HOLOMORPHIC CURVES IN EXPLODED MANIFOLDS —
KURANISHI STRUCTURE

BRETT PARKER

Abstract. This paper constructs a Kuranishi structure for the moduli stack of holomorphic curves in exploded manifolds. To avoid some technicalities of abstract Kuranishi structures, we embed our Kuranishi structure inside a moduli stack of curves. The construction also works for the moduli stack of holomorphic curves in any compact symplectic manifold.

1. Introduction

In this paper, we construct a species of Kuranishi structure on the moduli stack of holomorphic curves in exploded manifolds \(^1\) — leaving the construction of a virtual fundamental class from such a Kuranishi structure to \([22]\). Because the category of exploded manifolds extends that of smooth manifolds, our construction includes a new construction of Kuranishi structures on the moduli stack of holomorphic curves in any compact symplectic manifold.

Fukaya and Ono used Kuranishi structures in their definition of Gromov–Witten invariants in \([6]\). A similar approach to defining Gromov–Witten invariants was independently taken by Li and Tian in \([15]\), and much subsequent work has since refined the construction and use of Kuranishi structures; see \([5, 21, 22, 19, 20, 2, 14]\). Our Kuranishi structures differ from Fukaya and Ono’s: they are embedded in a moduli stack \(^2\) of \(C^\infty\) curves \(^3\) to avoid technicalities involved in using Kuranishi structures to define Gromov–Witten invariants.

In \([6]\), Fukaya and Ono use a homotopy of the linearization, \(D\dot{\partial}\), of the \(\dot{\partial}\) operator to a complex map for orienting their Kuranishi structures, and also to construct a stably-almost-complex structure. Moreover, in \([7]\), Fukaya and Ono sketched how, if their stably-almost-complex structure was globally defined, then they could define invariant integer counts of holomorphic curves. Similarly, in the preprint \([15]\), Dominic Joyce sketched a construction of integer invariants using similar almost-complex information and a modified version of Kuranishi structures. In the category of smooth manifolds, the construction of a stably-almost-complex structure must be treated with great care around singular curves. In contrast, using exploded manifolds, no curves are singular in this way, and we encounter no problems constructing a globally-defined stably-almost-complex structure using a homotopy of \(D\dot{\partial}\) to a complex map; Fukaya and Ono’s suggested construction of integer invariants is carried out in \([26]\).

Our Kuranishi structures consist of a collection of embedded Kuranishi charts. We identify holomorphic curves using a section, \(\bar{\partial}\), of a sheaf \(\mathcal{Y}\) over a moduli stack, \(\mathcal{M}^\infty\), of stable (not necessarily holomorphic) \(C^\infty\)-curves. In an open neighborhood \(\mathcal{O}\) around a holomorphic curve \(f\), we can choose a nice, finite-dimensional subsheaf \(V\subset\mathcal{Y}\). If \(D\bar{\partial}\) is transverse to \(V\) at \(f\), then in an open neighborhood \(\mathcal{U}\) of \(f\), the moduli stack of solutions \(h\) to \(\bar{\partial}h\in V\) is represented by the quotient of some \(C^\infty\)-family of curves \(\tilde{f}\) by a group \(G\) of automorphisms. Our embedded Kuranishi charts have the information \((\mathcal{U}, V, \tilde{f}/G)\). By putting further assumptions on \(V\), we construct embedded Kuranishi charts with nice properties such as being compatible with chosen evaluation maps, or having an equivalent of Fukaya and Ono’s stably-almost-complex structure.

---

\(^1\)For a brief introduction to exploded manifolds, see \([24]\); a more thorough introduction is \([23]\), and \([25]\) is a dictionary comparing log schemes and exploded manifolds.

\(^2\)The reader who is unfamiliar with stacks, but who likes to impose a Fréchet orbifold or polyfold structure on a space of maps may think of our Kuranishi structures as being embedded in such a space.

\(^3\) \(C^\infty\) indicates a kind of regularity, which for all practical purposes, the unfamiliar reader may regard as meaning ‘smooth’.

\(^4\) See the preprint \([21]\) by McDuff and Werheim for some discussion of issues that must be overcome when using abstract Kuranishi structures, and see the recent preprint \([5]\) of Fukaya, Oh, Ohta, and Ono for some improvements on Fukaya and Ono’s original definitions and a much more detailed version of their construction of Gromov–Witten invariants.
To define an embedded Kuranishi structure, a collection of Kuranishi charts must obey compatibility and extendibility conditions. For two embedded Kuranishi charts \((U_i, V_i, \hat{f}_i/G_i)\) to be compatible, we require that, on the intersection of \(U_i\) with \(U_j\), one of \(V_i\) or \(V_j\) must be a subsheaf of the other. There are weaker versions of compatibility sufficient for constructing Gromov–Witten invariants, but subject to compactness assumptions\(^5\) on the moduli stack of holomorphic curves, a covering by such compatible embedded Kuranishi charts always exists, and any two such embedded Kuranishi structures are homotopic, so a weaker version of compatibility is unnecessary. To construct something on a Kuranishi structure, (such as the weighted branched perturbation of \(\bar{\partial}\) used by Fukaya and Ono to define Gromov–Witten invariants), we often proceed chart by chart, shrinking the prior domain of definition slightly at each stage; see Proposition 2.3 of [32]. To facilitate such a procedure, we require that our Kuranishi charts have compatible extensions.

In section 2, we describe the moduli stack, \(\mathcal{M}^{\infty, 1}\), of \(C^{\infty, 1}\) curves, and an open substack, \(\mathcal{M}^{st}\), of well-behaved stable curves. Reading section 2 is essential for understanding the results of this paper. Section 2.3 contains an introduction to stacks over the category of exploded manifolds. The tangent space of \(\mathcal{M}^{st}\) is defined and demystified in section 2.9, then the linearization \(D\bar{\partial}\) of the \(\bar{\partial}\) operator on \(\mathcal{M}^{st}\) is defined at holomorphic curves in section 2.10. Finally, embedded Kuranishi structures are defined in Section 2.11.

Section 3 contains a quick summary of the results of [31] necessary for this paper. Sections 4.1 and 4.2 construct some evaluation maps from \(\mathcal{M}^{st}\). Section 5 defines a core family giving a concrete local model for \(\mathcal{M}^{st}\), used throughout the rest of the paper. Core families are constructed in Theorem 5.4 and Proposition 5.12. Section 5.2 uses core families to study the topology of \(\mathcal{M}^{st}\); for example, in Lemma 5.17 we show that the topology on \(\mathcal{M}^{st}\) is pulled back from a Hausdorff topological space. Section 6 is dedicated to locally analyzing the moduli stack of solutions to the weakened \(\bar{\partial}\) equation, \(\bar{\partial}f \in V\). The main theorem is Theorem 6.8, where we show that \(\bar{\partial}^{-1}V\) is locally represented by \(f/G\) for a family of curves \(f\) and finite group \(G\).

Section 7 constructs an embedded Kuranishi structure for the moduli stack of holomorphic curves in any family of exploded manifolds \(\hat{B} \rightarrow B_0\) satisfying the compactness condition that the map to \(B_0\) from the moduli stack of holomorphic curves within any connected component of \(\mathcal{M}^{st}\) is proper; see Theorem 7.3. In Corollary 7.5 we also prove that any two such Kuranishi structures are homotopic. We end the paper with a construction of a stably-almost-complex structure for our embedded Kuranishi structures.

2. Structure of the moduli stack of stable curves

In this section, we work towards describing embedded Kuranishi structures by first describing basic properties of the moduli stack \(\mathcal{M}^{\infty, 1}\) of \(C^{\infty, 1}\) curves, concentrating on a well-behaved open substack \(\mathcal{M}^{st} \subset \mathcal{M}^{\infty, 1}\) of stable \(C^{\infty, 1}\) curves. We use \(\mathcal{M} \subset \mathcal{M}^{st}\) for the moduli stack of stable holomorphic curves.

2.1. The functors \(F\) and \(C\).

This paper studies families of holomorphic curves in a smooth family of targets in the exploded category,

\[\pi_{B_0} : (\hat{B}, J) \rightarrow B_0\]
where \( \pi_{B_0} : \hat{B} \rightarrow B_0 \) is a smooth map of exploded manifolds, and each fiber of \( \pi_{B_0} \) is a complete, basic exploded manifold with an almost-complex structure \( J \).

For this paper, \( \hat{B} \rightarrow B \) will always refer to a family of exploded manifolds with such structure.

We will often talk about \( C^\infty_1 \) families of curves \( \hat{f} \) in \( \hat{B} \rightarrow B_0 \) — these are commutative diagrams

\[
\begin{array}{ccc}
\mathcal{C}(\hat{f}) & \xrightarrow{f} & \hat{B} \\
\downarrow_{\pi_{\mathcal{F}(\hat{f})}} & & \downarrow_{\pi_{B_0}} \\
\mathcal{F}(\hat{f}) & \xrightarrow{\mathcal{F}(\hat{f})} & B_0
\end{array}
\]

where \( f \), and all other maps in the above diagram are \( C^\infty_1 \) maps of exploded manifolds, and \( \pi_{\mathcal{F}(\hat{f})} : \mathcal{C}(\hat{f}) \rightarrow \mathcal{F}(\hat{f}) \) is a family of curves with a fiberwise complex structure \( j \).

We say that the exploded manifold \( \mathcal{F}(\hat{f}) \) parametrises the family of curves, and the exploded manifold \( \mathcal{C}(\hat{f}) \) is the domain of the family of curves. A particular case is when the exploded manifold \( \mathcal{F}(\hat{f}) \) is a single point. In this case, we call \( \hat{f} \) a curve, and generally use the notation \( f \) instead of \( \hat{f} \) to emphasise that \( f \) is a single curve instead of a family containing many curves. If we restrict a family \( \hat{f} \) to the fiber over any point in \( \mathcal{F}(\hat{f}) \), we get a curve \( f \), and we say that such curves are the curves in the family \( \hat{f} \), and use the notation \( f \in \hat{f} \).

So, for a family of curves \( \hat{f} \), \( \mathcal{C}(\hat{f}) \) and \( \mathcal{F}(\hat{f}) \) are exploded manifolds. Actually, \( \mathcal{F} \) and \( \mathcal{C} \) are functors from the category of \( C^\infty_1 \) families of curves to the category of \( C^\infty_1 \) exploded manifolds, and \( \pi_{\mathcal{F}} : \mathcal{C} \Rightarrow \mathcal{F} \) is a natural transformation. Concretely, as defined in Section 11 of [24], a morphism \( \psi : \hat{f} \rightarrow \hat{g} \) between \( C^\infty_1 \) families of curves is a commutative diagram

\[
\begin{bmatrix}
\mathcal{C}(\hat{f}) & \xrightarrow{\mathcal{C}(\psi)} & \mathcal{C}(\hat{g}) \\
\downarrow_{\pi_{\mathcal{F}(\hat{f})}} & & \downarrow_{\pi_{\mathcal{F}(\hat{g})}} \\
\mathcal{F}(\hat{f}) & \xrightarrow{\mathcal{F}(\psi)} & \mathcal{F}(\hat{g})
\end{bmatrix}
\]
such that restricted to each fiber of \( \pi_{F(f)} \) and \( \pi_{F(g)} \), the map \( C(\psi) : C(\hat{f}) \to C(\hat{g}) \) is a holomorphic isomorphism. So, \( C \) and \( F \) are functors from the category, \( M^{\infty, \perp} \), of \( C^{\infty, \perp} \) families of curves to the category of \( C^{\infty, \perp} \) exploded manifolds. Note that the morphism \( \psi : \hat{f} \to \hat{g} \) is entirely determined by the map \( C(\psi) : C(\hat{f}) \to C(\hat{g}) \) of exploded manifolds, and we will use the terminology of a ‘map’ \( \psi : \hat{f} \to \hat{g} \) instead of a ‘morphism’.

### 2.2. The moduli stack of curves.

The category, \( M^{\infty, \perp} \), of \( C^{\infty, \perp} \) families of curves together with the functor \( F \) to the category of exploded manifolds is a stack over the category of exploded manifolds; for an approachable introduction to stacks over various categories, see [4]. In this section, we verify that \( M^{\infty, \perp} \) is a stack. First, we discuss pullbacks of families of curves, verifying that \( (M^{\infty, \perp}, F) \) is a category fibered in groupoids over the category of exploded manifolds; see Definition 3.1 of [4]. We show below that \((M^{\infty, \perp}, F)\) is a category fibered in groupoids.

The square in (1) is a fiber product diagram of \( C^{\infty, \perp} \) exploded manifolds, moreover, Lemma 10.4 of [24] implies that given any \( C^{\infty, \perp} \) map \( h : A \to F(\hat{g}) \) of exploded manifolds, there exists a pulled back family of curves, \( h^* \hat{g} \) parametrised by \( A \) with a map \( \psi_h : h^* \hat{g} \to \hat{g} \) such that \( F(\psi_h) = h \).

\[
\begin{array}{ccc}
C(h^* \hat{g}) & \xrightarrow{C(\psi_h)} & C(\hat{g}) \\
\downarrow & & \downarrow \\
F(h^* \hat{g}) = A & \xrightarrow{F(\psi_h) = h} & F(\hat{g})
\end{array}
\]

Note that we can also pull back morphisms: the pullback of a map \( \alpha : \hat{g} \to \hat{f} \) is the map \( h^* \alpha : h^* \hat{g} \to \hat{f} \) defined as

\[ h^* \alpha := \alpha \circ \psi_h. \]

This pullback \((h^* \hat{g}, \psi_h)\) is unique up to a canonical isomorphism arising from the following:

**Universal property of the pullback of a family of curves:** Given any other family of curves \( \hat{f} \) with maps \( \psi' : \hat{f} \to \hat{g} \) and \( x : F(\hat{f}) \to A \) such that \( F(\psi') = h \circ x \), there exists a unique map \( \phi : \hat{f} \to h^* \hat{g} \) such that \( F(\phi) = x \) and the following diagram commutes.

\[
\begin{array}{ccc}
C(\hat{f}) & \xrightarrow{C(\phi)} & C(h^* \hat{g}) \\
\downarrow & & \downarrow \\
F(\hat{f}) & \xrightarrow{x} & F(h^* \hat{g}) = A & \xrightarrow{h} & F(\hat{g})
\end{array}
\]

Let \( M^{\infty, \perp}(B) \) be the category of \( C^{\infty, \perp} \) families of curves in \( B \). A category such as \( M^{\infty, \perp}(B) \) with such a functor \( F \) and pullbacks satisfying the above universal property is called a category fibered in groupoids over the category of exploded manifolds; see Definition 3.1 of [4]. We show below that \((M^{\infty, \perp}(B), F)\) has further nice properties making it a stack over the category of exploded manifolds, so we call \( M^{\infty, \perp}(B) \) the moduli stack of \( C^{\infty, \perp} \) curves in \( B \). When no ambiguity is present, we use \( M^{\infty, \perp} \) in place of \( M^{\infty, \perp}(B) \) to refer to this moduli stack of curves.

**Lemma 2.1.** Every descent datum for \( M^{\infty, \perp} \) is effective. In other words, given

---

14 Definition 9.1 of [24].
15 See Definition 4.3 of [4].
• an exploded manifold $A$ with an open cover $\{\iota_i : U_i \to A\}$ with inclusions $\iota_{ij} : U_i \cap U_j \to U_i$
• families $\tilde{f}_i$ in $\mathcal{M}^{\infty, \perp}$ parametrised by $U_i$;
• and transition maps that are isomorphisms $\alpha_{ij} : \iota_{ij}^* \tilde{f}_j \to \iota_{ij}^* \tilde{f}_i$
satisfying the cocycle condition that over $U_i \cap U_j \cap U_k$,
$$
\alpha_{ij} \circ \alpha_{jk} = \alpha_{ik}
$$
there exists a family of curves $\tilde{f}$ parametrized by $A$ with isomorphisms $\alpha_i : \iota_i^* \tilde{f} \to \tilde{f}_i$
such that
$$
\alpha_{ij} = \iota_j^* \alpha_i \circ (\iota_{ij}^* \alpha_j)^{-1}
$$
Proof: Exploded manifolds are defined as topological spaces with a sheaf of functions satisfying local conditions (see definitions 3.1 and 3.13 of [24]), and similarly, families of curves can be defined as exploded manifolds, $C(\tilde{f})$, with further structure $(\tilde{f}, \pi_{F(\tilde{f})}, j)$ satisfying local conditions using the topology from $F(\tilde{f})$. Accordingly, we can glue together families of curves over local charts on $F(\tilde{f})$ as usual. The statement that every descent datum is effective is a formalisation of this familiar gluing procedure.

\[\square\]

Lemma 2.2. Isomorphisms are a sheaf for $\mathcal{M}^{\infty, \perp}$. In other words, given
• families $\tilde{f}$ and $\tilde{g}$ in $\mathcal{M}^{\infty, \perp}$;
• an open cover $\{\iota_i : U_i \to F(\tilde{f})\}$ with intersections $\iota_{ij} : U_i \cap U_j \to U_i$;
• and maps $\alpha_i : \iota_i^* \tilde{f} \to \tilde{g}$ such that
$$
\iota_{ij}^* \alpha_j = \iota_{ij}^* \alpha_i
$$
there exists a unique map $\alpha : \tilde{f} \to \tilde{g}$ such that
$$
\iota_i^* \alpha = \alpha_i
$$
In particular, because the other sheaf axioms follow immediately from the existence of pullbacks, we get a sheaf of sets over $F(\tilde{f})$ by assigning to the open set $U$ the set of maps of $\tilde{f}|U$ to $\tilde{g}$.

Proof:

Morphisms $\psi$ of families of curves are maps, $C(\psi)$, of sets satisfying conditions which are local in $F(\tilde{f})$. It follows that we can uniquely glue together locally defined morphisms, so long as their restrictions are identical.

\[\square\]

2.3. Stacks over the category of exploded manifolds.

We have now verified that $\mathcal{M}^{\infty, \perp}$ satisfies the following standard definition\footnote{16} of a stack over the category of $C^{\infty, \perp}$ exploded manifolds. This section spells out some standard notions of stacks in the case of stacks over the category of $C^{\infty, \perp}$ manifolds.

Definition 2.3. A stack over the category of exploded manifolds is a category $X$ with a functor $F$ to the category of exploded manifolds, such that
• $(X, F)$ is a category fibered in groupoids;
• isomorphisms in $(X, F)$ form a sheaf;
and every descent datum is effective.

We shall think of an object \( \hat{f} \) in \( \mathcal{X} \) as a \( \mathcal{X} \)-family parametrised by \( F(\hat{f}) \). For this reason, we will avoid using the singular word ‘object’ to describe such an \( \hat{f} \) in \( \mathcal{X} \) unless \( F(\hat{f}) \) is a point.

**Definition 2.4.** An individual object, or curve in a stack \( \mathcal{X} \) over the category of exploded manifolds is an object \( f \) of the category \( \mathcal{X} \) with \( F(f) \) a point. A family \( \hat{f} \) in \( \mathcal{X} \) is an object in the category \( \mathcal{X} \), and this family is said to be parametrized by \( F(\hat{f}) \).

**Example 2.5.** The stack \( \mathcal{V} \) of rank \( n \) complex vectorbundles\(^{18}\) has families \( \hat{f} \) rank \( n \) complex vectorbundles \( V(\hat{f}) \to F(\hat{f}) \), and morphisms \( \psi: \hat{f} \to \hat{f}’ \) maps of vectorbundles

\[
\begin{align*}
V(\hat{f}) & \xrightarrow{V(\psi)} V(\hat{f}’) \\
F(\hat{f}) & \xrightarrow{F(\psi)} F(\hat{f}’)
\end{align*}
\]

so that restricted to fibers, \( V(\psi) \) is \( \mathbb{C} \)-linear isomorphism. In this case, the individual objects are \( n \)-dimensional complex vectorspaces.

**Example 2.6.** For an exploded manifold \( A \), there is a natural stack \( S(A) \) with families \( C^\infty \),\( 1 \) maps of exploded manifolds \( \hat{f}: F(\hat{f}) \to A \) and morphisms commutative diagrams of exploded manifolds

\[
\begin{array}{ccc}
F(\hat{f}) & \xrightarrow{\hat{f}} & A \\
\downarrow & & \downarrow \\
F(\hat{f’)’} & \xrightarrow{\hat{f’}} & A
\end{array}
\]

Given any \( C^\infty \),\( 1 \) map \( x: A_1 \to A_2 \) of exploded manifolds, there is an induced functor \( S(x): S(A_1) \to S(A_2) \) sending \( \hat{f} \) to \( x \circ \hat{f} \). An individual object in \( S(A) \) is a map of a point into \( A \), so isomorphism classes of individual objects correspond to points in \( A \).

**Example 2.7.** For a family \( \hat{f} \) in the stack \( \mathcal{X} \), we can associate a new stack \( \mathcal{X}/\hat{f} \), with

- families if \( \mathcal{X}/\hat{f} \) morphisms \( \hat{h} \to \hat{f} \) within \( \mathcal{X} \),
- morphisms in \( \mathcal{X}/\hat{f} \) commutative diagrams within \( \mathcal{X} \)

\[
\begin{array}{ccc}
\hat{h} & \xrightarrow{\hat{f}} & \hat{f} \\
\downarrow & & \downarrow \\
\hat{h’} & \xrightarrow{\hat{f’}} & \hat{f’}
\end{array}
\]

and obvious functor with \( F(\hat{h}) \to \hat{f} := F(\hat{h}) \).

We can generalise Example [2.6] by considering the stack quotient of an exploded manifold \( A \) under the action of a finite group \( G \). To describe this stack quotient, we need the following standard notions of an etale map and a \( G \)-bundle.

---

\(^{18}\)As for smooth manifolds, a complex vectorbundle over an exploded manifold is a submersion \( V \to A \) of exploded manifolds with a \( \mathbb{C} \)-linear structure on each fiber so that there exist local charts modeled on \( \mathbb{C}^n \times U \to U \) and transition maps that are \( \mathbb{C} \)-linear isomorphisms on fibers.
Definition 2.8. An etale map \( x : E' \to E \) of exploded manifolds is a map so that every point in \( E' \) has some open neighborhood \( U' \) in the standard topology on exploded manifolds from Definition 3.1 of \([24]\), so that \( x \) restricted to \( U' \) is an isomorphism onto an open subset of \( E \).

Unlike the case of smooth manifolds, a map of exploded manifolds with bijective derivative is not necessarily etale. We use equidimensional submersion to refer to a map with bijective derivative.

Remark 2.9. Recall the tropical structure of an exploded manifold, Definition 4.4 of \([24]\). An equidimensional submersion \( \pi : X \to Y \) of exploded manifolds is etale if and only if \( \mathcal{P}(\pi(x)) : \mathcal{P}(x) \to \mathcal{P}(\pi(x)) \) is a \( \mathbb{Z} \)-affine isomorphism for all \( x \in X \). Equivalently, there are local charts \( U \) on \( X \) and \( V \) on \( Y \) with \( \pi(U) \subset V \) such that \( \pi : U \to V \) is a \( \mathbb{Z} \)-affine isomorphism.

Definition 2.10. For \( G \) a finite group, a \( G \)-bundle over an exploded manifold \( E \) is an etale map \( E \rtimes G \to E \) of exploded manifolds with a free \( G \)-action on \( E \rtimes G \) whose orbits are the fibers of \( E \rtimes G \to E \). A morphism of \( G \)-bundles is a \( G \)-equivariant map \( E_1 \rtimes G \to E_2 \rtimes G \).

A \( G \)-bundle internal to \( X \) is a morphism \( f : X \to \tilde{X} \) in \( X \) with a \( G \)-action on \( f \) so that \( F(f) : F(f) \to F(f) \) is a \( G \)-bundle over the exploded manifold \( F(f) \). A morphism of \( G \)-bundles is a \( G \)-equivariant morphism \( \tilde{f} : \tilde{X} \to \tilde{Y} \).

Example 2.11. For \( G \) a finite group, the category of \( G \)-bundles over exploded manifolds is a stack \( BG \) over the category of exploded manifolds. The functor \( F \) applied to a \( G \)-bundle is the base of the bundle.

Definition 2.12. For \( A \) an exploded manifold with an action of a finite group \( G \), the stack quotient \( A/G \) is a stack over the category of exploded manifolds, with families \( G \)-equivariant maps, \( \tilde{f} \), of \( G \)-bundles into \( A \)

\[
\begin{align*}
F^G(\tilde{f}) & \to A \\
\downarrow & \\
F(f) & 
\end{align*}
\]

and morphisms \( \psi : \tilde{f}_1 \to \tilde{f}_2 \) that are \( G \)-equivariant morphisms \( F^G(\psi) : F^G(\tilde{f}_1) \to F^G(\tilde{f}_2) \) of \( G \)-bundles such that the following diagram commutes

\[
\begin{align*}
F^G(\tilde{f}_1) & \xrightarrow{F^G(\psi)} F^G(\tilde{f}_2) \\
\downarrow & \\
F(\tilde{f}_1) & \xrightarrow{F(\psi)} F(\tilde{f}_2)
\end{align*}
\]

Definition 2.13. A map, or morphism of stacks \( (X_1, F_1) \to (X_2, F_2) \) over the category of exploded manifolds is a covariant functor

\[
\Phi : X_1 \to X_2
\]
such that \( F_2 \circ \Phi = F_1 \).

Example 2.14. For \( A \) an exploded manifold, a map \( A \to X \) means a morphism \( \Phi : S(A) \to X \). Such a morphism is equivalent to the information of a family
\[ \hat{f} := \Phi(id_A) \text{ parametrized by } A \text{ in } \mathcal{X}, \text{ and a choice of pullback } h^* \hat{f} \text{ for every map } h : A' \rightarrow A. \]

**Example 2.15.** A map from a stack \( \mathcal{X} \) to an exploded manifold \( A \) is a map of stacks \( \Phi : \mathcal{X} \rightarrow S(A) \). We also refer to such a map as a \( C^\infty_1 \) map.

In particular, the functor \( \Phi \) applied to \( \hat{f} \) is a \( C^\infty_1 \) map

\[ \Phi(\hat{f}) : F(\hat{f}) \rightarrow A \]

and these maps must be compatible: given any map \( \psi : \hat{g} \rightarrow \hat{f} \), the following diagram commutes:

\[ \xymatrix{ F(\hat{g}) \ar@{.>}[r]_-{\Phi(\hat{g})} \ar[r]_-{F(\psi)} & F(\hat{f}) \ar[r]_-{\Phi(\hat{f})} & A } \]

For an individual object or curve \( f \), \( F(f) \) is a point, so \( \Phi(f) \) has image a point, \( \Phi(f) := \Phi(f)(F(f)) \in A \). This point \( \Phi(f) \) only depends on the isomorphism class of \( f \), and \( \Phi \) is determined by its values \( \Phi(f) \) on isomorphism classes of individual objects.

**Example 2.16.** A rank \( n \) complex vectorbundle over a stack \( \mathcal{X} \) is a map \( \mathcal{X} \rightarrow \mathcal{V} \) to the stack of rank \( n \) complex vectorbundles from Example 2.5.

For example, a vectorbundle over \( S(A) \) consists of a vectorbundle over \( A \) and a choice of pullback of this vectorbundle for each map of an exploded manifold into \( A \).

**Example 2.17.** Let \( A \) be an exploded manifold with a finite group action \( G \). There is a quotient map \( \pi : A \rightarrow A/G \) defined as follows: for a family \( \hat{f} : F(\hat{f}) \rightarrow A \) in \( S(A) \), \( \pi(\hat{f}) \) is the induced \( G \)-equivariant map of the trivial \( G \)-bundle to \( A \)

\[ \xymatrix{ F(\hat{f}) \times G \ar[r]_-{(x,g) \mapsto g \pi(f(x))} & A } \]

and for a morphism \( \psi : \hat{f} \rightarrow \hat{f}' \) in \( S(A) \), the morphism \( \pi(\psi) \) is the induced map of trivial \( G \)-bundles \( \pi(\psi)(x,g) = (F(\psi)(x),g) \).

The family \( \pi(id_A) \) in the stack \( A/G \) has automorphism group \( G \), which acts on the total space of the \( G \)-bundle \( A \times G \) diagonally as \( g \cdot (a,g') = (g \cdot a,g'g^{-1}) \). For a family \( \hat{f} \) in \( A/G \), a morphism \( \psi : \hat{f} \rightarrow \pi(id_A) \) is equivalent to a section of the \( G \)-bundle \( F^{\pi(\hat{f})} \rightarrow F(\hat{f}) \) — this is the section sent to \( A \times id \subset A \times G \).

**Example 2.18.** There is a morphism \( \Phi_X : \mathcal{X}/\hat{f} \rightarrow \mathcal{X} \) sending \( \hat{h} \rightarrow \hat{f} \) to \( \hat{h} \). Given a morphism \( \psi : \hat{f} \rightarrow \hat{g} \) within a stack \( \mathcal{X} \), there is an obvious induced map \( \psi_* : \mathcal{X}/\hat{f} \rightarrow \mathcal{X}/\hat{g} \), given by composition with \( \psi \). Moreover, the following diagram commutes strictly.

\[ \xymatrix{ \mathcal{X}/\hat{f} \ar[r]^-{\psi_*} \ar[d]^-{\Phi_X} & \mathcal{X}/\hat{g} \ar@{.>}[l]_-{\phi_X} } \]

\[ \text{---} \]

\[ \text{---} \]

Remember that pullbacks are only determined up to canonical isomorphism. The particular choice of pullback is irrelevant for all practical purposes. We have described the functor \( \Phi \) on families and morphisms to \( id_A \). On all other morphisms, \( \psi, \Phi(\psi) \) is uniquely determined by the universal property of pullbacks.
Definition 2.19. For \( \hat{f} \) a family of curves in \( X \) with a finite group \( G \) of automorphisms, the stack \( \hat{f}/G \) is a stack with a map \( \Phi_X : \hat{f}/G \longrightarrow X \) and

- each family \( \hat{h} \) a \( G \)-bundle \( \hat{h} \times_G \longrightarrow \Phi_X(\hat{h}) \) internal to \( X \) together with a \( G \)-equivariant map \( \psi_h : \hat{h} \times_G \longrightarrow \hat{f} \) within \( X \),
- and morphisms \( \alpha : \hat{g} \longrightarrow \hat{h} \) given by \( G \)-equivariant diagrams within \( X \).

\[
\begin{array}{ccc}
\hat{g} \times_G & \xrightarrow{\alpha \times_G} & \hat{h} \times_G \\
\downarrow & & \downarrow \\
\Phi_X(\hat{g}) & \xrightarrow{\Phi_X(\alpha)} & \Phi_X(\hat{h})
\end{array}
\]

Remark 2.20. For the purposes of thinking of \( \hat{f}/G \) as a stack of curves, the functors \( F \) and \( C \) are pulled back from \( X \) using \( \Phi_X \) so, for \( \hat{h} \) a family in the stack \( \hat{f}/G \), the domain of \( \hat{h} \) is \( C(\hat{h}) = C(\Phi_X(\hat{h})) \), and there is a map

\[
C(\hat{h}) \longrightarrow C(\hat{f})/G
\]

given by the \( G \)-equivariant map

\[
\begin{array}{ccc}
C(\hat{h} \times_G) & \xrightarrow{\psi_h} & C(\hat{f}) \\
\downarrow & & \downarrow \\
C(\hat{h}) & & 
\end{array}
\]

Example 2.21. For families \( \hat{h} \) and \( \hat{f} \) in \( X \), a map \( \Phi : \hat{h} \longrightarrow \hat{f}/G \) means a map of stacks \( \Phi : X/\hat{h} \longrightarrow \hat{f}/G \) such that the following diagram commutes strictly.

\[
\begin{array}{ccc}
X/\hat{h} & \xrightarrow{\Phi} & \hat{f}/G \\
\downarrow{\Phi_X} & & \downarrow{\Phi_X} \\
X & \xleftarrow{\Phi_X} & 
\end{array}
\]

Such a map is determined up to unique \( 2 \)-isomorphism by \( \Phi \) applied to \( \text{id}_{\hat{h}} : \hat{h} \longrightarrow \hat{h} \). Unpacking definitions, \( \Phi(\text{id}_{\hat{h}}) \) is a \( G \)-bundle \( \hat{h} \times_G \longrightarrow \hat{h} \) internal to \( X \), with a \( G \)-equivariant map

\[
\hat{h} \times_G \xrightarrow{\psi_{\Phi(\text{id}_{\hat{h}})}} \hat{f}
\]

so, up to unique \( 2 \)-isomorphism, a map \( \hat{h} \longrightarrow \hat{f}/G \) is a \( G \)-bundle over \( \hat{h} \) with a \( G \)-equivariant map to \( \hat{f} \).

Example 2.22. There is a quotient map

\[
\pi : \hat{f} \longrightarrow \hat{f}/G
\]

which sends the family \( \hat{h} \longrightarrow \hat{f} \) in \( X/\hat{f} \) to the family

\[
\hat{h} \times G \xrightarrow{(h,g) \mapsto g \cdot h} \hat{f}
\]

in the stack \( \hat{f}/G \).
Example 2.23. Let $X$ be a topological space. Recall, from Definition 3.1 of [24], that each exploded manifold $A$ is a topological space with topology pulled back from a Hausdorff topological space $\lceil A \rceil$, so there is a notion of continuous map from an exploded manifold $A$ to $X$. Define $S(X)$ to be the stack over the category of $C^\infty$ exploded manifolds with

- families continuous maps
  \[ \hat{f} : F(\hat{f}) \to X \]

- and morphisms $\psi : \hat{f} \to \hat{f}'$ commutative diagrams of continuous maps

\[
\begin{array}{ccc}
F(\hat{f}) & \xrightarrow{f} & X \\
\downarrow_{\psi} & & \downarrow_{\hat{f}'} \\
F(\hat{f}') & & \\
\end{array}
\]

where $F(\psi)$ is a $C^\infty$ map of exploded manifolds.

If $\mathcal{X}$ is a stack over the category of $C^\infty$ exploded manifolds, a continuous map $\Phi : \mathcal{X} \to X$ is a map $\Phi : \mathcal{X} \to S(X)$.

In particular, the functor $\Phi$ applied to a family $\hat{f}$ is a continuous map

\[ \Phi(\hat{f}) : F(\hat{f}) \to X \]

and these maps must be compatible: given any map $\psi : \hat{g} \to \hat{f}$, the following diagram commutes:

\[
\begin{array}{ccc}
F(\hat{g}) & \xrightarrow{\Phi(\hat{g})} & F(\hat{f}) \\
\downarrow_{F(\psi)} & & \downarrow_{\Phi(\hat{f})} \\
\end{array}
\]

For an individual object $f$, $\Phi(f)$ has image a point in $X$, and this point $\Phi(f)$ only depends on the isomorphism class of $f$, and $\Phi$ is determined by its values $\Phi(f)$ on isomorphism classes of individual objects.

A continuous function on a stack $\mathcal{X}$ is a continuous map from $\mathcal{X}$ to the topological space $\mathbb{R}$.

Definition 2.24. Given two morphisms $\Phi_1, \Phi_2 : \mathcal{X}_1 \to \mathcal{X}_2$ of stacks over the category of exploded manifolds, a 2–morphism between $\Phi_1$ and $\Phi_2$ is a natural transformation $\eta : \Phi_1 \Rightarrow \Phi_2$ such that for any $\hat{f}$ in $\mathcal{X}_1$, $F(\eta_{\hat{f}})$ is $id_{F(\hat{f})}$.

