EXTENDED GAMBLER’S RUIN PROBLEM

THEO VAN UEM

ABSTRACT. In the extended gambler’s ruin problem we can move one step forward or backward (classical gambler’s ruin problem), we can stay where we are for a time unit (delayed action) or there can be absorption in the current state (game is terminated without reaching an absorbing barrier). We obtain probabilities for maximum and minimum values of the ruin problem, expected time until absorption, asymptotic behaviour of the absorption probabilities and the value of the game. We introduce a conjugate version of our random walk.

1. Introduction

The gambler’s ruin problem is a special random walk. Random walk can be used in various disciplines: in physics as a simplified model of Brownian motion, in ecology to describe individual animal movements and population dynamics, in statistics to analyze sequential test procedures, in economics to model share prices and their derivatives, in medicine and biology where absorbing barriers give a natural model for a wide variety of phenomena.

In Feller [3] there is a complete chapter (XIV) devoted to random walk and ruin problems. El-Shehawey et al. [2] consider a gambler’s ruin problem in the case that the probabilities of winning/losing a particular game depend on the amount of the current fortune with ties allowed. Yamamoto [4] treats a random walk which hops either rightwards or leftwards, and in addition introduces the ‘halt’: the walker does not hop. In this paper we investigate an extended one dimensional random walk. We call it a $[pqrs]$ walk, where $p$ is the one-step forward probability, $q$ one-step backward, $r$ the probability to stay for a time unit in the same position and $s$ is the probability of absorption in the current state ($p + q + r + s = 1, pqs > 0$). In section 2 we solve a set of difference equations which is fundamental for all other sections. In section 3 we obtain results for maximum and minimum of the random walk. Section 4 covers the expected time until absorption (in any state) in a $[pqrs]$ random walk. In section 5 we investigate the asymptotic behaviour of the absorption probabilities when $s \to 0$. In section 6 we obtain the value of the game. In section 7 we introduce a conjugate random walk.

2020 Mathematics Subject Classification. 60G50, 60J05.
2. A RELATED SET OF DIFFERENCE EQUATIONS

For a discrete Markov chain we define the expected number of visits to state \( j \) when starting in state \( i \) by:

\[
x_j = x_{i,j} = \sum_{k=0}^{\infty} p_{i,j}^{(k)}
\]

We start in state \( i_0 \).

**Theorem 1.** The set of difference equations:

\[
(1) \quad (1 - r)x_n = \delta(n, i_0) + px_{n-1} + qx_{n+1} \quad (a < n < b)
\]

where \( pq > 0 \), \( p + q + r < 1 \), has unique solutions:

\[
(2) \quad x_n = \begin{cases} 
\zeta \xi_1^n + C_1 \xi_1^n + C_2 \xi_2^n & (a \leq n \leq i_0) \\
\zeta \xi_2^n + C_1 \xi_1^n + C_2 \xi_2^n & (i_0 \leq n \leq b)
\end{cases}
\]

where:

\[
\xi_1 = \frac{(1 - r) + \sqrt{(1 - r)^2 - 4pq}}{2q} > 1 \\
0 < \xi_2 = \frac{(1 - r) - \sqrt{(1 - r)^2 - 4pq}}{2q} < 1 \\
\zeta = \left( \frac{(1 - r)^2 - 4pq}{2q} \right)^{-\frac{1}{2}}
\]

**Proof.** General solution of homogeneous part of (1) is:

\[
x_n = C_1 \xi_1^n + C_2 \xi_2^n \quad (n \in \mathbb{Z})
\]

where \( \xi_1 \) and \( \xi_2 \) are the solutions of:

\[q\xi^2 - (1 - r)\xi + p = 0\]

A particular solution of (1) is (verified by substitution):

\[
x_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{\exp[-i\theta(n - i_0)]d\theta}{(1 - r) - p \exp(i\theta) - q \exp(-i\theta)}
\]

