diam}_{M_j}(W_j)$ is not bounded. The Gromov-Hausdorff limit does not exist because $(M \setminus S, g_0)$ is complete noncompact. Both intrinsic flat limit and the metric completion coincide with the complete noncompact manifold $(M \setminus S, g_0)$. □

**Remark 5.4.** From [26], we know that any complete noncompact manifold with nonnegative Ricci curvature has infinite volume, so Example 5.3 can not be constructed with the sequence having nonnegative Ricci curvature.

5.3. Pinching a torus.

**Example 5.5.** There are $(M^2, g_j)$ all diffeomorphic to the torus, $S^1 \times S^1$ which converge smoothly away from a singular set, $S = \{0\} \times S^1$, to

$$M_\infty = [0, 2\pi] \times S^1/\sim,$$

where

$$\text{and} (2\pi, s_1) \sim (2\pi, s_2) \quad \forall s_1, s_2 \in S^1.$$ 

However the Gromov-Hausdorff and Intrinsic Flat limits identify these two end points.

**Proof.** Let $g_j$ on $M$ be defined by

$$g_j = dt^2 + f_j^2(t)ds^2,$$

where $f_j : S^1 \to (0, 1]$ are smooth with $|f_j'(t)| \leq 1$ that decrease uniformly to $\sin(\frac{t}{2})$ and $f_j(t) = \sin(\frac{t}{2})$ for $t \in [1/j, 2\pi - 1/j]$. □
5.4. Examples of Slit Tori.

Example 5.6. Let \((M^2, g)\) be the standard flat 2 torus \(S^1 \times S^1\) and \(S \subset M^2\) a vertical geodesic segment of length \(\leq \pi\), then if \(g_j\) are a constant sequence of the standard flat metric, we see that \((M^2, g_j)\) converges smoothly to itself and thus the intrinsic flat and Gromov-Hausdorff limits are both the flat torus. However, the metric completion of \((M \setminus S, g_\infty)\) has two copies of the slit, \(S\) (with end points identified hence the limit has fundamental group \(\mathbb{Z}\)) one found taking limits of Cauchy sequences from the right and the other found taking limits of Cauchy sequences from the left. This example shows necessity of uniform well embeddedness condition in our Theorems.

Proof. Let \(M^2 = S^1 \times S^1 = [0, 2\pi] \times [0, 2\pi]/\sim\) such that \((x, 0) \sim (x, 2\pi)\) and \((0, y) \sim (2\pi, y)\). Without loss of generality, we can assume \(S = \{(\pi, y) : y \in [\pi/2, 3\pi/2]\}\). Then the metric completion of \(M^2 \setminus S\) is

\[
M_\infty = \frac{S^1 \times S^1 \times [0] \sqcup S^1 \times S^1 \times [1]}{\sim},
\]

where,

\[
(x, y, 0) \sim (x, y, 1) \quad \text{for} \quad (x, y) \notin S,
\]

with the distance \(d_\infty\) given by

\[
d_\infty([x, y, l], [x', y', l']) = \lim_{\delta \to 0^+} d_{M^2 \setminus S} \left(\left(\frac{x + (-1)^l \delta}{y}, \frac{x' + (-1)^{l'} \delta}{y'}\right)\right)
\]

for \(l, l' = 0, 1\). In particular,

\[
d_\infty([\pi, \pi, 0], [\pi, \pi, 1]) = \pi.
\]

Notice that \(M_\infty\) is not a manifold (not even Hausdorff as \(B_r([\pi, \pi, 0]) \cap B_{r'}([\pi, \pi, 1]) \neq \emptyset\) for all \(r, r'\). ) Taking the connected precompact exhaustion

\[
W_j = M^2 \setminus ([\pi/2 - 1/j, 3\pi/2 + 1/j] \times [\pi - 1/j, \pi + 1/j]),
\]

we observe that

\[
\text{diam}_{M_j}(W_j) \leq \text{diam}(M^2)
\]

\[
\text{Vol}(M_j) = \text{Vol}(M^2)
\]

\[
\text{Vol}_{g_j}(\partial W_j) \leq 2\pi + 4,
\]

are uniformly bounded, also

\[
\lim_{j \to \infty} \text{Vol}_{g_j}(N \setminus W_j) = \lim_{j \to \infty} (2/j)(\pi + 2/j) = 0,
\]

but,

\[
\lambda_{i,j,k} = \sup_{x,y \in \bar{W}_j} |d_{g_j}(x,y) - d_{g_j}(x,y)|
\]

\[
\geq |d_{g_j}(x,y) - d_{g_j}(x,y)|
\]

\[
\geq \frac{\pi + 2}{j + 2/k},
\]
Therefore,
\[
\lim_{j \to \infty} \lim_{i \to \infty} \lim_{k \to \infty} \lambda_{i,j,k} \geq \lim_{j \to \infty} \lim_{i \to \infty} \lim_{k \to \infty} (\pi + 2/j + 2/k) = \pi.
\]
\[\square\]

**Example 5.7.** Let \((M^2, g_0)\) be the standard flat torus with \(S\) as in Example 5.6. Let \(W_j = T_{1/j}(S)\) with respect to the flat norm. Let \(g_j\) be the flat metric on \(M^2 \setminus W_j\). There exists smooth metrics \(g_j\) on \(M^2\) which agree with \(g_0\) on \(M^2 \setminus W_j\) such that the Gromov-Hausdorff and Intrinsic Flat limits are the metric space created by taking the flat torus and identifying all points in \(S\) with each other. Then, \(g_j\) converges smoothly away from \(S\) to \(g_\infty = g_0\). The metric completion of \((M \setminus S, g_\infty)\) is the slit torus as described in example 5.6. These metrics demonstrate that the diameter condition may not be replaced by an extrinsic diameter condition in Theorem 1.4 and in Theorem ?? but not the Ricci theorem since they have negative curvature.