Every 2–morphism is actually a 2–isomorphism, because $\eta_{\hat{f}} : \Phi_1(\hat{f}) \Rightarrow \Phi_2(\hat{f})$ lifts the identity on $F(\hat{f})$, and is hence an isomorphism because stacks are categories fibered in groupoids.

Definition 2.25. An isomorphism of stacks is a morphism $\Phi : \mathcal{X}_1 \to \mathcal{X}_2$ such that there exists a morphism $\Phi^{-1} : \mathcal{X}_2 \to \mathcal{X}_1$ and 2–morphisms $\Phi \circ \Phi^{-1} \Rightarrow id_{\mathcal{X}_2}$ and $\Phi^{-1} \circ \Phi \Rightarrow id_{\mathcal{X}_1}$. Two stacks are called equivalent or isomorphic if there exists an isomorphism between them.

Two maps of stacks $\Phi : \mathcal{X}_1 \to \mathcal{X}_2$ and $\Phi' : \mathcal{X}_1' \to \mathcal{X}_2'$ are equivalent if there is diagram which commutes up to 2–isomorphism

\[
\begin{array}{ccc}
\mathcal{X}_1 & \xrightarrow{\Phi} & \mathcal{X}_2 \\
\downarrow_{\Phi'} & & \downarrow \\
\mathcal{X}_1' & & \mathcal{X}_2' \\
\end{array}
\]

and whose horizontal arrows are isomorphisms.
Example 2.26. The stack $\tilde{f}/G$ from Definition 2.23 is equivalent to the quotient stack $F(\tilde{f})/G$, and the quotient maps $\pi: F(\tilde{f}) \to F(\tilde{f})/G$ from Example 2.17 and $\pi: X/\tilde{f} \to F/\tilde{f}/G$ from Example 2.22 are equivalent.

Definition 2.27. A stack is represented by an exploded manifold $A$ if it is equivalent to $S(A)$. A morphism of stacks $\Phi: X_1 \to X_2$ is represented by a map $x: A_1 \to A_2$ of exploded manifolds if there is a commutative diagram

\[
\begin{array}{ccc}
X_1 & \xleftarrow{x} & S(A_1) \\
\downarrow{\Phi} & & \downarrow{S(x)} \\
X_2 & \xrightarrow{x} & S(A_2)
\end{array}
\]

whose horizontal arrows are equivalences.

Example 2.28. The stack $X/\tilde{f}$ from Example 2.27 is represented by $F(\tilde{f})$.

For a family of curves $\tilde{f}$ with a finite group of automorphisms $G$, we have the following notion of a stack $X$ being represented by $\tilde{f}/G$. This is slightly more specific than $X$ being equivalent to the quotient stack $F(\tilde{f})/G$.

Definition 2.29. Let $\tilde{f}$ be a family in a stack $X$, and let $G$ be a finite group of automorphisms of $\tilde{f}$. Say that $X$ is represented by $\tilde{f}/G$ if the map $\Phi_1: X/\tilde{f} \to X$ from Definition 2.19 is an isomorphism.

Example 2.30. The quotient stack $A/G$ is represented by $\pi(id_A)/G$.

When $G$ is the trivial group, this definition reduces to the following: $X$ is represented by $\tilde{f}$ if the map $X/\tilde{f} \to X$ is an isomorphism. This happens if and only if every family in $X$ has a unique map to $\tilde{f}$.

We can always take the fiber product of stacks (compare Definition 6.1 of [3]).

Definition 2.31. If $\Phi_i: X_i \to Z$ are morphisms of stacks, the fiber product $X_1 \times_Z X_2$ is a stack with

- families triples $(f_1, \psi, f_2)$ where $f_i$ are families in $X_i$ with $F(f_1) = F(f_2)$ and $\psi: \Phi_1(f_1) \to \Phi_2(f_2)$ is a morphism in $Z$ with $F(\psi) = id$; and
- morphisms $(f_1, \psi, f_2) \to (f_1', \psi', f_2')$ a pair of morphisms $\alpha_i: f_i \to f_i'$ such that $F(\alpha_1) = F(\alpha_2)$ and $\psi' \circ \Phi_1(\alpha_1) = \Phi_2(\alpha_2) \circ \psi$.

The stack fiber product comes with obvious morphisms $\pi_i: X_1 \times_Z X_2 \to X_i$ and a 2–isomorphism $\eta: \Phi_1 \circ \pi_1 \Rightarrow \Phi_2 \circ \pi_2$ defined by $\eta(f_1, \psi, f_2) = \psi$. This data satisfies the following universal property: Given maps $\Psi_i: X_i \to X'$ and a 2–morphism $\eta': \Phi_1 \circ \Psi_1 \Rightarrow \Phi_2 \circ \Psi_2$, there exists a unique map $\beta: X' \to X_1 \times_Z X_2$ such that the following diagram strictly commutes

\[
\begin{array}{ccc}
X' & \xleftarrow{\psi_1} & X_1 \\
\downarrow{\psi_2} & & \downarrow{\pi_1} \\
X_2 & \xleftarrow{\pi_2} & X_1 \times_Z X_2
\end{array}
\]

and such that

$$\eta' = \beta^* \eta: \Phi_1 \circ \pi_1 \circ \beta \Rightarrow \Phi_2 \circ \pi_2 \circ \beta.$$ In particular, $\beta(\tilde{f}) = (\Psi_1(\tilde{f}), \eta'_1, \Psi_2(\tilde{f}))$, and $\beta(\alpha) = (\Psi_1(\alpha), \Psi_2(\alpha))$. 

A special case of the stack fiber product is the fiber product of families \( \hat{f}_1 \) in a stack \( \mathcal{X} \). Recall that the stacks \( \mathcal{X}/\hat{f}_i \) from Example 2.7 come with natural maps \( \mathcal{X}/\hat{f}_i \rightarrow \mathcal{X} \).

**Example 2.32.** If \( \hat{f}_1 \) and \( \hat{f}_2 \) are families in the stack \( \mathcal{X} \), then \( \hat{f}_1 \times_{\mathcal{X}} \hat{f}_2 \) means \( \mathcal{X}/\hat{f}_1 \times_{\mathcal{X}} \mathcal{X}/\hat{f}_2 \). This stack has

- families \((\psi_1, \alpha, \psi_2)\), where \( \psi_1 : \hat{h}_1 \rightarrow \hat{f}_1 \) are morphisms in \( \mathcal{X} \); and \( \alpha : \hat{h}_1 \rightarrow \hat{h}_2 \) is an isomorphism with \( F(\alpha) \) the identity; and
- morphisms commutative diagrams in \( \mathcal{X} \):

\[
\begin{array}{ccc}
\hat{f}_1 & \xleftarrow{\psi_1} & \hat{h}_1 \\
& \downarrow & \downarrow \\
& \hat{h}_2 & \xrightarrow{\psi_2} \hat{f}_2 \\
\end{array}
\]

and the obvious functor with \( F(\psi_1, \alpha, \psi_2) := F(\hat{h}_1) = F(\hat{h}_2) \).

This stack is equivalent to the stack of families \( \hat{h} \) in \( \mathcal{X} \) with a pair of map of maps \( \psi_i : \hat{h} \rightarrow \hat{f}_i \).

For the fiber product of families \( \hat{f}_1 \) in \( \mathcal{X} \), we have the following notion of \( \hat{f}_1 \times_{\mathcal{X}} \hat{f}_2 \) being represented by a family \( \hat{h} \) in \( \mathcal{X} \). This notion is slightly stronger than the notion of the fiber product (and associated maps) being represented by exploded manifolds.

**Definition 2.33.** Given families \( \hat{f}_i \) in a stack \( \mathcal{X} \), the fiber product \( \hat{f}_1 \times_{\mathcal{X}} \hat{f}_2 \) is represented by a family \( \hat{h} \) in \( \mathcal{X} \) with maps \( \pi_i : \hat{h} \rightarrow \hat{f}_i \), if the family \((\pi_1, id_{\hat{h}}, \pi_2)\) in \( \hat{f}_1 \times_{\mathcal{X}} \hat{f}_2 \) is a final object: in other words, any other family in \( \hat{f}_1 \times_{\mathcal{X}} \hat{f}_2 \) has a unique morphism \( \hat{h} \rightarrow \hat{h} \).

In this case, we use the notation \( \hat{h} = \hat{f}_1 \times_{\mathcal{X}} \hat{f}_2 \).

Equivalently, \((\pi_1, \hat{h}, \pi_2)\) represents \( \hat{f}_1 \times_{\mathcal{X}} \hat{f}_2 \) if it satisfies the following universal property: Given any family \( \hat{h}' \) in \( \mathcal{X} \) with maps \( \pi'_i : \hat{h}' \rightarrow \hat{f}_i \), there exists a unique morphism \( \hat{h}' \rightarrow \hat{h} \) such that the following diagram commutes.

\[
\begin{array}{ccc}
\hat{h}' & \xrightarrow{\pi'_i} & \hat{f}_1 \\
\downarrow & \downarrow & \downarrow \pi_1 \\
\hat{f}_2 & \xleftarrow{\pi_2} & \hat{h} = \hat{f}_1 \times_{\mathcal{X}} \hat{f}_2 \\
\end{array}
\]

**Definition 2.34.** A map \( \mathcal{X} \rightarrow \mathcal{Z} \) of stacks is called etale, or a representable submersion if for all maps \( A \rightarrow \mathcal{Z} \), the map \( A \times_{\mathcal{Z}} \mathcal{X} \rightarrow A \) is represented by a map of exploded manifolds that is respectively etale, or a submersion. A representable submersion or etale map \( \mathcal{X} \rightarrow \mathcal{Z} \) is injective, closed, proper, complete, a refinement, or a degree \( n \) cover if all the maps \( A \times_{\mathcal{Z}} \mathcal{X} \rightarrow A \) are represented by maps of exploded manifolds that are respectively injective, closed, proper, complete, refinement or degree \( n \) covers.

Often, representable submersions are simply called submersions, however we also need a notion of a submersion with infinite dimensional fibers; see Definition 2.75.

**Example 2.35.** Given a finite group \( G \) acting on an exploded manifold \( A \), the quotient map \( \pi : A \rightarrow A/G \) from Example 2.7 is an etale map which is a degree

---

20 Definition 3.15 of [24].
21 Definition 10.5 of [24].
Given a map $\psi : \hat{f} \times_{A/G} \pi(\text{id}_A)$ is represented by the pullback $\hat{f} \times_{A/G} \pi(\text{id}_A)$ is represented by the G-bundle $E^{\times G} \to E$ parametrized by $E$.

For a family $f$ in $A/G$, the fiber product $f \times_{A/G} \pi(\text{id}_A)$ is represented by the pullback $\hat{f} \times_{A/G} \pi(\text{id}_A)$ is represented by the G-bundle $F^{\times G} \to F$, so $\hat{f} \times_{A/G} \pi(\text{id}_A)$ is represented by the G-bundle $F^{\times G} \to F$.

Let us check that $\hat{f} \times_{A/G} \pi(\text{id}_A)$ represents the fiber product $\hat{f} \times_{A/G} \pi(\text{id}_A)$ as in Definition 2.39. We have that $F^{\times G}((\hat{f} \times_{A/G} \pi(\text{id}_A))) = F^{\times G}(\hat{f}) \times_{F(\hat{f})} F^{\times G}(\hat{f})$, so the diagonal section gives a canonical section of $F^{\times G}((\hat{f} \times_{A/G} \pi(\text{id}_A))) = F^{\times G}(\hat{f})$, and hence a map $\hat{f} \times_{A/G} \pi(\text{id}_A)$ determines an object in the stack $\hat{f} \times_{A/G} \pi(\text{id}_A)$.

Given a map $\psi : \hat{h} \to \hat{f}$ with a section $s$ of $F(\hat{h} \times_{A/G} \pi(\text{id}_A))$, the universal property of the pullback $\hat{f} \times_{A/G} \pi(\text{id}_A)$ determines a unique map $\psi' : \hat{h} \to \hat{f}$ lifting $\psi$ so that $F(\psi' \times_{A/G}\pi(\text{id}_A)) = F^{\times G}(\psi) \circ s$. This section $s$ is equivalent to a map $\hat{h} \to \pi(\text{id}_A)$, and the map $\psi'$ is the unique map such that the following diagram commutes:

\[
\begin{array}{ccc}
\hat{h} & \to & \hat{f} \\
\downarrow\psi & & \downarrow\psi' \\
\pi(\text{id}_A) & \to & \pi(\text{id}_A)
\end{array}
\]

Accordingly, $\hat{f} \times_{A/G} \pi(\text{id}_A)$ is a final object, and $\hat{f} \times_{A/G} \pi(\text{id}_A)$ represents the fiber product $\hat{f} \times_{A/G} \pi(\text{id}_A)$, as required.

To a stack $\mathcal{X}$ over the category of exploded manifolds, we can associate the set $\mathcal{X}_{\text{top}}$ of isomorphism classes of individual objects in $\mathcal{X}$ (assuming the category $\mathcal{X}$ is equivalent to a small category) — for example if $\mathcal{X}$ is a moduli space of curves, $\mathcal{X}_{\text{top}}$ is the coarse moduli space. We want our substacks to act like subsets of $\mathcal{X}_{\text{top}}$, (with an obvious notion of union, intersection and complement) so we make a relatively strong definition of substack, using the following notion.

**Definition 2.36.** Let $\mathcal{U} \subset \mathcal{X}$ be a subcategory of a stack $\mathcal{X}$ over the category of exploded manifolds. For each family $f$ in $\mathcal{X}$, define the subset $\mathcal{U}(f) \subset F(f)$ to be the set of points $p \in F$ such that $\hat{f}$ restricted to $p$ is isomorphic to an object in $\mathcal{U}$.

**Definition 2.37.** A substack $\mathcal{U} \subset \mathcal{X}$ of a stack $\mathcal{X}$ over the category of exploded manifolds is a full subcategory $\mathcal{U}$ such that a family $f$ in $\mathcal{X}$ is in $\mathcal{U}$ if and only if $\mathcal{U}(f) = F(f)$.

In particular, a substack $\mathcal{U} \subset \mathcal{M}^{\infty}(\mathcal{B})$ means a full subcategory of $\mathcal{M}^{\infty}(\mathcal{B})$ such that a family of curves $\hat{f}$ in $\mathcal{M}^{\infty}(\mathcal{B})$ is in $\mathcal{U}$ if and only if each individual curve in $\hat{f}$ is isomorphic to a curve in $\mathcal{U}$. Accordingly, we can describe such a substack $\mathcal{U}$ by describing properties of the individual curves in $\mathcal{U}$.

**Definition 2.38.** An open substack $\mathcal{U} \subset \mathcal{X}$ of a stack $\mathcal{X}$ over the category of exploded manifolds is a substack $\mathcal{U}$ such that $\mathcal{U}(f) \subset F(f)$ is open (using the standard topology on the exploded manifold $F(f)$ from Definition 3.1 of [24]) for all families $f$ in $\mathcal{X}$.

A closed substack $\mathcal{C} \subset \mathcal{X}$ is a substack such that $\mathcal{C}(\hat{f}) \subset F(\hat{f})$ is closed for all families $\hat{f}$.

A compact substack $\mathcal{K} \subset \mathcal{X}$ is one with the property that any cover of $\mathcal{K}$ by open substacks admits a finite sub-cover.

As usual for topological subsets, the union of open substacks is an open substack, a finite intersection of open substacks is an open substack, and the complement of
Every open substack is a closed substack. For example, the closure of a substack is defined to be the intersection of all closed substacks containing it.

Although our definition of a substack is strong, our definition of an open substack above is equivalent to the standard definition of an injective etale map (or open embedding) \( U \to X \); compare Definition C.6 of [14]. In fact, \( U(f) \to F(f) \) is the injective etale map representing \( U \times_X f \to X/f \).

Remark 2.39. Given a substack \( C \subset X \), the intersection of \( C \) with an open or closed substack of \( X \) will always be an open or closed substack of \( C \), but \( C \) might have many more open or closed substacks, because exploded manifolds may not be degenerate enough to detect the subspace topology of \( C \). An example is given by the stacks corresponding to a subset of \( \mathbb{R}^2 \) that is connected but not path connected. Relevant to this paper, the moduli stack of holomorphic curves \( M \) is a closed substack of the moduli stack \( M^e \) of stable curves. In general, \( M \) is too degenerate to be analysed by itself as a stack over the category of exploded manifolds, and we need the extra structure of its inclusion into \( M^e \).

Example 2.40. Given any map \( \Phi: X_1 \to X_2 \), the inverse image of any (open) substack of \( X_2 \) is an (open) substack of \( X_1 \). Moreover, for \( A \) any exploded manifold and \( X \) any topological space, there is an obvious correspondence between (open) subsets of \( A \) or \( X \) and (open) substacks of \( S(A) \) or \( S(X) \) respectively. Accordingly, if \( x: X \to X \) is a continuous map from a stack to a topological space \( X \), as in Example 2.26 the inverse image of any open subset is an open substack of \( X \).

Example 2.41. Assuming \( X \) is equivalent to a category with a set of objects, define \( X_{\text{top}} \) to be the set with points isomorphism classes of individual objects in \( X \). Every substack \( U \subset X \) has a corresponding subset \( U_{\text{top}} \subset X_{\text{top}} \) such that \( f \in U \) if and only if \( f \) is in \( U_{\text{top}} \). Moreover \( X_{\text{top}} \) has a natural topology, with \( U_{\text{top}} \subset X_{\text{top}} \) an open subset if and only if \( U \) is an open substack. To any map of stacks \( \Phi: X \to X' \) over the category of exploded manifolds, there is an induced continuous map \( \Phi_{\text{top}}: X_{\text{top}} \to X'_{\text{top}} \) sending the isomorphism class \( f_{\text{top}} \) of \( f \) to the isomorphism class \( \Phi(f)_{\text{top}} \) of \( \Phi(f) \). Clearly \( (\Phi \circ \Phi')_{\text{top}} = \Phi_{\text{top}} \circ \Phi'_{\text{top}} \) and 2–isomorphic maps of stacks are sent to identical continuous maps, so the construction defines a functor from the 2–category of stacks over exploded manifolds to the more familiar 1–category of topological spaces.

Example 2.42. Just as the topology of an exploded manifold \( A \) is usually non-Hausdorff, but pulled back from a map to a Hausdorff topological space \( |A| \), the topology on a stack \( X \) and \( X_{\text{top}} \) is pulled back from the topology on a simpler topological space \( |X_{\text{top}}| \), defined as follows: Say that individual objects \( f \) and \( f' \) in \( X \) are topologically indistinguishable if every open or closed substack of \( X \) contains \( f \) if and only if it contains \( f' \). Define \( |X_{\text{top}}| \) to be the set equivalence classes of topologically indistinguishable individual objects. There is a topology on \( |X_{\text{top}}| \) such that each open or closed substack \( U \subset X \) corresponds to a (respectively open or closed) subset \( |U_{\text{top}}| \), where \( f \) is in \( U \) if and only if its equivalence class, \( [f_{\text{top}}] \) is in \( |U_{\text{top}}| \). As in Example 2.17 this construction defines a functor from the 2–category of stacks over exploded manifolds to the 1–category of topological spaces.

For \( A \) an exploded manifold, \( S(A)_{\text{top}} \) is canonically isomorphic to the topological space \( |A| \), and \( |S(A)|_{\text{top}} \) is canonically isomorphic to \( |A| \).

In many stacks of interest, curves \( f_1 \) and \( f_2 \) will be topologically indistinguishable if and only if they admit maps \( f_i \to \hat{f} \) to some family such that their image in \( F(f_i) \) is the same point. This property need not hold in general, but it is inherited by any closed or open substack. In Lemma 5.17 we show that an open substack
\(M^*\) of \(M^{\infty,1}\) enjoys this property, and we show that \([M^*_\top]\) is Hausdorff. In contrast, \([M^{\infty,1}_\top]\) is not Hausdorff.

Remark 2.43. As explained in [1][17][23], a good formalization of smooth orbifolds is as Deligne–Mumford stacks over the category of smooth manifolds. In the category of smooth manifolds, a Deligne–Mumford stack is a stack \(X\) over the category of smooth manifolds with a second-countable and Hausdorff topology, and locally equivalent to \(U/G\) for some manifold \(U\) with an action of a finite group \(G\). Equivalently, there exists a surjective etale map \(M \to X\) from a manifold \(M\) such that the map \(M \times_M M \to M \times M\) is proper.

Equivalently, \(X\) is a Deligne–Mumford stack if it is equivalent to the quotient stack of a etale proper groupoid in the category of smooth manifolds. Given a surjective etale map \(U \to X\), the Deligne–Mumford stack \(X\) is equivalent to the quotient stack of the etale proper groupoid with objects parametrized by \(U\), morphisms parametrized by \(U \times_X U\) and composition encoded in the three maps from \(U \times_X U \times_X U\) to \(U\).

Definition 2.44. An exploded orbifold is a stack \(X\) over the category of exploded manifolds which is Deligne–Mumford in the following sense: \(X\) is locally equivalent to \(A/G\) for \(A\) an exploded manifold with an action of a finite group \(G\), and \([X_\top]\) is second countable and Hausdorff. Equivalently, there exists a surjective etale map \(U \to X\) such that \(U \times_X U \to U \times U\) is represented by proper map of exploded manifolds.

An alternate, (and equivalent!) definition is that an exploded orbifold is a stack equivalent to the quotient stack of a proper etale groupoid in the category of exploded manifolds. To obtain an etale proper groupoid from a Deligne–Mumford stack \(X\), simply choose a surjective etale map \(U \to X\). Then, there is an etale proper groupoid \(U \times_X U \to U\) with objects parametrized by \(U\), morphisms parametrized by \(U \times_X U\), and composition encoded by the three natural maps \(U \times_X U \times_X U \to U \times_X U\). Moreover, the quotient stack of this groupoid is equivalent to \(X\). See Section 4 of [17] or Section 2.4 of [1] for how to define the quotient stack of an etale proper groupoid.

The following is a standard definition of a sheaf over a stack; compare Section 3.1 of [1].

Definition 2.45. A sheaf \(\mathcal{Y}\) (of sets) over a stack \(\mathcal{X}\) over the category of exploded manifolds is a contravariant functor \(\mathcal{Y}\) with domain \(\mathcal{X}\) (to the category of sets) such that \(\mathcal{Y}\) is a sheaf when restricted to the subcategory of open subfamilies \(\mathcal{F}\) of \(\hat{f}\).

A map of sheaves is a natural transformation \(\eta: \mathcal{Y}_1 \Rightarrow \mathcal{Y}_2\), and a global section of a sheaf \(\mathcal{Y}\) is a map from the trivial sheaf into \(\mathcal{Y}\). The pullback of a sheaf \(\mathcal{Y}\) over \(\mathcal{X}\) under a map \(\Phi: \mathcal{X}' \to \mathcal{X}\) is \(\Phi^*\mathcal{Y} := \mathcal{Y} \circ \Phi\).

For example:

- For a fixed \(\hat{g}\), there is a sheaf over \(\mathcal{X}\) which assigns to \(\hat{f}\) the set of maps from \(\hat{f}\) to \(\hat{g}\). Similarly, \(C^{\infty,1}\) maps to an exploded manifold, or continuous maps to a topological space form a sheaf.

- There is a natural sheaf of rings over \(\mathcal{X}\) which assigns to every family \(\hat{f}\) the ring \(C^{\infty,1}(\mathcal{F}(\hat{f}))\) of \(\mathbb{R}\)-valued \(C^{\infty,1}\) functions on the exploded manifold.

---

22Definition 2.43

23The reader might recall, from Definition 3.15 of [23], that the correct analogue of ‘proper’ in the category of exploded manifolds is usually ‘complete’. In this case, these maps will be complete if and only if they are proper, so we can continue to use the terminology of a etale proper groupoid.

24On a family \(f\), we use the standard topology of the exploded manifold \(\mathcal{F}(f)\), so an open subfamily is the restriction of \(f\) to an open subset of \(\mathcal{F}(f)\).
\( F(\hat{f}) \), and which assigns to every morphism \( \psi: \hat{f} \rightarrow \hat{g} \), the homomorphism \( C^\infty(\hat{F}(\hat{f})) \rightarrow C^\infty(\hat{F}(\hat{g})) \) induced from composition with the map \( F(\psi): F(\hat{f}) \rightarrow F(\hat{g}) \). A global section of this sheaf is a \( C^\infty \) map \( \hat{X} \rightarrow \mathbb{R} \).

- There is a sheaf which assigns to \( F(\hat{f}) \) the ring of \( C^\infty \) differential forms on \( F(\hat{f}) \).
- For \( V \) a stack of vectorbundles (like in Example 2.5), there is a sheaf, \( \Gamma \), which assigns to a family \( \hat{f} \) the \( C^\infty \) sections of the vectorbundle \( V(\hat{f}) \rightarrow F(\hat{f}) \). These sections form a locally free, finite rank module over the ring, \( C^\infty(\hat{F}(\hat{f})) \), of functions on \( F(\hat{f}) \). There is a similar sheaf of sections of a vectorbundle over a stack; see Example 2.16.

2.4. The sheaf \( \mathcal{Y} \) over the moduli stack of curves.

In this paper, we consider holomorphic curves in \( \mathcal{M}^\infty(\hat{\mathcal{B}}) \) as the solution of an equation \( \hat{\partial} \hat{f} = 0 \), where \( \hat{\partial} \) is a section of a sheaf \( \mathcal{Y} \) over the moduli stack of curves.

We shall often need the vertical (co)tangent space of families or submersions: given a submersion, \( x: \mathcal{A} \rightarrow \mathcal{B} \), use \( T\mathcal{A} \downarrow \mathcal{B} \) or \( T_{\text{vert}}\mathcal{A} \) to indicate the vertical tangent bundle of \( \mathcal{A} \) over \( \mathcal{B} \). In other words, \( T\mathcal{A} \downarrow \mathcal{B} \) is the sub bundle of \( T\mathcal{A} \) consisting of the kernel of the derivative of \( x \). Use the notation \( T^*\mathcal{A} \downarrow \mathcal{B} \) or \( T^*_{\text{vert}}\mathcal{A} \) to indicate the vertical cotangent bundle of \( \mathcal{A} \) over \( \mathcal{B} \). Define \( T^*\mathcal{A} \downarrow \mathcal{B} \) to be equal to the dual of \( T\mathcal{A} \downarrow \mathcal{B} \). We shall use the notation \( T_{\text{vert}} \) when no ambiguity shall arise, and when it is less cumbersome. For example, the notation \( T_{\text{vert}}C(\hat{f}) \) shall always mean \( TC(\hat{f}) \downarrow_{\hat{F}(\hat{f})} \), and given a family of targets, \( \hat{\mathcal{B}} \rightarrow \mathcal{B}_0 \), the notation \( T_{\text{vert}}\hat{\mathcal{B}} \) shall always mean \( T\mathcal{B} \downarrow_{\mathcal{B}_0} \).

**Definition 2.46.** Given a \( C^\infty \) family of curves \( \hat{f} \) in \( \hat{\mathcal{B}} \), define

\[ d_{\text{vert}} \hat{f}: T_{\text{vert}}C(\hat{f}) \rightarrow T_{\text{vert}}\hat{\mathcal{B}} \]

to be \( d\hat{f} \) restricted to the vertical tangent space, \( T_{\text{vert}}C(\hat{f}) \subset TC(\hat{f}) \).

Define

\[ \hat{\partial} \hat{f}: T_{\text{vert}}C(\hat{f}) \rightarrow T_{\text{vert}}\hat{\mathcal{B}} \]

as

\[ \hat{\partial} \hat{f} := \frac{1}{2} (d_{\text{vert}} f + J \circ d_{\text{vert}} f \circ j) \, . \]

This \( \hat{\partial} f \) is a section of the vectorbundle \( Y(\hat{f}) := \left( T_{\text{vert}}C(\hat{f}) \otimes \hat{f}^* T_{\text{vert}}\hat{\mathcal{B}} \right)^{0,1} \) over \( C(\hat{f}) \), and is also as a section of a corresponding sheaf \( \mathcal{Y}(\hat{f}) \) over \( F(\hat{f}) \).

Recall the notion of an integral vector from Definition 6.8 of [24]. The above section \( \hat{\partial} \hat{f} \) has regularity \( C^\infty \), and automatically vanishes on integral vectors. We can add such sections and multiply them by \( \mathbb{R} \)-valued \( C^\infty \) functions pulled back from the exploded manifold \( F(\hat{f}) \) parametrising \( \hat{f} \), so the set of such sections has the structure of a \( C^\infty(\hat{F}(\hat{f})) \)-module over \( F(\hat{f}) \).

**Definition 2.47.** Let \( \mathcal{Y}(\hat{f}) \) be the sheaf of \( C^\infty(\hat{F}(\hat{f})) \)-modules over \( F(\hat{f}) \) consisting of \( C^\infty \) sections of \( Y(\hat{f}) := \left( T_{\text{vert}}C(\hat{f}) \otimes \hat{f}^* T_{\text{vert}}\hat{\mathcal{B}} \right)^{0,1} \) vanishing on integral vectors within \( T_{\text{vert}}C(\hat{f}) \).

Given any map

\[ \hat{f} \rightarrow \hat{g} \]
there is a corresponding pullback diagram of vectorbundles

\[
\begin{array}{c}
Y(\hat{f}) \longrightarrow Y(\hat{g}) \\
\downarrow \quad \downarrow \\
C(\hat{f}) \longrightarrow C(\hat{g}) \\
\downarrow \quad \downarrow \\
F(\hat{f}) \longrightarrow F(\hat{g})
\end{array}
\]

and a functorial map of sheaves

\[
\mathcal{Y}(\hat{f}) \leftarrow \mathcal{Y}(\hat{g})
\]

compatible with the respective $C^\infty_1(F(\hat{f}))$ and $C^\infty_1(F(\hat{g}))$ module structures using the pullback of functions $C^\infty_1(F(\hat{g})) \to C^\infty_1(F(\hat{f}))$. Accordingly, $\mathcal{Y}$ is a sheaf over $M^\infty_\mathcal{L}$; see Definition 2.45.

2.5. Fiberwise holomorphic maps from moduli stacks of exploded curves.

We have defined some general notions of maps from stacks over the category of exploded manifolds (see Definition 2.13 and examples 2.14, 2.15, and 2.17) but we will also need the special notion of a fiberwise holomorphic map from stacks of exploded curves.

**Definition 2.48.** A stack of exploded curves is a stack $\mathcal{U}$ over the category of exploded manifolds with a map $\mathcal{U} \to M^\infty_\mathcal{L}$.

Any stack of exploded curves has functors $F$ and $C$ and a natural transformation $\pi_F: C \Rightarrow F$ pulled back from $M^\infty_\mathcal{L}$ so that $C(\hat{f}) \to F(\hat{f})$ is a family of exploded curves.

Given any stack of exploded curves $\mathcal{U} \to M^\infty_\mathcal{L}$, use the notation $\mathcal{U}^+ \to \mathcal{U}$ for the universal curve over $\mathcal{U}$, or the stack of curves obtained from curves in $\mathcal{U}$ by adding an extra end (or puncture) — see Section 4.2 for the construction of the lift $\hat{f}^+ \to \hat{f}$ of a family of curves in $\mathcal{U}$ to a family in $\mathcal{U}^+$ with an extra end. In fact $\mathcal{U}^+ \to \mathcal{U}$ is a complete representable submersion (Definition 2.34) and $C(\hat{f}) \to F(\hat{f})$ represents $f \times \mu \to \mathcal{U}^+$ in the sense of Definition 2.27, but we are also interested in the fiberwise-complex structure on $C(\hat{f}) \to F(\hat{f})$ not recorded by these general notions.

**Definition 2.49.** A fiberwise holomorphic map $\Phi$ between stacks of exploded curves

\[
\begin{array}{c}
\mathcal{U}^+ \xrightarrow{\Phi^+} \mathcal{X}^+ \\
\downarrow \quad \downarrow \\
\mathcal{U} \xrightarrow{\Phi} \mathcal{X}
\end{array}
\]

is a map of stacks $\Phi: \mathcal{U} \to \mathcal{X}$ and a natural transformation $\Phi^+: C \Rightarrow C \circ \Phi$ such that the maps $\Phi^+_j: C(\hat{f}) \to C(\Phi(\hat{f}))$ are fiberwise holomorphic.

\[
\begin{array}{c}
C(\hat{f}) \xrightarrow{\Phi^+_j} C(\Phi(\hat{f})) \\
\downarrow \quad \downarrow \\
F(\hat{f}) \xrightarrow{id} F(\Phi(\hat{f}))
\end{array}
\]

\^ See Definition 8.3 of [24].
A 2-isomorphism between fiberwise holomorphic maps is a natural transformation \( \eta : \Phi_1 \Rightarrow \Phi_2 \) such that \( C(\eta) \circ \Phi_1^+ = \Phi_2^+ \).

We also need a notion of fiberwise holomorphic map to a stack with \( C(\hat{f}) \to \mathcal{F}(\hat{f}) \) replaced by a family of almost complex manifolds. Instead of a general definition, we only need the following concrete case.

**Definition 2.50.** Let \( \mathcal{U} \to \mathcal{M}^{\infty \mathbb{F}}(\mathcal{B}) \) be a stack of exploded curves, and let \( \hat{\mathcal{A}} \to \mathcal{X} \) be a family of almost-complex exploded manifolds with a choice of a finite group \( G \) of automorphisms. Define a fiberwise-holomorphic map

\[
\begin{array}{ccc}
\mathcal{U}^+ & \xrightarrow{\Phi^+} & \hat{\mathcal{A}}/G \\
\downarrow & & \downarrow \\
\mathcal{U} & \xrightarrow{\Phi} & \mathcal{X}/G
\end{array}
\]

to be,

- for every \( \hat{f} \) in \( \mathcal{U} \), a choice of \( G \)-bundle \( \hat{f}^G \to \hat{f} \), and a map \( \Phi^+_\hat{f} : C(\hat{f}) \to \hat{\mathcal{A}}/G \)

  determined by \( \Phi^+_\hat{f} \) a \( G \)-equivariant family \( \Phi^+_\hat{f}(\hat{f}) \) of holomorphic curves in \( \hat{\mathcal{A}} \to \mathcal{X} \)

  \[
  \begin{array}{ccc}
  C(f^G) & \xrightarrow{\Phi^+_\hat{f}(f)} & \hat{\mathcal{A}} \\
  \downarrow & & \downarrow \\
  \mathcal{F}(f^G) & \xrightarrow{\Phi(f)} & \mathcal{X}
  \end{array}
  \]

- and, for any map \( \psi : \hat{g} \to \hat{f} \) in \( \mathcal{U} \), a \( G \)-equivariant map \( \psi^G : \hat{g}^G \to \hat{f}^G \) such that \( (\psi_1 \circ \psi_2)^G = \psi_1^G \circ \psi_2^G \) and such that the following diagram

  \[
  \begin{array}{ccc}
  C(\hat{g}^G) & \xrightarrow{\Phi^+_\hat{g}(\hat{f})} & \hat{\mathcal{A}} \\
  \downarrow & & \downarrow \\
  \mathcal{F}(\hat{g}^G) & \xrightarrow{\Phi(\hat{g})} & \mathcal{X}
  \end{array}
  \]

  commutes. Say that this fiberwise holomorphic map has an effective \( G \)-action if the map

  \( \Phi^+_\hat{f} : C(f^G) \to \hat{\mathcal{A}} \)

  is never preserved by the action of a nontrivial element of \( G \) on \( \hat{\mathcal{A}} \).