Substituting \( z = e^{-i\theta} \) gives

\[
x_n = \frac{i}{2\pi} \int \frac{z^{n-i_0}dz}{qz^2 - (1 - r)z + p} = \frac{i}{2\pi} \int \frac{z^{n-i_0}dz}{q(z - \xi_1)(z - \xi_2)}
\]

where the integration is counterclockwise around the circle \(|z| = 1\). After applying the residue theorem we obtain a particular solution. We get:

\[
(3) \quad x_n = \begin{cases} 
\zeta \xi_1^{n-i_0} + C_{11} \xi_1^{n-i_0} + C_{12} \xi_2^{n-i_0} & (n \leq i_0) \\
\zeta \xi_2^{n-i_0} + C_{21} \xi_1^{n-i_0} + C_{22} \xi_2^{n-i_0} & (n \geq i_0)
\end{cases}
\]

By substituting \( n = i_0 \) twice in (3) and taking \( n = i_0 \) in (1) we get: \( C_{11} = C_{21} \) and \( C_{12} = C_{22} \). The \( x_n \) are unique: given an arbitrary solution of (1), the constants \( C_1 \) and \( C_2 \) can be chosen so that (2) will agree with it for two consecutive numbers. From these two values all other values can be found by using (1). \( \square \)
3. Maximum and minimum of extended ruin problem

Let \( D ([0, N], [0, \infty) \) or \((-\infty, \infty)) \) be the domain of our extended discrete random walk. We define for \( a \in D \):

\[
a|D = \begin{cases} 
[a, N] & \text{if } D = [0, N] \\
[a, \infty) & \text{if } D = [0, \infty) \text{ or } D = (-\infty, \infty)
\end{cases}
\]

where state \( a \) is transformed in an absorbing barrier. We define for \( b \in D \):

\[
D|b = \begin{cases} 
[0, b] & \text{if } D = [0, N] \text{ or } D = [0, \infty) \\
(-\infty, b] & \text{if } D = (-\infty, \infty)
\end{cases}
\]

where state \( b \) is transformed in an absorbing barrier. The solution of (1), restricted to domain \( D \) will be written as \( x^D_n \). In this section we focus on maximum \( M \) and minimum \( m \) of the \([pqrs] \) random walk with domain \( D \).

**Theorem 2.** On \([0, N]\):

\[
P(m = 0) = x^D_0
\]

\[
P(M = N) = x^D_N
\]

On \([0, \infty)\):

\[
P(m = 0) = x^D_0
\]

If no absorption barriers are involved:

\[
P(m = a) = x^D_a - x^D_{a-1} \quad (a \leq i_0)
\]

\[
P(M = b) = x^D_b - x^D_{b+1} \quad (b \geq i_0)
\]

**Proof.** For a state \( j \) with absorption probability \( s_j \) we have: \( P(\text{absorption in } j \text{ when starting in } i) = \sum_{k=0}^{\infty} P_j^{(k)} s_j = s_j x_j \). For an absorbing barrier we have \( s_j = 1 \), so the probability of absorption in a barrier is \( x_j \). If \( a \) is not an absorbing barrier then we can detect a visit to \( a \) by transforming \( a \) in an absorbing barrier. Notice: \( \{m \leq a\} = \{\text{random walk visits } a \text{ after } n \text{ steps for some } n \geq 0\} \), where \( a \leq i_0 \), so:

\[
P(m = a) = x^D_a - x^D_{a-1} \quad (a \leq i_0)
\]

We can apply the same procedure in case of \( M \geq b \).

\[
P(M = b) = x^D_b - x^D_{b+1} \quad (b \geq i_0)
\]

\(\square\)
3.1. Maximum and minimum on $[0, N]$.

**Theorem 3.** The probabilities of absorption in the barriers $a$ and $b$ in a $[pqrst]$ random walk on $[a, b]$ when starting in $i_0$, $(a < i_0 < b)$ are:

\[
\begin{align*}
 x_a^{[a,b]} &= \frac{\xi_1^{b-i_0} - \xi_2^{b-i_0}}{\xi_1^{b-a} - \xi_2^{b-a}} \\
 x_b^{[a,b]} &= \frac{\xi_1^{a-i_0} - \xi_2^{a-i_0}}{\xi_1^{a-b} - \xi_2^{a-b}}
\end{align*}
\]