**Proof.** Let \(g_j = dt^2 + f_j(s, t)^2 ds^2\) where \(f_j(s, t) = 1\) on \(W_j\) and \(f_j(s, t) = 1/j\) on \(S\), and smooth with values in \([1/j, 1]\) everywhere. Let \(\sim\) be defined as follows:
\[
x \sim y \iff x, y \in S
\]

To estimate the GH and SWIF distance between \((M^2, g_j)\) and \((\frac{M^2}{\sim}, d_0)\) we use the Theorem 2.3. First we need to find an estimate on the distortion \(\lambda_j\), which is defined by
\[
\lambda_j = \sup_{x,y \in W_j} |d_{M^2}(x,y) - d_{\sim}(x,y)|.
\]

Now let \(P : M^2 \to \frac{M^2}{\sim}\) be the quotient map and Suppose \(x_j, y_j \in \tilde{W}_j\) achieve the maximum in the definition of \(\lambda_j\). Since \(\frac{M^2}{\sim}\) is flat outside \(\tilde{S}\), any shortest path, \(\tilde{C}_{x_j,y_j}\), joining \(x_j, y_j\) has to be a straight line. As a result, \(P^{-1}(\tilde{C}_{x_j,y_j})\) is either the straight line \(C_{x_j,y_j}\) in \(M^2\) joining \(x_j, y_j\) or the same straight line union the singular set \(S\). And since the metric in \((M^2, g_j)\) is smaller than the flat metric on outside \(W_j\) and coincide with the flat metric in \(W_j\), we get
\[
\lambda_j \leq L(\tilde{C}_{x_j,y_j}) - L(C_{x_j,y_j})
\]
\[
\leq \text{diam}_{\frac{M^2}{\sim}}(M^2 \setminus W_j) + \text{diam}_{\frac{M^2}{\sim}}\left(\frac{M^2 \setminus W_j}{\sim}\right).
\]

Any two points in \(M^2 \setminus W_j\) can be joined by a few horizontal segments, whose lengths add up to at most \(2/j\) and a segment in \(S\) with length less than \(\pi/j\) and vertical segments, whose lengths add up to \(2/j\) therefore,
\[
\text{diam}_{\frac{M^2}{\sim}}(M^2 \setminus W_j) \leq \frac{\pi + 4}{j},
\]
and projecting these segments by \(P\) we get
\[
\text{diam}_{\frac{M^2}{\sim}}\left(\frac{M^2 \setminus W_j}{\sim}\right) \leq \frac{4}{j},
\]
hence,

\begin{equation}
\lambda_j \leq \frac{\pi + 8}{j} \to 0 \text{ as } j \to \infty.
\end{equation}

Now letting \( \epsilon = 0 \) in Theorem 2.3 we have \( a = 0 \) and

\begin{equation}
\bar{h}_j = h_j = \sqrt{\lambda_j \left( \max \{ \text{diam}(W_j) , \text{diam} \left( \frac{W_j}{\sim} \right) \} + \lambda_j / 4 \right)} \to 0 \text{ as } j \to \infty.
\end{equation}

So we conclude that

\begin{equation}
d_{GH} \left( (M^2, g_j), \left( \frac{M^2}{\sim}, d \right) \right) \leq a + 2\bar{h} + \max \left\{ d_H^\mu (W_j, M^2), d_H^\mu \left( \frac{W_j}{\sim}, \frac{M^2}{\sim} \right) \right\} \to 0,
\end{equation}

as \( j \to \infty \) and also, it is easy to see that

\begin{equation}
d_{F} \left( (M^2, g_j), \left( \frac{M^2}{\sim}, d \right) \right) \leq \left( \bar{h} + a \right) \left( \text{Vol}_2(W_j) + \text{Vol}_2 \left( \frac{W_j}{\sim} \right) + \text{Vol}_1(\partial W_j) + \text{Vol}_1 \left( \frac{\partial W_j}{\sim} \right) \right) + \text{Vol}_2(M^2 \setminus W_j) + \text{Vol}_2 \left( \frac{M^2}{\sim} \setminus \frac{W_j}{\sim} \right) \to 0 \text{ as } j \to \infty.
\end{equation}

As we observed,

\begin{equation}
\lim_{j \to \infty} \text{diam}_{(M^2, g_j)}(\partial W_j) \leq \lim_{j \to \infty} \frac{\pi + 4}{j} = 0,
\end{equation}

but,

\begin{equation}
\lim_{j \to \infty} \text{diam}_{(W_j, g_j)}(\partial W_j) \geq \pi.
\end{equation}