We can get an isomorphic fiberwise-holomorphic map \( \Phi' \) with isomorphic choices of \( G \)-bundles \( f^G \to \hat{f} \). A 2-isomorphism \( \eta : \Phi \Rightarrow \Phi' \) consists of isomorphisms of \( G \)-bundles

\[
\begin{array}{ccc}
f^G & \xrightarrow{\eta^G} & f'^G \\
\downarrow & & \downarrow \\
\hat{f} & \xrightarrow{\eta^G} & \hat{f}'
\end{array}
\]

\[26\text{See Definition 8.1 of [24] for almost complex structures.}\]

\[27\text{Definition 2.10.}\]

\[28\text{Example 2.14 and Definition 2.12.}\]

\[29\text{In the notation of Definition 2.12, } \Phi^+_\hat{f} = \Phi^+_\hat{f}(\text{id}_{C(f)})\]
such that $\psi^{xG} \circ \eta_f = \eta_g \circ \psi^{xG}$ and

$$(\Phi')^{-1}(\hat{f}) \circ C(\eta_f) = \Phi^{-1}(\hat{f}).$$

A unique fiberwise holomorphic map $\Phi$ means one that is unique up to canonical $2$-isomorphism.

**Remark 2.51.** With the assumption of an effective $G$–action, there is only one map $\psi^{xG} : \hat{g}^{xG} \to \hat{f}^{xG}$ such that the required diagrams commute. Moreover, the effectivity of the $G$–action ensures that there is at most one $2$-isomorphism between any two fiberwise-holomorphic maps with effective $G$–actions.

Section 4.1 constructs a fiberwise-holomorphic map:

$$M^{\infty,1}(\hat{B})^{+1} \to M(pt)^{+1}$$

This map may be insufficient for our purposes because it collapses bubbles in the domain of curves. In section 5, we construct ‘core families’ $\hat{f}$ with a group of automorphisms $G$ (of finite order, $|G|$) so that there is a neighborhood $U$ of $\hat{f}$ with a fiberwise-holomorphic map

$$U^{+1} \xrightarrow{\Phi^{+1}} C(\hat{f})/G$$

where, for any curve $f$ in $U$, the corresponding $|G|$ connected components of the map $\Phi^{+1}(f) : C(f) \times G \to C(\hat{f})$ are holomorphic isomorphisms onto curves in $C(\hat{f})$.

### 2.6. Topology of the moduli stack of curves.

A family of curves $\hat{f}$ comes with a natural topology on the exploded manifold $F(\hat{f})$. Definition 11.4 of [24], gives a notion of convergence of a sequence of $C^{\infty,1}$ curves. Accordingly, we could define an open substack of $M^{\infty,1}$ as a substack $U \subset M^{\infty,1}$ so that every sequence of curves in $M^{\infty,1}$ converging to a curve in $U$ is eventually contained in $U$. It is not immediately clear that such a notion of open substack is sensible. Hence, in this section, we show that such open substacks $U$ of $M^{\infty,1}$ are the substacks intersecting any family of curves in an open subset; and hence satisfying Definition 2.38.

**Lemma 2.52.** Given any sequence of curves in $M^{\infty,1}$ converging to $f$ in $C^{\infty,1}$, there exists a family $\hat{f}$ of curves containing $f$ and a subsequence $f_i$ of the given sequence such that each $f_i \in \hat{f}$, and within $F(\hat{f})$, $f_i$ converges to $f$.

**Proof:**

The definition of the $C^{\infty,1}$ topology on $M^{\infty,1}$ (from sections 7 and 11 of [24]) states that there exists

- a family of curves $\hat{g}$ containing $f$,
- a sequence of curves $f_i$ in $\hat{g}$ converging to $f$,
- a sequence of fiberwise almost-complex structures $j_i$ on $C(\hat{g})$ converging in $C^{\infty,1}$ to the given almost-complex structure on $C(\hat{g})$,
- and a sequence of sections $\psi_i$ of $\hat{g}^* T_{vert} \hat{B}$ converging in $C^{\infty,1}$ to $0$.
so that there is an identification of $C(f_i)$ with $C(\hat{f})$ with the almost-complex structure $j'$, and so that the map $f_i$ is $f'$ followed by exponentiation of $\psi_i$ in some (fixed) metric.

Let $\hat{f}_0$ be $\hat{g} \times \mathbb{R}$. The section $\psi_i$ being small in $C^{\infty, 1}$ implies that there exists a section $\psi'_i$ of $\hat{f}_0 T_{\text{vert}} B \subset \hat{g} \times \mathbb{R}$ equal to $\psi$ at $\hat{g} \times \{i^{-1}\}$, supported within the region $\hat{g} \times ((i + 1)^{-1}, (i - 1)^{-1})$, and small in $C^{\infty, 1}$. As noted before Definition 7.6 of [24], convergence in $C^{\infty, 1}$ for fiberwise complex structures on $C(\hat{f}_0)$ or sections of $\hat{f}_0 T_{\text{vert}} B$ is equivalent to convergence in some countable sequence of norms. By passing to a subsequence, we may assume that this $\psi'_i$ has size less than $2^{-i}$ in the first $i$ norms. Then $\sum \psi'_i$ is a $C^{\infty, 1}$ section of $\hat{f}_0 T_{\text{vert}} B$, which restricts to be $\psi_i$ on $\hat{g} \times \{i^{-1}\}$ and which is zero on $\hat{g} \times \{0\}$. Define the map $\hat{f}$ to be $\hat{f}_0$ followed by exponentiation of $\sum \psi'_i$.

Similarly, by passing to a subsequence we may construct a $C^{\infty, 1}$ fiberwise complex structure $j$ on $C(\hat{f})$ which restricts to $C(\hat{g}) \times \{i^{-1}\}$ to be $j_i$, and which is the original fiberwise complex structure on $C(\hat{g}) \times \{0\}$. Now there is a sequence of inclusions $f_i \rightarrow \hat{f}$ converging to $f \rightarrow \hat{f}$, as required.

\[ \square \]

**Lemma 2.53.** For a substack $\mathcal{U}$ of $\mathcal{M}^{\infty, 1}$, the following two conditions are equivalent.

1. Every sequence of curves in $\mathcal{M}^{\infty, 1}$ that converges in $C^{\infty, 1}$ to a curve in $\mathcal{U}$ is eventually contained in $\mathcal{U}$.
2. $\mathcal{U}$ is open in the sense of Definition 2.38 for all families $\hat{f}$ in $\mathcal{M}^{\infty, 1}$, the subset $\mathcal{U}(\hat{f}) \subset F(\hat{f})$ consisting of curves in $\mathcal{U}$ is open.

**Proof:**

Suppose that $\mathcal{U}$ is a substack of $\mathcal{M}^{\infty, 1}$. Denote by $\mathcal{U}(\hat{f})$ the subset of $F(\hat{f})$ consisting of curves in $\mathcal{U}$.

Suppose that any sequence of curves converging to a curve in $\mathcal{U}$ is eventually contained in $\mathcal{U}$. Then convergence within $\hat{f}$ is at least as strong as convergence within $\mathcal{M}^{\infty, 1}$, so any sequence of points in $F(\hat{f})$ converging to a point in $\mathcal{U}(\hat{f}) \subset F(\hat{f})$ is eventually contained in $\mathcal{U}(\hat{f})$. The topology on $F$ is pulled back from a metrisable topology on $[F]$, so $\mathcal{U}(\hat{f}) \subset F(\hat{f})$ is open as required.

Alternately, suppose that $\mathcal{U}(\hat{f}) \subset F(\hat{f})$ is open for all families $\hat{f}$ in $\mathcal{M}^{\infty, 1}$. Then if $f_i$ is a sequence of curves converging to $f$, Lemma 2.52 implies that there exists a subsequence converging to $f$ within some family $\hat{f}$, so that subsequence is eventually contained in $\mathcal{U}(\hat{f})$, and therefore eventually contained in $\mathcal{U}$. This implies that every sequence of curves converging to a curve in $\mathcal{U}$ is eventually contained in $\mathcal{U}$.

\[ \square \]

**Remark 2.54.** Lemma 2.53 does not immediately imply that $C^{\infty, 1}$ convergence of a sequence $f_i$ to $f$ is equivalent to $f_i$ eventually being in every open neighborhood of $f$ — without further study, it is not obvious that there are enough open substacks.

For $f$ any stable curve, the equivalence of these two notions of convergence follows from Proposition 5.12; see Lemma 5.14.

### 2.7. Stable curves, $\mathcal{M}^{\text{st}}$.

**Definition 2.55.** Call a $C^{\infty, 1}$ curve $f: C(f) \rightarrow B$ stable if it has only a finite number of automorphisms and its smooth part $[f]$ has only a finite number of automorphisms.

---

30 See remark 6.6 of [24] for metrics on an exploded manifold.

Let \( \mathcal{M}^{st} \) be the substack of \( \mathcal{M}^{\infty,1} \) consisting of families of stable curves.

**Remark 2.56.** We only need the condition that \( f \) has a finite number of automorphisms if \( C(f) \) is the exploded manifold \( T \) from Example 3.4 of [24], which has smooth part a point. Otherwise, every nontrivial automorphism of \( f \) is also a nontrivial automorphism of \([f]\). There are a number of possible candidates for a definition of a stable curve \( f \). A weaker definition, agreeing with the above on holomorphic curves, is to require that \( f \) has only a finite number of automorphisms and that \( f \) is not a nontrivial refinement\(^{32}\) of another curve. A much weaker definition is to just require that \( f \) has a finite number of automorphisms; the stack of curves satisfying this much weaker definition of stability is not sufficiently well behaved for us.

For example, the stack of ‘stable’ curves mapping to a point is an exploded orbifold using the two stronger definitions, but not the much weaker definition of ‘stable’.

We shall use the notation \( \mathcal{M} \subset \mathcal{M}^{st} \) for the stack of stable holomorphic curves.

**Remark 2.57.** Each non-constant holomorphic curve \( f \) in \( \mathcal{M}^{\infty,1}(\hat{B}) \) has a stabilization \( f^{st} \) in \( \mathcal{M}^{st}(\hat{B}) \), and a degree-1 genus-and-end preserving map \( \psi : C(f) \to C(\hat{f})^{st} \) such that \( f = \psi \circ f^{st} \); see Lemma 4.8. For curves mapping to a point, this construction works in families, and defines a stabilization map \( \mathcal{M}(pt) \to \mathcal{M}^{st}(pt) \); see Lemma 4.9. If the domain \( C(f^{st}) \) is not the exploded manifold \( T \), then within \( \mathcal{M}^{\infty,1}(\hat{B}) \), there exists a family of curves \( \hat{f} \) containing \( f \) and \( f^{st} \) such that the image of \( f \) in \([F(\hat{f})]\) is in the closure of the image of curves isomorphic to \( f^{st} \). It follows that every open substack containing \( f \) also contains \( f^{st} \). The set of stable curves within a family \( \hat{f} \) in \( \mathcal{M}^{\infty,1} \) is always open, so \( \mathcal{M}^{st} \) is an open substack containing \( f^{st} \) but not \( f \) if \( f \) is unstable. Accordingly, \([\mathcal{M}^{\infty,1}]\) is not Hausdorff. In contrast, we prove in Lemma 5.17 that \([\mathcal{M}^{st}]\) is Hausdorff.

### 2.8. Decorated curves, \( \mathcal{M}^{st}_{\bullet} \)

It is sometimes desirable to consider a stack of stable curves with some extra structure — for example, we may wish to label ends of curves or consider extra structure on the tropical part of curves, as is necessary for proving the tropical gluing formulae from [29].

**Definition 2.58.** Say that a map \( \pi : \mathcal{M}^{st}_{\bullet} \to \mathcal{M}^{st} \) of stacks (over the category of \( C^{\infty,1} \) exploded manifolds) is a moduli stack of decorated curves if it obeys the following:

- Given any family \( \hat{f} \) in \( \mathcal{M}^{st} \), there exists a pulled-back family of decorated curves \( \pi^{*} \hat{f} \) in \( \mathcal{M}^{st}_{\bullet} \) along with a map \( \pi^{*}(\pi^{*} \hat{f}) \to \hat{f} \) so that the following holds: Given any \( \hat{g} \) in \( \mathcal{M}^{st}_{\bullet} \) and map \( \psi : \pi(\hat{g}) \to \hat{f} \) in \( \mathcal{M}^{st} \), there exists a unique map \( \pi^{*} \psi : \hat{g} \to \pi^{*} \hat{f} \) in \( \mathcal{M}^{st}_{\bullet} \) making the following diagram

that do not act compatibly on the tangent space at different sides of a node do not come from automorphisms of \( f \).

\( ^{32}\)Refinements are a special kind of blowup, described in section 10 of [23].

\( ^{33}\)Recall from section 8 of [23] that an ‘end’ of an exploded curve is a stratum with tropical part a half infinite line, corresponding to a ‘marked point’ or ‘puncture’ on the smooth part of the curve.
commute:
\[
\begin{array}{ccc}
\hat{g} & \mapsto & \pi^* \hat{f} \\
\downarrow \pi & \Rightarrow & \downarrow \pi \\
\pi(\hat{g}) & \mapsto & \pi(\pi^* \hat{f}) \\
\downarrow \psi & \Rightarrow & \downarrow \hat{f}
\end{array}
\]

• The derivative of the map

\[ F(\pi^* \hat{f}) \longrightarrow F(\hat{f}) \]

at any point in \( F(\pi^* \hat{f}) \) is bijective. Moreover, this map is proper in the sense that the inverse image of any compact closed subset of \( F(\hat{f}) \) is a compact subset of \( F(\pi^* \hat{f}) \).

Using the general language of Definition 2.34, \( \pi^* : \mathcal{M}^d \longrightarrow \mathcal{M}^d \) is a proper representable submersion which is also an immersion.

From now on, we use \( \mathcal{M}^d \) to refer to a moduli stack of decorated curves satisfying the above definition. We shall also use the notation \( \mathcal{M} \subset \mathcal{M}^d \) for the stack of holomorphic decorated curves. Of course, \( \mathcal{M}^d \) itself is a moduli stack of (trivially) decorated curves, so any theorem stated for \( \mathcal{M}^d \) (or \( \mathcal{M} \)) applies also to \( \mathcal{M}^d \) (or \( \mathcal{M} \)).

In the category of smooth manifolds, the conditions on the map \( F(\pi^* \hat{f}) \longrightarrow F(\hat{f}) \) make it into a finite cover. This is not quite the case here, because \( \pi \) need not be étale; see Remark 2.9. Moreover, recall (Definition 3.15 of [24]), that the correct analogue of ‘compact’ or ‘proper’ in the category of exploded manifolds is ‘complete’. An example of a map which is proper but not complete is the inclusion \( T^1_{[0,1]} \) into \( T^1_{[0,1]} \); see examples 3.8 and 3.12 in [24].

The universal property defining \( \pi^* \hat{f} \) implies that any morphism \( \hat{g} \longrightarrow \hat{f} \) in \( \mathcal{M}^d \) lifts canonically to \( \pi^* \hat{g} \longrightarrow \pi^* \hat{f} \) in \( \mathcal{M}^d \). In particular, the group of automorphisms of \( \hat{f} \) act on \( \pi^* \hat{f} \). Another important consequence of this universal property is that if \( \hat{f}/G \) represents a substack of \( \mathcal{M}^d \) (in the sense of Definition 2.29), then \( \pi^* \hat{f}/G \) represents a substack of \( \mathcal{M}^d \).

**Remark 2.59.** Given any base change\(^{34}\) of our targets,

\[
\begin{array}{ccc}
\hat{B}' & \longrightarrow & \hat{B} \\
\downarrow & & \downarrow \\
B'_0 & \longrightarrow & B_0
\end{array}
\]

if we have \( \mathcal{M}^d(\hat{B}) \) defined, we may define \( \mathcal{M}^d(\hat{B}') \) as the fiber product of \( \mathcal{M}^d(\hat{B}) \) with \( \mathcal{M}^d(\hat{B}') \) over \( \mathcal{M}^d(\hat{B}) \). So, a decorated family of curves in \( \hat{B}' \) is a family of curves in \( B' \) with a choice of decoration (when this family of curves is considered as a family in \( B \)).

Be warned that this definition of \( \mathcal{M}^d(\hat{B}') \) sometimes depends on the particular choice of map \( \hat{B}' \longrightarrow \hat{B} \).

---

\(^{34}\) Lemma 10.4 of [24] implies that we can change the base of families using fiber products as usual.
2.9. Tangent space of $\M^s$ and $\M^s_{\ast}$.

In this section, we define the tangent space of the open substack $\M^s \subset \M_{\infty, \underline{\ast}}$ of stable curves. The discussion also applies to any moduli stack of decorated curves $\M^s_{\ast}$ — in fact, the tangent space will never depend on the decorations because the lifting property of Definition 2.58 implies that a deformation (parametrized by $\mathbb{R}$) of a decorated family $f$ of curves in $\M^s_{\ast}$ is equivalent to a deformation of the undecorated image of $f$ in $\M^s$. We first discuss the tangent space to a single curve $f$ in a single target $B$, and then define the relative tangent space in the case of a family of targets $B \to B_0$ and the (relative) tangent sheaf in the case of a family of curves.

2.9.1. $T_f \M^s_{\ast}(B)$.

In this section, we give an explicit construction of $T_f \M^s_{\ast}(B)$ — and hence $T_f \M^s_{\ast}(B)$ — as a vectorspace, with a natural action of the automorphism group of $f$. Lemmas 2.63 and 2.64 will imply that this $T_f \M^s_{\ast}(B)$ is equivalent to the following natural definition:

**Definition 2.60.** Suppose that $\tilde{f}_1$ are families parametrized by $\mathbb{R}$ in a stack $\mathcal{X}$ over the category of exploded manifolds, with a given inclusion $f \to \tilde{f}_1$ over 0. Say that $\tilde{f}_1$ is **tangent** to $\tilde{f}_2$ at $f$ if there exists a family $\tilde{g}$ (parametrised by some $\mathbb{R}^n$) and a commutative diagram

\[
\begin{array}{ccc}
\tilde{f}_1 & \to \tilde{g} \\
\alpha & \downarrow & \tau \\
\tilde{f}_2 & \to f
\end{array}
\]

such that the corresponding maps $F(\tilde{f}_1) = \mathbb{R} \to F(\tilde{g})$ have the same derivative at 0.

Define the deformations of $f$, $\text{DEF}_{\tilde{f}_1}$, to be the set of families $\tilde{f}$ with $F(\tilde{f}) = \mathbb{R}$, and with a chosen isomorphism of $f$ with $\tilde{f}|_0$. Then define $T_f \mathcal{X}$ to be the quotient of $\text{DEF}_{\tilde{f}_1}$ by the equivalence relation generated by being tangent at $f$.

Given any map of stacks $\Phi : \mathcal{X} \to \mathcal{X}'$ and individual object $f \in \mathcal{X}$, there is an induced derivative $T_f \Phi : T_f \mathcal{X} \to T_{\Phi(f)} \mathcal{X}'$ sending the equivalence class of $\iota : f \to \tilde{f}$ to the equivalence class of $\Phi(\iota) : \Phi(f) \to \Phi(\tilde{f})$.

Similarly, given any isomorphism $\psi : f \to f'$, there is a bijection $T_f \psi : T_f \mathcal{X} \to T_{f'} \mathcal{X}$ sending the equivalence class of $\iota : f \to \tilde{f}$ to the equivalence class of $\iota \circ \psi^{-1}$.

In the case of a stack represented by an exploded manifold, this definition coincides with the usual tangent space. Moreover, it works for exploded orbifolds; see Definition 2.44.

**Example 2.61.** Let $\pi : U \to U/G$ be the quotient map from Example 2.77. Then $T_{x, \pi} : T_{x, U} \to T_{\pi(x)}(U/G)$ is a bijection. In $U$, deformations of $x$ are just smooth maps $\gamma : \mathbb{R} \to U$ with $\gamma(0) = x$. In $U/G$, these are sent to the families with domain the trivial $G$–bundle over $\mathbb{R}$ and $\pi(\gamma)(t, g) = g \ast \gamma(t)$. Similarly $\pi(x)$ is the map $G \to U$ given by $g \to g \ast x$. Any deformation of $\pi(x)$ is therefore canonically trivialized, and is $\pi(\gamma)$ for a unique deformation $\gamma$ of $x$. Similarly deformations of $x$ parametrized by $\mathbb{R}^n$ are in bijection with deformations of $\pi(x)$ parametrized by $\mathbb{R}^n$, so two deformations are tangent in $U$ if and only if they are tangent in $U/G$.}

\[35\]Assuming that $\mathcal{X}$ is small enough that there is a set of such deformations of $f$ — any stack of interest to us is equivalent to such a small stack.
More generally, given a surjective etale map \( \Phi: \mathbf{U} \to X \) (so the exploded orbifold is the quotient stack of the groupoid \( \mathbf{U} \times_{\mathcal{X}} \mathbf{U} \rightrightarrows \mathbf{U} \)) the derivative \( T_{x} \Phi: T_{x} \mathbf{U} \to T_{\Phi(x)} \mathcal{X} \) is a bijection. This is in agreement with defining \( T \mathcal{X} \) as the quotient stack of the groupoid \( T(\mathbf{U} \times_{\mathcal{X}} \mathbf{U}) \rightrightarrows \mathbf{TU} \).

Let us now give an explicit description for \( T_{f} \mathcal{M}_{\bullet}^{\mathbf{a}} \) equipping the set from Definition 2.60 with the structure of a vectorspace. Given a curve \( f: \mathcal{C} \to \mathcal{B} \), the tangent space \( T_{f} \mathcal{M}_{\bullet}^{\mathbf{a}} \) of \( \mathcal{M}_{\bullet}^{\mathbf{a}} \) at \( f \) is defined using the following short exact sequence, discussed below.

\[
0 \to \Gamma(T\mathcal{C}) \xrightarrow{\partial} \Gamma^{0,1}(T\mathcal{C} \otimes T^{*}\mathcal{C}) \times \Gamma(f^{*}TB) \to T_{f} \mathcal{M}_{\bullet}^{\mathbf{a}} \to 0
\]

Let \( \Gamma(f^{*}TB) \) denote the space of \( C^{\infty} \) sections of \( f^{*}TB \). The action of the almost complex structure \( J \) on sections of \( f^{*}TB \) makes \( \Gamma(f^{*}TB) \) a complex vectorspace. Think of \( \Gamma(f^{*}TB) \) as the infinitesimal variations of a map from a fixed domain \( \mathcal{C} \) to \( \mathcal{B} \).

Let \( \Gamma^{0,1}(T\mathcal{C} \otimes T^{*}\mathcal{C}) \) denote the space of \( C^{\infty} \) \( j \)-anti-linear sections \( \alpha \) of \( T\mathcal{C} \otimes T^{*}\mathcal{C} \) that vanish on edges of \( \mathcal{C} \). This \( \Gamma^{0,1}(T\mathcal{C} \otimes T^{*}\mathcal{C}) \) is the space of infinitesimal variations of almost-complex structure on a fixed domain \( \mathcal{C} \). The action of \( j \) on the left makes \( \Gamma^{0,1}(T\mathcal{C} \otimes T^{*}\mathcal{C}) \) a complex vectorspace.

To obtain \( T_{f} \mathcal{M}_{\bullet}^{\mathbf{a}} \), we quotient \( \Gamma(T\mathcal{C}) \times \Gamma^{0,1}(T\mathcal{C} \otimes T^{*}\mathcal{C}) \) by the reparametrization action: in particular, we quotient by the image of the map \( h \) below.

\[
h: \Gamma(T\mathcal{C}) \to \Gamma^{0,1}(T\mathcal{C} \otimes T^{*}\mathcal{C}) \times \Gamma(f^{*}TB),
\]

\[
v \quad \mapsto \quad (\mathcal{L}_{v}j, df(v))
\]

If \( f \) is in \( \mathcal{M}_{\bullet}^{\mathbf{a}} \), then \( f \) has no infinitesimal automorphisms and \( h \) is injective. We define \( T_{f} \mathcal{M}_{\bullet}^{\mathbf{a}} \) to be the quotient of \( \Gamma^{0,1}(T\mathcal{C} \otimes T^{*}\mathcal{C}) \times \Gamma(f^{*}TB) \) by the image of \( h \).

The following lemma shows that change of \( j \) under the flow of a vectorfield \( \partial_{v} \), \( \mathcal{L}_{v}j \), may be regarded as \( 2j \circ \partial_{v} \).

**Lemma 2.62.** Let \( \nabla \) be any holomorphic connection on \( T\mathcal{C} \), then

\[
\mathcal{L}_{v}j = j \circ \nabla v - \nabla j \circ v
\]

and, in local holomorphic coordinates

\[
\mathcal{L}_{v}j = 2j \circ \partial_{v}.
\]

**Proof:**

If \( e \) is any holomorphic vectorfield, then \( j \circ \nabla e = (\nabla e) \circ j = 0 \), so \( j \circ \nabla he - (\nabla he) \circ j = j \circ 2(\partial_{h})e \). Therefore, in holomorphic coordinates where \( v \) may be considered as a complex function,

\[
\partial_{v} = \partial_{v_{1}} + v_{2} \partial_{y},
\]

\( j \circ \nabla v = j \circ 2\partial_{v} \)

Now we may calculate in holomorphic coordinates, where \( j = \partial_{y} \otimes dx - \partial_{x} \otimes dy \).

Write \( v = v_{1} \partial_{x} + v_{2} \partial_{y} \). Then

\[
\mathcal{L}_{v}j = - (\partial_{y}v_{1} \partial_{x} + \partial_{y}v_{2} \partial_{y}) \otimes dx + \partial_{y} \otimes (\partial_{x}v_{1} \partial_{x} dx + \partial_{y}v_{1} dy)
\]

\[
+ (\partial_{x}v_{1} \partial_{x} + \partial_{x}v_{2} \partial_{y}) \otimes dy - \partial_{x} \otimes (\partial_{x}v_{2} dx + \partial_{y}v_{2} dy)
\]

\[
= (\partial_{y}v_{1} + \partial_{x}v_{2}) (- \partial_{x} \otimes dx + \partial_{y} \otimes dy)
\]

\[
+ (\partial_{x}v_{1} - \partial_{y}v_{2}) (\partial_{y} \otimes dx + \partial_{x} \otimes dy)
\]

\[\text{Note that for now, we are using } \mathcal{C} \text{ as shorthand for } \mathcal{C}(f), \text{ so } \mathcal{C} \text{ means an exploded manifold, not a functor.}\]

\[\text{Recall, from Definition 8.3 [24], that an edge of a curve } \mathcal{C} \text{ is a stratum isomorphic to } \mathcal{T}^{1}_{(a,b)}.\]

The tropical part of such a stratum is an edge of the graph \( \mathcal{C} \). Each edge corresponds to a node or marked point in the nodal curve that is the smooth part of \( \mathcal{C} \). For the stratified structure of an exploded manifold and the tropical part functor, see Section 4 of [24].
On the other hand,
\[
j \circ 2\partial v = j \circ dv - dv \circ j
\]
\[
= \partial_x v_1 \partial_y \otimes dx + \partial_y v_1 \partial_y \otimes dy - \partial_x v_2 \partial_z \otimes dx - \partial_y v_2 \partial_z \otimes dy
\]
\[
+ \partial_x v_1 \partial_z \otimes dy - \partial_y v_1 \partial_z \otimes dx + \partial_x v_2 \partial_y \otimes dy - \partial_y v_2 \partial_y \otimes dx
\]
\[
= L_v j
\]

Lemma 2.62 implies that \( L_{j \circ \partial v} = j \circ L_v j \), so the corresponding map
\[
\Gamma(T^*C) \rightarrow \Gamma^{0,1}(T^*C \otimes T^*C)
\]
\[
v \mapsto L_v j
\]
is complex linear, and \( h \) is complex linear if and only if \( f \) is holomorphic. Accordingly, \( T_f M^*_t(B) \) is a complex vector space whenever \( f \) is holomorphic, and is otherwise a real vector space.

2.9.2. \( T_f M^*_t(B) \) and \( T_f M^*_t(B)|_{B_0} \).

In the case of a family of targets \( B \rightarrow B_0 \), define the relative tangent space \( T_f M^*_t(B)|_{B_0} \) as \( T_f M^*_t(B) \), where \( B \) is the member of the family \( B \) containing the image of \( f \). The following is the defining short exact sequence:
\[
(2) \quad 0 \rightarrow \Gamma(T^*C) \xrightarrow{\partial} \Gamma^{0,1}(T^*C \otimes T^*C) \times \Gamma(f^*T_{vert}B) \rightarrow T_f M^*_t(B)|_{B_0} \rightarrow 0
\]

We define the tangent space \( T_f M^*_t(B) \) similarly to the case of a single target, except we use the notation \( \Gamma_{B_0}(f^*TB) \) to denote sections of \( f^*TB \) that become constant when composed with the derivative of the map \( B \rightarrow B_0 \). We use \( \Gamma_{B_0}(f^*TB) \) instead of \( \Gamma(f^*TB) \) because we are interested in infinitesimal variations of \( f \) as a curve contained in a fiber of \( B \rightarrow B_0 \) instead of variations of \( f \) as a map to \( B \). So, the following is the defining exact sequence for \( T_f M^*_t(B) \).
\[
0 \rightarrow \Gamma(T^*C) \xrightarrow{\partial} \Gamma^{0,1}(T^*C \otimes T^*C) \times \Gamma_{B_0}(f^*TB) \rightarrow T_f M^*_t(B) \rightarrow 0
\]

2.9.3. Derivatives.

Given any family of curves \( \tilde{f} \) in \( M^*_t \) containing \( f \) and any vector \( v \) in \( T_f F(\tilde{f}) \), define an element \([v] \) of \( T_f M^*_t \) by differentiating \( \tilde{f} \) in the direction of \( v \) as follows: Extend \( v \) to a vector field, and lift it to a \( C^\infty \) section \( v' \) of \( T^*C(\tilde{f}) \), then define
\[
[v] := [L_{v'} j_{|C(\tilde{f})}, df(v')]
\]
where the right hand side indicates the image of \((L_{v'} j_{|C(\tilde{f})}, df(v'))\) in \( T_f M^*_t \) under the quotient by the image of \( h \).

We must verify that \([v] \) is well defined. The fiberwise almost-complex structure \( j \) is a section of \( T^*C(\tilde{f}) \otimes T^*C(\tilde{f}) \), and the Lie derivative of \( j \) with respect to any lifted vector field is again a section of \( T^*C(\tilde{f}) \otimes T^*C(\tilde{f}) \), because the flow of lifted vector fields respects the fibers of \( C(\tilde{f}) \rightarrow F(\tilde{f}) \). The Lie derivative \( L_{v'} j_{|C(\tilde{f})} \) does not depend on the choice of extension of \( v \), because the flow of any vector field vanishing on a fiber preserves that fiber, so \( L_{v'} j_{|C(\tilde{f})} \) does not depend on a choice of extension. Moreover, Lemma 2.62 implies that \( L_{v'} j_{|C(\tilde{f})} \) is a section of \( \Gamma^{0,1}(T^*C(\tilde{f}) \otimes T^*C(\tilde{f})) \), because \( v' \) is locally equal to a \( j \)-preserving vector field plus a section of \( T^*C(\tilde{f}) \) — so \([v] := [L_{v'} j_{|C(\tilde{f})}, df(v')]\) really is an element of \( T_f M^*_t \). It remains to check that \([v] \) does not depend on our choice of lift \( v' \): any other lift \( v'' \) of \( v \) will differ on \( C(\tilde{f}) \) from \( v' \) by a section of \( T^*C(\tilde{f}) \), so \((L_{v''} j_{|C(\tilde{f})}, df(v''))\) will differ
from $(L_v, j, df(v'))$ by a vector in the image of $h$. Therefore, $[v] := [L_v, j|_{C(f)}, df(v')]$ gives a well-defined element of $T_f \mathcal{M}^st_\bullet$.

Therefore for any curve $f$ in $\hat{f}$, we have a well-defined linear map

$$T_f\hat{f}: T_f \mathbf{F}(\hat{f}) \to T_f \mathcal{M}^st_\bullet$$

sends $v$ to $[v]$. Moreover, this map restricts to a well-defined linear map

$$T_f\hat{f}: T_f \mathbf{F}(\hat{f})_{|_{B_0}} \to T_f \mathcal{M}^st_\bullet(\hat{B})_{|_{B_0}}.$$ 

Lemmas 2.63 and 2.64 below imply that, as a set, $T_f \mathcal{M}^st_\bullet$ is the quotient of the set of families of curves parametrized by $\mathbb{R}$ containing $f$ at 0 by an equivalence relation generated by declaring two such families equivalent if they are tangent at 0 within a two-dimensional family of curves. It follows that given any $C^\infty_\mathbb{A}$ map

$$\Phi: \mathcal{M}^st_\bullet \to \mathbf{A}$$

there is an induced linear tangent map

$$T_f\Phi: T_f \mathcal{M}^st_\bullet \to T_{\Phi(f)}\mathbf{A}$$

so that if $\Phi(\hat{f})$ is the induced map $\mathbf{F}(\hat{f}) \to \mathbf{A}$,

$$T_f\Phi(\hat{f}) = T_f\Phi \circ T_f\hat{f}.$$ 

**Lemma 2.63.** Given any curve $f$ in $\mathcal{M}^st_\bullet(\hat{B})$ and vector in $T_f \mathcal{M}^st_\bullet(\hat{B})$, there exists a family of curves $f_t$ parametrized by $\mathbb{R}$ with that vector in the image of $T_f f_t$.

**Proof:**

We must construct a family with a given derivative. The definition of $T_f \mathcal{M}^st_\bullet$ does not depend on the particular decoration chosen. So, we shall prove this lemma for $T_f \mathcal{M}^st_\bullet$. Then Definition 2.58 implies that to complete the proof for any $\mathcal{M}^st_\bullet$, we can construct the required family of curves in $\mathcal{M}^st$ then lift them to $\mathcal{M}^st_\bullet$.

To avoid any issues with the precise nature of almost-complex structures at edges of a curve, we can reduce to the case that the variation in almost-complex structure on the domain $C$ is described by a section of $\Gamma^{0,1}(T\mathcal{C} \otimes T^*\mathcal{C})$ vanishing in a neighborhood of all edges of $C$. Consider a neighborhood of an edge of the domain $C$ of $f$. A small such neighborhood is isomorphic to an open subset of $T_{[0, \infty)}$ with its standard complex structure. A vector field $v$ in standard coordinates is then the real and imaginary parts of $\hat{z} \frac{\partial}{\partial z}$ times $C^\infty_\mathbb{A}$ functions. As noted in Lemma 2.62 in these coordinates $L_{v, \hat{f}}$ is $2j$ times the standard $\hat{\partial}$ operator. Therefore, Theorem 3.3 implies that given any section in $\Gamma^{0,1}(T\mathcal{C} \otimes T^*\mathcal{C})$, there exists a $C^\infty_\mathbb{A}$ vector field $v$ so that $L_{v, \hat{f}}$ is equal to the given section in a neighborhood of each edge. We can therefore represent any given vector in $T_f \mathcal{M}^st_\bullet(\hat{B})$ using a section of $\Gamma^{0,1}(T\mathcal{C} \otimes T^*\mathcal{C})$ vanishing on a neighborhood of edges of $C$.