**Proof.** We start in $i_0$, $(a + 2 \leq i_0 \leq b - 2)$. The set of difference equations:

\[(1-r)x_n = \delta(n, i_0) + px_{n-1} + qx_{n+1} \quad (a + 2 \leq n \leq b - 2)\]

has solutions (using Theorem (1)):

\[
x_n = \begin{cases} 
\zeta \xi_1^{n-i_0} + C_1 \xi_1^n + C_2 \xi_2^n & (a + 1 \leq n \leq i_0) \\
\zeta \xi_2^{n-i_0} + C_1 \xi_1^n + C_2 \xi_2^n & (i_0 \leq n \leq b - 1)
\end{cases}
\]

Notice that the solution is also valid for $n = a + 1$ and $n = b - 1$, which can be seen by observing the difference equations for $n = a + 2$ and $n = b - 2 : x_{a+1}$ and $x_{b-1}$ satisfy the difference pattern. Using $(1-r)x_{a+1} = qx_{a+2}$ and $(1-r)x_{b-1} = px_{b-2}$, where $b - 2 > a$, we get:

\[
C_1 = \frac{\zeta \xi_2^{b-i_0} (\xi_1^{a-i_0} - \xi_2^{a-i_0})}{\xi_1 \xi_2^{b-a} - \xi_1^{b-a}}
\]

\[
C_2 = \frac{\zeta \xi_2^{b-i_0} (\xi_1^{a-i_0} - \xi_2^{a-i_0})}{\xi_1 \xi_2^{b-a} - \xi_1^{b-a}}
\]

and:

\[
x_n = x_n^{[a,b]} = \begin{cases} 
\frac{\zeta \xi_1^{n-i_0} (\xi_2^{a-i_0} - \xi_1^{a-i_0}) (\xi_2^n - \xi_1^n)}{\xi_1^{n-a} - \xi_2^{n-a} (\xi_2^n - \xi_1^n)} & (a + 1 \leq n \leq i_0) \\
\frac{\zeta \xi_2^{n-i_0} (\xi_1^{a-i_0} - \xi_2^{a-i_0}) (\xi_2^n - \xi_1^n)}{\xi_1^{n-b} - \xi_2^{n-b} (\xi_2^n - \xi_1^n)} & (i_0 \leq n \leq b - 1)
\end{cases}
\]

$x_a = qx_{a+1}$ and $x_b = px_{b-1}$ leads to the desired result. After some calculation we find the result also valid for $i_0 = a, a + 1, b - 1, b$. \qed

After some calculations we have:

\[
\sum_{n=0}^N s_n x_n = 1 \quad (s_0 = s_N = 1; s_i = s \quad (i = 1, 2, \ldots, N - 1))
\]

The combination of Theorem (2) and Theorem (3) gives the probabilities of maximum and minimum on $[0, N]$:

\[
P(M = N) = x_N^{[0,N]} = \frac{\xi_2^{-i_0} - \xi_1^{-i_0}}{\xi_2^N - \xi_1^N}
\]

\[
P(m = 0) = x_0^{[0,N]} = \frac{\xi_1^{N-i_0} - \xi_2^{N-i_0}}{\xi_1^N - \xi_2^N}
\]
\( P(\text{absorption in an absorbing barrier}) = \)

\[
P(M = N) + P(m = 0) = \frac{\xi_1^{N-i_0}(1 - \xi_2^N) - \xi_2^{N-i_0}(\xi_1^N - 1)}{\xi_1^N - \xi_2^N}
\]

\( P(\text{absorption not in an absorbing barrier}) = \)

\[
(1 - \xi_1^{N-i})(1 - \xi_2^N) - (1 - \xi_2^{N-i})(1 - \xi_1^N)
\]

This probability plays a role in the expected time until absorption (see (16)).

3.2. **Maximum and minimum on \([0, \infty)\).** We need \(x_n^{(a, \infty)}\) to calculate the max/min probabilities (see Theorem 2).