\hfill \square

5.5. Splines with Positive Scalar Curvature. In this section, we will present two examples that demonstrate that in our Theorems, the uniform lower Ricci curvature bound condition can not be replaced by a uniform scalar curvature bound. In the first example we construct a sequence of metrics on the 3 - sphere which converge to the canonical sphere away from a singular point and also in the intrinsic flat sense but converges to a sphere with an interval attached to it in the Gromov-hausdorff sense. In the second example of this section, we will construct a sequence of metrics with positive scalar curvature which converge to the 3 - sphere away from a singular point and also in the intrinsic flat sense while having no Gromov-hausdorff limit. The second example was in fact presented by Tom Ilmanen in a talk in 2004 at Columbia without details. Both examples play an important role in [22] however the fact that they have positive scalar curvature was never presented in detail in that paper.

**Lemma 5.8.** For any \( L > 0 \) and \( 0 < \delta < 1 \), there exists a smooth Riemannian metric on the 3-sphere with positive scalar curvature which is obtained by properly gluing a spline of length \( L + O(\delta^5) \) and width \( \leq \delta \) to the unit 3 - sphere.
Example 5.9. There are metrics $g_j$ on the sphere $M^3$ with positive scalar curvature such that $M_j = (S^3, g_j)$ converge smoothly away from a point singularity $S = \{p_0\}$ to the sphere, $S^3$, with $\text{diam}(M_j) \leq \pi + L + 2$ and such that

$$d_F(M_j, S^3), \quad d_{\hat{F}}(M_j, S^3) \to 0,$$

and,

$$d_{GH}(M_j, M_0) \to 0,$$

where $M_0 = S^3 \sqcup [0, L]$ (the round sphere with an interval of length $L$ attached to it).

Remark 5.10. Example 5.9 demonstrates that the uniform lower Ricci curvature bound condition in Theorem 1.3 and 1.5 cannot be replaced by a uniform lower bound on the scalar curvature.

Example 5.11. There are metrics $g_j$ on the sphere $M^3$ with positive scalar curvature such that $M_j \to (S^3, g_j)$ converge smoothly away from a point singularity $S = \{p_0\}$ to the sphere, $S^3$, with $\text{diam}(M_j) \leq \pi + L + 2$ and such that

$$d_F(M_j, S^3), \quad d_{\hat{F}}(M_j, S^3) \to 0,$$

and there is no Gromov-Hausdorff limit.

Proof. of Lemma 5.8. The goal here is to attach a spline of finite length and arbitrary small width to a sphere with positive scalar curvature. For this, we need to employ some ideas related to the Mass of rotationally symmetric manifolds. (c.f. [14]). The construction goes as follows; we first find an admissible Hawking mass function (c.f. [14]) which will provide us with a three manifold embedded in $\mathbb{E}^4$ which is a hemisphere to which spline of finite length and small width is attached; we then, attach a hemisphere along its boundary.

Let $\delta < 1$ (this later will become the width of the spline). and let $r_{\text{min}} = 0$. Now we take an admissible Hawking mass function, $m_H(r)$ (which has to be smooth and increasing) that satisfies ($\epsilon$ to be determined later)

$$m_H(r) = r(1 - \epsilon^2)/2 \quad \text{for} \quad r \in [0, \delta^3],$$

and,

$$m_H(r) = r^3/2 \quad \text{for} \quad r \in [\delta, 1].$$

As in [14], define the function $z(r)$ via

$$z(\bar{r}) = \int_{r_{\text{min}}}^{\bar{r}} \sqrt{\frac{2m_H(r)}{r - 2m_H(r)}} \, dr.$$

Note that $z$ depend on $\delta$.

$z(r)$ is unique up to a constant and gives our desired three manifold as a graph over $\mathbb{B}^3$. By our choice of $m_H(r)$ we get,

$$z'(r) = \sqrt{\frac{1 - \epsilon^2}{\epsilon^2}} \quad \text{for} \quad r \in [0, \delta^3],$$
and,
\[ z'(r) = \sqrt{\frac{r^2}{1 - r^2}} \text{ for } r \in [\delta, 1], \]

and, since
\[ \frac{\delta^3}{2}(1 - \epsilon^2) \leq m_H(r) \leq \frac{\delta^3}{2} \text{ for } r \in [\delta^3, \delta], \]
on one obtains
\[ \sqrt{\frac{\delta^3(1 - \epsilon^2)}{r - \delta^3(1 - \epsilon^2)}} \leq z'(r) \leq \sqrt{\frac{\delta^3}{r - \delta^3}} \text{ for } r \in [\delta^3, \delta]. \]

Now, choose the \( \epsilon \) that solves
\[ \frac{\delta^3}{2}(1 - \epsilon^2) = L, \]

For some fixed \( L \). From (176), we have,
\[ L(\delta) = z(\delta) - z(\delta^3) \leq \int_\delta^{\delta^3} \sqrt{\frac{\delta^3}{r - \delta^3(1 - \epsilon^2)}} = 2\delta^{3/2} \left( \delta - \delta^3 \right)^{1/2} < 2, \]

which goes to 0 as \( \delta \) goes to 0.