Given any section $\alpha$ in $\Gamma^{0,1}(T\mathcal{C} \otimes T^*\mathcal{C})$ vanishing in a neighborhood of edges of $C$, we can construct a family of almost-complex structures $j_t$ on $C$ so that $j_t$ is the original almost-complex structure when $t = 0$ and near edges, and $\frac{\partial}{\partial t} j_t = \alpha$ at $t = 0$. Also, we can construct a $C^\infty_\mathbb{A}$ family of maps $f_t$ from $C$ to $\hat{B} \to B_0$ so that $\frac{\partial}{\partial t} f_t$ is any given $C^\infty_\mathbb{A}$ section of $f^*TB_\mathcal{B}$ projecting to a constant map to $TB_{B_0}$. It follows that given any vector in $T_f \mathcal{M}^st_\bullet$, there exists a family of curves parametrized by $\mathbb{R}$ with the given derivative. 

\[\square\]
Lemma 2.64. Suppose that \( \tilde{f}_1 \) and \( f_2 \) are two families parametrized by \( \mathbb{R} \), containing \( f \), and with the same image in \( T_f \mathcal{M}_f^{\infty} \). Then there exists another family \( \tilde{f}_0 \) containing \( f \) and two 2-dimensional families \( \tilde{g}_i \) with given maps \( \tilde{f}_0 \rightarrow \tilde{g}_i \) and \( \tilde{f}_i \rightarrow \tilde{g}_i \) so that the maps
\[
\mathbf{F}(\tilde{f}_0) \rightarrow \mathbf{F}(\tilde{g}_i) \\
\mathbf{F}(\tilde{f}_i) \rightarrow \mathbf{F}(\tilde{g}_i)
\]
are tangent at \( f \).

Proof: Again, the lifting property of Definition 2.58 implies that it suffices to prove this lemma for \( \mathcal{M}_f^{\infty} \).

The reason that an extra family \( \tilde{f}_0 \) is needed, and the heart of the technical problem to be overcome, is the following observation: Given a smooth section of an infinite-dimensional vectorbundle over the real line, there may not exist a finite-dimensional sub-vectorbundle containing the given smooth section. This problem disappears if we require some kind of non-degeneracy at zeros of the section.

Let \( t \) indicate the coordinate parametrizing \( \mathbf{F}(\tilde{f}_i) \), and suppose that \( f \) is the curve over 0. The following claim is a version of Hadamard’s lemma:

Claim 2.65. If a \( C^{\infty,1} \) section \( \nu \) of a vectorbundle over \( \mathbf{C}(\tilde{f}_i) \) vanishes at \( t = 0 \), then \( \nu = \nu' \) where \( \nu' \) is also a \( C^{\infty,1} \) section. If \( \nu \) vanishes on all edges of curves in \( \mathbf{C}(\tilde{f}_i) \), then \( \nu' \) does too.

To prove Claim 2.65, choose a connection \( \nabla \) on our vectorbundle, and a lift, \( v \), of \( \frac{\partial}{\partial t} \) to a \( C^{\infty,1} \) vectorfield on \( \mathbf{C}(\tilde{f}_i) \). The flow of \( v \) identifies \( \mathbf{C}(\tilde{f}_i) \) with \( \mathbf{C}(f) \times \mathbb{R} \) and together with \( \nabla \) allows us to trivialize the vectorbundle in the \( \mathbb{R} \) direction. Then we may write
\[
\nu(z,t) = \int_0^1 (\nabla_{tv}(z,ts))ds = t \int_0^1 (\nabla_v
\nu)(z,ts)ds
\]
\( \nabla_v \nu \) is a \( C^{\infty,1} \) section of our vectorbundle vanishing on edges of curves in \( \mathbf{C}(\tilde{f}_i) \) if \( \nu \) does, therefore
\[
\nu'(z,t) := \int_0^1 (\nabla_v\nu)(z,ts)ds
\]
is a \( C^{\infty,1} \) section of our vectorbundle vanishing on edges of curves in \( \mathbf{C}(\tilde{f}_i) \) if \( \nu \) does. This completes the proof of Claim 2.65.

Claim 2.65 implies that, if a section of a vectorbundle over \( \mathbf{C}(\tilde{f}_i) \) vanishes at \( t = 0 \) to order \( n \), but has nonvanishing \( n \)th derivative, then it is equal to \( t^n \) times a \( C^{\infty,1} \) section not vanishing at 0.

If the domain of \( f \) is not stable, then we can choose some (not necessarily closed or connected) codimension 2 surface \( S \) in \( \mathbf{B} \) so that \( f \) is transverse to \( S \), and \( \mathbf{C}(f) \) with the extra marked points in \( f^{-1}S \) is stable. Then a neighborhood of \( f \) in \( \tilde{f}_i \) will remain transverse to \( S \). For simplicity, assume that \( \tilde{f}_i \) remains everywhere transverse to \( S \) — as it suffices to prove our lemma for a neighborhood of \( f \) in \( \tilde{f}_i \), we shall repeatedly assume \( \tilde{f}_i \) is small enough as needed.

As explained in Section 4.1, there is a unique \( C^{\infty,1} \) map \( s_i : \mathbb{R} \rightarrow \mathcal{M}(pt) \) so that the pullback of the universal curve over \( \mathcal{M}(pt) \) is \( \mathbf{C}(\tilde{f}_i) \) with extra edges at each of the points in \( \tilde{f}_i^{-1}(S) \). Moreover, as proved in Section 4.1, we may locally represent \( \mathcal{M}(pt) \) the quotient of a given family of stable curves by a finite group of automorphisms. These two maps \( s_i : \mathbb{R} \rightarrow \mathcal{M}(pt) \) are tangent at 0. Chose another map \( s_0 : \mathbb{R} \rightarrow \mathcal{M}(pt) \) tangent to both \( s_i \) at 0, but not equal to either of them to second order. Then Claim 2.65 implies that there exist two smooth maps \( \tilde{s}_i : \mathbb{R}^2 \rightarrow \mathcal{M}(pt) \) so that \( s_i(t) \) is equal to \( \tilde{s}_i(t,0) \), and \( s_0(t) = \tilde{s}_i(t,t^2) \).
Define the domain $C(\hat{g}_i)$ of $\hat{g}_i$ to be the pullback of the universal curve by $\hat{s}_i$, with extra ends (corresponding to $\hat{s}_i^{-1}(S)$) removed — this removal operation replaces a neighborhood of an end with its smooth part — replacing an open subset of $T_1^i$ with the corresponding open subset $C = [T_1^i]$. Around the image of $f$ in $\mathcal{M}(pt)$, identify all the domains of curves in the the universal curve over $\mathcal{M}(pt)$, and make the identifications holomorphic in a neighborhood of edges. Then, restricted to a neighborhood of $0 \in \mathbb{R}^2$, we can regard $C(\hat{g}_i)$, and hence $C(\hat{f}_i)$, to be given by a family of almost-complex structures on a fixed domain, and regard $C(\hat{f}_i)$ to be identical, but have different almost-complex structures for $i = 0, 1, 2$. With these identifications, the fact that $\hat{f}_i$ are tangent for $i = 1, 2$ implies that the maps $\hat{f}_i$ are equal to first order restricted to $C(f)$. We may therefore choose a map $\hat{f}_0$ sending $f_i^{-1}(S)$ to $S$, equal $\hat{f}_i$ to first order at $C(f)$, but not equal to either of them to second order at $C(f)$. Claim 2.65 then implies that there exist families $\hat{g}_i : C(\hat{g}_i) \rightarrow B$ so $\hat{f}_i$ is the restriction of $\hat{g}_i$ to $C(\hat{f}_i)$, and $\hat{f}_0$ is the restriction of $\hat{g}_i$ to $C(\hat{f}_0)$.

□

Lemmas 2.63 and 2.64 allow us to differentiate any $C^{\infty, 1}$ map $\Phi : M^{st}_{\bullet} \rightarrow X$ to obtain a linear map

$$T_f \Phi : T_f M^{st}_{\bullet} \rightarrow T_{\Phi(f)} X$$

defined so that for all $C^{\infty, 1}$ families of curves $\hat{f}$ containing $f$, the diagram

$$
\begin{array}{ccc}
T_f M^{st}_{\bullet} & \xrightarrow{T_f \Phi} & T_{\Phi(f)} X \\
\downarrow_{T_f \hat{f}} & & \downarrow_{T_{\Phi(f)}} \\
T_f F(\hat{f}) & &
\end{array}
$$

commutes, where $\Phi(\hat{f}) : F(\hat{f}) \rightarrow X$ is the map induced by $\Phi$. Lemma 2.63 implies that $T_f \Phi$ is unique, and Lemma 2.64 implies that it is well defined.

2.9.4. $\mathbb{R}$–nil vectors.

Recall that the integral vectors of an exploded manifold are the vectors, $v$, so that $\partial v \partial \bar{z}$ is always an integer for any exploded function $v$. Such a vector always act as zero derivations on smooth or $C^{\infty, 1}$ functions, and is an example of a $\mathbb{R}$–nil vector.

**Definition 2.66.** A $\mathbb{R}$–nil vector $v$ on an exploded manifold is a vector which acts as a zero derivation on any $C^{\infty, 1}$, $\mathbb{R}$–valued function.

There is a canonical complex structure on the $\mathbb{R}$–nil vectors at a point so that $(Jv)(\bar{z}) = i(v \bar{z})$, and the $\mathbb{R}$–nil vectors at a point are always the complex-linear span of the integral vectors. Clearly, derivatives always send $\mathbb{R}$–nil vectors to $\mathbb{R}$–nil vectors, and such derivative maps are always complex with respect to the canonical complex structure on $\mathbb{R}$–nil vectors.

The bundle of $\mathbb{R}$–nil vectors on a strata of an exploded manifold have a canonical flat connection: the connection preserving the canonical complex structure and the lattice of integral vectors — so a constant $\mathbb{R}$–nil vectorfield is some sum of complex numbers times integral vectorfields.

There is a similar notion of integral and $\mathbb{R}$–nil vectors on $T_f M^{st}_{\bullet}$ and $T_f M^{st, 1}_{\bullet}$.0.

**Definition 2.67.** A vector $v$ in $T_f M^{st}_{\bullet}$ is $\mathbb{R}$–nil or integral if there exists a family of curves $\hat{f}$ containing $f$ and an $\mathbb{R}$–nil vector $v' \in T_f F(\hat{f})$ such that $v = T_f \hat{f}(v')$. 

As the canonical complex structure on $\mathbb{R}\text–nil$ vectors is compatible with all exploded maps, it follows that there is a canonical complex structure on the $\mathbb{R}\text–nil$ vectors within $T_fM^\ast_t$.

2.9.5. $T_fM^\ast_t$.

For a family of curves $\hat{f}$, it is not clear that the vectorspaces $T_fM^\ast_t$ for all $f$ in $\hat{f}$ fit together to form a vectorbundle. On the other hand, there is a natural tangent sheaf, $T_fM^\ast_t$ over the exploded manifold $F(\hat{f})$, encoding first order deformations of $\hat{f}$ parametrized by $F(\hat{f})$. This tangent sheaf is defined by the short exact sequence

$$
\Gamma(T_{vert}C(\hat{f})) \xrightarrow{h} \Gamma^0(1)(T_{vert}C(\hat{f}) \otimes T_{vert}C(\hat{f})) \times \Gamma_{B_0}(\hat{f}^*TB)
$$

(3)

and defined in the relative case by the following short exact sequence:

$$
\Gamma(T_{vert}C(\hat{f})) \xrightarrow{h} \Gamma^0(1)(T_{vert}C(\hat{f}) \otimes T_{vert}C(\hat{f})) \times \Gamma(\hat{f}^*T_{vert}B)
$$

(4)

Again, $\Gamma^0(1)(T_{vert}C(\hat{f}) \otimes T_{vert}C(\hat{f}))$ indicates $C^\infty$ sections of $(T_{vert}C(\hat{f}) \otimes T_{vert}C(\hat{f}))$ that vanish on edges of curves and that anti commute with $\hat{j}$. These sections represent infinitesimal variations of complex structure on the domain. Also, $\Gamma_{B_0}(\hat{f}^*TB)$ indicates $C^\infty$ sections of $\hat{f}^*TB$ lifting sections over $F(\hat{f})$ using the following diagram.

Sections of $T_{vert}C(\hat{f})$ represent the infinitesimal reparametrizations of $C(\hat{f})$ fixing the parametrization of $F(\hat{f})$. The action of reparametrization is again given by the map $h$:

$$
h(v) := (L_v \hat{j}, df(v))
$$

With the above definition, $T_fM^\ast_t$ is a sheaf of $C^\infty$($F(\hat{f})$)–modules — because given any $\lambda \in C^\infty$($F(\hat{f})$), $h(\lambda v + w) = \lambda h(v) + h(w)$. Note that if $f$ is a curve in $\hat{f}$, we can restrict any section of $T_fM^\ast_t$ to give a tangent vector in $T_fM^\ast_t$, and more generally, given any map $\hat{g} \rightarrow \hat{f}$, there is an induced map $T_fM^\ast_t \rightarrow T_{\hat{g}}M^\ast_t$ making the assignment $\hat{f} \mapsto T_fM^\ast_t$ into a contravariant functor and a sheaf over $M^\ast_t$. Accordingly, the sheaf $T_fM^\ast_t$ should be regarded as the pullback of the tangent sheaf of $M^\ast_t$. When the family $\hat{f}$ has bubbling or node formation behavior, it is not clear that $T_fM^\ast_t$ represents sections of a vectorbundle over $F(\hat{f})$, however we will use a notion of a finite-dimensional sub-vectorbundle: when subsheaf of $T_fM^\ast_t$ is locally free and finitely generated over $C^\infty$($F$), we regard it a sheaf of sections of a finite-dimensional sub-vectorbundle of $T_fM^\ast_t$.

Consider a 1-dimensional deformation $\hat{f}_t$ of $\hat{f}$. We may take the derivative of this deformation with respect to $t$ to obtain a section of $T_fM^\ast_t$ as follows. Choose
a lift, $\tilde{v}$, of $\frac{∂}{∂\theta}$ to a section of the restriction of $TC(\hat{f}_t)$ to $C(\hat{f})$. Then $(L_{\tilde{v}}j, d\tilde{f}_t(\tilde{v}))$ is contained in $\Gamma^{0,1}(T_{vert}C(\hat{f}) \otimes T_{vert}C(\hat{f})) \times \Gamma_{B_{\hat{f}}}(\hat{f}^*TB)$. The choice of lift, $\tilde{v}$, is determined up to a choice of vertical vectorfield, so $(L_{\tilde{v}}j, d\tilde{f}_t(\tilde{v}))$ projects to a section of $T_jM_{\bullet}^{st}$ that is well defined independent of our choice of lift of $\frac{∂}{∂\theta}$. The following lemma shows that all sections of $T_jM_{\bullet}^{st}$ may be constructed in this way.

**Lemma 2.68.** Given any section $v$ of $T_jM_{\bullet}^{st}$, there is a one-dimensional deformation $\hat{f}_t$ of $\hat{f}$ with derivative at $t = 0$ equal to $v$.

**Proof:**

The lifting property of Definition 2.58 implies that, without loss of generality, we may prove this lemma for $M_{\bullet}^{st}$.

Claim 2.62 tells us that, in holomorphic coordinates, $L_wj$ is $2j$ times the standard $\partial$ operator applied to $w$. Around any curve $f$ in $\hat{f}$, Theorem 3.8 implies that we can construct a vertical vectorfield $w$ so that $L_wj$ equals a given section of $\Gamma^{0,1}(T_{vert}C(\hat{f}) \otimes T_{vert}^*C(\hat{f}))$ on a neighborhood in $C(\hat{f})$ of all the edges of $C(f)$. We can patch together such vectorfields for different $f$, using a fiberwise constant partition of unity, to obtain a globally defined section $w$ of $T_{vert}C(\hat{f})$ so that $L_wj$ is equal to the given section of $\Gamma^{0,1}(T_{vert}C(\hat{f}) \otimes T_{vert}^*C(\hat{f}))$ on a neighborhood of the edges of all the curves in $C(\hat{f})$. Therefore, we can reduce to the case that our section $v$ of $T_jM_{\bullet}^{st}$ is equal to $(\theta, r)$ where $\theta$ is a section of $\Gamma^{0,1}(T_{vert}C(\hat{f}) \otimes T_{vert}^*C(\hat{f}))$ vanishing on a neighborhood of all edges of curves in $C(\hat{f})$, and $r$ is a $C^{\infty, 1}$ section of $\hat{f}^*T_{vert}B$.

Extend $j$ to a family $j_t$ of almost-complex structures on $C(\hat{f})$ with derivative at $0$ equal to $\theta$, and extend $\hat{f}$ to a family of maps $\hat{f}_t$ with derivative at $0$ equal to $r$. The family of maps $\hat{f}_t$ with domain $(C(\hat{f}), j_t)$ is the required deformation of $\hat{f}$ with derivative at $0$ equal to $v$. \hfill $\Box$

### 2.10. $D\partial$

In this section, we construct the linearization, $D\partial$, of the $\partial$ operator at holomorphic curves $f$ — we restrict to holomorphic curves because, to define a linearization of the $D\partial$ operator at a non-holomorphic curve $f$, a connection is required on the sheaf $\mathcal{Y}$ over $M_{\bullet}^{st}$ (recall that $\mathcal{Y}$ is the pullback of the sheaf from Definition 2.37 under the map $M_{\bullet}^{st} \rightarrow M^{\infty, 1}$). It is not clear to me that such a connection always exists globally.

For a $C^{\infty, 1}$ family of curves $\hat{f}$ containing a homomorphic curve $f$, let us define a linear map

$$D\partial: T_jF(\hat{f}) \rightarrow \mathcal{Y}(f).$$

First, regard $\partial\hat{f}$ as a section of the vectorbundle $Y(\hat{f})$ over $C(\hat{f})$, and choose a connection $\nabla$ on $Y(\hat{f})$. To define $D\partial(v)$, lift $v$ to a section $v'$ of $TC(\hat{f})$ over $C(f)$. Then $D\partial(v) := \nabla_{v'}\partial\hat{f}$. Because $\partial\hat{f}$ vanishes on $C(\hat{f})$, $\nabla_{v'}\partial\hat{f}$ does not depend on the choice $\nabla$ or the lift $v'$ of $v$. Moreover, because $\partial\hat{f}$ vanishes on edges of $C(\hat{f})$, $\nabla_{v'}\partial\hat{f}$ vanishes on all edges of curves in $C(\hat{f})$, so it is a section in $\mathcal{Y}(f)$. 

Our $D\bar{\partial}$ is natural in the following sense: given any commutative diagram,

$$\begin{array}{ccc}
  f & \longrightarrow & \hat{f} \\
  \downarrow & & \downarrow \\
  \hat{h} & \longrightarrow & h
\end{array}$$

the following diagram commutes.

$$\begin{array}{ccc}
  T_f F(\hat{f}) & \longrightarrow & \mathcal{Y}(f) \\
  \downarrow & & \downarrow D\bar{\partial} \\
  T_f F(\hat{h}) & \longrightarrow & \mathcal{Y}(h)
\end{array}$$

Therefore, Lemmas 2.63 and 2.64 imply that the maps $D\bar{\partial}$ all factor through a fixed linear map from $T_f M_{\text{st}}$.

$$T_f F(\hat{f}) \longrightarrow T_f M_{\text{st}} \overset{D\bar{\partial}}{\longrightarrow} \mathcal{Y}(f)$$

An elementary extension of the calculation of the linearized $\bar{\partial}$ operator in [31] gives a formula for $D\bar{\partial}$ in terms of $\Gamma^0,1(T_{\text{vert}}^* C(f) \otimes T_{\text{vert}}^* C(\hat{f})) \times \Gamma_{\text{Ba}}(f^* TB)$. 

Recall that both $\mathcal{Y}(f)$ and $T_f M_{\text{st}} \downarrow_{\text{Ba}} \subset T_f M_{\text{st}}$ are complex at holomorphic curves $f$. The restriction of $D\bar{\partial}$ to $T_f M_{\text{st}} \downarrow_{\text{Ba}}$ is not usually $C$–linear unless $J$ is integrable. We shall see that $D\bar{\partial}$ has a finite-dimensional kernel and cokernel throughout the linear homotopy of $D\bar{\partial}$ to its complex-linear part. This allows us to canonically orient the kernel of $D\bar{\partial}$ relative to the cokernel, and construct orientations and a kind of almost-complex structure on embedded Kuranishi structures; see Section 8.

2.11. Embedded Kuranishi structures.

If $D\bar{\partial}$ is surjective at a holomorphic curve $f$, then we shall show that the moduli stack of holomorphic curves close to $f$ is represented by the quotient of some $C^\infty$ family of curves $\hat{f}$ by a finite group of automorphisms; see Definition 2.29. If, however, $D\bar{\partial}$ is not surjective at $f$, we need to choose a nice subsheaf $V$ of $\mathcal{Y}$ in a neighborhood of $f$ so that the moduli stack of curves with $\bar{\partial}$ in $V$ is well behaved. Below is a standard definition of a subsheaf $V$ of $\mathcal{Y}$.

**Definition 2.69.** Let $\mathcal{U}$ be a substack of $M_{\text{st}}$. A subsheaf $V$ of $\mathcal{Y}$ on $\mathcal{U}$ is, for all $\hat{f}$, a subsheaf $V(\hat{f}) \subset \mathcal{Y}(\hat{f})$ such that given any map $\psi: \hat{f} \longrightarrow \hat{g}$, $V(\hat{f})$ is the sheaf of $C^\infty$–modules generated by the image of $V(\hat{g})$ under $\mathcal{Y}(\psi)$: $\mathcal{Y}(\hat{g}) \longrightarrow \mathcal{Y}(\hat{f})$.

We want our subsheaves $V$ of $\mathcal{Y}$ to be pulled back from nice geometrically defined sheaves. For example, if $f$ is embedded and has a stable domain, we might pull back $V$ from a sheaf defined over $M_{g,n} \times \hat{B}$. The following defines what we mean by pullback.

**Definition 2.70.** Given a family $\mathbf{A} \longrightarrow \mathbf{X}$ of exploded manifolds with a fiberwise almost-complex structure, define

$$\Gamma^0,1(T_{\text{vert}}^* \mathbf{A} \otimes T_{\text{vert}}^* \hat{B})$$

to be the sheaf of $C^\infty$–modules on $\mathbf{X}$ with global sections consisting of anti-holomorphic, $C^\infty$–sections of $T_{\text{vert}}^* \mathbf{A} \otimes T_{\text{vert}}^* \hat{B}$ over $\mathbf{A} \times \hat{B}$ vanishing on integral vectors within $T_{\text{vert}} \hat{A}$, (and with sections over $U \subset \mathbf{X}$ consisting of the same thing with $\hat{A}$ replaced by the inverse image of $U$ in $\mathbf{A}$).
Given a family of curves \( \hat{f} \) in \( B \) and a fiberwise-holomorphic map \[
\begin{align*}
C(\hat{f}) & \xrightarrow{\psi} \hat{A} \\
\downarrow & \\
F(\hat{f}) & \longrightarrow X
\end{align*}
\]
sections \( \nu \) of \( T_{\text{vert}}^{*}A \) pull back to sections \( \psi^{*}\nu \) of \( T_{\text{vert}}^{*}C(\hat{f}) \) by composing with the derivative of \( \psi \). As \( \psi \) is fiberwise holomorphic, the pullback map, \( \psi^{*} \), is complex. Any section vanishing on integral vectors of \( T_{\text{vert}}A \) pulls back to a section also vanishing on integral vectors of \( T_{\text{vert}}C(\hat{f}) \).

A section \( v \) of \( T_{\text{vert}}B \) also pulls back to a section \( \hat{v}^{*}v \) of \( T_{\text{vert}}B \). This map \( \hat{v}^{*} \) is also complex, therefore there is an induced complex map:

\[
\psi^{*} \circ \hat{v}^{*} : \Gamma^{0,1}(T_{\text{vert}}^{*}A \otimes T_{\text{vert}}B) \longrightarrow \mathcal{Y}(\hat{f}) := \Gamma^{0,1}(T_{\text{vert}}^{*}C(\hat{f}) \otimes f^{*}T_{\text{vert}}B)
\]

Say that the pullback of a section or subsheaf of \( \Gamma^{0,1}(T_{\text{vert}}^{*}A \otimes T_{\text{vert}}B) \) to \( \mathcal{Y}(\hat{f}) \) is the image of the section or subsheaf under the map \( \psi^{*} \circ \hat{v}^{*} \).

The following defines what we mean by a ‘nice’ subsheaf \( V \) of \( \mathcal{Y} \).

**Definition 2.71.** Say that a subsheaf \( V \) of \( \mathcal{Y} \) on \( U \) is **simply generated** if there exists a fiberwise-holomorphic map

\[
\begin{align*}
U^{+1} & \xrightarrow{\Phi^{+1}} \hat{A}/G \\
\downarrow & \\
U & \xrightarrow{\Phi} X/G
\end{align*}
\]

with an effective \( G \)-action in the sense of Definition 2.30 and sections \( v_{1}, \ldots, v_{n} \) of \( \Gamma^{0,1}(T_{\text{vert}}^{*}A \otimes T_{\text{vert}}B) \) so that the following holds:

1. For any family of curves \( \hat{f} \) in \( U \), the pulled back sections

\[
((\Phi(\hat{f})^{-1} \otimes (\hat{f}^{G})^{*})v_{i}
\]

of \( \mathcal{Y}(\hat{f}^{G}) \) are linearly independent, and generate \( V(\hat{f}^{G}) \) as a sheaf of \( C^{\infty}(\mathcal{Y}(\hat{f}^{G})) \)-modules. (As in Definition 2.30, \( \hat{f}^{G} \) indicates the \( G \)-fold cover of \( f \) with a \( G \)-equivariant fiberwise-holomorphic map \( \Phi^{+1}(\hat{f}) : C(\hat{f}^{G}) \longrightarrow A \).)

2. The sheaf of \( C^{\infty}(X) \)-modules over \( X \) generated by \( v_{1}, \ldots, v_{n} \) is \( G \)-invariant.

Theorem 6.3 states that if \( V \) is a simply-generated subsheaf of \( \mathcal{Y} \) transverse to \( D\partial \) at a holomorphic curve \( f \), then there exists an open neighborhood \( \mathcal{O} \subset M_{f}^{\ast} \) of \( f \) and a \( C^{\infty}(X) \) family of curves \( \hat{f} \) with automorphism group \( G \) so that \( \hat{f}/G \) represents the substack, \( \partial^{-1}(V) \subset \mathcal{O} \), consisting of curves \( h \) with the property that \( \partial h \in V(h) \). The substack of holomorphic curves within \( \hat{f}/G \) therefore represents the moduli stack of holomorphic curves in \( \mathcal{O} \). So, the moduli stack of holomorphic curves in \( \mathcal{O} \) is represented by \( \{\partial f^{-1}(0)\}/G \subset \hat{f}/G \).

**Definition 2.72.** Say that a subsheaf \( V \) of \( \mathcal{Y} \) is **complex** if \( V(f) \) is a complex-linear subspace of \( \mathcal{Y}(f) \) for all curves \( f \).

Recall that if \( f \) is holomorphic, \( T_{f}M_{f}^{\ast} \downarrow_{B_{f}} \) is a complex vectorspace, and there is a well-defined linearization of the \( \partial \) operator

\[
D\partial : T_{f}M_{f}^{\ast} \downarrow_{B_{f}} \longrightarrow \mathcal{Y}(f)
\]

\[39\text{See Definition 2.22 for the definition of the stack } \hat{f}/G.\]
constructed in Section 2.10. This map $D\bar{\partial}$ is not necessarily $\mathbb{C}$–linear, however we shall show that there is a homotopy

$$(1 - t)D\bar{\partial} + tD\bar{\partial}C$$

from $D\bar{\partial}$ to its complex-linear part, transverse to a finite-dimensional $\mathbb{C}$–linear subspace $V$ of $\mathcal{Y}(f)$ for all $t \in [0, 1]$, so

$$K_t(f) := ((1 - t)D\bar{\partial} + tD\bar{\partial}C)^{-1}(V)$$

is a family of vectorspaces in $T_fM_{st} \downarrow_{B_0}$ of some finite dimension.

**Definition 2.73.** Say that a subsheaf $V$ of $\mathcal{Y}$ is strongly transverse to $D\bar{\partial}$ at a holomorphic curve $f$ if

$$(1 - t)D\bar{\partial} + tD\bar{\partial}C : T_fM_{st} \downarrow_{B_0} \rightarrow \mathcal{Y}(f)$$

is transverse to $V$ for all $t \in [0, 1]$.

Combining notions from definitions 2.38, 2.58, 2.71, 2.47, 2.73 and 2.29, we make the following important definition of Kuranishi charts.

**Definition 2.74.** A Kuranishi chart $(U, V, \hat{f}/G)$ on $M_{st}(\hat{B})$ is

- an open substack
  $$U \subset M_{st}(\hat{B})$$
- a simply-generated complex subsheaf $V$ of $\mathcal{Y}$, defined on $U$, and strongly transverse to $\partial$ at all holomorphic curves in $U$,
- and a $C^\infty$ family of curves $\hat{f}$ in $U$ with automorphism group $G$ so that
  1. $\hat{f}/G$ represents the substack $\partial^{-1}V \subset U$,
  2. and so that the map $F(\hat{f}) \rightarrow B_0$ is a submersion.

$F(\hat{f})$ with the vectorbundle $V(\hat{f})$, the section of this vectorbundle given by $\bar{\partial}$, and the action of $G$ is our version of a Kuranishi chart defined by Fukaya and Ono in [6].

Our final condition, that $F(\hat{f}) \rightarrow B_0$ is a submersion, is included to ensure that any base change of our family of targets

$$\begin{array}{ccc}
B' & \longrightarrow & B \\
\downarrow & & \downarrow \\
B'_0 & \longrightarrow & B_0
\end{array}$$

pulls back Kuranishi charts on $M_{st}(B)$ to Kuranishi charts on $M_{st}(B')$; similarly, Kuranishi charts on $M_{st}(B)$ pull back to Kuranishi charts on $M_{st}(B')$, but see Remark 2.59.

We include the condition of strong transversality to $V$ and require $V$ be complex to ensure that the information of the stable almost-complex structure, defined by Fukaya and Ono in [6], is reflected in our Kuranishi chart. This information may be used to orient a Kuranishi chart (as in Section 3.1 of [32]), and to define integer counts of holomorphic curves using Fukaya and Ono’s method from [7]; see [26] for details. In [13], Joyce also outlines a method to use such structure to obtain integrality results for Gromov–Witten invariants. Such structures and invariants are compatible with evaluation maps that are holomorphic submersions, defined below.
Definition 2.75. A submersion $\Phi$ to a family $X \to X_0$ of exploded manifolds or orbifolds is a commutative diagram of $C^\infty$ maps

$$
\begin{array}{ccc}
\mathcal{M}_0^\bullet & \xrightarrow{\Phi} & X \\
\downarrow & & \downarrow \\
B_0 & \to & X_0
\end{array}
$$

such that $T_f \Phi: T_f \mathcal{M}_0^\bullet \to T_{\Phi(f)}X$ is surjective for all $f$, where we use Definition 2.60 and Example 2.61 in the orbifold case.

Say that a submersion $\Phi: \mathcal{M}_0^\bullet \to X$ is holomorphic if $X \to X_0$ has a fiberwise almost-complex structure, and for each holomorphic curve $f$, the map

$$
T_f \Phi: T_f \mathcal{M}_0^\bullet \to T_{\Phi(f)}X
$$

is complex.

Examples of such holomorphic submersions include the maps $ev^+_n$ defined in section 4.2, and the usual evaluation map from Gromov–Witten theory, evaluating curves at marked points.

Definition 2.76. Given a submersion

$$
\Phi: \mathcal{M}_0^\bullet \to X
$$

where $X$ is a finite dimensional exploded manifold or orbifold, say that a Kuranishi chart $(U, V, \hat{f}/G)$ on $\mathcal{M}_0^\bullet$ is $\Phi$–submersive if the induced map

$$
\Phi: F(\hat{f}) \to X
$$

is a submersion, and if for all holomorphic curves $f$ in $\hat{f}$, $D\bar{\partial}$ restricted to $\ker T_f \Phi$ is strongly transverse to $V(f)$ in the sense that

$$
((1 - t)D\bar{\partial} + tD\bar{\partial}^G)(T_f \mathcal{M}_0^\bullet \cap B_0 \cap \ker T_f \Phi)
$$

is transverse to $V(f)$ for all $t$ in $[0, 1]$.

Definition 2.77. Two Kuranishi charts $(U_1, V_1, \hat{f}_1/G_1), (U_2, V_2, \hat{f}_2/G_2)$ are compatible if restricted to $U_1 \cap U_2$, either $V_1$ is a subsheaf of $V_2$ or $V_2$ is a subsheaf of $V_1$.

In the case that $V_1$ is a subsheaf of $V_2$, $\hat{f}_1|_{U_1 \cap U_2}$ is a family in the stack represented by $\hat{f}_2/G_2$ (see definitions 2.22 and 2.29), so there is a unique (up to unique 2-isomorphism) $C^\infty$ transition map

$$
\hat{f}_1|_{U_1 \cap U_2} \to \hat{f}_2/G_2
$$

in the sense of Example 2.21, so this transition map can be expressed in the form

$$
\hat{f}_1 \times \mathcal{M}_0^\bullet \xrightarrow{\psi} \hat{f}_2
$$

where $\pi$ is a $G_1$–equivariant $G_2$–bundle internal to $\mathcal{M}_0^\bullet$, and $\psi$ is a $G_2$–invariant map.

Definition 2.78. A Kuranishi chart $(U, V, \hat{f}/G)$ is extendible if it has an extension, which is a Kuranishi chart $(U^0, V^\circ, \hat{f}/G)$ satisfying the following conditions.

- There exists a continuous map

$$
\rho: U^0 \to [0, 1]
$$

so that
\[ U = \rho^{-1}(1/2, 1) \]

- for any \( t > 0 \), all holomorphic curves in the closure of \( \rho^{-1}([t, 1]) \) within \( \mathcal{M}_*^\bullet \) are contained within \( \rho^{-1}([t, 1]) \);
- for any \( t > 0 \), the closure within \( \mathcal{M}_*^{\sharp} \) of the subset of \( \hat{f}^\sharp \) where \( \rho > t \) is contained within \( \hat{f}^\sharp \);

\[ \bullet \text{ V is the restriction of V}^\sharp \text{ to } U, \text{ and } \hat{f} \text{ is the restriction of } \hat{f}^\sharp \text{ to } U. \]

Note that extendible Kuranishi charts pull back to extendible Kuranishi charts. The condition of extendability is designed to prevent pathological behavior from occurring at the boundary of Kuranishi charts. We shall have cause to repeatedly shrink the size of extensions during inductive constructions — restricting \( (U^\sharp, V^\sharp, \hat{f}^\sharp/G) \) to \( \rho > t \) for any \( t \in (0, 1/2) \) gives an extension of \( (U, V, \hat{f}/G) \).

As we shall have no reason to distinguish between \( V \) and \( V^\sharp \), we sometimes use the notation \( V \) to refer to \( V^\sharp \).