**Theorem 4.** The probability of absorption in the barrier \(a\) in a \([pqr\]) random walk on \([a, \infty)\) when starting in \(i_0\) is:

\( \quad x_n^{(a, \infty)} = \xi_1^{a-i_0} \quad (a \leq i_0) \)

**Proof.** We look at a \([pqr\]) random walk on \([a, \infty)\) where \(a\) is an absorbing barrier. We start in \(i_0\) with \(a + 2 \leq i_0\). The set of difference equations:

\[
(1 - r)x_n = \delta(n, i_0) + px_{n-1} + qx_{n+1} \quad (a + 2 \leq n)
\]

has solutions (using Theorem (11)):

\[
x_n = \begin{cases} 
\xi_1^{a-i_0} + \frac{C_2\xi_2^n}{\xi_1^n} & (a + 1 \leq n \leq i_0) \\
\xi_2^{a-i_0} + \frac{C_2\xi_1^n}{\xi_2^n} & (i_0 \leq n)
\end{cases}
\]

Notice that the solution is also valid for \(n = a + 1\), which can be seen by observing the difference equations for \(n = a + 2\): \(x_{a+1}\) satisfy the difference pattern. Using \((1 - r)x_{a+1} = qx_{a+2}\) we get:

\[
C_2 = -\xi_1^{a-i_0}\xi_2^{-a}.
\]

\[
x_n = x_n^{(a, \infty)} \begin{cases} 
\xi_1^{a-i_0}(\xi_1^n - \xi_2^n) & (a + 1 \leq n \leq i_0) \\
\xi_2^{a-i_0}(\xi_2^n - \xi_1^n) & (i_0 \leq n)
\end{cases}
\]

\( x_a = qx_{a+1} \) leads to the desired result. \(\Box\)

This result can also be obtained by taking \(b \to \infty\) in (11), but we prefer this way because we also get the absorption probabilities \(sx_n\) in all states. We can use Theorem 2 and Theorem 4 on \([0, \infty)\), e.g.:

\[
P(m = 0) = x_0^{(0, \infty)} = \xi_1^{-i_0}
\]

\[
P(m = a) = x_a^{(a)} - x_{a-1}^{(a)} = x_0^{(a, \infty)} - x_{a-1}^{(a-1, \infty)} = \xi_1^{a-i_0-1}(\xi_1 - 1)
\]

\((1 \leq a \leq i_0)\)

After some calculations we have:

\[
\sum_{n=0}^{\infty} s_n x_n = 1 \quad (s_0 = 1; s_i = s \quad (i > 1))
\]

so \(P(\text{absorption not in the absorption barrier}) = \)

\[
1 - \xi_1^{-i_0}
\]

This plays a role in expected time until absorption. See (17).
3.3. Maximum and minimum on \((-\infty, \infty)\). We need \(x_b^{(-\infty,b]}\) to calculate the max/min probabilities (see Theorem 2), so we look at a \([pqrs]\) random walk on \((-\infty,b]\) where  \(b\) is an absorbing barrier.

**Theorem 5.** The probability of absorption in the barrier \(b\) in a \([pqrs]\) random walk on \([-\infty,b]\) when starting in \(i_0\) is:

\[
x_b^{(-\infty,b]}(i_0, b) = \xi^{b-i_0}_2 \quad (b \geq i_0)
\]

**Proof.** We start in \(i_0\) with \(b \geq i_0 + 2\). Proceeding along the same lines as with \(x_{\alpha,\infty}\) (or taking \(a \rightarrow -\infty\) in (5)) we get:

\[
x_n = x_n^{(-\infty,b]} = \begin{cases} \xi_1^{n-b}(\xi_1^{b-i_0} - \xi_2^{b-i_0}) & (n \leq i_0) \\ \xi_2^{n-b}(\xi_2^{b-i_0} - \xi_1^{b-i_0}) & (i_0 \leq n \leq b - 1) \end{cases}
\]

\[x_b = px_{b-1}.\]

Note: Theorem 1 can be seen as the reflection image of Theorem 4.

We apply Theorem 2 on \((-\infty, \infty)\), e.g.:

\[P(M = b) = x_b^{D[b]} - x_{b+1}^{D(b+1)} = x^{(-\infty,b]}_b - x^{(-\infty,b+1]}_{b+1} = \xi^{b-i_0}_2 (1 - \xi_2) \quad (b \geq i_0)\]

Using Theorem 1 with \(C_1 = C_2 = 0\):

\[
x_n = x_n^{(-\infty,\infty)} = \begin{cases} \xi_1^{n-i_0} & (n \leq i_0) \\ \xi_2^{n-i_0} & (n \geq i_0) \end{cases}
\]

After some calculations we have:

\[
\sum_{n=-\infty}^{\infty} s x_n = 1
\]

4. Expected time until absorption

In this section we are interested in the expected time until absorption in any state in a \([pqrs]\) random walk with \(pqs > 0\). We define \(m_i = m_i^D\) as the expected time until absorption in any state when starting in state \(i\) on domain \(D\). In section 3 we proved that absorption always occurs.