We also get
\[ z(\delta^3) - z(0) = \delta^3 \sqrt{\frac{1 - \epsilon^2}{\epsilon^2}} = L. \]

The metric in terms of the distance from the pole, can be written as
\[ \bar{g}_\delta = ds^2 + f^2(s)g_{S^2} = (1 + [z'(r)]^2)dr^2 + r^2g_{S^2}. \]

In the virtue of the Theorem 5.4 in [14], we know that when \( r \in [\delta, 1] \), we are on a unit sphere, and since
\[ \lim_{r \to 1^-} z'(r) = \infty, \]
we have
\[ \lim_{r \to 1^-} f'(s) = \lim_{r \to 1^-} r'(s) = \lim_{r \to 1^-} \frac{1}{\sqrt{1 + [z'(r)]^2}} = 0. \]

Therefore, the boundary \( r = 1 \) is in fact a great 2-sphere along which we can smoothly attach a 3 - hemisphere, as follows

So far we have got the metric
\[ \bar{g}_\delta = (1 + [z'(r)]^2)dr^2 + r^2g_{S^2} \text{ for } r \in [0, 1]. \]

Letting \( r = \sin(\rho) \), one sees that
\[ \bar{g}_\delta = (1 + [z'_\rho(\sin(\rho))]^2)\cos^2(\rho)d\rho^2 + \sin^2(\rho)g_{S^2} \text{ for } \rho \in [0, \pi/2]. \]

Therefore, on the sphere we define \( g_\delta \) to be
\[ (1 + [z'_\rho(\sin(\rho))]^2)\cos^2(\rho)d\rho^2 + \sin^2(\rho)g_{S^2} \text{ for } \rho \in [0, \pi/2]. \]
and,

$$d\rho^2 + \sin^2(\rho)g_{S^2} \quad \text{for} \quad \rho \in [\pi/2, \pi],$$

which has positive scalar curvature when \( \rho \leq \pi/2 \) because it is isometric to \( \bar{g}_\delta \) and has positive scalar curvature when \( \rho \geq \pi/2 \) because it is isometric to a round hemisphere. \( g_\delta \) is smooth at \( \rho = \pi/2 \) because by \[177\] near \( \rho = \pi/2 \),

$$z_\delta'(\sin(\rho)) = \sqrt{\frac{\sin^2(\rho)}{1 - \sin^2(\rho)}} = \tan(\rho).$$

So,

$$(1 + [z_\delta'(\sin(\rho))]^2) \cos^2(\rho)d\rho^2 + \sin^2(\rho)g_{S^2} = (1 + \tan^2(\rho)) \cos^2(\rho) + \sin^2(\rho)g_{S^2}$$

$$= d\rho^2 + \sin^2(\rho)g_{S^2}.$$  }

The key idea is that, using this method, one can attach symmetric spline of length \( L + \bar{L}(\delta) \) and arbitrary small width \( \delta < 1 \) to a sphere while keeping the scalar curvature positive and \( \text{diam}(M_j) \leq \pi + L + 2 \). And the metric found can actually be written as a warped metric.

\[\square\]

**Proof.** of Example 5.9. Now let \( \delta_j \to 0 \) and take the sequence \( M_j = (S^3, g_\delta) \), where \( g_\delta \) is given by the above construction for \( \delta_j \), we are going to prove that \( M_j \) converges to \( M_0 \) in Gromov-Hausdorff sense where \( M_0 \) is the unit three sphere to which an interval of length \( L \) is attached; and \( M_j \) converges to \( S^3 \) in intrinsic flat sense.

First notice that \( M_j \) contains a subdomain \( U_j \) which is isometric to \( U_j' = S^3 \setminus B_p(\arcsin(\delta_j)) \) also letting \( V_j = M_j \setminus U_j \) and \( V_j' = S^3 \setminus U_j' \) one observes that since

$$\text{Vol}(V_j) \leq \int_0^\delta (4\pi r^2)(1 + [z'(r)]^2)^{1/2} \, dr$$

$$\leq \int_0^\delta (4\pi r^2)(1 + |z'(r)|) \, dr$$

$$\leq (4\pi\delta^2)(\delta + L + \bar{L}(\delta)),

one gets \( \text{Vol}(V_j) \to 0 \) as \( \delta_j \to 0 \). Also it is obvious that \( \text{Vol}(V_j') \to 0 \) as \( \delta_j \to 0 \).