**Definition 2.79.** A collection of extendible Kuranishi charts is locally finite if there exists an extension \( (U^\sharp, V^\sharp, \hat{f}^\sharp/G) \) of each Kuranishi chart \( (U, V, \hat{f}/G) \) such that each holomorphic curve has a neighborhood intersecting only finitely many of the \( U^\sharp \), and each \( U^\sharp \) intersects only finitely many of the other \( U^\sharp \).

The collection is compatible if every pair of extended Kuranishi charts is compatible.

The collection is said to cover any substack of \( \mathcal{M}_*^{\sharp} \) covered by \( \{U\} \).

Now, combining definitions 2.74, 2.77, 2.78, and 2.79 we arrive at the definition of an embedded Kuranishi structure.

**Definition 2.80.** An embedded Kuranishi structure on the moduli stack of stable holomorphic curves \( \mathcal{M} \subset \mathcal{M}^{\sharp} \) is a countable, locally finite, compatible collection of extendible Kuranishi charts \( \{(U_i, V_i, \hat{f}_i/G_i)\} \) covering the holomorphic curves \( \mathcal{M} \subset \mathcal{M}^{\sharp} \).

In many cases, the moduli stack of stable holomorphic curves, \( \mathcal{M} \), has the following compactness property: The map \( \mathcal{M} \longrightarrow B_0 \) is proper when \( \mathcal{M} \subset \mathcal{M}^{\sharp} \) is restricted to any connected component of \( \mathcal{M}^{\sharp} \); see [28] for details. Definition 2.80 implies that in this case, the same compactness holds for \( \mathcal{M} \subset \mathcal{M}^{\sharp} \). When \( \mathcal{M} \) satisfies this compactness property, Theorem 7.3 states that there exists an embedded Kuranishi structure on \( \mathcal{M} \), and that, given any submersion \( \Phi: \mathcal{M}^{\sharp} \longrightarrow X \), there exists a \( \Phi \)-submersive embedded Kuranishi structure on \( \mathcal{M} \).

Given any base change of our family of targets,

\[
\begin{array}{ccc}
\mathcal{B}' & \longrightarrow & \mathcal{B} \\
\downarrow & & \downarrow \\
B'_0 & \longrightarrow & B_0
\end{array}
\]

the pullback of any embedded Kuranishi structure on \( \mathcal{M}(\mathcal{B}) \subset \mathcal{M}^{\sharp}(\mathcal{B}) \) is an embedded Kuranishi structure on \( \mathcal{M}(\mathcal{B}') \). Corollary 7.3 proves that any two embedded Kuranishi structures on \( \mathcal{M}(\mathcal{B}) \) are homotopic — there exists an embedded Kuranishi structure on \( \mathcal{M}(\mathcal{B} \times \mathbb{R}) \) pulling back to give each of the original embedded Kuranishi structures under the inclusions of \( \mathcal{B} \) over 0 and 1 in \( \mathbb{R} \).

\[ ^{40} \text{In particular, the closure of } \hat{f} \text{ within } \hat{f}^\sharp \text{ is closed within } \mathcal{M}_*^{\sharp}. \text{ This means wild behavior at the boundary of } f \text{ can be excluded by requiring extensions to } \hat{f}^\sharp. \]

\[ ^{41} \text{See for example Proposition 2.3 of [32].} \]
Given an embedded Kuranishi structure \( \{U_i, V_i, \hat{f}_i/G_i\} \), we shall construct in Section 8 a canonical homotopy class of complex structure on \( T\hat{f}F(\hat{f}_i)^\dagger/B_0 \) for all holomorphic curves \( f \) in \( \hat{f}_i \) so that

- all \( \mathbb{R} \)-nil vectors at holomorphic curves are given the canonical complex structure;
- the action of \( G_i \) is complex: if an element of \( G_i \) sends \( f \) to \( f' \), the corresponding map \( T_fF(\hat{f}_i)^\dagger/B_0 \rightarrow T_{f'}F(\hat{f}_i)^\dagger/B_0 \) is complex;
- if \( f \) is a holomorphic curve in \( \hat{f}_i^2 \) and \( \hat{f}_j^2 \), and \( V_i(f) \subset V_j(f) \), then the following is a complex short exact sequence

\[
0 \rightarrow T_fF(\hat{f}_i)^\dagger/B_0 \rightarrow T_fF(\hat{f}_j)^\dagger/B_0 \xrightarrow{D\pi\nu\hat{\partial}} V_j/V_i(f) \rightarrow 0
\]

- there exists a complex structure on \( T\hat{f}F(\hat{f}_i)^\dagger/B_0 \), defined on a neighborhood of the holomorphic curves, and restricting to the given complex structure at holomorphic curves.

We shall also show in section 8 that given a holomorphic submersion (from Definition 2.75),

We may construct this complex structure so that

\[
T_f\Phi: T_fF(\hat{f}_i)^\dagger/B_0 \rightarrow T_{\Phi(f)}X|_{X_0}
\]

is complex for all \( f \) in \( \hat{f}_i \).

3. Trivializations and pre-obstruction models

This section summarizes the results of [31] necessary for this paper. The notion, from Definition 1.4 of [31], of a trivialization \((\mathcal{F}, \Phi)\) associated to a family of curves \( \hat{f} \), allows us to identify sections of \( \hat{f}^*T_{\text{vert}}B \) with families of curves parametrized by \( C(\hat{f}) \), and to identify \( \hat{\partial} \) of such a family of curves with a section of \( \mathcal{Y}(\hat{f}) \).

**Definition 3.1.** Given a \( C^\infty,1 \) family of curves \( \hat{f} \), a choice of trivialization \((\mathcal{F}, \Phi)\) is the following information:

1. A \( C^\infty,1 \) map \( \mathcal{F} \) such that the following diagram of \( C^\infty,1 \) maps commutes

\[
\begin{array}{ccc}
\hat{f}^*T_{\text{vert}}B & \xrightarrow{\mathcal{F}} & B \\
\downarrow & & \downarrow \\
\mathcal{F}(\hat{f}) & \rightarrow & B_0
\end{array}
\]

and such that

- \( \mathcal{F} \) restricted to the zero section equals \( \hat{f} \),
- \( T\mathcal{F} \) restricted to the canonical inclusion of \( \hat{f}^*T_{\text{vert}}B \) over the zero section is the identity,
- \( T\mathcal{F} \) restricted to the vertical tangent space at any point of \( \hat{f}^*T_{\text{vert}}B \) is injective.
A $C^{\infty, 1}$ vectorbundle map, $\Phi$

\[
\begin{array}{ccc}
F^*T_{\text{vert}}B & \xrightarrow{\Phi} & \hat{f}^*T_{\text{vert}}B \\
\downarrow & & \downarrow \pi \\
\hat{f}^*T_{\text{vert}}B & \xrightarrow{\pi} & C(\hat{f})
\end{array}
\]

which is a $C$–linear isomorphism on each fiber, and which is the identity when the vectorbundle $F^*T_{\text{vert}}B \rightarrow \hat{f}^*T_{\text{vert}}B$ is restricted to the zero section of $\hat{f}^*T_{\text{vert}}B$.

A trivialization allows us to define $\hat{\partial}$ of a section

\[\nu: C(\hat{f}) \rightarrow \hat{f}^*T_{\text{vert}}B\]

as follows: $F \circ \nu$ is a map $C(\hat{f}) \rightarrow B$, so $\hat{\partial}(F \circ \nu)$ is a section of

\[\mathcal{Y}(F \circ \nu) = \Gamma^{0, 1}\left(T_{\text{vert}}^*C(\hat{f}) \otimes (F \circ \nu)^*T_{\text{vert}}B\right).
\]

Applying the map $\Phi$ to the second component of this tensor product identifies $\mathcal{Y}(F \circ \nu)$ with $\mathcal{Y}(\hat{f})$, and identifies $\hat{\partial}(F \circ \nu)$ with a section of $\mathcal{Y}(\hat{f})$. Define $\hat{\partial}\nu$ to be this section of $\mathcal{Y}(\hat{f})$.

For example, we may construct a trivialization by extending $\hat{f}$ to a map $F$ satisfying the above conditions — for instance by choosing a smooth connection on $T_{\text{vert}}B$ and reparametrising the exponential map on a neighborhood of the zero section in $f^*T_{\text{vert}}B$ — and defining $\Phi$ using parallel transport along a linear path to the zero section using a smooth $J$–preserving connection on $T_{\text{vert}}B$.

Given a choice of trivialization for $f$ and a $C^{\infty, 1}$ section $\nu$ of $f^*T_{\text{vert}}B$, there is an induced choice of trivialization for the family $F(\nu)$.

**Definition 3.2.** A $C^{\infty, 1}$ pre-obstruction model $(\hat{f}, V, F, \Phi, \{s_i\})$, is given by

1. A $C^{\infty, 1}$ family of curves $\hat{f}$;
2. A choice of trivialization $(F, \Phi)$ for $\hat{f}$;
3. A finite collection $\{s_i\}$ of extra marked points on $C(\hat{f})$ corresponding to $C^{\infty, 1}$ sections

\[s_i: F(\hat{f}) \rightarrow C(\hat{f})\]

so that, restricted to any curve $C$ in $C(\hat{f})$, these marked points are distinct and contained inside the smooth component $\mathcal{C}$ of $C$;
4. A finite-dimensional sub-vectorbundle $V$ of $\mathcal{Y}(\hat{f})$ — so, $V \subset Y$ is locally free, and finitely generated as a sheaf of $C^{\infty, 1}(F(\hat{f}))$–modules.

We shall usually use the notation $(\hat{f}, V)$ for a pre-obstruction bundle.

**Definition 3.3.** Given any family of curves, $\hat{f}$, and a collection, $\{s_i\}$, of extra marked points on $C(\hat{f})$, let $X^{\infty, 1}(\hat{f})$ indicate the space of $C^{\infty, 1}$ sections of $f^*T_{\text{vert}}B$ vanishing on the extra marked points $\{s_i\}$ on $C(\hat{f})$.

Note that both $X^{\infty, 1}(\hat{f})$ and $\mathcal{Y}(\hat{f})$ are complex vectorspaces because they consist of sections of complex vectorbundles.

We may restrict any pre-obstruction bundle $(\hat{f}, V)$ to a single curve $f$ in $\hat{f}$. The restriction of $V$ to this curve $f$ is a finite-dimensional linear subspace $V(f) \subset \mathcal{Y}(f)$.

Let $D\hat{\partial}(f): X^{\infty, 1}(f) \rightarrow \mathcal{Y}(f)$ indicate the derivative of $\hat{\partial}$ at $0 \in X^{\infty, 1}(f)$. We are most interested in pre-obstruction bundles $(\hat{f}, V)$ containing holomorphic curves $f$ such that $D\hat{\partial}(f)$ is injective and has image complementary to $V(f)$. If there are

\[\text{See Definition 8.3 of [24].}\]
Definition 3.4. Given a trivialization for \( \hat{f} \), a simple perturbation of \( \hat{\nu} \) is a map

\[
\bar{\nu}': X^{\infty,y}(\hat{f}) \rightarrow \mathcal{Y}(\hat{f})
\]

so that

\[
\bar{\nu}' = \bar{\nu}(\nu) + \Psi(\nu)
\]

where \( \Psi \) is a (usually nonlinear) \( C^{\infty,y} \) map

\[
f^*T_{\text{vert}}\hat{\mathcal{B}} \xrightarrow{\Psi} Y(\hat{f}) \quad \xrightarrow{\text{\( C(\hat{f}) \)}} \quad \mathcal{C}(\hat{f})
\]

equal to the zero-section restricted to edges of curves in \( \mathcal{C}(\hat{f}) \).

Example 3.5 (Construction of a simple perturbation).

Let \( \theta \) be a section of \( \Gamma^{0,1}\left(T^*_\text{vert}\mathcal{C}(\hat{f}) \otimes T^*_{\text{vert}}\hat{\mathcal{B}}\right) \) and suppose that \( \hat{f} \) comes with a trivialization \( (\mathcal{F},\Phi) \). A section \( \nu \) of \( \hat{\mathcal{F}}^*T_{\text{vert}}\hat{\mathcal{B}} \) defines a map

\[
(id,\mathcal{F}(\nu)): C(\hat{f}) \rightarrow C(\hat{f}) \times \hat{\mathcal{B}}
\]

Pulling back the section \( \theta \) over \( (id,\mathcal{F}(\nu)) \) gives a section of \( \mathcal{Y}(\mathcal{F}(\nu)) \), which we can identify as a section of \( \mathcal{Y}(\hat{f}) \) using the map \( \Phi \) from our trivialization. Therefore, we get a modification \( \bar{\nu}' \) of the usual \( \bar{\nu} \) equation on sections \( \hat{f}^*T_{\text{vert}}\hat{\mathcal{B}} \) given by the trivialization

\[
\bar{\nu}' := \bar{\nu} - \Phi((id,\mathcal{F}(\nu))^*\theta).
\]

As \( \mathcal{F}, \theta \) and \( \Phi \) are \( C^{\infty,y} \) maps, we may define a \( C^{\infty,y} \) map \( \psi(\nu) := -\Phi((id,\mathcal{F}(\nu))^*\theta) \), so \( \bar{\nu}' \) is a simple perturbation of \( \bar{\nu} \).

The following theorem is the main result of [31].

Theorem 3.6. Suppose that \( (\hat{f},V) \) is a \( C^{\infty,y} \) pre-obstruction model containing the curve \( f \), so that \( \bar{\nu} \bar{f} \in V(\hat{f}) \), and

\[
D\bar{\nu}'(f): X^{\infty,y}(\hat{f}) \rightarrow \mathcal{Y}(\hat{f})
\]

is injective and has image complementary to \( V(\hat{f}) \).

Then there exists a neighborhood \( \hat{f}' \) of \( f \) within \( \hat{f} \) and a solution \( \nu \in X^{\infty,y}(\hat{f}') \) to the equation

\[
\bar{\nu}' \nu = 0 \mod V.
\]

Moreover, there exists a neighborhood \( O \) of \( 0 \in X^{\infty,y}(\hat{f}') \) so that \( \nu \) is the unique solution to \( \bar{\nu}' \nu = 0 \mod V \) within \( O \). Moreover, given any curve \( f' \in \hat{f}' \), let \( \nu(f') \) and \( O(f') \) be the restriction of \( \nu \) and \( O \) to \( X^{\infty,y}(f') \); then \( \nu(f') \) is the unique solution to the equation \( \bar{\nu}' \nu(f') = 0 \mod V(f') \) within \( O(f') \).

We also need the following corollary of Theorem 3.6.
Corollary 3.7. Let \((\hat{f}, V)\) be a \(C^\infty_{\frac{1}{\lambda}}\) pre-obstruction model containing \(f\), and let \(\hat{\partial}'\) be a simple perturbation of \(\partial\) such that \(\hat{\partial}' f\) is tangent to \(V\) at \(f\), and \(D\hat{\partial}'(f)\) is complementary to \(V\). Then the unique section \(\nu\) of \(X^\infty_{\frac{1}{\lambda}}(f)\) so that \(\hat{\partial}'(\nu)\) is a section of \(V\) is tangent to 0 at \(f\).

Proof: We may restrict \((\hat{f}, V)\) to a pre-obstruction model \((\hat{f}', V)\) where \(\hat{f}'\) is parametrized by \(\mathbb{R}\) and \(f\) is the curve over 0. We may also restrict \(\hat{\partial}'\) to \((\hat{f}', V)\). The uniqueness part of Theorem 3.6 implies that \(\nu\) pulls back to the unique section \(\nu'\) with \(\hat{\partial}'\nu' \subset V\). It therefore suffices to prove that \(\nu'\) is tangent to the zero section at 0.

Claim 2.20 implies that \(\hat{\partial}' \hat{f}'\) is equal to a section of \(V\) plus \(t^2\theta\) where \(\theta\) is a section of \(\mathcal{Y}(\hat{f}')\), and \(t\) is the coordinate on \(\mathbb{R}\). The family of curves \(\hat{f}' \times \mathbb{R}\). We may pull back our pre-obstruction model, \(\hat{\partial}'\) and \(\theta\) to \(\hat{f}' \times \mathbb{R}\). Theorem 3.6 then implies that in a neighborhood of \((f, 0)\), there is a unique \(C^\infty_{\frac{1}{\lambda}}\) solution \(\psi\) to the equation

\[
(\hat{\partial}' \psi - x\theta) \in V
\]

where \(x\) is the coordinate on the extra \(\mathbb{R}\) factor of \(\hat{f}' \times \mathbb{R}\). The uniqueness part of Theorem 3.6 implies that

\[
\psi(t, t^2) = 0
\]

and

\[
\psi(t, 0) = \nu'(t)
\]

therefore \(\nu'\) is tangent to the zero section at \(t = 0\), as required.

The following theorem, Theorem 1.2 of [31], implies that for any simple perturbation \(\hat{\partial}'\) of \(\partial\), \(D\hat{\partial}'(f)\) is a Fredholm operator, and that \(D\hat{\partial}'\) over a family \(\hat{f}\) can be locally approximated by a \(C^\infty_{\frac{1}{\lambda}}\) map of finite dimensional vectorbundles.

Theorem 3.8. Given any family of curves \(\hat{f}\) with a trivialization and a simple perturbation \(\hat{\partial}'\) of \(\partial\), the restriction of \(D\hat{\partial}'\) to \(f\),

\[
D\hat{\partial}'(f): X^\infty_{\frac{1}{\lambda}}(f) \longrightarrow \mathcal{Y}(f)
\]

has closed image, finite-dimensional kernel and cokernel, and index

\[
\dim \ker D\hat{\partial}'(f) - \dim \text{coker } D\hat{\partial}'(f) = 2c_1 - 2n(g - 1)
\]

where \(c_1\) is the integral of the first Chern class of \((T_{\text{vert}}\mathcal{B}, J)\) over the curve \(f\), \(2n\) is the rank of the vectorbundle \(T_{\text{vert}}\mathcal{B}\) and \(g\) is the genus of the domain of \(f\).

Given any finite-dimensional sub-vectorbundle \(V \subset \mathcal{Y}(\hat{f})\) so that \(D\hat{\partial}'(f)\) is transverse to \(V(f) \subset \mathcal{Y}(f)\), there exists a neighborhood \(\hat{f}'\) of \(f\) in \(\mathcal{F}\), where \(D\hat{\partial}'\) surjects onto \(\mathcal{Y}(\hat{f}')/V\) with kernel a finite-dimensional sub-vectorbundle \(K = D\hat{\partial}'^{-1}(V)\) of \(X^\infty_{\frac{1}{\lambda}}(\hat{f}')\).

Remark 3.9. The formula for \(D\hat{\partial}'\) derived in [31] implies that the set of maps

\[
X^\infty_{\frac{1}{\lambda}}(\hat{f}) \longrightarrow \mathcal{Y}(\hat{f})
\]

equal to some \(D\hat{\partial}'\) for some simple perturbation \(\hat{\partial}'\) of \(\partial\) is convex and contains the complex map

\[
\frac{1}{2}(\nabla \cdot + J \circ \nabla \cdot c_J): X^\infty_{\frac{1}{\lambda}}(\hat{f}) \longrightarrow \mathcal{Y}(\hat{f})
\]

for any \(C^\infty_{\frac{1}{\lambda}}\) \(J\)-preserving connection \(\nabla\) on \(T_{\text{vert}}\mathcal{B}\). In particular, we can apply Theorem 3.5 to a linear homotopy from \(D\hat{\partial}'\) to the above complex map — we shall use this homotopy to orient the kernel relative to the cokernel of \(D\hat{\partial}'\).

\[\text{See equations (4) and (25) in [31].}\]
4. Evaluation maps

4.1. The map $ev^0$.

In this section we show that the moduli stack of $\mathcal{C}^\infty$ families of stable curves, $\mathcal{M}(pt)$, is an exploded orbifold, and construct a fiberwise-holomorphic map

$$ev^0: \mathcal{M}^\infty(\hat{B}) \longrightarrow \mathcal{M}(pt).$$

Remark 4.1. We also show that this moduli stack of stable exploded curves $\mathcal{M}(pt)$ is (represented by) the explosion of the usual Deligne–Mumford space considered as a complex orbifold with normal-crossing divisors corresponding to the boundary. More specifically, the usual Deligne–Mumford space $\bar{\mathcal{M}}$ is a stack over the category of complex manifolds with normal-crossing divisors. It is locally represented by $U/G$ where $U$ is some complex manifold with normal-crossing divisors, and with some effective action of a finite group $G$. The inverse image $U^{+1}$ of $U$ under the forgetful map

$$\bar{\mathcal{M}}^{+1} \longrightarrow \bar{\mathcal{M}}$$

from Deligne–Mumford space with one extra marked point, is a family of curves

$$U^{+1} \longrightarrow U$$

with automorphism group $G$. The explosion functor applied to this family gives a family of exploded curves

$$\text{Expl} U^{+1} \longrightarrow \text{Expl} U$$

with a group $G$ of automorphisms and this family locally represents the moduli stack of stable exploded curves; see Definition 2.29.

Thinking of Deligne–Mumford space as an orbifold locally equivalent to (the stack of holomorphic maps into) $U/G$, we shall prove that $\mathcal{M}(pt)$ is locally equivalent to (the stack of all $\mathcal{C}^\infty$ maps into) $\text{Expl} U/G$, and is, in this sense, the explosion of Deligne–Mumford space.

Definition 4.1 and Theorem 3.1 of [27] introduce the concept of families of curves with universal tropical structure. We shall need the following two results, respectively Theorem 4.8 and Lemma 4.6 from [27]:

Theorem 4.2. For any stable curve $f$ in $\mathcal{M}^\text{st}(\hat{B})$ with domain not equal to $T$, there exists a family of curves $\hat{f}$ containing $f$ with universal tropical structure so that

1. there is a group $G$ of automorphisms of $\hat{f}$ acting freely and transitively on the set of maps of $f$ into $\hat{f}$;
2. there is only one stratum $F_0$ of $\text{F}(\hat{f})$ containing the image of a map $f \longrightarrow \hat{f}$, and the smooth part of this stratum, $[F_0]$ is a single point;
3. the action of $G$ on $[\text{C}(\hat{f})]$ restricted to the inverse image of $[F_0]$ is effective, so $G$ is a subgroup of the group of automorphisms of $[f]$.

Note that as $G$ is a subgroup of the group of automorphisms of $[f]$ and $f$ is stable, $G$ is a finite group.

Lemma 4.3. Let $\hat{f}$ be a family of curves with universal tropical structure at $f$. Let $\hat{h}$ be a family of curves containing a curve $f'$ with a degree 1 holomorphic map

$$\phi: \text{C}(f') \longrightarrow \text{C}(f)$$

44The stratification on an exploded manifold is discussed in Section 4 of [23].
so that $f' = f \circ \phi$. Then, after possibly restricting to a neighborhood of $f'$ in $\hat{h}$, there exists an extension of $\phi$ to a map

$$
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{\phi} & C(\hat{f}) \\
\downarrow & & \downarrow \\
F(\hat{h}) & \rightarrow & F(\hat{f})
\end{array}
$$

so that, in a metric on $\hat{B}$, the distance between the maps $\hat{h}$ and $\hat{f} \circ \Phi$ is bounded.

Now we can prove the following key lemma for constructing a representation of our moduli stack of stable $C^\infty$ curves mapping to a point, $M(\text{pt})$.

**Lemma 4.4.** Suppose that $\hat{f}$ is a family of stable curves (mapping to a point) with universal tropical structure at some curve $f$ in $\hat{f}$ so that the map

$$T_f \hat{f} : T_f F(\hat{f}) \rightarrow T_f M(\text{pt}) := T_f M^{\text{st}}(\text{pt})$$

is bijective. Then given any family of curves $\hat{h}$ containing a curve $f'$ with the same genus as $f$ and with a degree 1 holomorphic map

$$C(f') \rightarrow C(f)$$

there exists an open neighborhood of $f'$ in $\hat{h}$ with an extension of the above map to a fiberwise-holomorphic map

$$
\begin{array}{ccc}
C(\hat{h}) & \rightarrow & C(\hat{f}) \\
\downarrow & & \downarrow \\
F(\hat{h}) & \rightarrow & F(\hat{f})
\end{array}
$$

**Proof:**

By restricting to a neighborhood of $f'$ in $\hat{h}$ if necessary, Lemma 4.3 gives a (not necessarily holomorphic) map

$$
\begin{array}{ccc}
C(\hat{h}) & \rightarrow & C(\hat{f}) \\
\downarrow & & \downarrow \\
F(\hat{h}) & \rightarrow & F(\hat{f})
\end{array}
$$

equal to the given holomorphic map when restricted to $C(f')$. Our goal is to modify this map to a holomorphic map, with the help of Theorem 3.6.

In order to effectively use Theorem 3.6 we first need to extend the above map. Pull back $T_F(\hat{f})$ along this map to give a vectorbundle $E$ over $F(\hat{h})$, then pull back $\hat{h}$ over $E \rightarrow F(\hat{f})$ to give a family $\hat{h}'$ of curves:

$$
\begin{array}{ccc}
C(\hat{h}') & \rightarrow & C(\hat{h}) \\
\downarrow & & \downarrow \\
F(\hat{h}') = E & \rightarrow & F(\hat{h})
\end{array}
$$

Now extend our previous map to a map $\hat{h}'$

$$
\begin{array}{ccc}
C(\hat{h}') & \xrightarrow{\phi'} & C(\hat{f}) \\
\downarrow & & \downarrow \\
F(\hat{h}') & \rightarrow & F(\hat{f})
\end{array}
$$

so that, restricted to the zero-section, we have our old map, and normal to the zero-section, the derivative of $E \rightarrow F(\hat{f})$ is the identity — the vertical tangent space to $E$ at the zero-section is the pullback of $T_F(\hat{f})$, so this makes sense.

Note that calling the above map $\hat{h}'$ involves a sleight of hand, because before, our notation implied that $\hat{h}'$ was a family of curves mapping to a point instead of

\footnote{See remark 6.6 of \cite{24}.}
into $\mathbb{C}(\hat{f})$. At the zero section, we have a canonical inclusion of $\mathbb{C}(f')$ into $\mathbb{C}(\hat{h}')$ — we shall further abuse notation by calling $f'$ the restriction of $\hat{h}'$ to $\mathbb{C}(f') \subset \mathbb{C}(\hat{h}')$, so $f'$ now means a map $\mathbb{C}(f') \rightarrow \mathbb{C}(\hat{f})$ — our original holomorphic map $\mathbb{C}(f') \rightarrow \mathbb{C}(\hat{f})$.

Consider $\mathbb{C}(\hat{f}) \rightarrow \mathbb{F}(\hat{f})$ as a family of targets for using Theorem 3.6 and choose a trivialization for $\hat{h}'$ in the sense of Definition 5.1 using a connection $\nabla$ on $T_{vert} \mathbb{C}(\hat{f})$, holomorphic restricted on $\mathbb{C}(f)$. Let us check the injectivity of the linearization, $D\hat{\partial}(f')$, of the $\hat{\partial}$ operator at $f'$ in $\hat{h}'$ using this trivialization. The domain, $X^{\infty,1}(f')$ of $D\hat{\partial}(f')$ consists of $C^{\infty,1}$ sections of the complex vectorbundle $(f')^* T\mathbb{C}(f)$, and $D\hat{\partial}(f')$ is $\frac{1}{2}(\nabla + j \circ \nabla \circ j)$. Any component of $\mathbb{C}(f')$ collapsing to a point in $[\mathbb{C}(f)]$ is a sphere, and, on these components, $D\hat{\partial}(f')$ is the usual $\hat{\partial}$ operator acting on complex-valued functions — and hence has no cokernel and has kernel equal to the constant functions. It follows that any element of the kernel of $D\hat{\partial}(f)$ must be constant on all these components, and must therefore be the pullback of a holomorphic vectorfield from $T\mathbb{C}(f)$ because $\mathbb{C}(f') \rightarrow \mathbb{C}(f)$ has degree 1. As $\mathbb{C}(f)$ is stable, it has no nonzero holomorphic vectorfields, so $D\hat{\partial}(f)$ has trivial kernel.

What is the cokernel of $D\hat{\partial}(f)$? Restricted to the inverse image of any small enough open subset of $\mathbb{C}(f)$, $D\hat{\partial}(f')$ is surjective — this is because all the collapsed strata of $\mathbb{C}(f')$ are spheres or extra edges, and each connected component of $\mathbb{C}(f')$ which is collapsed has zero genus. It follows that the cokernel of $D\hat{\partial}(f')$ is equal to the cokernel of $\frac{1}{2}(\nabla + j \circ \nabla \circ j)$ acting on the space of vectorfields on $\mathbb{C}(f)$. We can identify this cokernel with $T_f M(st)(pt)$ as follows: $T_f M(st)(pt)$ is the quotient of $\mathcal{Y}(f)$ by the image of $L_{\psi j}$, which is also the image of $\frac{1}{2}(\nabla + j \circ \nabla \circ j)$, because Lemma 2.72 tells us that

$$\nabla v + j \circ \nabla (jv) = -j \circ L_v j$$

and $\frac{1}{2}(\nabla + j \circ \nabla \circ j)$ and $L_{\psi j} j$ are both complex linear. So, the cokernel of $D\hat{\partial}(f)$ equals $T_f M(st)(pt)$, which, by assumption, equals $T_f \mathbb{F}(\hat{f})$.

We now have that the derivative of $\hat{\partial}h'$ at $f'$ in the fiber direction of $E$ is an isomorphism onto the cokernel of $D\hat{\partial}(f')$. So, choose a pre-obstruction model $(h', V)$ with $V(f')$ equal to the image of the derivative of $\hat{\partial}h'$ in the $E$ direction at $f'$. Then, Theorem 3.6 implies that, in a neighborhood of $f'$ in $h'$, there exists a $C^{\infty,1}$ section $\nu$ of $(h')^* T_{vert} \mathbb{C}(\hat{f})$ so that $\hat{\nu} \circ \nu$ is a section of $V$. As $f'$ in $h$ started off holomorphic, and the derivative of $\hat{\partial}h'$ in the $E$ direction at $f'$ is in $V(f)$, Corollary 3.7 then implies that $\nu$ vanishes to first order in the $E$ direction at $f$. Therefore the derivative of $\hat{\partial}h'$ in the $E$ direction at $f'$ is equal to the derivative of $\hat{\partial}h'$ in the $E$ direction at $f'$, which is an isomorphism onto $V(f)$.

Therefore, on a neighborhood of $f'$, the intersection of $\hat{\partial}\nu$ with the zero section is a section of $E \rightarrow \mathbb{F}(h')$. This section composed with the map $F(\nu)$ is the required $C^{\infty,1}$ holomorphic map from a neighborhood of $f'$ in $h$ to $\hat{f}$.

\[\square\]

Lemma 4.5. Suppose that $\hat{f}$ is a family of stable curves (mapping to a point) with a finite group $G$ of automorphisms so that for every curve $f$ in $\hat{f}$

1. $G$ acts freely and transitively on the set of maps $f \rightarrow \hat{f}$, and each of these maps have different smooth part $[f] \rightarrow [\hat{f}]$;
2. $\hat{f}$ has universal tropical structure at $f$;
3. and the map

$$T_f \hat{f} : T_f \mathbb{F}(\hat{f}) \rightarrow T_f M(st)(pt) := T_f M(st)(pt)$$

is bijective.
Then an open substack of \(\mathcal{M}(pt)\) is represented by \(\hat{f}/G\) and hence represented by \(F(\hat{f})/G\).

**Proof:**

Lemma 4.3 implies that, if a curve \(h\) in \(\hat{h}\) is isomorphic to a curve in \(\hat{f}\), then there is a map from a neighborhood of \(h\) in \(\hat{h}\) into \(\hat{f}\) extending the given isomorphism. Let \(\mathcal{U}\) indicate the substack of \(\mathcal{M}(pt)\) consisting of families of curves isomorphic to some curve in \(\hat{f}\). We have that the curves in \(h\) which are in \(\mathcal{U}\) form an open subset of \(\hat{h}\). So \(\mathcal{U}\) is open in the sense of Definition 2.38.

Now let \(h\) be a family of curves in \(\mathcal{U}\) with two maps \(\phi_1: h \rightarrow f\). Let us show that, if \(\hat{h}\) is connected, then \(\phi_1\) is \(\phi_2\) composed with the action of an element of \(G\). If these two maps are different at a curve \(h\) in \(\hat{h}\), then the \(\phi_i(h)\) must differ by the action of an element of \(G\), and therefore have different smooth parts. It follows that the two maps \(\phi_1\) differ on an open subset of \(F(\hat{h})\). Similarly, \(\phi_1\) is equal to \(\phi_2\) composed with the action of a given element of \(G\) on a closed subset of \(F(\hat{h})\). As restricted to any curve, \(\phi_1\) is always equal to \(\phi_2\) composed with some element of \(G\), and \(G\) is finite, it follows that the subset on which \(\phi_1\) is equal to \(\phi_2\) composed with a given element of \(G\) is both open and closed. In particular, if \(\hat{h}\) is a connected family of curves, then \(\phi_1\) is equal to \(\phi_2\) composed with some element of \(G\).

Around every curve \(h\) in a family \(\hat{h}\) of curves in \(\mathcal{U}\), Lemma 4.3 gives us the existence of \(|G|\) maps of a neighborhood of \(h\) in \(\hat{h}\) to \(f\), permuted by the action of \(G\) on \(f\). (Throughout this paper, \(|G|\) indicates the order of the group \(G\).) As argued above, these maps are unique up to the action of \(G\), so they patch together to form a unique \(G\)-bundle \(h \rightarrow \hat{h}\) with a \(G\)-equivariant map into \(\hat{f}\). In other words, there exists a unique (up to canonical isomorphism) map of \(\hat{h}\) into \(\hat{f}/G\), in the sense of Example 2.21. It follows that \(\mathcal{U}\) is equivalent to the stack \(\hat{f}/G\).

\[\square\]

Given any stable curve \(f\), we could construct \(\mathcal{M}(pt)\) near \(f\) by using Lemma 4.2 to construct a family containing \(f\) obeying the first two criteria of Lemma 4.5, then extending this family to also satisfy the last condition of Lemma 4.5. Instead, we will apply the explosion functor 48 to the universal curve over Deligne–Mumford space in a neighborhood of \([f]\).

Let \(\pi: U^{+1} \rightarrow U\) be a family of nodal curves with marked points (in the category of complex manifolds, or schemes over \(\mathbb{C}\)) which, when quotiented by its group \(G\) of automorphisms, locally represents the universal curve over Deligne-Mumford space — as constructed by Deligne, Mumford and Knudsen in [3] and [16], or as constructed more geometrically by Robbin and Salamon in [33], where \(\pi: U^{+1} \rightarrow U\) is called a universal unfolding.

In either case, the following holds:

1. \(G\) acts freely and transitively on the set of inclusions of a given nodal curve into \(U^{+1} \rightarrow U\).
2. \(U\) and \(U^{+1}\) are (or may be considered as) complex manifolds and \(\pi\) is a holomorphic map.

---

46See Definition 2.29.

47We had to check that \(\phi_1\) coincide on a closed subset because in general, two maps from an exploded manifold can be equal on a subset which is neither open nor closed.

48A unique \(G\)-bundle is one that is unique up to canonical isomorphism. When we have such local uniqueness, the cocycle condition for a descent datum is automatically satisfied, so we can patch together our locally defined \(G\)-bundles to a unique (up to canonical isomorphism) global \(G\)-bundle.