**Theorem 6.** The set of difference equations

\[
(1-r)m_i = pm_{i+1} + qm_{i-1} + 1 \quad (i \in \mathbb{Z}) \quad (s + p + q + r = 1, pqs > 0)
\]

has solution

\[
m_i = a \xi_1^{-i} + b \xi_2^{-i} + \frac{1}{s} \quad (i \in \mathbb{Z})
\]

**Proof.** By substitution. \(\square\)

The expected times in the next subsections are unique by the same argument given after Theorem 4.
4.1. **Expected time until absorption on** $[0,N]$.

**Theorem 7.** The expected time until absorption when starting in $i$ ($i = 0,1,\ldots,N$) in a $[pqrs]$ random walk on $[0,N]$ is:

$$m_i = \frac{1}{s} \left\{ \frac{(1 - \xi_1^{N-i})(1 - \xi_2^N) - (1 - \xi_2^{N-i})(1 - \xi_1^N)}{\xi_1^N - \xi_2^N} \right\}$$  

**Proof.**

$$(1 - r)m_i = pm_{i+1} + qm_{i-1} + 1 \quad (i = 1,2,\ldots,N-1)$$

$m_0 = m_N = 0$

Use theorem 6 to get the result.  

Combination of (7) and (16) gives:

$$m_i = \frac{u_i^{[0,N]}}{s}$$

where $u_i^{[0,N]} = P(\text{absorption not in an absorbing barrier | start in } i)$.

4.2. **Expected time until absorption on** $[0,\infty)$.

**Theorem 8.** The expected time until absorption when starting in $i$ ($i = 0,1,\ldots$) in a $[pqrs]$ random walk on $[0,\infty)$ is:

$$m_i = \frac{1}{s}(1 - \xi_1^{-i})$$

**Proof.**

$$(1 - r)m_i = pm_{i+1} + qm_{i-1} + 1 \quad (i = 1,2,\ldots)$$

$m_0 = 0$

Use theorem 6 (with $b = 0$).  

We get the same result by taking $N \to \infty$ in theorem 7. Combination of (17) and (10) gives:

$$m_i = \frac{u_i^{[0,\infty]}}{s}$$

where $u_i^{[0,\infty]} = P(\text{absorption not in an absorbing barrier | start in } i)$.

4.3. **Expected time until absorption on** $(-\infty,\infty)$.

**Theorem 9.** The expected time until absorption when starting in $i$ ($i \in \mathbb{Z}$) in a $[pqrs]$ random walk on $(-\infty,\infty)$ is:

$$m = \frac{1}{s}$$

**Proof.** We give three proofs. P1: $m = p(m+1) + q(m+1) + r(m+1) + s.1$

P2: Take $a = b = 0$ in theorem 6. P3: $m = s \sum_{k=1}^{\infty} k(1-s)^{k-1}$

Note: $m_i = \frac{u_i^{(-\infty,\infty)}}{s}$ where $u_i^{(-\infty,\infty)} = P(\text{absorption not in an absorbing barrier | start in } i)=1$. (See (13)).
5. ASYMPTOTIC BEHAVIOUR OF ABSORPTION PROBABILITIES

In this section we obtain asymptotic results for the probabilities of absorption when \( s \to 0 \). We define \( t = \sqrt{ps} \).