Now, to be able to use Theorem 2.3 we need an estimate on

$$\lambda_j = \sup_{x,y \in U_j} |d_{M_j}(x,y) - d_{S^3}(x,y)|.$$  }

Let \( x,y \in U_j \) and let \( \gamma \) and \( c_{x,y} \) be the minimizing geodesic connecting \( x \) and \( y \) in \( (M_j, g_j) \) and \( S^3 \) (resp.). If \( \gamma \) lies completely in \( U_j \), then, so does \( c_{x,y} \) and \( \gamma = c_{x,y} \) hence, \( d_{M_j}(x,y) = d_{S^3}(x,y) \). If \( \gamma \not\subset U_j \), therefore \( \gamma = \gamma_1 + \gamma_2 + \gamma_3 \) where \( x \in \gamma_1 \), \( y \in \gamma_3 \) and \( \gamma_1, \gamma_3 \subset U_j \) and \( \gamma_2 \subset V_j \). We are in either of the following cases

**Case I:** \( c_{x,y} \subset U_j \)

Obviously \( L(\gamma_2) \leq 2\pi\delta_j \), also we have

$$|d_{S^3}(x,p) - L(\gamma_1)| \leq \arcsin \delta_j.$$  

$$\lambda_j = \sup_{x,y \in U_j} |d_{M_j}(x,y) - d_{S^3}(x,y)|.$$
and

\[ |d_{S^3}(y, p) - L(\gamma_3)| \leq \arcsin \delta_j. \]

Since \( \delta_j \to 0 \), for \( j \) large enough,

\[ L(\gamma) \approx d_{S^3}(x, p) + d_{S^3}(y, p) > L(c_{x, y}), \]

which is a contradiction.

Case II: \( c_{xy} \not\in U_j \).

Let \( c_{xy} = c_1 + c_2 + c_3 \) where \( x \in c_1, y \in c_3 \) and \( c_1, c_3 \subset U_j \) and \( c_2 \subset V_j' \). Then, \( L(c_2) \leq 2 \arcsin(\delta_j) \) and also

\[ |L(\gamma_j) - L(c_j)| \leq 2 \arcsin(\delta_j). \]

Therefore,

\[ |d_{M_j}(x, y) - d_{S^3}(x, y)| = |L(\gamma) - L(c_{x, y})| \leq 4 \arcsin(\delta_j) + 2\pi \delta_j. \]

This argument shows that \( \lambda_j \to 0 \) as \( j \to \infty \). Since the intrinsic diameter \( D_{U_j} \leq \pi \) (both in \( M_j \) and \( S^3 \)), \( h_j \) in Theorem 2.3 goes to 0 as \( j \to \infty \). Letting \( \epsilon = 0 \) in Theorem 2.3, we get \( a = 0 \) and \( \bar{h}_j = h_j \) therefore,

\[ d_{\bar{F}}(M_j, S^3) \leq \bar{h}_j \left( 2 \text{Vol}(U_j) + 2 \text{Vol}(\partial U_j) \right) + \text{Vol}(V_j) + \text{Vol}(V_j'). \]

which gives

\[ d_{\bar{F}}(M_j, S^3) \to 0 \text{ as } j \to \infty. \]

To prove that \( M_j \) converges to \( M_0 \) in Gromov-hausdorff sense, we will estimate \( d_{GH}(M_j, M_0) \) using the fact that

\[ d_{GH}(M_j, M_0) = \frac{1}{2} \inf_R (\text{dis } R), \]

where, the infimum is over all correspondences \( R \) between \( M_j \) and \( M_0 \) and \( \text{dis } R \) is the distortion of \( R \) given by

\[ \text{dis } R = \sup \left\{ |d_{M_j}(x, x')| - |d_{M_0}(y, y')| : (x, y), (x', y') \in R \right\}. \]

We need to find correspondences \( R_j \) between \( M_j \) and \( M_0 \) such that \( \text{dis } R_j \to 0 \) as \( j \to \infty \). Consider \( W_j \subset \mathbb{B}^d \) given by

\[ W_j = M_j \cup M_0 = M_0 \cup V_j = M_j \cup \left( M_0 \setminus U_j \right). \]

In fact, we can picture \( W_j \) as the union of sphere, an interval of length \( L \) and a spline of length \( L + \bar{L}(\delta_j) \) around the spline. Then we have, \( M_j \subset W_j \) and \( M_0 \subset W_j \) define the following surjective maps \( f : W_j \to M_j \) and \( g : W_j \to M_0 \)

\[ f|_{M_j} = \text{id}. \]

\[ f(w) = (r(z(w)), 0, 0, z(y)) \in V_j \text{ for } w \in \left( M_0 \setminus U_j \right). \]

Note that when \( w \in \left( M_0 \setminus U_j \right) \), \( f(w) \) is the point in \( V_j \cap xz - \text{plane closest to } w \).
Similarly let

\[ g|_{M_0} = \text{id}. \]

\[ g(w) = \text{the point in } (M_0 \setminus U_j) \text{ closest to } w \text{ for } w \in V_j. \]

Let \( \mathcal{R}_j \) be the following correspondence between \( M_j \) and \( M_0 \),

\[ \mathcal{R}_j = \{(f(w), g(w)) : w \in W_j\}. \]

**Claim:** dis(\( \mathcal{R}_j \)) → 0 as \( j \to \infty \).

Pick \( w_1, w_2 \in W_j \), and suppose \( \gamma + \lambda \) is the minimal geodesic in \( M_j \) connecting \( f(w_1) \) and \( f(w_2) \) where \( \gamma \subset U_j \) and \( \lambda \subset V_j \). and let \( \gamma' + \lambda' \) be the (possibly) broken minimal geodesic connecting \( g(w_1) \) and \( g(w_2) \) where, \( \gamma' \subset U_j \) and \( \lambda' \subset (M_0 \setminus U_j) \).