49For the explosion functor, see section 5 of [24].
(3) $U$ minus the set of smooth curves is a normal-crossing divisor $D$, and $\pi^{-1}D$ is also a normal-crossing divisor, as is the union, $D'$, of $\pi^{-1}D$ with the locus of all marked points.

(4) If a curve $\pi^{-1}(p)$ has $n$ nodes, then around $p$ there exist holomorphic coordinates $(z_1, \ldots, z_m)$ centered on $p = (0, \ldots, 0)$, such that $D$ is locally $z_1 \cdots z_n = 0$. At the $i$th node of this curve, $\pi^{-1}(p)$, there are local holomorphic coordinates such that $\pi^*z_j$ are coordinate functions for $j \neq i$, and there are two extra coordinate functions $z_i^\pm$ so that

$$\pi^*z_i = z_i^+ z_i^-.$$ 

Away from nodes, all the $z_i$ pull back to be coordinate functions. And, around a marked point in $\pi^{-1}(p)$, there are local coordinates $(z, \pi^*z_1, \ldots, \pi^*z_m)$ so that $D' = \{ z \prod_i \pi^*z_i = 0 \}$.

We may therefore apply the explosion functor (described in Section 5 of [24]) to $\pi$.

**Lemma 4.6.** Expl $\pi$ satisfies the conditions of Lemma 4.5, so Expl $U/G$ represents an open substack $U$ of $\mathcal{M}(pt)$ consisting of curves isomorphic to some curve in Expl $\pi$.

**Proof:**

The property (1) of $\pi$ implies that Expl $\pi$ is a family of curves. As the smooth part of Expl $\pi$ is equal to $\pi$, Expl $\pi$ is a family of stable curves, and the property (1) of $\pi$ implies condition (1) of Lemma 4.5.

Property (1) of $\pi$ implies that the tropical structure $\mathcal{P}(x)$ of Expl $U$ at any point $x \in U$ is equal to $[0, \infty)^n$ where $n$ is the number of nodes of the curve $\pi^{-1}(x)$. Furthermore, at the $i$th internal edge $e_i$ of Expl $\pi^{-1}(x)$, the tropical structure of Expl $U^{+1}$ is given by the fiber product

$$
\begin{array}{ccc}
\mathcal{P}(e_i) & \rightarrow & [0, \infty)^2 \\
\downarrow & & \downarrow^{z+b} \\
\mathcal{P}(x) & \rightarrow & [0, \infty)
\end{array}
$$

where the bottom arrow is projection onto the $i$th factor of $\mathcal{P}(x) = [0, \infty)^n$. Therefore, the tropical structure Expl $\pi$ restricted to any curve $f$ is the universal extension of the tropical structure of $f$; see Remark 3.3 of [27]. So, condition (2) of Lemma 4.5 holds.

All that remains is to show that condition (3) of Lemma 4.5 holds. In particular, we must show that for any curve $f$ in Expl $\pi$, the map

$$T_f \text{Expl} \pi : T_f \text{Expl} U \rightarrow T_f \mathcal{M}(pt)$$

is bijective.

Recall, from section 2.5 that $T_f \mathcal{M}(pt)$ is the cokernel of the map $L_j$, and Claim 2.62 implies that $T_f \mathcal{M}(pt)$ is also the cokernel of the $\bar{\partial}$ operator acting on $C^\infty f$ vectorfields on $\mathcal{C}(f)$. The complex dimension of $T_f \mathcal{M}(pt)$ is $3g-3+k$ — this follows from Theorem 5.3 and a calculation of the first Chern class of $T\mathcal{C}(f)$ as $2-2g-k$ where $k$ is the number of infinite ends of $\mathcal{C}(f)$ and $g$ is the genus of $\mathcal{C}(f)$. So, $T_f \mathcal{M}(pt)$ has the same dimension as Deligne–Mumford space and therefore Expl $U$.

It follows that to check that $T_f \text{Expl} \pi$ is bijective, we need only check that it is injective.

Let $v$ be in the kernel of the map $T_f \text{Expl} \pi : T_f \text{Expl} U \rightarrow T_f \mathcal{M}(pt)$. The description of this map from section 2.9.3 implies that there must be a lift $v'$ of $v$...
to a section of $T\,\text{Expl}U^{+1}$ restricted to $C(f)$ so that $L_{v'}j = 0$. It remains to show that such a $v'$ must be 0.

Use $[v']$ to indicate the image of $v'$ under the derivative of the smooth part map $\text{Expl}U^{+1} \rightarrow U^{+1}$, and $[v]$ to indicate the image of $v$ under the derivative of the map $\text{Expl}U \rightarrow U$. We have that $[v']$ is a lift of $[v]$ and that $L_{[v']}j = 0$ where $j$ now indicates the fiberwise almost-complex structure on $U^{+1} \rightarrow U$ induced by the complex structure on $U^{+1}$. As defined, it is not obvious that $[v']$ is smooth at nodes and marked points of $[C(f)]$, however, in the coordinates around nodes from property 4 such a vectorfield must be a constant vectorfield plus a vectorfield which is continuous and holomorphic away from the node or marked point, so it must be smooth. As $U^{+1} \rightarrow U$ represents Deligne–Mumford space, it follows that $[v']$ and $[v]$ must be 0.

We now have that $[v] = 0$. If $[C(f)]$ has no nodes, then around $f$ the smooth part map $\text{Expl}U \rightarrow U$ is an isomorphism, so $[v] = 0$ implies that $v = 0$. Now suppose that $[C(f)]$ has $n$ nodes, and use the coordinates from property 4 of Deligne–Mumford space. In particular, around the $i$th node we have coordinates including $z_i^+$ such that $\pi^+z_i = z_i^+z_i^-$. These coordinates correspond to coordinates $z_i^\pm$ on $\text{Expl}U^{+1}$ and a coordinate $\bar{z}_i = \bar{z}_i^+\bar{z}_i^−$ from $\text{Expl}U$. As $z_i^\pm$ are coordinates around the $i$th node, and $[v^i z_i^\pm] = [v^i]z_i^\pm = 0$, it follows that $v^i\bar{z}_i^\pm = 0$, and therefore $\bar{v}_i^\pm = 0$. As the divisor $D$ in $U$ is defined by the product of these $z_i$ corresponding to each node, it follows that $v$ must be equal to 0. We have now shown that the map $Tf : \text{Expl}π : U \rightarrow T\,\text{Expl}M(pt)$ is injective, and hence an isomorphism. And, our proof is complete.

Corollary 4.7. $\mathcal{M}(pt)$ is a $C^\infty$ exploded orbifold, and the explosion of Deligne–Mumford space.

Proof: We have shown that $\mathcal{M}(pt)$ is locally represented by $\hat{f}/G$, where $\hat{f}$ is obtained by exploding a holomorphic family of stable nodal curves $U^{+1} \rightarrow U$, whose quotient by $G$ represents an open substack of Deligne–Mumford space (with the analytic topology). As Deligne–Mumford space has a second countable and Hausdorff topology, it follows that $[\mathcal{M}(pt)_{\text{top}}]$ is second countable and Hausdorff, so $\mathcal{M}(pt)$ is an exploded orbifold.

Lemma 4.8. Suppose that $f$ is a holomorphic curve in $\mathcal{M}^{\infty,1}(\mathcal{B})$. Then either $f$ is constant, and has genus zero with less than three ends, or has genus 1 and no ends, or there exists a unique stable curve $f^1$ in $\mathcal{M}^1(\mathcal{B})$ with degree 1 holomorphic map

$$\psi : C(f) \rightarrow C(f^1)$$

such that

$$f = f^1 \circ \psi$$

and such that $f^1$ has the same genus, and the same number of ends as $f$.

Proof: For this proof, call a holomorphic map $\psi : C(f) \rightarrow C(f')$ a partial stabilisation if it has degree 1, preserves the number of ends and genus, and satisfies

$$f = f' \circ \psi.$$ 

Call this map a stabilisation if $f'$ is stable. Note that any stabilization of a stable curve must be an isomorphism.

50 See Definition 40. 
51 Unique up to unique isomorphism.
The idea is to 'remove' all unstable strata using a series of partial stabilisations. Each unstable component consists of an unstable punctured Riemann surface on which \([f]\) is constant. The set of points in \(\mathcal{B}\) sent to a single point in \([\mathcal{B}]\) and \(\mathcal{B}\) is always \((\mathbb{C}^*)^k\) for some \(k\). All holomorphic maps from a connected unstable Riemann surface to \((\mathbb{C}^*)^k\) are either constant, or the Riemann surface is isomorphic to \(\mathbb{C}^*\) and the holomorphic map is a monomial map \(z \mapsto (c_1 z^{a_1}, \ldots, c_k z^{a_k})\). So, \(f\) on such unstable components is either constant, or a monomial map.

1. If a smooth component of \(\mathcal{C}(f)\) is a sphere attached to exactly one edge, and \(f\) is constant on this component, either \(f\) is constant and has genus 0 and exactly one end, or there are holomorphic coordinates on a neighborhood of the edge modelled on an open subset of \(T_{[0,\ell]}\) with coordinate \(\tilde{z}\) so that \([\tilde{z}]\) gives coordinates on the smooth component of \(\mathcal{C}(f)\) attached to the other end of the edge. Replace this coordinate chart with the corresponding open subset of \(\mathbb{C}\) with coordinate \(z = [\tilde{z}]\). There is an obvious partial stabilisation from our old curve to this new one \(f'\), given in this coordinate chart by \(\tilde{z} \mapsto [\tilde{z}]\), and sending our unstable sphere and the edge attached to it to \(\{z = 0\}\). (This map is the identity everywhere else.)

As stable curves have no constant once-punctured-sphere strata, the resulting partial stabilisation \(\mathcal{C}(f) \rightarrow \mathcal{C}(f')\) has the property that any stabilisation of \(f\) factors uniquely through it.

2. If a smooth component of \(\mathcal{C}(f)\) is a sphere attached to exactly two edges, and \([f]\) is constant on this component, there exists a holomorphic identification of a neighborhood of this smooth component with a refinement of an open subset of \(T_{[0,\ell]}\), \(T\) or \(T_{[0,\ell]}\), and \(f\) factors through this refinement map because it is a monomial map on our sphere component. Replace this open set with the corresponding open subset of \(T_{[0,\ell]}\), \(T\) or \(T_{[0,\ell]}\).

The partial stabilisation from the old exploded curve to the new curve \(f'\) is this refinement map. (Refer to Section 10 of [24] for the definition of refinements.)

Again, the resulting partial stabilisation \(\mathcal{C}(f) \rightarrow \mathcal{C}(f')\) has the property that any stabilisation of \(f\) must factor uniquely through it.

Each of the above types of partial stabilisations removes one smooth component, so after applying maps of the above type a finite number of times, we either obtain a constant curve with \(2g + n < 3\), or obtain a connected exploded curve \(\mathcal{C}(f^{st})\) with no smooth one-or-two-punctured-sphere components on which \(f\) is constant. Our curve \(f^{st}\) is therefore stable. Moreover, the stabilization \(\psi: \mathcal{C}(f) \rightarrow \mathcal{C}(f^{st})\) has the property that any stabilisation \(\psi': \mathcal{C}(f) \rightarrow \mathcal{C}(f')\) of \(f\) factors uniquely through it. As the resulting map \(\mathcal{C}(f^{st}) \rightarrow \mathcal{C}(f')\) is a stabilisation of a stable curve, it must be an isomorphism. So our stabilisation is unique up to unique isomorphism, as required.

\[\square\]

**Lemma 4.9.** Suppose that \(\hat{f}\) is a connected \(C^\infty\) family of curves for which \(2g + n \geq 3\), where \(g\) is the genus and \(n\) the number of ends of curves in \(f\). Then there exists a unique\(^{52}\) stabilization, \(f^{st}\), of \(f\), which is a \(C^\infty\) family of stable curves \(f^{st}\) in.

\(^{52}\)Unique up to canonical isomorphism.
\( M(\text{pt}) \) with a degree 1, fiberwise-holomorphic, \( C^\infty \) map
\[
\begin{array}{c}
\mathbb{C}(\hat{f}) \\
\downarrow
\end{array}
\xrightarrow{\phi^{+1}}
\begin{array}{c}
\mathbb{C}(\hat{f}^{st}) \\
\downarrow
\end{array}
\]
\[
\begin{array}{c}
\mathbb{F}(\hat{f}) \\
\downarrow
\end{array}
\xrightarrow{\text{id}}
\begin{array}{c}
\mathbb{F}(\hat{f}^{st}) = \mathbb{F}(\hat{f})
\end{array}
\]

preserving the genus and number of ends of fibers.

In particular, the above defines a fiberwise-holomorphic \( M^{\infty} \) map
\[
\begin{array}{c}
\mathcal{M}^{\infty}(\hat{\mathcal{B}}) + 1 \xrightarrow{(ev^0)^{+1}} \mathcal{M}(\text{pt}) + 1
\end{array}
\]
on the components of \( \mathcal{M}^{\infty}(\hat{\mathcal{B}}) \) for which \( 2g + n \geq 3 \).

\textbf{Proof:}

Lemma 4.8 gives us a stabilisation \( f^{st} \) of a single curve. Let us extend our stabilisation of \( f \) to a family \( \hat{f} \) of curves containing \( f \). Let \( \hat{g} \) be a family of stable curves containing \( f^{st} \), and satisfying the requirements of Lemma 4.5 — such a family of curves exists, as proved by Lemma 4.6. By restricting \( \hat{f} \) to a smaller neighborhood of \( f \) if necessary, Lemma 4.4 then gives us a fiberwise holomorphic map
\[
\begin{array}{c}
\mathbb{C}(\hat{f}) \\
\downarrow
\end{array}
\xrightarrow{\phi^{+1}}
\begin{array}{c}
\mathbb{C}(\hat{g}) \\
\downarrow
\end{array}
\]
\[
\begin{array}{c}
\mathbb{F}(\hat{f}) \\
\downarrow
\end{array}
\xrightarrow{\phi}
\begin{array}{c}
\mathbb{F}(\hat{g})
\end{array}
\]
extending the given stabilisation \( \mathbb{C}(f) \rightarrow \mathbb{C}(f^{st}) \subset \mathbb{C}(\hat{g}) \). So long as \( \hat{f} \) is connected, \( \phi^{+1} \) is fiberwise degree 1 and preserves genus and number of ends. We may therefore pull back \( \hat{g} \) over the map \( \phi \) to obtain a stabilization \( \phi^* \hat{g} \) of \( \hat{f} \):
\[
\begin{array}{c}
\mathbb{C}(\hat{f}) \\
\downarrow
\end{array}
\xrightarrow{\psi}
\begin{array}{c}
\mathbb{C}(\hat{f}^{st}) = \mathbb{C}(\phi^* \hat{g}) \\
\downarrow
\end{array}
\]
\[
\begin{array}{c}
\mathbb{F}(\hat{f}) \\
\downarrow
\end{array}
\xrightarrow{\text{id}}
\begin{array}{c}
\mathbb{F}(\hat{f})
\end{array}
\]

Suppose that \( \hat{h} \) is a family with a stabilization \( \hat{h}^{st} \) and a map \( \alpha: \hat{h} \rightarrow \hat{f} \). We must construct a canonical map \( \alpha^{st}: \hat{h}^{st} \rightarrow \hat{f}^{st} \). We have assumed that there is a group \( G \) of automorphisms of \( \hat{g} \) so that given any curve \( h \) in \( \hat{h} \), \( G \) acts freely and transitively on the set of maps \( h^{st} \rightarrow \hat{g} \), and each of these maps has a different smooth part. As every fiberwise-degree-1 holomorphic map \( \mathbb{C}(h) \rightarrow \mathbb{C}(\hat{g}) \) factors uniquely through a map \( h^{st} \rightarrow \hat{g} \), it follows that \( G \) acts freely and transitively on the set of fiberwise-degree-1 holomorphic maps \( \mathbb{C}(h) \rightarrow \mathbb{C}(\hat{g}) \), and each of these maps has a different smooth part. As in the proof of Lemma 4.5 Lemma 4.3 then implies that, if \( \hat{h} \) is small enough, there are exactly \( |G| \) degree 1 fiberwise-holomorphic maps \( \mathbb{C}(h) \rightarrow \mathbb{C}(\hat{g}) \), permuted by the action of \( G \), and corresponding to \( |G| \) maps \( \hat{h}^{st} \rightarrow \hat{g} \), also unique up to the action of \( G \). There must therefore be

53See Definition 2.49
exactly one of these maps $\alpha_1$ such that the following diagram commutes

$$
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{C(\alpha)} & C(\hat{f}) \\
\downarrow & & \downarrow \phi^{*+1} \\
C(\hat{h}^{st}) & \xrightarrow{C(\alpha_1)} & C(\hat{g})
\end{array}
$$

Then, as $\hat{f}^{st} = \phi^{*+1} \hat{g}$ and $F(\alpha) = F(\alpha_1)$, the map $\alpha_1 : \hat{h}^{st} \to \hat{g}$ factors uniquely as a composition $\hat{h}^{st} \stackrel{\alpha^{st}}{\to} \hat{f}^{st} \to \hat{g}$ of maps such that the following diagram commutes

$$
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{C(\alpha)} & C(\hat{f}) \\
\downarrow & & \downarrow \\
C(\hat{h}^{st}) & \xrightarrow{C(\alpha_1)} & C(\hat{f}^{st})
\end{array}
$$

The unique-factorization property of stabilizations of individual curves implies that the map $\alpha^{st} : \hat{h}^{st} \to \hat{f}^{st}$ is the unique map so that the above diagram commutes. In this argument, we assumed that $\hat{h}$ was 'small enough', so we have only constructed the $\alpha^{st}$ locally, however, the uniqueness of this map implies that all such local constructions patch together to a globally defined map $\alpha^{st}$.

To summarize, we have shown that every 'small enough' family $\hat{f}$ has a stabilization $\hat{f}^{st}$, and that if $\hat{h}$ also has a stabilization $\hat{h}^{st}$ and there is a map $\alpha: \hat{h} \to \hat{f}$, then there is a unique map $\alpha^{st}: \hat{h}^{st} \to \hat{f}^{st}$ so that the above diagram commutes. This uniqueness of locally defined stabilizations implies that locally defined stabilizations glue together. Therefore, every family of curves $\hat{f}$ satisfying the requirements of our lemma has a stabilization, and given any map $\alpha: \hat{h} \to \hat{f}$, there exists a unique map $\alpha^{st}: \hat{h}^{st} \to \hat{f}^{st}$ so that the above diagram commutes. This uniqueness implies that $(\alpha_1 \circ \alpha_2)^{st} = \alpha_1^{st} \circ \alpha_2^{st}$, so we have defined a map of stacks $ev^0 : \mathcal{M}^{\infty, \downarrow(B)} \to \mathcal{M}(pt)$. Moreover, the fiberwise holomorphic maps $C(\hat{f}) \to C(\hat{f}^{st})$ lift this map to a fiberwise holomorphic map in the sense of Definition 2.49.

We therefore obtain a fiberwise-holomorphic map on the connected components of $\mathcal{M}^{\infty, \downarrow(B)}$ for which $2g + n \geq 3$.

$$
\begin{array}{ccc}
\mathcal{M}^{\infty, \downarrow(B)} & \xrightarrow{(ev^0)^{+1}} & \mathcal{M}(pt)^{+1} \\
\downarrow & & \downarrow \\
\mathcal{M}^{\infty, \downarrow(B)} & \xrightarrow{ev^0} & \mathcal{M}(pt)
\end{array}
$$

4.2. The evaluation maps $ev^{+n}$ and adding extra marked points to families.

In what follows, we define an 'evaluation map' for a family of curves using a functorial construction of a family of curves $\hat{f}^{+n}$ with $n$ extra (labeled) punctures — or rather (labeled) ends — from a given family of curves $\hat{f}$.

---

54 Unique here means that $\hat{h}^{st}$ is defined up to canonical isomorphism, and with such a choice of $\hat{h}^{st}$, the map $\alpha^{st}$ to $\hat{f}^{st}$ is unique.

55 Our uniqueness ensures that every collection of local choices for $\hat{h}^{st}$ give a descent datum for $\hat{h}^{st} \to \hat{f}^{st}$ in the stack $\mathcal{M}(pt)/\hat{f}^{st}$ because cocycle conditions are automatically satisfied.
Definition 4.10. Given a submersion $f: D \rightarrow E$ of exploded manifolds, use the following notation for the fiber product of $D$ over $E$ with itself $n$ times:

$$D^n_E := D \times_f D \times_f \cdots \times_f D$$

Definition 4.11. Given a family of curves $\hat{f}$ in $\hat{B} \rightarrow B_0$, define the family of curves $\hat{f}^{+1}$ to be a family of curves in $\hat{B} \times_{B_0} \hat{B}$ with one extra end

\[
\begin{array}{ccc}
C(\hat{f}^{+1}) & \xrightarrow{\hat{f}^{+1}} & \hat{B} \times_{B_0} \hat{B} \\
\downarrow \pi_{F(\hat{f}^{+1})} & & \downarrow \\
F(\hat{f}^{+1}) = C(\hat{f}) & \xrightarrow{\hat{f}} & \hat{B}
\end{array}
\]

and satisfying the following conditions:

1. The fiber of $\pi_{F(\hat{f}^{+1})}: C(\hat{f}^{+1}) \rightarrow F(\hat{f}^{+1})$ over a point $p \in F(\hat{f}^{+1}) = C(\hat{f})$ is equal to the fiber of $\pi_{F(\hat{f})}: C(\hat{f}) \rightarrow F(\hat{f})$ containing $p$ with an extra end at the point $p$.
2. There exists a fiberwise-holomorphic, degree 1 map

\[
\begin{array}{ccc}
C(\hat{f}^{+1}) & \xrightarrow{\hat{f}^{+1}} & C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) \\
\downarrow & & \downarrow \\
C(\hat{f}) & \xrightarrow{id} & C(\hat{f})
\end{array}
\]

so that the following diagram commutes.

\[
\begin{array}{ccc}
C(\hat{f}^{+1}) & \xrightarrow{\hat{f}^{+1}} & \hat{B} \times_{B_0} \hat{B} \\
\downarrow C(\hat{f}) & \xrightarrow{\hat{f}} & \hat{B} \\
\downarrow & & \downarrow \\
F & \xrightarrow{} & B_0
\end{array}
\]

Define $\hat{f}^{+0}$ to be $\hat{f}$, and for positive integers $n$, define $\hat{f}^{+n}$ inductively using

$$\hat{f}^{+n} = \left(\hat{f}^{+(n-1)}\right)^{+1}$$

---

As usual, a submersion of exploded manifolds means a map with surjective derivative. See Section 6 of [24] for a discussion of tangent spaces of exploded manifolds, and see Section 9 for a discussion of fiber products.
so \( \hat{f}^+ \) is a family of curves in \( \hat{B}_{B_0}^{n+1} \rightarrow \hat{B}_{B_0}^n \).

\[
\begin{array}{ccc}
C(\hat{f}^+) & \xrightarrow{\hat{f}^+} & \hat{B}_{B_0}^{n+1} \\
\downarrow & & \downarrow \\
C(\hat{f}^{+(n-1)}) & \xrightarrow{\hat{f}^{+(n-1)}} & \hat{B}_{B_0}^n \\
\downarrow & & \downarrow \\
C(\hat{f}) & \xrightarrow{\hat{f}^+} & \hat{B} \\
\downarrow & & \\
P(\hat{f}) & \xrightarrow{} & B_0 \\
\end{array}
\]

Combining \( \hat{f}^{+(n-1)} \) with the map \( ev^0: F(\hat{f}^{+(n)}) \rightarrow \mathcal{M}(pt)^+ \) given by Lemma 4.9 when \( n \) is large enough, we get the evaluation map

\[(5) \quad ev^{+n}(\hat{f}) := (ev^0, \hat{f}^{+(n-1)}): F(\hat{f}^{+(n)}) \rightarrow \mathcal{M}(pt)^+ \times \hat{B}_{B_0}^n \]

We construct \( \hat{f}^{+1} \) satisfying the above requirements below; then we show that such a family is unique (up to canonical isomorphism) and that the construction is functorial.

Construct the total space of the domain, \( C(\hat{f}^{+1}) \) by ‘exploding’ the diagonal of \( C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) \) as follows: Consider the diagonal map \( \Delta: C(\hat{f}) \rightarrow C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) \). The image of the tropical part of this map, \( \Delta \), defines a subdivision of the tropical part of \( C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) \). As noted in section 10 of [24], any such subdivision determines a unique refinement \( C' \rightarrow C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) \). Note that the diagonal map to this refinement \( C' \) is still defined,

\[(6) \quad C(\hat{f}) \xrightarrow{\Delta} C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) \xrightarrow{\Delta'} C' \]

and a neighborhood of the image of \( \Delta' \) in \( C' \) is isomorphic to a neighborhood of 0 in a \( \mathbb{C} \)-bundle over \( C(\hat{f}) \). Now ‘explode’ the image of the diagonal \( \Delta' \) in \( C' \) as follows: Choose coordinate charts on \( C' \) so that any coordinate chart intersecting the image of the diagonal is some subset of \( \mathbb{C} \times U \) where \( U \) is a coordinate chart on \( C(\hat{f}) \), the projection to \( C(\hat{f}) \) is the obvious projection to \( U \), the complex structure on the fibers of this projection is the standard complex structure on \( \mathbb{C} \), and the image of the diagonal is \( 0 \times U \). Replace these charts with the corresponding subsets of \( \mathbb{T} \times U \), and leave coordinate charts that do not intersect the image of the diagonal unchanged. Any transition map between coordinate charts of the above type is of the form \((z, u) \mapsto (g(z, u)z, \phi(u))\) where \( g(z, u) \) is \( \mathbb{C} \)-valued and fiberwise-holomorphic in \( z \). In the corresponding ‘exploded’ charts, the transition map is \((\tilde{z}, u) \mapsto (g(\tilde{z}), u)\tilde{z}, \phi(u))\), and transition maps between other charts remain unchanged. This defines \( C(\hat{f}^{+1}) \). The map \( C(\hat{f}^{+1}) \rightarrow C' \) is given in the above coordinate charts by \((\tilde{z}, u) \mapsto ([\tilde{z}], u)\). Composing this map with
the refinement map $C' \to C(\hat{f}) \times_{F(\hat{f})} C(\hat{f})$ then gives a degree-one fiberwise-holomorphic map

$$
\begin{array}{c}
C(\hat{f}+1) \\
\downarrow \\
C(\hat{f}) \\
\downarrow \\
\text{id} \\
\end{array} \to \begin{array}{c}
C(\hat{f}) \\
\downarrow \\
C(\hat{f}) \\
\downarrow \\
\end{array}
$$

The map $\hat{f}+1: C(\hat{f}+1) \to C(\hat{f}) \times_{F(\hat{f})} C(\hat{f})$ is given by the above constructed map $C(\hat{f}+1) \to C(\hat{f}) \times_{F(\hat{f})} C(\hat{f})$ composed with the map

$$
C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) \to \hat{B} \times_{B_0} B
$$

which is $\hat{f}$ in each component. All the above maps are smooth or $C^\infty$ if $\hat{f}$ is. This constructed family of curves $\hat{f}+1$ obeys the requirements of Definition 4.11.

The following lemma implies that $\hat{f}+n$ is unique (up to unique isomorphism) and that the construction of $\hat{f}+n$ is functorial.

**Lemma 4.12.** Given a map of families $\psi: \hat{f} \to \hat{g}$ and families $\hat{f}+1$ and $\hat{g}+1$ satisfying the requirements of Definition 4.11 there is a unique induced map $\psi: \hat{f}+1 \to \hat{g}+1$ such that the diagram

$$
\begin{array}{c}
C(\hat{f}+1) \\
\downarrow \\
C(\hat{f}) \\
\downarrow \\
C(\hat{f}) \\
\downarrow \\
\end{array} \to \begin{array}{c}
C(\hat{g}+1) \\
\downarrow \\
C(\hat{g}) \\
\downarrow \\
C(\hat{g}) \\
\downarrow \\
\end{array}
$$

commutes.

**Proof:**

Both $C(\hat{g}+1)$ and $C(\hat{g}) \times_{F(\hat{g})} C(\hat{g})$ are families over $C(\hat{g})$, but the fiber in $C(\hat{g}+1)$ over a point $p \in C(\hat{g})$ has one extra end. Away from this end, the map $C(\hat{g}+1) \to C(\hat{g}) \times_{F(\hat{g})} C(\hat{g})$ is a fiberwise-holomorphic isomorphism. Therefore, away from the extra end, the required map

$$
\begin{array}{c}
C(\hat{f}+1) \\
\downarrow \\
C(\hat{f}) \\
\downarrow \\
C(\hat{f}) \\
\downarrow \\
\end{array} \to \begin{array}{c}
C(\hat{g}+1) \\
\downarrow \\
C(\hat{g}) \\
\downarrow \\
C(\hat{g}) \\
\downarrow \\
\end{array}
$$

exists, is unique, and is fiberwise holomorphic.

On a neighborhood of the extra end in the fiber over $p \in C(\hat{g})$, there exists a fiberwise-holomorphic exploded coordinate function $\tilde{z}$ so that the extra end is at $[\tilde{z}] = 0$. The fiberwise-holomorphic function $[\tilde{z}]$ is a fiberwise-holomorphic coordinate function on $C(\hat{g}) \times_{F(\hat{g})} C(\hat{g})$ vanishing on the image of the diagonal. Therefore, $[\tilde{z}]$ pulls back to a fiberwise-holomorphic coordinate function on $C(\hat{f}) \times_{F(\hat{f})} C(\hat{f})$ vanishing on the image of the diagonal. It follows that, if $\tilde{z}'$ is a locally defined fiberwise-holomorphic coordinate function on $C(\hat{f}+1)$ so that the extra end is at.
\[ \tilde{z}' = 0, \text{ then the pullback of } \tilde{z} \text{ is } h[\tilde{z}'] \text{ where } h \text{ is some } C^* \text{-valued fiberwise-holomorphic function. Therefore there locally exists a unique map} \]
\[
\begin{array}{ccc}
C(\hat{f}^+) & \longrightarrow & C(\hat{g}^+)
\downarrow & & \downarrow \\
C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) & \longrightarrow & C(\hat{g}) \times_{F(\hat{g})} C(\hat{g})
\end{array}
\]

which is fiberwise holomorphic and pulls back \( \tilde{z} \) to \( h \tilde{z}' \). As our locally defined maps all satisfy the same uniqueness property, they glue together to give the required unique map. Restricted to each fiber, this map is a holomorphic isomorphism. The fact that \( \hat{f}^+ \) factors through \( C(\hat{f}) \times_{F(\hat{f})} C(\hat{f}) \) implies that our map \( C(\hat{f}^+) \longrightarrow C(\hat{g}^+) \) corresponds to a unique map \( \hat{f}^+ \longrightarrow \hat{g}^+ \).

\[ \square \]

5. Core families

Core families provide a local description of the moduli stack \( \mathcal{M}\hat{s}t \) of stable \( C^\infty_1 \) curves. Some such notion is necessary, because the ‘space’ of stable curves in \( \hat{B} \longrightarrow B_0 \) of a given regularity is not locally modeled on (an orbifold version of) a Banach space — this is because the domain of curves that we study are not fixed, and because of bubble and node formation. The moduli stack of stable curves could be described as a ‘orbifold’ by using an adaption of the theory of polyfolds developed by Hofer, Wysocki and Zehnder in \[8, 9, 13, 11, 12, 10\]. Such an adaption of the theory of polyfolds to the exploded setting is a worthwhile direction for further research, not explored in this paper.

**Definition 5.1.** A core family \( (\Phi, \hat{f}/G, \{s_i\}) \) for an open substack \( O \) of \( \mathcal{M}\hat{s}t(\hat{B}) \) or \( \mathcal{M}\hat{s}t^*(\hat{B}) \) is

- a \( C^\infty_1 \) family, \( \hat{f} \), of stable curves in \( O \) with a group, \( G \), of automorphisms,

\[
\begin{array}{ccc}
C(\hat{f}) & \longrightarrow & \hat{B} \\
\downarrow & & \downarrow \\
F(\hat{f}) & \longrightarrow & B_0
\end{array}
\]

- a finite, nonempty \( G \)-invariant collection of \( C^\infty_1 \) ‘marked point’ sections \( s_i : F(\hat{f}) \longrightarrow C(\hat{f}) \) which do not intersect each other, and which do not intersect the edges of curves in \( C(\hat{f}) \),

- and a fiberwise-holomorphic map

\[
\begin{array}{ccc}
O^{+1} & \Phi^{+1} & C(\hat{f})/G \\
\downarrow & \downarrow & \downarrow \\
O & \Phi & F(\hat{f})/G
\end{array}
\]

with an effective \( G \)-action in the sense of Definition \[2.50\] such that the following holds:

1. Using the notation of Definition \[2.57\],

\[ \Phi^{+1}_f : C(\hat{f}) \longrightarrow C(\hat{f})/G \]

is (canonically 2-isomorphic to) the quotient map

\[ \pi : C(\hat{f}) \longrightarrow C(\hat{f})/G \]
Definition 2.58 implies that \( \pi \) uniquely specifies the map \( \hat{h} \) for the undecorated family. Given any core family \( \hat{O} \) of a family of decorated curves is uniquely defined by deforming the underlying fiberwise holomorphic map \( \pi \) to be the unique lift of this to a map \( \hat{h} \) constructed in Example 2.17.

\[
\begin{array}{ccc}
C(\hat{f}) & \xrightarrow{\Phi^+ (f)} & C(\hat{f}) \\
\downarrow \pi & & \downarrow \pi \\
C(\hat{f}) & \xrightarrow{\pi} & C(\hat{f})/G
\end{array}
\]

(2) For any curve family of curves \( \tilde{h} \) in \( O \), there exists a \( C^\infty \) family of curves \( \hat{h}_t : C(\hat{h}) \to B \) parametrized by \( \mathbb{R} \times F(\tilde{h}) \), with domain \( \mathbb{R} \times C(\hat{h}) \), such that
- \( \hat{h}_0 \) is \( \tilde{h} \),
- \( \hat{h}_1 \) is the composition

\[
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{\Phi^+ (f)} & C(\hat{f})/G \\
\gamma^+_h & \downarrow & \downarrow \pi \\
C(\hat{h}) & \xrightarrow{\pi} & C(\hat{f})/G
\end{array}
\]

\( \Phi^+ : C(f) \to C(\hat{f})/G \)

(3) Conversely, given any curve \( f \) in \( \hat{f} \) and family of curves \( \hat{f}_t : C(f) \to B \) independent of \( t \) on the image of \( s_i \), and with \( f_0 = f \), consider the open set of \( t \) such that \( f_t \) is in \( O \). For all such \( t \)

\[
\Phi^+_f : C(f) \to C(\hat{f})/G
\]

is independent of \( t \).

Proposition 5.12 constructs a core family containing any given stable holomorphic curve with at least one smooth component. Note that conditions 1 and 3 determine \( \Phi \) (up to unique 2-isomorphism) from \( \hat{f}/G \) and \( \{s_i\} \), so we can specify a core family using only \( (\hat{f}/G, \{s_i\}) \).