**Lemma 10.** If \( s \to 0 \) then:

If \( p > q \):
\[
\xi_1 \sim \frac{ps}{q} (1 + \frac{ps}{q-p}) \quad \xi_2 \sim 1 - \frac{ps}{q-p} + \frac{ps^2}{(p-q)^2} \quad \zeta \sim \frac{1}{p-q} \left[ 1 - \frac{(p+q)s}{(p-q)^2} \right]
\]

If \( p < q \):
\[
\xi_1 \sim 1 + \frac{ps}{q-p} \quad \xi_2 \sim \frac{ps}{q} (1 - \frac{ps}{q-p}) \quad \zeta \sim \frac{1}{q-p} \left[ 1 - \frac{(p+q)s}{(p-q)^2} \right]
\]

If \( p = q \):
\[
\xi_1 \sim 1 + t + \frac{1}{2} t^2 + \frac{1}{8} t^3 \quad \xi_2 \sim 1 - t + \frac{1}{2} t^2 - \frac{1}{8} t^3 \quad \zeta \sim \frac{1}{2pt} (1 - \frac{1}{8} t^2)
\]

**Proof.** We proof the last one: \( \zeta = ((1-r)^2 - 4p^2)^{-\frac{1}{2}} = (4ps + s^2)^{-\frac{1}{2}} = (4ps)^{-\frac{1}{2}} (1 + \frac{s^2}{4ps})^{-\frac{1}{2}} \sim \frac{1}{2\sqrt{ps}} (1 - \frac{s}{8p}) = \frac{1}{2pt} (1 - \frac{1}{8} t^2) \) \( \square \)

We define \( u = \frac{p}{q} \). In the next subsections we use Lemma 10.

5.1. **Asymptotic behaviour on** \([0, N]\). We use (4), (5) and (6).

If \( s \to 0 \) and \( p > q \):
\[
x_0^{[0,N]} \sim \frac{u^{N-i_0} - 1}{u^N - 1} + \frac{u}{1-u} \left\{ \frac{2N(u^N - u^{N-i_0})}{(u^N - 1)^2} - \frac{i_0(u^{N-i_0} + 1)}{u^N - 1} \right\} \frac{s}{p}
\]

\[
x_N^{[0,N]} \sim \frac{u^N - u^{N-i_0}}{u^N - 1} + \frac{u}{1-u} \left\{ \frac{-N(u^N - u^{N-i_0})}{(u^N - 1)^2} + \frac{i_0(u^N + u^{N-i_0})}{u^N - 1} \right\} \frac{s}{p}
\]

\[
s \sum_{n=1}^{N-1} x_n \sim \frac{u}{u-1} \left\{ \frac{N(u^N - u^{N-i_0})}{u^N - 1} - i_0 \right\} \frac{s}{p}
\]

If \( s \to 0 \) and \( p < q \) we get similar results. If \( s \to 0 \) and \( p = q \):
\[
x_0^{[0,N]} \sim (1 - \frac{i_0}{N}) - \left\{ \frac{i_0(N-i_0)(2N-i_0)}{6N} \right\} \frac{s}{p}
\]
\[
x_N^{[0,N]} \sim \frac{i_0}{N} - \left\{ \frac{i_0(N-i_0)(N+i_0)}{6N} \right\} \frac{s}{p}
\]

\[
s \sum_{n=1}^{N-1} x_n \sim \left\{ \frac{i_0(N-i_0)}{2} \right\} \frac{s}{p}
\]

The results for \( p = q \) can also be obtained from the results of \( p > q \) by repeated application of L'Hospital's rule.
5.2. Asymptotic behaviour on $[0, \infty)$. We use Theorem 4 and (8).

If $s \to 0$ and $p > q$:

\[
x_0 \sim u^{-i_0} - \frac{i_0 u^{1-i_0}}{u-1} \frac{s}{p}
\]

\[
s \sum_{n=1}^{i_0-1} x_n \sim \left\{ \frac{u(1-u^{-i_0})}{(u-1)^2} - \frac{(i_0 - 1)u^{1-i_0}}{u-1} \right\} \frac{s}{p}
\]

\[
s \sum_{n=i_0}^{\infty} x_n \sim 1 - u^{-i_0} - \left\{ \frac{u(1-u^{-i_0})}{(u-1)^2} + \frac{2i_0 u^{1-i_0}}{u-1} \right\} \frac{s}{p}
\]

If $s \to 0$ and $p < q$:

\[
x_0 \sim 1 + \left\{ \frac{i_0 u}{1-u} \right\} \frac{s}{p}
\]

\[
s \sum_{n=1}^{i_0-1} x_n \sim \frac{u}{1-u} \left\{ i_0 - 1 - \frac{u-u^{i_0}}{1-u} \right\} \frac{s}{p}
\]

\[
s \sum_{n=i_0}^{\infty} x_n \sim \left\{ \frac{u(1-u^{-i_0})}{(u-1)^2} \right\} \frac{s}{p}
\]