Without loss of generality we assume that \( z(w_1) \leq z(w_2) \). Next we need estimates on the lengths of \( \gamma, \lambda, \gamma', \lambda' \). Let \( q \) and \( q' \) be starting points on \( \lambda \) and \( \lambda' \) respectively, then

\[ \int_q^{f(w_2)} s'(z) \, dz \leq \int_q^{f(w_2)} L(\lambda) \leq \int_q^{f(w_2)} s'(z) \, dz + 2\pi \delta_j, \]

where, the term \( 2\pi \delta_j \) is the maximum perimeter of the well and note that any two point on the we can be joined by a radial geodesic followed by a curve of length less than \( 2\pi \delta_j \).

Since \( ds^2 = (1 + [r'(z)]^2) \, dz^2 \) we get

\[ \int_q^{f(w_2)} s'(z) \, dz \leq \int_q^{f(w_2)} dz + \int_q^{f(w_2)} |r'(z)| \, dz \leq \int_q^{f(w_2)} dz + \delta_j (L + \bar{L}(\delta_j)). \]

We also have

\[ \int_q^{g(w_2)} dz \leq L(\lambda') \leq \int_q^{g(w_2)} dz + 2 \arcsin(\delta_j). \]

The last inequality comes from the fact that any two points in \( M_0 \setminus U_j \) can be joined by a (broken) geodesic which is a straight line followed by a curve of length at most \( \text{diam}(V_j) = 2 \arcsin(\delta_j) \).

On the other hand by our construction

\[ |\int_q^{q'} dz| \leq \tilde{L}(\delta_j), \]

and,

\[ |\int_q^{g(w_2)} dz| \leq L(\delta_j). \]

Therefore,

\[ |\int_q^{f(w_2)} dz - \int_q^{g(w_2)} dz| \leq 2\tilde{L}(\delta_j). \]
From [209]–[214] we get

\begin{equation}
|L(\lambda) - L(\lambda')| \leq \delta_j \left( L + \bar{L}(\delta_j) + 2\pi \right) + 2\bar{L}(\delta_j) + 2 \arcsin(\delta_j).
\end{equation}

Also one observes that when \( w_1 \in U_j \), then \( \gamma \) and \( \gamma' \) are geodesics on the sphere starting from the same point and ending up in \( V \) which means that

\begin{equation}
|L(\gamma) - L(\gamma')| \leq \text{diam}(V) = 2 \arcsin(\delta_j).
\end{equation}

From (215) and (216),

\begin{equation}
|d_{M_j}(f(w_1), f(w_2)) - d_{M_0}(g(w_1), g(w_2))| \leq |L(\gamma) - L(\gamma')| + |L(\lambda) - L(\lambda')|
\end{equation}

\begin{equation}
\leq \delta_j \left( L + \bar{L}(\delta_j) + 2\pi \right) + 2\bar{L}(\delta_j) + 4 \arcsin(\delta_j).
\end{equation}

Therefore,

\begin{equation}
\text{dis} \mathcal{R}_j \leq \delta_j \left( L + \bar{L}(\delta_j) + 2\pi \right) + 2\bar{L}(\delta_j) + 4 \arcsin(\delta_j),
\end{equation}

which shows that \( \text{dis} \mathcal{R}_j \to 0 \) as \( j \to \infty \). This completes the proof of the claim.

To prove that the convergence of the singular set \( S = \{p_0\} \), which is the bottom of the well, let \( \rho_0 > 0 \), then

\begin{equation}
g_{\delta_j} \to g_{S_3} \ \text{on} \ \rho^{-1}(\{\rho_0, \pi\}),
\end{equation}

because for \( j \) sufficiently large, \( \delta_j < \rho_0 \), which by our construction means that \( g_{\delta_j} = g_{S_3} \ \text{on} \ \rho^{-1}(\{\rho_0, \pi\}). \)

\textbf{Proof:} of Example 5.11. Let \( g(p_0, s) \) denote a symmetric spline of length \( L \) centered at the point \( p_0 \) with width \( s \) (as constructed in the previous examples). Also fix a great circle and a point 0 in \( S^2 \), so now, when we say a point given by the angle \( \theta \), it means a point on this great circle given by the angle \( \theta \). On the round sphere, \( r = \pi - \frac{1}{2} \) is a 2-sphere with radius \( \sin(\pi - \frac{1}{2}) \). Therefore, balls with radius \( s_j = \frac{1}{j} \sin(\pi - \frac{1}{2}) \sqrt{2 - 2 \cos(\frac{2\pi}{2})} \) centered at points \( p_k \) given by the angle \( \theta = \frac{2\pi}{2j} \) are disjoint. Now for each \( j \), we can glue metrics \( g(p_k, s_j) \) which agree with the metric on the spline given in Example 5.9. Outside of each \( B_{p_k}(s_j) \), we set \( g_j = g_0 \). It is easy to see that by our construction, \( g_j \) agrees with the round metric for \( r < \pi - \frac{1}{2j} - s_j \) and has \( 2^j \) splines of length \( L \) and width \( s_j \) and also the volume of the non spherical part is going to 0 as \( j \to \infty \). So by taking \( U_j = r^{-1}(\{0, \pi - \frac{1}{2j} - s_j\}) \), we see that again all conditions in Theorem 2.10 are satisfied therefore we have the flat convergence to the settled completion. \( \square \)