Remark 5.2. The lifting property of Definition 2.58 implies that a deformation of a family of decorated curves is uniquely defined by deforming the underlying undecorated family. Given any core family \( \hat{f}/G \) for \( \hat{O} \subset \mathcal{M}^\text{ad} \), consider the pullback \( \pi^* \hat{f} \) of \( \hat{f} \) to \( \mathcal{M}^\text{ad} \). Then, the lifting property of Definition 2.58 implies that \( \pi^* \hat{f}/G \) is a core family for the inverse image of \( O \) in \( \mathcal{M}^\text{ad} \). In particular, we can define a fiberwise holomorphic map \( \pi^* \Phi : \pi^* O \to \pi^* \hat{f}/G \) as follows. Given a family \( \tilde{h} \) in \( \pi^{-1} O \), let \( (\pi \tilde{h} \hat{t}) \) be the \( \mathbb{R} \)-deformation of \( \tilde{h} \) from Definition 2.57 part 3 and let \( h_t \) be the unique lift of this to a \( \mathbb{R} \)-deformation of \( \tilde{h} \) such that \( \pi (h_t) = (\pi \tilde{h} \hat{t}) \). Then \( \Phi^+ h : C(\pi h) \to C(\hat{f})/G \) is compatible with the maps \( h_t \) and \( \tilde{f}/G \), so defines a map \( \phi : h_1 \to \tilde{f}/G \) and therefore a map \( \pi^* \phi : h_1 \to \pi^* \tilde{f}/G \). We can then define \( \pi^* \Phi^+ h \) to be \( C(\pi^* \phi) : C(\hat{h}) \to C(\pi^* \tilde{f}/G) \). Condition 3 of Definition 2.57 ensures that \( \pi^* \Phi^+ h \) is independent of choice of deformation \( (\pi \tilde{h}) \hat{t} \), and that \( \pi^* \Phi \) satisfies Definition 2.59. Because \( \Phi^+ f \) represents the functor \( C \) applied to the quotient map \( q : \hat{f} \to \tilde{f}/G \), \( \pi^* \Phi^+ f \) represents \( C \) applied to \( \pi^* q : \pi^* \hat{f} \to \pi^* \tilde{f}/G \), and Definition 2.58 implies that \( \pi^* q \) is also a quotient map.

\[\text{As this is a composition of maps of stacks, we can only say that } h_1 \text{ represents the composition, however this uniquely specifies the map } h_1.\]
Remark 5.3. Suppose we have a fiberwise holomorphic map \((\Phi, \tilde{f}/G, \{s_i\})\) for an open substack \(U\) satisfying conditions 1 and 2 of Definition 5.1 and satisfying the following weaker version of Condition 2:

\[
\hat{h} = \tilde{f} \circ \Phi^1_h
\]

(7) for all \(\hat{h}\) in \(U\). Then, we can choose a \(G\)-equivariant trivialization \((F, \Psi)\) for \(\tilde{f}\) as in Definition 5.1 and there exists a neighborhood \(O\) of \(\tilde{f}\) with each family \(\hat{h}\) uniquely expressible as

\[
\hat{h} = (F/G) \circ (\nu_h)
\]

for a unique lift \(\nu_h\) of \(\Phi_h\) as follows

\[
\xymatrix{\hat{f}^*T_{vert}\hat{B}/G \ar[r]^-{\nu_h} \ar[d] & C(\hat{h}) \ar[d] \ar[r]^-{\Phi^1_h} & C(\hat{f})/G \ar[l]_F}
\]

such that \(\nu_h\) vanishes at the image of the sections \(s_i\). Then, we have a canonical deformation \(\hat{h}_t := (F/G) \circ ((1-t)\nu_h)\) satisfying condition 2 of Definition 5.1. Moreover, we can choose this neighborhood such that \(\hat{h}_t\) remains in this neighborhood for \(0 \leq t \leq 1\). Unpacking definitions, \(\Phi_h^{1}\) is a \(G\)-bundle \(\hat{h}^{xG} \rightarrow \hat{h}\) with a \(G\)-equivariant map \(\Phi^1_h(\hat{h})\): \(C(\hat{h}^{xG}) \rightarrow C(\tilde{f})\) and \(\nu_h\) is a \(G\)-equivariant lift \(\nu'_h\) of this map such that the following diagram commutes

\[
\xymatrix{\hat{B} \ar[r]^-{\nu'_h} \ar[d] & \hat{f}^*T_{vert}\hat{B} \ar[d] \ar[l]_F \ar[r]^-{\Phi^1_h(\hat{h})} & C(\hat{f}) \ar[l]_{C(\hat{h}^{xG})}}
\]

and \(\nu'_h\) vanishes on the image on the sections \(s_i\).

In particular, conditions 1a and 1b of Definition 5.1 imply that, given a metric on \(B\) (as in Remark 6.6 of 24) there exists some continuous positive function \(m: C(\tilde{f}) \rightarrow (0, \infty)\) such that there exists a unique \(\nu'_h\) as above whenever \(d(\hat{h}^{xG}, \tilde{f} \circ \Phi^1_h(\hat{h})) < \Phi^1_h(\hat{h}) \circ m\). Equation 7 ensures that this distance is a continuous function, so this equation is satisfied on an open subset of \(C(\hat{h}^{xG})\). Define \(O\) as the substack consisting of curves \(h\) satisfying the above such that \(h_t\) remains in \(U\) for \(t \in [0,1]\). As \(U\) is open, an open subfamily of \(h\) is in \(O\), so \(O\) is open. Whenever \(h = \tilde{f} \circ \Phi^1_h\), \(h\) is automatically in \(O\), so \(O\) is an open neighborhood of \(\tilde{f}\), and also contains any refinement of a curve in \(\tilde{f}\) that is already in \(U\).

In the case that \(F\) is determined by exponentiation using a connection on \(T_{vert}B\), we can think of \(\nu_h\) as a section of \((\tilde{f}/G \circ \Phi^1_h)^*T_{vert}B\) vanishing on \(\Phi^1_h^{-1}s_i\) such that

\[
\hat{h} = \text{Exp}_{\nu_h} \circ \tilde{f}/G \circ \Phi^1_h
\]

5.1. Construction of a core family.

The following theorem gives sufficient criteria for when a given family with a collection of marked point sections is a core family:

Theorem 5.4. Let \(\tilde{f}\) be a family in \(\mathcal{M}^{s_1}\) with a group \(G\) of automorphisms, and a finite nonempty set of disjoint sections \(s_i\): \(F(\tilde{f}) \rightarrow C(\tilde{f})\) not intersecting the edges of the curves in \(C(\tilde{f})\), such that the following conditions are satisfied:
(1) For all curves $f$ in $\hat{f}$, the action of $G$ on the set of maps $f \to \hat{f}$ is free and transitive.

(2) For all curves $f$ in $\hat{f}$, $[C(f)]$ with the extra marked points from $\{s_i\}$ has no nontrivial automorphisms.

(3) The action of $G$ preserves the set of sections $\{s_i\}$ so there is some action of $G$ as a permutation group on the set of indices $\{i\}$ such that for all $g \in G$ and $s_i$,

$$s_i \circ g = g \circ s_{g(i)}$$

where the action of $g$ is on $\mathbf{F}(\hat{f})$, $\mathbf{C}(\hat{f})$ or the set of indices $\{i\}$ as appropriate.

(4) There exists a neighborhood $U$ of the image of the section

$$s: \mathbf{F}(\hat{f}) \to \mathbf{F}(\hat{f}^+)$$

defined by the $n$ sections $\{s_i\}$ such that

$$ev^{+n}(\hat{f}): \mathbf{F}(\hat{f}^+) \to \mathcal{M}(pt)^{+n} \times \mathbf{B}_{B_n}$$

restricted to $U$ is an injective equi-dimensional submersion.

(5) The tropical structure of $f$ is universal; see Definition 4.1 and Theorem 3.1 of [27].

(6) For any curve $f$ in $\hat{f}$, there are exactly $|G|$ points $x$ in $\mathbf{F}(\hat{f}^+)$ such that $ev^{+n}(f)(x)$ is in the closure of the image of $ev^{+n}(\hat{f}) \circ s$.

Then $(\hat{f}/G, \{s_i\})$ is a core family for an open substack $\mathcal{O}$ of $\mathcal{M}^{\infty, \frac{1}{2}}$ containing every refinement of any curve $f$ in $\hat{f}$.

Proof: We must construct $\Phi$ and $\Phi^{+1}$; an overview of the construction is as follows: $\Phi(\hat{h})$ is a $G$–bundle $\pi_\hat{h}: \hat{h}^{sg} \to \hat{h}$ with a $G$–equivariant map $\Phi(\hat{h})$: $\mathbf{F}(\hat{h}^{sg}) \to \mathbf{F}(\hat{f})$. We construct $\mathbf{F}(\hat{h}^{sg})$ as

$$\mathbf{F}(\hat{h}^{sg}) := \mathbf{F}(\hat{h}^+) ev^{+n}(\hat{h})^{\times} ev^{+n}(\hat{f}) \circ s \mathbf{F}(\hat{f}).$$

As a fiber product, $\mathbf{F}(\hat{h}^{sg})$ has natural maps $\Phi(\hat{h})$ and $s_\hat{h}$ as follows.

$$\mathbf{F}(\hat{h}^{sg}) \xrightarrow{\Phi(\hat{h})} \mathbf{F}(\hat{f})$$

$$\mathbf{F}(\hat{h}^+) ev^{+n}(\hat{h}) \xrightarrow{\pi_\hat{h}} \mathbf{M}(pt)^{+n} \times \mathbf{B}_{B_n}^{n}$$

Criterion [3] implies that the map

$$ev^{+n} \circ s: \mathbf{F}(\hat{f}) \to \mathbf{M}(pt)^{+n} \times \mathbf{B}_{B_n}^{n}$$

is $G$–equivariant for some action of $G$ permuting labels of extra marked points in $\mathbf{M}(pt)^{+n} \times \mathbf{B}_{B_n}^{n}$. The map $ev^{+n}(\hat{h})$ is $G$–equivariant with this action of $G$ permuting the labels of the extra punctures, so both $s_\hat{h}$ and $\Phi(\hat{h})$ are $G$–equivariant. The map $\mathbf{F}(\pi_\hat{h}): \mathbf{F}(\hat{h}^{sg}) \to \mathbf{F}(\hat{h})$ is defined as the composition of $s_\hat{h}$ with the natural projection forgetting the $n$ extra ends.

$$\mathbf{F}(\hat{h}^{sg}) \xrightarrow{s_\hat{h}} \mathbf{F}(\hat{h}^+) \xrightarrow{\Phi(\hat{h})} \mathbf{F}(\hat{h})$$

This projection $\mathbf{F}(\hat{h}^+) \to \mathbf{F}(\hat{h})$ is $G$–invariant so $\mathbf{F}(\pi_\hat{h})$ is $G$–invariant. Below, we define an open substack $\mathcal{O}_2$ containing $\hat{f}$ and every refinement of a curve in $\hat{f}$ such that, for $\hat{h}$ in $\mathcal{O}_2$, $\mathbf{F}(\hat{h}^{sg})$ is an exploded manifold, and $\mathbf{F}(\pi_\hat{h})$ is a $G$–bundle —
and therefore defines a $G$–bundle $\pi_h: h^G \to h$ as the pullback of $\hat{h}$ over $F(\pi_\hat{h})$. (See Claims \ref{claim:10} and \ref{claim:11}) Given any map $\psi: \hat{g} \to \hat{h}$, the naturally induced map $\psi^+: \hat{g}^+ \to \hat{h}^+$ is $G$–equivariant, and induces $G$–equivariant map of fiber products $F(\psi^+): F(\hat{g}^G) \to F(\hat{h}^G)$ and therefore induces a $G$–equivariant map $\psi^G: \hat{g}^G \to \hat{h}^G$ of $G$–bundles. Moreover this map satisfies

$$\Phi(\hat{h}) \circ F(\psi^G) = \Phi(\hat{g}) \quad \text{and} \quad s_h \circ F(\psi^G).$$

Because $(\psi_1 \circ \psi_2)^+ = \psi_1^+ \circ \psi_2^+$, it follows that $(\psi_1 \circ \psi_2)^G = \psi_1^G \circ \psi_2^G$, so the above defines a map $\Phi: O_2 \to F(\hat{f})/G$.

Note that $s_h$ induces a section of $(\hat{h}^G)^+ \to \hat{h}^G$ and hence $n$ sections $s_{h,i}$ of $C(\hat{h}^G) \to F(\hat{h}^G)$. We lift $\Phi$ to $\Phi^+: O_2^+ \to C(\hat{f})/G$ by defining

$$C(\hat{h}^G) \xrightarrow{\Phi^+(\hat{h})} C(\hat{f})$$

$$\downarrow$$

$F(\hat{h}^G) \xrightarrow{\Phi(\hat{h})} F(\hat{f})$

as the unique fiberwise holomorphic map which is fiberwise degree 1, and pulls back the sections $s_i$ to $s_{h,i}$, so

$$\Phi^+(\hat{h}) \circ s_{h,i} = s_i \circ \Phi(\hat{h}).$$

We show in Claim \ref{claim:20} that $\Phi^+(\hat{h})$ exists and is $C^\infty \mathcal{L}$. Condition \ref{condition:2} ensures that it is unique, because there is at most one degree 1 holomorphic map from any curve with $n$ marked points to a curve in $C(\hat{f})$ with its marked points from $s_i$. The defining property of this map ensures that it is $G$–equivariant, and (9) implies that

$$\Phi^+(\hat{h}) \circ C(\psi^G) = \Phi^+(\hat{g})$$

so we have defined a fiberwise holomorphic map $\Phi^+: O_2^+ \to C(\hat{f})/G$.

Let us verify Condition \ref{condition:1} of Definition \ref{def:5.1}. The map $s: F(\hat{f}) \to F(\hat{f}^+)$ induces a section, $s'$ of the $G$–bundle $F(\hat{f}^+)$ that $F(\hat{f}^+)$ induces a section, $s'$ of the $G$–bundle $F(\hat{f}^+)$ that $F(\hat{f}^+)$ such that $\Phi(\hat{f}) \circ s' = s$. It follows that $\Phi_f : F(\hat{f}) \to F(\hat{f})/G$ is equivalent to the quotient map from Example \ref{example:2.14} and Condition \ref{condition:1} of Definition \ref{def:5.1} holds.

Condition \ref{condition:3} of Definition \ref{def:5.1} also holds. For a curve $g$, the map $\Phi^+(g)$ is determined by the domain $C(g)$ of $g$ and the $|G|$ points in $ev^{+n}(g)^{-1}(ev^{+n}(\hat{f}) \circ s(\Phi(\hat{f})))$. It follows that for a family $\hat{f}_t$ as in Condition \ref{condition:3} $\Phi^+(\hat{f}_t)$ is independent of $t$, so Condition \ref{condition:3} is satisfied.

So, $\Phi$ satisfies conditions \ref{condition:1} and \ref{condition:3}. Moreover, Definition \ref{def:5.5} and Claim \ref{claim:5.6} ensure that Equation \ref{equation:7} holds, so Remark \ref{remark:4.3} implies that, by restricting to a smaller neighborhood $O$ of $\hat{f}/G$ still containing every refinement of every curve in $\hat{f}$, $\Phi$ will also satisfy Condition \ref{condition:2} of Definition \ref{def:5.1}.

Let us construct a substack $O_1$ on which the fiber product $F(h^G)$ is a $C^\infty \mathcal{L}$ exploded manifold. Define $O_1 \subset \mathcal{M}^\infty \mathcal{L}$ to be the substack consisting of curves $h$ such that $ev^{+n}(h)$ intersects the closure of the image of $ev^{+n}(\hat{f}) \circ s$ exactly $|G|$ times, and each of these intersections is a transverse intersection with the image of
For any family of curves $\hat{h}$ in $O_1$, lemmas 9.7 and 9.8 of [24] imply that \[ ev^{+n}(\hat{f}) \circ s. \]
Conditions [4] and [5] ensure that any curve in $\hat{f}$ is in $O_1$, and similarly any refinement of a curve in $\hat{f}$ is also in $O_1$.

For any family of curves $\hat{h}$ in $O_1$, lemmas 9.7 and 9.8 of [24] imply that
\[ F(\hat{h}^{xG}) := F(\hat{h}^{+n}) \times_{ev^{+n}(\hat{f})} F(\hat{f}) \]
is a $C^{\infty}$ exploded manifold with a $G$ action discussed above, and the map $F(\pi_\hat{h}): F(\hat{h}^{xG}) \to F(\hat{h})$ is $G$ invariant, and a degree $|G|$ equi-dimensional submersion. It is not clear, however, that this map is a $G$–bundle, because it might not be etale, and it is also not clear that $O_1$ is open. (To prove these properties, we will make a further assumption on our substack, and use that $\hat{f}$ has universal tropical structure). Nevertheless, we can still define a family of curves $\hat{h}^{xG}$ by pulling back $h$ over the map $F(\pi_\hat{h}): F(\hat{h}^{xG}) \to F(\hat{h})$, and $\Phi(\hat{h}): F(\hat{h}^{xG}) \to F(\hat{f})$ is still a well-defined $G$-equivariant map, and Equation (9) is still valid.

Let us construct $\Phi^{+1}(\hat{h}): C(\hat{h}^{xG}) \to C(\hat{f})$. There is a natural map
\[ (11) \quad \Phi^{+1}(\hat{h}): C(s^*\hat{h}^{+n}) \to C(s^*\hat{f}^{+n}) \]
induced by thinking of $C(s^*\hat{f}^{+n})$ as a fiber product as follows. Consider the map
\[ (12) \quad ev^{+n}(\hat{f}): C(\hat{f}^{+n}) \to M(pt)^{+(n+1)} \times \hat{B}^{n+1} \]
constructed from the composition of $ev^{+(n+1)}(\hat{f})$ with the projection map
\[
\begin{array}{ccc}
C(\hat{f}^{+n}) & \xrightarrow{ev^{+(n+1)}(\hat{f})} & M(pt)^{+(n+1)} \times \hat{B}^{n+1} \\
\downarrow & & \downarrow \\
C(\hat{f}^{+n}) & \xrightarrow{ev^{+n}(\hat{f})} & M(pt)^{+(n+1)} \times \hat{B}^{n}
\end{array}
\]
forgetting the last factor of $\hat{B}$ — so, on the second component, $ev^{+n}(\hat{f})$ is the composition of the projection $C(\hat{f}^{+n}) \to F(\hat{f}^{+n})$ with the map $\hat{f}^{+(n-1)}$. Criteria [2] and [3] imply that $ev^{+n}(\hat{f})$ is an injective equidimensional submersion when restricted to a neighborhood of $C(s^*\hat{f}^{+n}) \subset C(\hat{f}^{+n})$, and that, on this neighborhood, the following is a pullback diagram of families of curves.
\[
\begin{array}{ccc}
C(\hat{f}^{+n}) & \xrightarrow{ev^{+n}(\hat{f})} & M(pt)^{+1} \times \hat{B}^{n} \\
\downarrow & & \downarrow \\
F(\hat{f}^{+n}) & \xrightarrow{ev^{+n}(\hat{f})} & M(pt) \times \hat{B}^{n}
\end{array}
\]
Therefore, $C(s^*\hat{f}^{+n})$ is the following fiber product:
\[
\begin{array}{ccc}
C(s^*\hat{f}^{+n}) & \xrightarrow{ev^{+n}(\hat{f})} & M(pt)^{+1} \times \hat{B}^{n} \\
\downarrow & & \downarrow \\
F(\hat{f}) & \xrightarrow{ev^{+n}(\hat{f})} & M(pt) \times \hat{B}^{n}
\end{array}
\]
Accordingly, for any $\hat{h}$ in $O_1$ there is a unique $C^\infty_-$ map $\Phi^+1(\hat{h})$ such that the following diagram commutes

\[
\begin{array}{ccc}
C(s^+_h\hat{h}^{+n}) & \overset{\Phi^+1(\hat{h})}{\longrightarrow} & C(\hat{h}^{+n}) \\
\downarrow & & \downarrow \\
F(\hat{h}^{+n}) & \overset{s_{\hat{h}}}{\longrightarrow} & F(\hat{h}^{+n}) \\
\end{array}
\]

Moreover, on each fiber, $\Phi^+1(\hat{h})$ is holomorphic and degree 1, because $\epsilon ev^n(\hat{h})$ is fiberwise holomorphic and degree 1.

**Definition 5.5.** Define a substack $O_2 \subset O_1$ consisting of curves $h$ such that there exists a family of curves $h_i$ parametrized by $\mathbb{R}$ with domains $C(h_i)$ identified with $C(h)$ and satisfying

- $h_0 = h$,
- $s^n_i h_i^{+n} = s^n f^{+n} \circ \Phi^+1(h)$.

Note that this implies that $s^n_i h_i^{+n} = f^{+n} \circ \Phi^+1(h)$ for $h$ in $O_2$, because $s^n_i h_i^{+n}$ is independent of $t$. As $O_1$ contains every refinement of every curve in $\hat{f}$, $O_2$ contains all these refinements too. We will show in Claim 5.11 that $O_2$ is open, and show in Claim 5.11 that $\pi_\hat{h} : \hat{h}^{+n} \longrightarrow \hat{h}$ is a $G$-bundle for $\hat{h}$ in $O_2$.

The following claim tells us that, for curves in $O_2$, we can forget the extra ends of $C(s^n f^{+n})$ and $C(s^n_i \hat{h}^{+n})$ to define $\Phi^+1(\hat{h})$.

**Claim 5.6.** For $\hat{h}$ in $O_2$, there exists a $C^\infty_-$ map $\Phi^+1(\hat{h})$ such that the following diagram commutes.

\[
\begin{array}{ccc}
C(s^+_h \hat{h}^{+n}) & \overset{\Phi^+1(\hat{h})}{\longrightarrow} & C(s^n \hat{f}^{+n}) \\
\downarrow & & \downarrow \\
C(\hat{h}^{+n}) & \overset{\Phi^+1(\hat{h})}{\longrightarrow} & C(\hat{f}) \\
\downarrow & & \downarrow \\
F(\hat{h}^{+n}) & \overset{\Phi(\hat{h})}{\longrightarrow} & F(\hat{f}) \\
\end{array}
\]

Moreover, $\Phi^+1(\hat{h})$ is fiberwise holomorphic and degree 1, and pulls back the sections $s_i$ to $s_{\hat{h},i}$, so

\[s_i \circ \Phi(\hat{h}) = \Phi^+1(\hat{h}) \circ s_{\hat{h},i}\]

(13)

To prove Claim 5.6, note that the pullback under $\Phi^+1$ of the $n$ extra ends of $C(s^n f^{+n})$ are the $n$ extra ends of $C(s^n_i \hat{h}^{+n})$. Moreover, the image of all these extra ends in $C(\hat{f})$ do not intersect, and do not intersect the edges of curves. It follows that the same property holds for the image of the extra ends in $C(\hat{h}^{+n})$ — if one was on an edge of a curve $g$ in $C(\hat{h}^{+n})$, (13) would imply that $g$ is constant on that edge, so it would be impossible for $ev^{+n}(g)$ to be transverse to $ev^{+n}(\hat{f}) \circ s$. In the construction of $\hat{f}^{+1}$, below Equation (4), there are two steps: a refinement of $C(\hat{f}) \times F(\hat{f})$ at the image of the diagonal, and the subsequent
explosion of the diagonal. Because our new ends stay away from each other and edges of curves in \( C(\hat{f}) \) or \( C(\hat{h}) \), the refinement step will not affect our domains, so we only need to undo the explosion step. Locally, around one of our extra ends we have coordinates on \( C(s^*_{h \circ g} e^{+n} h^{+n}) \) and \( C(s^* f^{+n}) \) in the form of open subsets of \( \mathbf{T}^1_{[0,\infty)} \times U \) and \( \mathbf{T}^1_{[0,\infty)} \times V \), where \( U \) and \( V \) are open subsets of \( F(h^{+n}) \) and \( F(\hat{f}) \) respectively, and \( \Phi^{+1}(\hat{h}) \) is in the form \((\hat{z}, u) \mapsto (\hat{z} h, \Phi(\hat{h})(u))\) with \( h \in \mathbb{C}^* \)-valued and fiberwise holomorphic function on our coordinate chart. Noting that the smooth part of \( \mathbf{T}^1_{[0,\infty)} \) is \( \mathbb{C} \), the image of our coordinates in \( C(h^{+n}) \) and \( C(f) \) are the corresponding open subsets of \( \mathbf{T}^1_{[0,\infty)} \times U \) and \( \mathbf{T}^1_{[0,\infty)} \times V \) respectively.

The holomorphic function \( \Phi^{+1}(\hat{h}) \) factors through our chart on \( C(h^{+n}) \), and in these coordinates \( \Phi^{+1}(\hat{h}) \) is then \((\hat{z}, u) \mapsto ([\hat{z}] h, \Phi(\hat{h})(u))\). This is the unique map fitting into the commutative diagram above, so it follows that \( \Phi^{+1}(\hat{h}) \) is globally well defined. Of course, \( \Phi^{+1}(\hat{h}) \) is fiberwise holomorphic and degree 1 because \( \Phi^{+1}(\hat{h}) \) is, and by construction \( s_t \circ \Phi(\hat{h}) = \Phi^{+1}(\hat{h}) \circ s_{\hat{h}, i} \), because the \( i \)th extra end of \( s^* h^{+n} \) is sent to the \( i \)th extra end of \( s^* f^{+n} \). So, Claim 5.6 is valid.

**Claim 5.7.** If \( \hat{h} \) is a family of curves containing a curve \( h \) in \( \mathcal{O}_2 \), recall the deformation \( h_t \) of \( h \) from Definition 5.5. This deformation \( h_t \) extends to a deformation \( \hat{h}_t \) of \( \hat{h} \). In other words, \( \hat{h}_t \) is a smooth family of maps \( \hat{h}_t : C(\hat{h}) \rightarrow A \) parametrized by \( \mathbb{R} \), and the restriction of \( \hat{h}_t \) to \( C(h) \) is \( h_t \).

To extend the deformation \( h_t \), we use the following fact.

**Remark 5.8.** Let \( V \) be a vectorbundle over the total space of a family \( \pi : \hat{A} \rightarrow A_0 \). Then any \( C^{\infty, \perp} \) section of \( V \) over a fiber of \( \pi \) extends to a \( C^{\infty, \perp} \) section of \( V \) over \( \hat{A} \).

The key case is extending from a fiber over the central stratum of a coordinate chart \( \mathbf{T}^1_{\mathcal{P}} \). As \( \pi \) is a family in the sense of Definition 10.1 of [24], a section of \( V \) over such a fiber extends uniquely to a section over \( \pi^{-1}(\mathbf{T}^1_{\mathcal{P}}) \), where \( \mathcal{P} \) is the interior of the polytope \( \mathcal{P} \). The section can then locally extended using the operator \((1 - \Delta)^{-1}(P^n)\), where \( \pi^{-1}(P^n) \) is the set of strata in the inverse image of \( P^n \), and \( \Delta \) is the operator from Definition 7.3 of [24]. Local extensions can then be patched together using a partition of unity. We can obtain \( h_t \) using the flow of a \( C^{\infty, \perp} \) vectorfield on \( C(h) \times \mathbb{R} \) in the form \((0, \partial_t, v(p, t))\) where for all \((p, t) \in C(h) \times \mathbb{R}, v(p, t) \) is a section of \( T_{\text{vert}} B \) with

\[
v(p, t)|_{h_t(p)} = \frac{\partial h_t(p)}{\partial t}.
\]

Using Remark 5.8 we can extend this vectorfield to a \( C^{\infty, \perp} \) vectorfield on \( C(\hat{h}) \times \mathbb{R} \) in the form \((0, \partial_t, \tilde{v}(p, t))\) with \( \tilde{v}(p, t) \) a section of \( T_{\text{vert}} B \). The flow of this vectorfield then gives an extension of \( h_t \) to a deformation \( \hat{h}_t \) of \( \hat{h} \) satisfying

\[
\tilde{v}(p, t)|_{h_t^{\infty} (p)} = \frac{\partial \hat{h}_t(p)}{\partial t}.
\]

This completes the proof of Claim 5.7.

**Claim 5.9.** Let \( h \) be in \( \mathcal{O}_2 \), and let \( \hat{h} \) be a family of curves containing \( h \). Consider the following fiber product.

\[
\begin{align*}
F(\hat{h}^{+n})_{ev^{+n}(\hat{h})} & \times_{ev^{+n}(\hat{f})} F(\hat{f}^{+n}) & \xrightarrow{\pi_2} & F(\hat{f}^{+n}) \\
\downarrow \pi_1 & & \downarrow ev^{+n}(\hat{f}) \\
F(\hat{h}^{+n}) & \xrightarrow{ev^{+n}(\hat{h})} & \mathcal{M}(pt)^{+n} \times \hat{B}_B^{\infty}.
\end{align*}
\]
There exists an open neighborhood \( O \) of 
\[
F(h^{\pi}) = F(h^{\pi})_{ev^{+n}(f)} \times_{ev^{+n}(\hat{g})} F(\hat{f}^{+n}) \subset (F(\hat{h}^{+n})_{ev^{+n}(\hat{h})} \times_{ev^{+n}(f)} F(\hat{f}^{+n})
\]
such that the restriction of \( \pi_1 \) to \( O \) is an isomorphism onto an open subset.

Recall from Criterion 4.3 that \( ev^{+n}(\hat{f}) \) is an injective equidimensional submersion on a neighborhood \( U \) of \( s(f) \); so, \( \pi_1 : F(\hat{h}^{+n})_{ev^{+n}(\hat{h})} \times_{ev^{+n}(f)} F(\hat{f}^{+n}) \rightarrow F(\hat{h}^{+n}) \) is also an injective equidimensional submersion. Remark 2.9 tells us that this injective equidimensional submersion \( \pi_1 \) will be an isomorphism in a neighborhood of each point \( x \) where its tropical structure \( \mathcal{P}_{\pi_1}(x) \) is an isomorphism. From Claim 5.7, we have a family of curves \( \hat{h}_1 : C(h) \rightarrow B \) whose restriction to \( C(h) \) is the curve \( h_1 \) from Definition 5.5 with \( h_1^{\pi} = f \circ \Phi^+(h) \). The \( |G| \) different points \( x \) in \( F(\hat{h}^{\pi}) \) correspond to \( |G| \) different maps \( \Phi^+(h)_x : C(h) \rightarrow C(f) \) with \( h_1 = \hat{f} \circ \Phi^+(h)_x \). By assumption, \( \hat{f} \) has universal tropical structure so, after replacing \( \hat{h} \) by an open subfamily if necessary, Lemma 4.3 implies that each of these maps \( \Phi^+(h)_x \) extend to maps \( \Phi^+_x : C(h) \rightarrow C(f) \) such that \( \hat{f} \circ \Phi^+_x = \hat{h}_1 = \hat{x} \). Without loss of generality, we can assume that \( \hat{h} \) is connected, and so \( \Phi^+_x \) is fiberwise genus-preserving, degree one, and sends ends to ends. It follows that the induced maps \( \Phi^+_x : F(\hat{h}^{+n}) \rightarrow F(\hat{f}^{+n}) \) satisfy
\[
(14) \quad ev^{+n}(\hat{f}) \circ \Phi^+_x = ev^{+n}(\hat{h}).
\]
This map \( \Phi^+_x \) induces a section \( l_x \) of \( \pi_1 \) defined on a neighborhood of \( \pi_1(x) \) with \( l_x(\pi_1(x)) = x \). Equation (14) implies that \( \mathcal{P}_{\pi_1}(x) \) is inverse to \( \mathcal{P}_{l_x}(\pi_1(x)) \), so Remark 2.9 implies \( \pi_1 \) is etale in a neighborhood of \( x \). Claim 5.9 follows.

Claim 5.10. If \( h \) is a curve in \( O_2 \) and \( \hat{h} \) is a family of curves containing \( h \), then \( F(\pi_1) : F(\hat{h}^{\pi}) \rightarrow F(\hat{f}) \) is etale in a neighborhood of \( F(\hat{h}^{\pi}) \subset F(\hat{h}^{\pi}) \). In particular, if \( h \) is in \( O_2 \), then \( F(\pi_1) : F(\hat{h}^{\pi}) \rightarrow F(\hat{h}) \) is etale, and hence a \( G \)-bundle.

Claim 5.10 follows from Claim 5.9. Because \( h \) is in \( O_1 \), we have that \( ev^{+n}(\hat{h}) \) intersects \( ev^{+n}(\hat{f}) \circ s(F(\hat{f})) \) transversely exactly \( |G| \) times, so \( F(\hat{h}^{\pi}) \rightarrow F(\hat{f}) \) has derivative an isomorphism at \( F(\hat{h}^{\pi}) \). As all the marked point sections defining \( s : F(f) \rightarrow F(f^{+n}) \) are non-intersecting and in smooth components of curves, it follows that the tropical structure of \( s \) is an isomorphism \( \mathcal{P}_s(x) \) at each point \( x \). It follows the the tropical structure of \( s_{\hat{h}} : F(\hat{h}^{\pi}) \rightarrow F(\hat{h}^{+n}) \) at any point in \( F(\hat{h}^{\pi}) \) coincides with the tropical structure of the map \( \pi_2 \), which is an isomorphism, by Claim 5.9. As with any family, the tropical structure of the projection \( \pi : F(\hat{h}^{\pi}) \rightarrow \hat{h} \) at any point is either an isomorphism, or a projection from a higher dimensional polytope. As \( F(\pi_1) \) has bijective derivative at each point in \( F(\hat{h}^{\pi}) \), its tropical structure can't be a nontrivial projection. As \( F(\pi_1) = \pi_1 s_{\hat{h}} \), it follows that the tropical structure of \( F(\pi_1) \) is also an isomorphism. Remark 2.9 then implies that \( F(\pi_1) \) is etale in a neighborhood of \( F(\hat{h}^{\pi}) \subset F(\hat{h}^{+n}) \). If \( \hat{h} \) is in \( O_2 \), it follows that \( F(\pi_1) \) is etale. This completes the proof of Claim 5.10.

Claim 5.11. \( O_2 \) is an open substack of \( \mathcal{M}^n \).

Let \( h \) be in \( O_2 \) and let \( \hat{h} \) be a family of curves containing \( h \). To prove Claim 5.11, we must show that a neighborhood of \( h \) within \( \hat{h} \) is contained in \( O_2 \). Around any point in \( F(\hat{h}^{\pi}) \subset F(\hat{h}^{\pi}) \), Claim 5.10 gives that \( F(\hat{h}^{\pi}) \rightarrow F(\hat{h}) \) is etale, so, for all curves \( g \) in a neighborhood \( ev^{+n}(g) \) remains transverse to \( ev^{+n}(f) \circ s \) at \( |G| \) points. Moreover, on an open neighborhood, there are no further intersections
with the closure of the image of \( ev^+h_1(f) \circ s \). If follows that a neighborhood of \( h \) in \( \hat{h} \) is in \( O_1 \).

It remains to show that a neighborhood of \( h \) in \( \hat{h} \) is in \( O_2 \). Without loss of generality, we can assume that \( h \) is in \( O_1 \). As \( s_1^+h_1^+ = \hat{f}^+h_1^+ \circ \Phi^+1(h) \) and \( ev^+h_1 \circ s_1 = ev^+h_1(f) \circ s \circ \Phi(h) \), it follows that, after restricting \( h \) to an open neighborhood of \( h \) if necessary,

\[
(15) \quad s_1^+h_1^+ = \hat{f}^+h_1^+ \circ \Phi^+1(h).
\]

This is because a small enough open neighborhood of \( C(s_1^+h_1^+ \subset C(s_1^+h_1^+) \) has tropical part consisting of the closure of the strata containing \( h \). Given any metric \( C \) on \( h \), their restriction to \( C(s_1^+h_1^+) \), and to the strata corresponding to the \( n \) extra ends, where these maps agree.