If $s \to 0$ and $p = q$:

\[
x_0 \sim 1 - i_0 t + \frac{1}{2} i_0^2 t^2
\]

\[
s \sum_{n=1}^{i_0-1} x_n \sim \frac{i_0(i_0 - 1)}{2} t^2
\]

\[
s \sum_{n=i_0}^{\infty} x_n \sim i_0 t - \frac{1}{2} i_0^2 (2i_0 - 1) t^2
\]

5.3. Asymptotic behaviour on $(-\infty, \infty)$. We use (11) and (12). Without limitation we can take $i_0 = 0$.

If $s \to 0$ and $p > q$:

\[
s \sum_{n=-1}^{-\infty} x_n \sim \left\{ \frac{u}{(u-1)^2} \right\} \frac{s}{p}
\]

\[
sx_0 \sim \left\{ \frac{u}{(u-1)} \right\} \frac{s}{p}
\]

\[
s \sum_{n=1}^{\infty} x_n \sim 1 - \left\{ \frac{u^2}{(u-1)^2} \right\} \frac{s}{p}
\]

If $s \to 0$ and $p = q$:

\[
s \sum_{n=1}^{\infty} x_n \sim s \sum_{n=-1}^{-\infty} x_n \sim \frac{1}{2} - \frac{1}{4} \sqrt{s} \frac{p}{p}
\]

\[
sx_0 \sim \frac{1}{2} \sqrt{s} \frac{p}{p}
\]
6. Value of the game

Let \( n \) be our final position after absorption. We define the value of the game as the expectation of \( n \).

6.1. Value of the game on \([0, N]\).

**Theorem 11.**

(19) \[
E(n) = i_0 + \frac{(p - q)}{s} \left\{ 1 - \frac{\xi_2^{N-i_0} (1 - \xi_1^N) + \xi_1^{N-i_0} (\xi_1^N - 1)}{\xi_1^N - \xi_2^N} \right\}
\]

**Proof.** Calculating \( \sum_{n=1}^{i_0-1} \xi^n \) and \( \sum_{n=i_0}^{N-1} \xi^n \) and differentiating we get:

\[
\sum_{n=1}^{i_0-1} n \xi^{n-1} = \frac{\xi^{i_0} - \xi - N(1 - \xi) \xi^{N-1} + i_0 (1 - \xi) \xi^{i_0-1}}{(1 - \xi)^2}
\]

\[
\sum_{n=i_0}^{N-1} n \xi^{n-1} = \frac{\xi^{i_0} - \xi - N(1 - \xi) \xi^{N-1} + i_0 (1 - \xi) \xi^{i_0-1}}{(1 - \xi)^2}
\]

\[E(n) = s \sum_{n=1}^{N-1} n x_n + N x_N = s \sum_{n=1}^{i_0-1} n \xi (\xi_2^{N-i_0} - \xi_1^{N-i_0})(\xi_1^n - \xi_2^n) + \sum_{n=i_0}^{N-1} n \xi (\xi_2^{N-i_0} - \xi_1^{N-i_0})(\xi_1^n - \xi_2^n)
\]

We first concentrate on the terms linear in \( N \): a simple calculation shows that these vanish. Next we concentrate on terms linear in \( i_0 \): a calculation reduces to \( i_0 \). The remaining terms can be written as (after some calculation):

\[
\frac{s \zeta}{\xi_1^N - \xi_2^N} \left\{ \frac{\xi_2 \Phi}{(1 - \xi_2)^2} - \frac{\xi_1 \Phi}{(1 - \xi_1)^2} \right\} = \frac{(p - q) \Phi}{s (\xi_1^N - \xi_2^N)}
\]

where \( \Phi = (\xi_1^N - \xi_2^N) - (\xi_1^{N-i_0} - \xi_2^{N-i_0}) + \xi_1^{N-i_0} (\xi_1^{N-i_0} - \xi_2^{N-i_0}) \).

\[\square\]

6.2. Value of the game on \([0, \infty)\).

**Theorem 12.**

(20) \[
E(n) = i_0 + \frac{(p - q)(1 - \xi_1^{-i_0})}{s}
\]

**Proof.** Use the method of the proof of Theorem [11] \[\square\]

We get the same result by letting \( N \to \infty \) in (19).
6.3. Value of the game on \((-\infty, \infty)\).