6. Applications

6.1. Background. In this section, we will briefly outline one the applications of our Theorems which is proving a conjecture of Candelas and de la Ossa for conifold flops and transitions. Different versions of this conjecture have been proved in [17] and [20]. Both their proofs require advanced PDE methods and Nash-Moser iteration to get uniform \( C^{k, \alpha} \) bounds on the potential functions. Our approach on the other hand only relies on our main theorems.
Let $M_0$ be a singular normal projective variety of dimension $n$ with singular set $S$. One way to disingularize $M_0$ is called the resolution of singularities of $M_0$ the definition of which is as follows:

**Definition 6.1** (Resolution). A pair $\left(\bar{M}, \bar{\pi}\right)$ of a projective manifold $\bar{M}$ and a morphism $\bar{\pi} : \bar{M} \to M_0$ is called a resolution of $M_0$ if $\bar{\pi} : \bar{M} \setminus \bar{\pi}^{-1}(S) \to M_0 \setminus S$ is biholomorphic.

Another usual method of disingularization is called smoothing and defined as follows

**Definition 6.2** (Smoothing). Let $D \subset \mathbb{C}$ be the unit disc. A pair $\left(M, \pi\right)$ of a projective $n+1$–dimensional manifold $M$ and proper flat morphism $\pi : M \to D$ is called a smoothing if $\pi^{-1}(0) = M_0$ and $\pi^{-1}(t) = M_t$ is a smooth projective $n$–dimensional manifold for $t \in D \setminus \{0\}$.

**Definition 6.3.** [Conifold] A normal variety $M_0$ with $\dim_{\mathbb{C}}(M_0) = n$ is called a conifold if its singularities are all ordinary double points i.e. any singular point is locally given by

$$z_0^2 + z_1^2 + \cdots + z_n^2 = 0.$$  

**Definition 6.4** (Extremal and Conifold Transitions). If $\left(\bar{M}, \bar{\pi}\right)$ and $\left(M, \pi\right)$ are a resolution and smoothing of $M_0$ respectively, then, the diagram

$$\bar{M} \to M_0 \leadsto M_t \quad (t \neq 0),$$

denotes the process of going from $\bar{M}$ to $M_t$ and is called an extremal transition. Whenever $M_0$ is a conifold, the transition is called a conifold transition.

**Definition 6.5** (Flops). If $\left(\bar{M}_1, \bar{\pi}_1\right)$ and $\left(\bar{M}_2, \bar{\pi}_2\right)$ are two resolutions of $M_0$, then the process of going from $\bar{M}_1$ to $\bar{M}_2$ is called a flop and is denoted by the following diagram

$$\bar{M}_1 \to M_0 \leadsto \bar{M}_2.$$ If $M_0$ is a conifold, then the flop is called a conifold flop.

Here, we will mention a mathematical formulation of the Candelas and de la Ossas conjecture due to Rong-Zhang [17]:

**Conjecture 6.6** (Candelas - de la Ossa). Let $M_0$ be a singular $n$–dimensional normal variety then,

(i) Extremal transitions $\bar{M} \to M_0 \leadsto M_t \quad (t \neq 0)$ are continuous with respect to the Gromov-Hausdorff distance i.e. there exist families of Ricci-flat Kähler metrics $\bar{g}_s$ on $\bar{M}$ and $g_t$ on $M_t$ and compact metric space $(X, d_X)$ such that

$$\left(\bar{M}, \bar{g}_s\right) \xrightarrow{G-H} (X, d_X) \xleftarrow{G-H} (M_t, g_t).$$
(ii) Flops $\bar{M}_1 \to M_0 \to \bar{M}_2$ are continuous with respect to the Gromov-Hausdorff distance i.e. there families of Ricci-flat Kähler metrics $\bar{g}_{1,s}$ and a compact metric space $(X, d_X)$ such that

$$\lim_{s \to 0} (\bar{M}_1, \bar{g}_{1,s}) \xrightarrow{G-H} (X, d_X) \xrightarrow{G-H} (\bar{M}_2, \bar{g}_{2,s})$$

**Proposition 6.7** (Generalized Calabi-Yau Theorem). Let $M_0$ be a Calabi-Yau variety, then to any ample line bundle $L_0$ there corresponds a unique Ricci-flat Kähler form $\omega \in c_1(L_0)$.

6.3. Smooth Convergence and Diameter Bounds. Here, we will briefly mention two theorems that establish the smooth convergence away from the singular set $S$.

Tosatti in [25] proved a convergence result for Calabi-Yau metrics which can be paraphrased as follows:

**Proposition 6.8** (Tosatti[25]). Suppose the Calabi-Yau variety $M_0$ admits a crepant resolution $(\bar{M}, \bar{\pi})$ and an ample line bundle $L_0$. Let $\beta_s \in H^{1,1}(\bar{M}, \mathbb{R}), s \in (0, 1)$ be a family of Kähler classes such that

$$\lim_{s \to 0} \beta_s = \bar{\pi}^* c_1(L_0).$$

Let $\bar{g}_s$ be the unique Ricci-flat Kähler corresponding to the Kähler form $\bar{\omega}_s \in \beta_s$ then, as $s \to 0$,

$$\bar{g}_s \xrightarrow{C^\infty} \bar{\pi}^* g \quad \text{and} \quad \bar{\omega}_s \xrightarrow{C^\infty} \bar{\pi}^* \omega$$

on any compact subset $K \subset\subset \bar{M} \setminus \bar{\pi}^{-1}(S)$.