**Theorem 13.**

\[ E(n) = i_0 + \frac{(p - q)}{s} \]

**Proof.** Use the method of the proof of Theorem 11. \(\square\)

Note: Let \(g\) be our final gain. Using (16), (17), (18), (19), (20), (21) we get \(E(g) = E(n) - i_0 = (p - q)m_{i_0}\) where \((p - q)\) is the unit time gain expectation and \(m_{i_0}\) is the expected duration of the game.

7. A conjugate random walk

We define \(P_r = \frac{q}{q - r}, Q_r = \frac{q}{q - r}, S_r = \frac{s}{s - r}\). Besides our original \([pqr]s\) random walk with \(p + q + r + s = 1\) and \(pqs > 0\) we also consider the conjugate \([p_r, q_r, s_r]\) walk with \(p_r + q_r + s_r = 1\) and \(p_r q_r s_r > 0\). We define \(\Xi_i(P_r, Q_r, S_r) = \xi_i(P_r, Q_r, 0, S_r)\) \((i = 1, 2)\) and \(Z_1(P_r, Q_r, S_r) = \zeta_i(P_r, Q_r, 0, S_r)\), \(-\).

**Lemma 14.** \(\Xi_i(P_r, Q_r, S_r) = \xi_i(p, q, r, s)\) \((i = 1, 2)\) and \(Z_1(P_r, Q_r, S_r) = (1 - r)\zeta_i(p, q, r, s)\)

**Proof.** \(\xi_i(p, q, r, s) = \frac{(1 - r)^{1 - 1}[(1 - r)^{2 - 4pq}]}{2q} = \frac{(1 - r)^{1 - 1}[-1 - 4pq]}{2q} = \xi_i(p, q, r, 0, S_r)(i = 1, 2)\). \((1 - r)\zeta(p, q, r, s) = (1 - r)[(1 - r)^{2 - 4pq}]^{-\frac{1}{2}} = (1 - 4p q r)^{-\frac{1}{2}} = \zeta(p, q, r, 0, S_r)\) \(\square\)

The conjugate walk is non-delayed and gives insight in the behaviour of the original delayed walk.

**Theorem 15.** The \([pqr]s\) walk and the conjugate \([p_r, q_r, s_r]\) walk gives the same results for: maximum and minimum of the walks, absorption probabilities, asymptotic behaviour and the value of the game. The expected time until absorption in the conjugate case is \((1 - r)\) times the expected time until absorption in the original walk.

**Proof.** By Lemma 14 we have: all results with only \(\xi_i\) \((i = 1, 2)\) will hold for both walks. For example: all formulas with relation to maximum and minimum. But there is more. Absorption probabilities are given by \(s_{x_{max}}\) and in (6) (8) (12) we see that these probabilities are always of the form \(s_{xF}\) where \(F\) is a function of \(\xi_i\) \((i = 1, 2)\). By Lemma 14 we have \(s_{x\zeta(p, q, r, s)} = s_{z_{1}}Z_1(P_r, Q_r, S_r) = S_rZ_1(P_r, Q_r, S_r)\), so the \(s_{x}\) part in our original formulas can be changed to \(S_rZ_1\) in the conjugate walk, which doesn’t change the value. The section about asymptotic behaviour also stays unchanged: \(u = \frac{p}{q} = \frac{p}{q}\) and \(\frac{s}{s} = \zeta_{s}\). The value of the conjugate game is the same as the value of the original game: \(\frac{p_r - q_r}{s_r} = P_r - Q_r\). The expected time until absorption needs some attention. The basis of all calculations in section 3 is Theorem 6. Besides the \(\xi_i\) \((i = 1, 2)\) we have a term \(\frac{1}{s}\) in the original walk. This will be changed in \(\frac{1}{s}\) in the conjugate one, and all the formulas
in the delayed walk are of the form $G \xi_i$, where $G$ is a function of $\xi_i$ ($i = 1, 2$) so the expected time until absorption in the conjugate case is $(1 - r)$ times the expected time until absorption in the original walk. □