On the other hand Ruan-Zhang[17] proved convergence (off the singular set) and diameter bound results for smoothings of a Calabi-Yau conifold. Although their result is sufficient for our purpose, we will mention a generalization of convergence results in [18] due to Rong-Zhang [17] for the sake of being thorough.

**Proposition 6.9** (Rong-Zhang[17]). Let $M_0$ be a Calabi-Yau variety with $\dim_{\mathbb{C}}(M_0) = n$ $(n \leq 2)$ with singular set $S$. Assume that $M_0$ admits a smoothing $\pi : \bar{M} \to D$ and an ample line bundle $L$ whose relative canonical bundle $K_{\bar{M}/D} \equiv O_{\bar{M}}$. Let $g_t$ be the unique Ricci-flat Kähler metric with Kähler form $\omega_t \in c_1(L)|_{M_t} \in H^{1,1}(M_t, \mathbb{R})$ $(t \neq 0)$, and $\omega$ be the unique singular Ricci-flat Kähler form on $M_0$ with $\omega \in c_1(L)|_{M_0} \in (M_0, P^*H_{M_0})$, then

$$F_t^* g_t \xrightarrow{C^\infty} g \quad \text{and} \quad F_t^* \omega_t \xrightarrow{C^\infty} \omega$$

on any compact subset $K \subset\subset M_0 \setminus S$, where $F_t : M_0 \setminus S \to M_t$ is a smooth family of embeddings and $g$ is the corresponding Kähler metric of $\omega$ on $M_0 \setminus S$. Furthermore, the diameter of $(M_t, g_t)$ $(t \neq 0)$ enjoys the uniform upper bound

$$\text{diam}_{g_t}(M_t) \leq D$$

where $D$ is a constant independent of $t$. 
6.4. **Good Exhaustion of the Regular Set.** In this section, we will consider the case of finitely many ordinary double point singularities $S = \{p_1, p_2, \ldots, p_m\} \subset M$ and will give a very natural exhaustion, $\{K_i\}$, of the regular set $M \setminus S$ that satisfy all the hypotheses in Theorem 1.3.

Recall from Definition 6.3 that a double point singularity is locally modelled as $p = (0, 0, \ldots, 0)$ in $\{z \in \mathbb{C}^{n+1} | z_0^2 + z_1^2 + \cdots + z_n^2 = 0\}$.

We construct the exhaustion by just taking out metric balls around singular points, i.e. let $r_i$ be a sequence of positive numbers such that $\lim_{i \to \infty} r_i = 0$ and let

$$W_i = M_0 \setminus \bigcup_j B(p_j, r_i)$$

At this point we recall the Bishop-Gromov relative volume comparison theorems which will show that we have chosen a good exhaustion.

**Theorem 6.10** (Bishop-Gromov Relative Volume Comparison). *Suppose $M^n$ has Ricci$_M \geq (n - 1)H$ then,*

$$\frac{\text{Vol}(\partial B(p, r))}{\text{Vol}_H(\partial B(r))} \text{ and } \frac{\text{Vol}(B(p, r))}{\text{Vol}_H(B(r))}$$

*are nonincreasing in $r$.*

We also need the following well-known expansion of volume ratio for Riemannian manifolds:

**Proposition 6.11.** *For any Riemannian manifold $M$, we have:*

$$\frac{\text{Vol}(B(\epsilon, p) \subset M)}{\text{Vol}(B(p) \subset \mathbb{R}^n)} = 1 - \frac{\text{Scal}}{6(n + 2)} \epsilon^2 + O(\epsilon^4),$$

*and,*

$$\frac{\text{Vol}(\partial B(\epsilon, p) \subset M)}{\text{Vol}(\partial B(p) \subset \mathbb{R}^n)} = 1 - \frac{\text{Scal}}{6n} \epsilon^2 + O(\epsilon^4)$$

Applying Theorem 6.10 and Proposition 6.11 to our Ricci flat metrics prove that the exhaustion we have chosen and their boundaries satisfy the volume and diameter conditions in Theorems 1.3 and 1.4 namely,

$$\text{Vol}_g(\partial W_j) \leq A_0,$$

and

$$\text{Vol}_g(M \setminus W_j) \leq V_j \text{ where } \lim_{j \to \infty} V_j = 0,$$

**Remark 6.12.** *We are allowed to use the comparison theorems because we are in the setting of Kähler manifolds.*
6.5. **Proof of Theorem 1.6.** Propositions 6.8 and 6.9 provide the diameter bounds and convergence off the singular set assumptions in Theorems 1.3 and 1.4 and by using Theorem 6.10 and Proposition 6.11 we get the uniform volume bounds for the exhaustion $W_j$ and their boundaries as are required in Theorems 1.3 and 1.4.