Consider the extension \( \hat{h} \) of the deformation \( h \) from Claim [5,7]. The tropical part of \( \hat{h} \) is independent of \( t \), so we also have \( s_1^+h_1^+ = \hat{f}^+h_1^+ \circ \Phi^+1(h) \). In particular, given any metric \( \hat{h}_1 \) on \( \hat{B} \), the geodesic distance between \( s_1^+h_1^+ \) and \( \hat{f}^+h_1^+ \) is a continuous function on the domain, \( C(\hat{s}^+h_1^+) \). As \( s_1^+h_1^+ = \hat{f}^+h_1^+ \circ \Phi^+1(h) \), it follows that this distance is small on a neighborhood of \( C(\hat{s}^+h_1^+) \), and in particular, for all curves \( g \) in some neighborhood of \( h \), our deformation \( \hat{h} \) restricted to \( C(g) \) can be followed by a deformation to a curve \( g_1 \) with \( s_1^+h_1^+ = \hat{f}^+h_1^+ \circ \Phi^+1(g) \). In particular, this neighborhood is in \( O_2 \), and Claim [5,11] follows.

This completes the proof of Theorem [5.4].

The following proposition constructs a core family containing a given stable curve with at least one smooth component (so its domain is not \( T \)). Note that although Proposition 5.8 constructs a core family on the moduli stack of undecorated curves, Remark 5.24 implies that core families also exist around any curve in the moduli stack of decorated stable curves, \( \mathcal{M}^{st} \) (so long as this curve has at least 1 smooth component).

**Proposition 5.12.** Given a curve \( f \) in \( \mathcal{M}^{st} \) with a domain not equal to \( T \), and a collection of marked points \( \{p_j\} \) in the interior of the smooth components of \( C(f) \), there exists a \( C^\infty \) core family \( (\hat{f}/G, \{s_i\}) \) satisfying the requirements of Theorem 5.24 with \( \hat{f} \) a family containing \( f \) so that the restriction of \( \{s_i\} \) to \( f \) contains the given marked points \( \{p_j\} \).

**Proof:** Theorem 4.12 allows us to construct a family of curves \( \hat{f} \) containing \( f \), with universal tropical structure, and with a finite group \( G' \) of automorphisms acting freely and transitively on the set of maps of \( f \) into \( \hat{f} \). Moreover, Theorem 4.12 gives that the smooth part \( F(f) \) of the stratum of \( F(\hat{f}) \) containing \( f \) consists of a single point, and \( G' \) is a subgroup of the group \( G \) of automorphisms of the smooth part \( \hat{f} \) of \( f \). We may also assume that there is only one nodal curve in \( \hat{f} \) isomorphic to \( f \).

Let \( \hat{f}_0 \) be the quotient of \( G \times \hat{f} \) by the equivalence relation \( (g, \hat{f}) \simeq (gh^{-1}, h \cdot \hat{f}) \) for any \( h \in G' \). In other words, \( \hat{f}_0 \) is \( [G/G'] \) disjoint copies of \( \hat{f} \). \( G \) acts as a group of automorphisms on \( \hat{f}_0 \) by multiplying the \( G \) factor on the left; this \( G \)–action is free and transitive on the set of maps of \( f \) into \( \hat{f}_0 \). Moreover, this new family \( \hat{f}_0 \)

---

58See Remark 6.6 of [24].
59Definition 3.14 of [24].
also has universal tropical structure because having universal tropical structure is a locally-defined condition.

Choose an inclusion of \( f \) into \( \hat{f}_0 \), then choose a \( G \)-invariant collection of \( n \) non-intersecting sections \( s_i \) of \( C(\hat{f}_0) \rightarrow F(\hat{f}_0) \) such that the intersection of these sections \( s_i \) with \( C(f) \subset C(\hat{f}_0) \) correspond to a set of marked points \( \{p_i\} \) satisfying the following conditions:

1. These marked points \( \{p_i\} \) contain the set of marked points given in the statement of the theorem.
2. Each \( p_i \) is in a smooth component of \( C(f) \).
3. The action of \( G \) as the automorphism group of \( [f] \) permutes the marked points \( p_i \), and the action of \( G \) on the set of sections \( s_i \) is compatible: if \( g \) as an automorphism of \([C(f)]\) sends \( p_i \) to \( p_j \), then the action of \( g \) on \( F(\hat{f}_0) \) followed by \( s_j \) is equal to \( s_i \) followed by the action of \( g \) on \( C(\hat{f}_0) \). Representing the various actions of \( g \) simply as \( g \), we may write this condition as
   \[ g \ast p_i = p_j \quad \text{implies that} \quad s_j \circ g = g \circ s_i . \]
4. \( C(f) \) with the set of points \( p_i \) such that \( df \) is injective at \( p_i \) is stable.
5. The nodal Riemann surface \([C(f)]\) with the extra marked points \( \{p_i\} \) has no automorphisms.
6. There is at least one marked point on each smooth component of \( C(f) \).

Items 2, 3, 4 and 5 above remain true for the marked points obtained by intersecting \( \{s_i\} \) with \( C(f') \) for \( f' \) in a neighborhood of \( f \).

Following the notation of the proof of Theorem 5.4, let \( s: F(\hat{f}_0) \rightarrow F(\hat{f}_0 + n) \) be the map determined by the \( n \) sections, \( \{s_i\} \) — so the domain of the family of curves \( s^*\hat{f}_0 + n \) is \( C(\hat{f}_0) \) with extra ends at the images of \( s_i \).

**Claim 5.13.** If a curve \( h \) in \( f + n \) has smooth part \([h]\) isomorphic to the smooth part of a curve in \( s^*\hat{f}_0 + n \), then \( h \) is actually isomorphic to a curve in \( s^*\hat{f}_0 + n \).

To prove Claim 5.13 forget the extra marked points, and consider the corresponding isomorphism of \([f]\) with a curve in \([\hat{f}_0]\). As there was only one curve in \([\hat{f}_0]\) isomorphic to \([f]\), this isomorphism must decompose as an automorphism \( g_i \) of \([f]\) followed by our chosen inclusion \([f] \rightarrow \hat{f}_0 \), followed by the action of some \( g_2 \in G \). Item 3 implies that the pullback of \([s_i]\) under such an isomorphism is equal to the pullback of \([s_i]\) under our chosen inclusion \([f] \rightarrow \hat{f}_0 \) followed by the action of \( g_2 g_1 \). Therefore, the extra ends of \( h \) are located at the pullback of the sections \( s_i \) via our chosen inclusion of \( f \) into \( \hat{f}_0 \) followed by the action of an element of \( G \) — so, \( h \) is isomorphic to a curve in \( s^*\hat{f}_0 + n \), and Claim 5.13 is true.

Item 5 implies that each of the \([G]\) inclusions of \( f \) into \( \hat{f}_0 \) corresponds to a different intersection of \( ev^+n(f) \) with the image of \( ev^+n(\hat{f}_0) \circ s \), however some of these intersections may have the same smooth part. Claim 5.13 implies that no other curve in \( f + n \) has the same smooth part as a curve in \( s^*\hat{f}_0 + n \). We may therefore add extra marked points satisfying the above properties until \([ev^+n(f)]\) has precisely \([G]\) intersections with the image of \([ev^+n(\hat{f}_0) \circ s]\).

Let us verify that \( ev^+n(\hat{f}_0) \circ s \) has injective derivative. As the smooth part of the strata of \( F(\hat{f}_0) \) containing \( f \) is 0–dimensional, \( T_f F(\hat{f}_0) \) consists of only \( \mathbb{R} \)-nil vectors (whose fate is determined by the integral vectors). Let us determine what happens to integral vectors by considering the tropical structure of the map \( ev^+n(\hat{f}_0) \circ s \) at the curve \( f \). This is some integral-affine map \( P_0 \rightarrow P' \). This tropical structure records the image of \( \hat{f}_0 \circ s_i \), in \( \mathbb{R} \), and because of item 4 above, it also records
the length of the internal edges of curves in \( \hat{\mathcal{f}}_0 \). Because \( \hat{\mathcal{f}}_0 \) has universal tropical structure, Remark 3.3 of \cite{27} implies that the map \( P_u \rightarrow P' \) is injective and sends integral vectors on \( P_u \) to a full sublattice of the integral vectors on \( P' \). In other words, \( ev^{+n}(\hat{\mathcal{f}}_0) \circ s \) sends integral vectors in its domain to a full sublattice of the integral vectors in its target. Therefore, if \( f_0 \) is chosen small enough, \( ev^{+n}(\hat{\mathcal{f}}_0) \circ s \) is injective and has injective derivative.

Now let us prove that \( ev^{+n}(\hat{\mathcal{f}}_0) \) has injective derivative on a neighborhood of the image of \( s \). Item \( \mathfrak{A} \) above, ensures that, at the point \( s(f) \in \mathbf{F}(\hat{\mathcal{f}}_0^{+n}) \), the derivative of the smooth part of \( ev^{+n}(f) \) is injective. As each of the \( p_i \) are distinct and on smooth components of \( \mathbf{C}(f) \), a neighborhood of \( s(f) \) in \( \mathbf{F}(f^{+n}) \) is isomorphic to \( \mathbb{R}^{2n} \). So, the derivative of \( ev^{+n}(f) \) at this point is injective and has no nontrivial \( \mathbb{R} \)–nil vectors in its image. As the derivative of \( ev^{+n}(\hat{\mathcal{f}}_0) \circ s \) has only \( \mathbb{R} \)–nil vectors in its image, \( ev^{+n}(\hat{\mathcal{f}}) \) has injective derivative at the point \( s(\mathbf{F}(f)) \). Therefore, so long as \( f_0 \) is chosen small enough, \( ev^{+n}(\hat{\mathcal{f}}_0) \) is injective and has injective derivative, when restricted to a neighborhood of the image of \( s \).

To satisfy Criterion \( \mathfrak{B} \) of Theorem 5.4, we now extend \( \{\hat{\mathcal{f}}_0, \{s_i\}\} \) to \( \{\hat{\mathcal{f}}, \{s_i\}\} \) so that \( ev^{+n}(\hat{\mathcal{f}}) \) has bijective derivative on a neighborhood of the image of \( s \). The action of \( G \) permutes the \( n \) sections \( \{s_i\} \) — there is an action of \( G \) on \( \hat{\mathcal{f}}_0^{+n} \) lifting the action of \( G \) on \( \hat{\mathcal{f}}_0 \) and permuting the extra end labels so that \( s: \mathbf{F}(\hat{\mathcal{f}}_0) \rightarrow \mathbf{F}(\hat{\mathcal{f}}^{+n}) \) is \( G \)–equivariant. There is a corresponding \( G \)–action on \( \mathcal{M}(pt)^{+n} \times \hat{\mathcal{B}}_{n}^{\mathbf{B}} \), so that

\[
ev^{+n}(\hat{\mathcal{f}}_0): \mathbf{F}(\hat{\mathcal{f}}_0^{+n}) \rightarrow \mathcal{M}(pt) \times \hat{\mathcal{B}}_{n}^{\mathbf{B}} \]

is also \( G \)–equivariant. Choose a \( G \)–invariant metric\(^{60}\) on \( \mathcal{M}(pt)^{+n} \times \hat{\mathcal{B}}_{n}^{\mathbf{B}} \), and let \( U \) be some small \( G \)–invariant tubular neighborhood of the image of \( ev^{+n}(\hat{\mathcal{f}}_0) \) restricted to a neighborhood of the section \( s \). Let \( V \) be the restriction of this disk bundle \( U \) to the image of \( ev^{+n}(\hat{\mathcal{f}}_0) \circ s \), (so \( V \) has codimension \( 2n \) in \( U \)). As \( ev^{+n}(\hat{\mathcal{f}}_0) \) and \( ev^{+n}(\hat{\mathcal{f}}_0) \circ s \) are \( G \)–equivariant and the metric used to define our tubular neighborhood is \( G \)–invariant, \( V \) is \( G \)–invariant. Define \( \mathbf{F}(\hat{\mathcal{f}}) \) to be \( V \), and define \( \mathbf{C}(s^*\hat{\mathcal{f}}) \) by the following pullback diagram.

\[
\begin{array}{ccc}
\mathbf{C}(s^*\hat{\mathcal{f}}) & \longrightarrow & \mathcal{M}(pt)^{+(n+1)} \times \hat{\mathcal{B}}_{n}^{\mathbf{B}} \\
\downarrow & & \downarrow \\
\mathbf{F}(\hat{\mathcal{f}}) & \longrightarrow & \mathcal{M}(pt)^{+n} \times \hat{\mathcal{B}}_{n}^{\mathbf{B}}
\end{array}
\]

The action of \( G \) on \( \mathcal{M}(pt)^{+n} \times \hat{\mathcal{B}}_{n}^{\mathbf{B}} \) lifts to an action of \( G \) on \( \mathcal{M}(pt)^{+(n+1)} \times \hat{\mathcal{B}}_{n}^{\mathbf{B}} \), permuting the same end labels. Therefore, there is an action of \( G \) on the family of curves \( \mathbf{C}(s^*\hat{\mathcal{f}}) \) making the above diagram \( G \)–equivariant. By removing the extra edges in \( \mathbf{C}(s^*\hat{\mathcal{f}}) \), and remembering their location with sections \( s_i \), we get a \( G \)–invariant family of curves \( \mathbf{C}(\hat{\mathcal{f}}) \) making the \( \mathcal{M}(pt)^{+n} \times \hat{\mathcal{B}}_{n}^{\mathbf{B}} \) as the topology induced by a metric on an exploded manifold is finer than the usual topology.

\[^{60}\text{See Remark 6.6 of \cite{24} for a discussion of metrics on exploded manifolds. In the topology induced by a metric, an exploded manifold is a disjoint union of manifolds. Because metrics can be averaged, there is no obstruction to constructing a metric on an exploded orbifold using partitions of unity, or Proposition 2.3 of \cite{32}. In general, \( U \) will not be an open neighborhood in the usual topology on \( \mathcal{M}(pt)^{+n} \times \hat{\mathcal{B}}_{n}^{\mathbf{B}} \), as the topology induced by a metric on an exploded manifold is finer than the usual topology.}\]
There is a \( G \)-equivariant inclusion of \( C(f_0) \) as a subfamily of \( C(\hat{f}) \) via the diagram

\[
\begin{array}{ccc}
C(f_0) & \rightarrow & C(\hat{f}) \\
\downarrow & & \downarrow \\
F(f_0) & \rightarrow & F(\hat{f})
\end{array}
\]

and, the restriction of the sections \( s_i \) of \( C(\hat{f}) \rightarrow F(\hat{f}) \) are our original sections \( s_i \).

As \( F(f) \) is a disk bundle over \( F(f_0) \), \( C(f) \) is a disk bundle over \( C(f_0) \). We may therefore extend the map \( f_0 \) to a map \( \hat{f} \)

\[
\begin{array}{ccc}
C(\hat{f}) & \rightarrow & B \\
\downarrow & & \downarrow \\
F(\hat{f}) & \rightarrow & B_0
\end{array}
\]

so that \( ev^+(f) \circ s : F(\hat{f}) \rightarrow M(gt) \times B^n \) is the identity inclusion of \( V \). As this condition is \( G \)-equivariant and the original map \( f_0 \) is \( G \)-invariant, we may construct our map \( \hat{f} \) to be \( G \)-invariant.

As \( f \) is just the extension of \( f_0 \) to a disk bundle, Lemma 4.4 of [27] implies that \( \hat{f} \) has universal tropical structure. Therefore \( \hat{f} \) satisfies condition 5 of Theorem 5.4.

By construction, \( ev^+(f) \circ s \) is injective, and the derivative of \( ev^+(f) \) at \( s(f) \) is an isomorphism. Therefore, by restricting \( \hat{f} \) to a smaller \( G \)-invariant neighborhood of \( f \) if necessary, \( ev^+(\hat{f}) \) is an injective equidimensional submersion in a neighborhood of the image of \( s \). In other words, \( \hat{f} \) satisfies condition 4 of Theorem 5.4.

Condition 3 of Theorem 5.4 is satisfied because \( s \) is \( G \)-equivariant. Condition 2 is satisfied because of item 5 from the construction of \( \{ s_i \} \).

We shall now verify Condition 1 of Theorem 5.4. We have already established that there are precisely \( |G| \) intersections of \( [ev^+(f)] \) with \( [ev^+(f_0) \circ s] \) corresponding to the \( |G| \) maps of \( f \) into \( f_0 \). The corresponding intersections of \( ev^+(f) \) with the image of \( ev^+(f) \circ s \) are transverse (and 0-dimensional), and the same holds for the intersections of \( [ev^+(f)] \) with the image of \( [ev^+(f) \circ s] \), because the smooth part of the derivative of \( ev^+(f) \) at the intersection points is still injective. By restricting \( \hat{f} \) to a smaller \( G \)-equivariant neighborhood of \( f_0 \) if necessary, we therefore get that there are precisely \( |G| \) intersections of \( [ev^+(f)] \) with the closure of the image of \( [ev^+(f) \circ s] \), and that for any \( f' \) sufficiently close to \( f \) in \( \hat{f} \), there are also \( |G| \) transverse intersections of \( ev^+(f') \) with \( ev^+(f) \circ s \). Furthermore, we may ensure that there are no further intersections of \( [ev^+(f')] \) with the closure of \( [ev^+(f) \circ s] \). Therefore, by further reducing the size of \( \hat{f} \), we may ensure that for all \( f' \) in \( \hat{f} \), \( ev^+(f') \) intersects the closure of the image of \( ev^+(f) \circ s \) exactly \( |G| \) times. In other words, Condition 1 of Theorem 5.4 holds.

To verify Condition 1 of Theorem 5.4, we must verify that for all \( f' \) in \( \hat{f} \), the action of \( G \) on the set of maps \( f' \rightarrow f \) is free and transitive. As we have already shown that there are precisely \( |G| \) intersections of \( ev^+(f') \) with \( ev^+(f) \circ s \), there are at most \( |G| \) maps \( f' \rightarrow f \), and it remains to verify that the action of \( G \) on the set of these maps is free. This is easy, because the action of \( G \) does not fix the image of \( [C(f)] \) in \( [C(\hat{f})] \) under the inclusion \( f \rightarrow \hat{f} \), so the action of \( G \) can not fix any curve in a \( G \)-equivariant neighborhood of \( f \) within \( \hat{f} \). Therefore, Condition 1 of Theorem 5.4 will hold if we restrict \( \hat{f} \) to a small enough \( G \)-invariant open neighborhood of \( f \).
We have now verified that \((\hat{f}/G, \{s_1\})\) satisfies all the conditions of Theorem 5.3, so \((\hat{f}/G, \{s_1\})\) is a core family of curves.

\[\square\]

### 5.2. Topology of \(M^st\).

**Lemma 5.14.** Suppose that a sequence of curves \(f_i\) in \(M^st\) is eventually contained in every open substack of \(M^st\) that contains \(f\). Then \(f_i\) converges in \(C^{\infty, 1}_\top\) to \(f\) in the sense of Definition 11.4 of [23].

**Proof:**

The case when \(C(f) = T\) is easy, because curves with domain \(T\) form an easily analyzable open substack of \(M^st\); see Section 7.1. Accordingly, we assume that \(C(f) \neq T\), and construct a core family \((\hat{f}/G, \{s_1\})\) for an open substack \(O \subset M^st\) using Proposition 5.12 and Remark 5.2.

By assumption \(f_i\) is eventually contained in \(O\). Moreover, because the inverse image of any open substack of \(F(\hat{f})/\hat{G}\) under the map \(\Phi: O \rightarrow F(\hat{f})/\hat{G}\) is open, the image of \(\Phi(f_i)\) in \(F(\hat{f})/\hat{G}\) converges to the \(G\)-orbit of \(f \in F(\hat{f})\). So, by a judicious resolution of the \(G\)-fold ambiguity of \(\Phi(f_i)\) and \(\Phi^{+1}(f_i)\) from Definition 5.1 we can pick fiberwise-holomorphic maps

\[
\begin{align*}
C(f_i) & \xrightarrow{\Phi^{+1}(f_i)} C(\hat{f}) \\
\downarrow & \quad \downarrow \\
F(f_i) & \xrightarrow{\Phi} F(\hat{f})
\end{align*}
\]

whose image converge to \(C(f) \subset C(\hat{f})\). Given any fiberwise holomorphic map \(x: C(\hat{h}) \rightarrow C(\hat{f})\), there is an open subset of \(F(\hat{h})\) comprised of points \(p\) such that \(x\) restricted to the fiber over \(p\) an isomorphism onto a fiber of \(C\). This is because the degree of these maps is constant, and a degree–1 holomorphic map \(x\) between exploded curves is an isomorphism if its smooth part \([x]\) does not contract any components. Accordingly, there is an open subset of \(O\) such that the maps \(\Phi^{+1}(\hat{h})\) are isomorphisms restricted to each fiber, so our maps \(\Phi^{+1}(f_i)\) are eventually isomorphisms onto fibers.

After choosing a family of metrics on \(\hat{B} \rightarrow B_0\), so we exponentiate vectors, Remark 5.3 implies that there is an open substack of \(O\) comprised of curves \(h\) for which \(h = \text{Exp}_{\psi_h} \circ \hat{f}/G \circ \Phi^{+1}_h\) where \(\psi_h\) is a section of \((\hat{f}/G \circ \Phi^{+1}_h)^*T_{\text{vert}}B\) vanishing on the image of the sections \(s_i\), and \(\psi_h\) is small in any appropriately continuous norm. Moreover, we can choose a sequence of such norms so that convergence in these norms implies \(C^{\infty, 1}_\top\) convergence. As argued in the proof of Lemma 2.5.2 we can then extend each \(\psi_f\) to a section \(\psi_i\) of \((\hat{f}^*T_{\text{vert}}B)\) such that \(\psi_i\) converges in \(C^{\infty, 1}_\top\) to 0, and therefore \(f_i\) converges to \(f\) in the sense of Definition 11.4 of [23].

\[\square\]

We need the following technical lemma to prove that \(M^st\) has topology pulled back from a Hausdorff topological space, \([M^st\]^\top\].

**Lemma 5.15.** Let \(f_1\) and \(f_2\) be families of curves, and let \(g_k: C(g_k) \rightarrow C(f_1) \times C(f_2)\) be a sequence of stable holomorphic curves in the family of targets \(C(f_1) \times C(f_2) \rightarrow F(f_1) \times F(f_2)\) such that the sequence of points \(F(g_k)\) in \(F(f_1) \times F(f_2)\) converges. Suppose further that the projection of \(g_k\) to each \(C(f_i)\) is a degree 1 map, and that the genus and number of ends of \(C(g_k)\) is the same as the curves in...
\( \hat{f}_i \). Then there exist refinement \( g'_k \) of \( g_k \) and a subsequence of \( \{g'_k\} \) converging to a holomorphic curve in \( \mathcal{M}^{\infty,1}(C(f_1) \times C(f_2)) \).

**Proof:** We use Theorem 6.1 from [28] on the holomorphic curves \( g_k \) in the family of targets \( C(f_1) \times C(f_2) \rightarrow F(\hat{f}_1) \times F(\hat{f}_2) \). One condition of Theorem 6.1 is that the targets be basic, but a curve \( C(f) \) is basic if and only if its tropical part \( C(f) \) has no edge with both ends attached to a single vertex. Assuming that \( C(\hat{f}_1) \rightarrow F(\hat{f}_1) \) are indeed basic, Theorem 6.1 of [28] implies that some subsequence of these curves converges in \( C^{\infty,1} \) to a stable holomorphic curve.

**Claim 5.16.** There exists a basic family of curves \( \hat{f}'_1 \), an open subset \( U_1 \times U_2 \subset F(\hat{f}_1) \times F(\hat{f}_2) \) containing the limit of \( F(g_k) \) and complete finite degree maps \( r_i \) and \( r^{i+1} \) such that the following diagram commutes

\[
\begin{align*}
\text{C}(\hat{f}'_1) & \xrightarrow{r^{i+1}} \text{C}(\hat{f}_1|U_i) \subset \text{C}(\hat{f}_i) \\
\text{F}(\hat{f}'_1) & \xrightarrow{r_i} U_i \subset \text{F}(\hat{f}_i)
\end{align*}
\]

and such that the induced map \( \text{C}(\hat{f}'_1) \rightarrow \text{C}(r^{i+1}_* \hat{f}_i) \) is a refinement map and fiberwise holomorphic.

Before proving Claim 5.16 let us verify that Lemma 5.13 follows. Pass to a subsequence so that \( F(g_k) \) is contained \( U_1 \times U_2 \). As \( (r_1, r_2) \) is complete and finite degree, we can choose a sequence of points \( p_k \in (r_1, r_2)^{-1}(F(g_k)) \) that converge within \( F(\hat{f}_1) \times F(\hat{f}_2) \). Note that \( C(\hat{f}_1) \times C(\hat{f}_2) \rightarrow C(r_1^* \hat{f}_1) \times C(r_2^* \hat{f}_2) \) is a refinement map, so every stable holomorphic curve in \( C(r_1^* \hat{f}_1) \times C(r_2^* \hat{f}_2) \) lifts uniquely to a stable holomorphic curve in \( C(\hat{f}_1) \times C(\hat{f}_2) \) with a refined domain. (The domain of this lift is the fiber product with the refinement map.) In particular, we obtain a sequence of stable holomorphic curves \( g''_k \) in \( C(\hat{f}_1) \times C(\hat{f}_2) \) over the converging sequence of points \( p_k \), such that \( r^{i+1} : C(g''_k) \rightarrow C(g_k) \) is a refinement map, and the curve \( g^{i+1}_k = r^{i+1} \circ g''_k \) is a refinement of \( g_k \). Theorem 6.1 of [28] gives that a subsequence of \( g''_k \) converges to some stable curve \( g'' \), so the corresponding subsequence of \( g^{i+1}_k \) converges to \( r^{i+1} \circ g'' \), which is a refinement of a stable holomorphic curve in \( C(\hat{f}_1) \times C(\hat{f}_2) \).

To complete the proof of Lemma 5.16 it remains to prove Claim 5.16. If \( C(\hat{f}_i) \) is not basic, choose a coordinate chart \( \mathbb{R}^n \times T^m_P \) on \( F(\hat{f}_i) \) with the limit of the points \( F(g_k) \) contained in the stratum with tropical part the interior of the \( m \)-dimensional polytope \( P \). For notational convenience, we can assume that this chart covers \( F(\hat{f}_i) \). Local charts on \( C(\hat{f}_i) \rightarrow \mathbb{R}^n \times T^m_P \) containing interior edges of curves in \( \hat{f}_i \) are then isomorphic to maps \( \mathbb{R}^n \times T^m_{Q+1} \rightarrow \mathbb{R}^n \times T^m_P \), in the form \( (x, \tilde{z}_1, \ldots, \tilde{z}_m, \tilde{z}_{m+1}) \mapsto (z, \tilde{z}_1, \ldots, \tilde{z}_m) \), where the polytope \( Q \) is a subset of the inverse image of \( P \) under the projection \( \mathbb{R}^m \times \mathbb{R} \rightarrow \mathbb{R}^m \), constructed by intersecting with two half spaces, creating two extra faces, both projecting isomorphically to \( P \) — so these faces must be cut out by an equation in the form

\[
a_1 \tilde{z}_1 + \cdots + a_m \tilde{z}_m + \tilde{z}_{m+1} = c
\]

\[\text{See definitions 10.5 and 10.9 of [24] for refinements of curves. The need to take refinements is because of an assumption of Theorem 6.1 in [28] that an exploded manifold be basic. It should be possible to remove this assumption using a family of curves with universal tropical structure, from Theorem 4.8 of [27], then we would get that a subsequence of \( f_i \) converges to a stable holomorphic curve.}\]

\[\text{Definition 4.6 of [24].}\]
where $c \in \mathbb{R}$, $\alpha_1, \ldots, \alpha_m$ are integers, and $\alpha_{m+1} = 1$. This condition corresponds to the derivative of our family being surjective on integral vectors, a condition of Definition 10.1 of \cite{22}. Our exploded manifold $C(f_i)$ is non-basic if and only if there is some such stratum with both these faces glued to a single stratum in $C(f_i)$. We can deal with this problem by refining $C(f_i)$ in such a coordinate chart — subdividing $Q$ into two polytopes meeting at another face projecting isomorphically to $P$. However, the equation for this new face must be in the form \([10]\). If the top and bottom faces of $Q$ meet, there may be no such plane in the form \([10]\) between the top and bottom faces. If the function $h: P \to \mathbb{R}$ measuring the distance between the top and bottom faces has derivative divisible by $2$, the plane halfway between the top and bottom faces will be in the form \([10]\), so we can bisect $Q$ in this plane, refining our coordinate and obtaining a new family of curves. Similarly, if $h$ is divisible by $k$, then we can subdivide $Q$ by a plane $1/k$-th the distance between the top and bottom planes.

We are left with the case that $h$ has primitive integral derivative. After a $Z$-affine change of coordinates, we can assume that $h = \frac{1}{z_1}$. In this case we make a base change of our family using a complete degree 2 map $r: \mathbb{R}^n \times T^n_p \to \mathbb{R}^n \times T^n_p$, in the form $r(x, \hat{z}_1, \ldots, \hat{z}_m) = (x, \hat{z}_1^2, \hat{z}_2, \ldots, \hat{z}_m)$, obtaining a new family $\hat{f}_{i,1}$ of curves such that the following is a pullback diagram

$$
\begin{array}{ccc}
C(r^*\hat{f}_i) & \to & C(\hat{f}_i) \\
\downarrow & & \downarrow \\
\mathbb{R}^n \times T^n_p & \xrightarrow{r} & \mathbb{R}^n \times T^n_p
\end{array}
$$

Then we can refine $C(\hat{f}_{i,1})$ by bisecting $Q \times_p P'$ as above. Similarly, if there are other problematic edges, by using some complete finite degree map $r$ we can pull back our family, then refine the resulting family $r^*\hat{f}_i$ to obtain a basic family of curves $\hat{f}'_i$. This completes the proof of Claim 5.16 and therefore the proof of Lemma 5.15.

Recall Example 2.42 where we defined a topological space $[X_{top}]$ with points equivalence classes of topologically indistinguishable individual objects in $X$.

**Lemma 5.17.** Two curves $f_i$ in $M_{\bullet}^t$ are topologically indistinguishable if and only if there is some family $\hat{f}$ with maps $f_i \to \hat{f}$ whose image in $[F(\hat{f})]$ is the same point. Moreover, $[M_{\bullet}^t_{top}]$ is Hausdorff.

**Proof:** Again, we neglect the easy case of a curve with domain $T$; see Section 7.1 for a description of the moduli stack in this case. Choose a core family $(O, f/G, s_i)$ containing $f_1$ such that the action of $G$ fixes $[f_1] \subset [F(\hat{f})]$. For any family $\hat{h} \in \mathcal{O}$, there is a closed subset of $\mathcal{F}(\hat{h})$ comprised of $h$ such that $\hat{f} \circ \Phi^1(\hat{h}) = h \cdot G$, and the image of $[\Phi^1(\hat{h})]$ in $\mathcal{F}(\hat{f})$ is $[f] \subset \mathcal{F}(\hat{f})$. Accordingly, there is a closed substack of $O$ comprised of such curves. As this closed substack contains $f_1$, it must also contain any topologically indistinguishable curve $f_2$. Moreover, $\Phi^1(f_2)$ defines $[G]$ maps $f_2 \to f$, all sent to the same point in $[F(\hat{f})]$. So, we now have two inclusions $f_1 \to f_\hat{f}$ sent to the same point in $[F(\hat{f})]$, and the first part of our lemma is proved.

Let us verify that $[M_{\bullet}^t_{top}]$ is Hausdorff. Suppose that $f_1$ and $f_2$ are curves in $[M_{\bullet}^t_{top}]$ without disjoint open neighborhoods. It follows from Lemma 5.14 that there is some sequence of curves $g_k$ converging in $C^\infty_{-\infty}$ to both $f_1$ and $f_2$. We must prove that $f_1$ and $f_2$ are topologically indistinguishable.

Choose core families $\hat{f}_i/G_i$ containing $f_i$ with corresponding fiberwise holomorphic maps $\Phi_i: O_i \to \hat{f}_i/G_i$. By passing to a subsequence, we assume that our
sequence \( g_k \) is contained in both \( \mathcal{O}_1 \) and \( \mathcal{O}_2 \). Recall that \( \Phi_\ast(g_k) \) is a \( G_\ast \)-bundle \( g_k \to g_k \) with a \( G_\ast \)-equivariant holomorphic map \( \Phi_\ast^{-1}(g_k): C(g_k) \to C(\hat{f}_i) \). Choose a metric on \( \mathcal{B} \), and note that there is an open substack of \( \mathcal{O}_1 \) comprised of curves \( g \) such that the distance between the maps \( \hat{f}_i \circ \Phi_\ast(g_k) \) and \( g \to g \) is less than \( \epsilon \). Accordingly, we can assume that the distance in our metric between \( \hat{f}_i \circ \Phi_\ast(g_k) \) and \( g_k \to g_k \) converges to 0. After a judicious choice of sections of \( g_k \to g_k \), and passing to a subsequence, we then get maps \( \Phi_{i,k}: C(g_k) \to C(\hat{f}_i) \) that are isomorphisms onto fibers of \( C(f_i) \to C(\hat{f}_i) \), and whose image converge to \( C(f_i) \subset C(\hat{f}_i) \) (and also converge to the domain of any curve topologically indistinguishable from \( f_i \)).

It follows from Lemma 5.15 that the holomorphic curves \( (\Phi_{1,k}, \Phi_{2,k}): C(g_k) \to C(f_1) \times C(f_2) \) have a subsequence of refinements that converge in \( C^\infty \) to a refinement \( \phi' \) of some stable holomorphic curve \( \phi: C(h) \to C(\hat{f}_1) \times C(\hat{f}_2) \). As the distance in our metric between the maps \( \hat{f}_1 \circ \Phi_{1,k}: C(g_k) \to \mathcal{B} \) and \( \hat{f}_2 \circ \Phi_{2,k}: C(g_k) \to \mathcal{B} \) converges to 0 (and the same is true of our refinements of these curves) it follows that we can choose our limit \( \phi' \) such that \( \hat{f}_1 \circ \pi_1 \circ \phi' = \hat{f}_2 \circ \pi_2 \circ \phi' \) where \( \pi_i \) is the projection \( C(\hat{f}_1) \times C(\hat{f}_2) \to C(\hat{f}_i) \). We need a little care, because this distance is only defined at points in \( C(\hat{f}_1) \times C(\hat{f}_2) \) sent by \( \hat{f}_1 \circ \pi_1 \) to the same point in \( \mathcal{B} \). There is a refinement of \( C(\hat{f}_1) \times C(\hat{f}_2) \) such that the set of all such points is a union of strata, and so that for any sequence of points converging to a stratum where the distance is undefined, the distance converges to infinity. We can choose our limit \( \phi' \) to also be a limit in this refinement, so our distance must be defined, and 0 on the image of \( \phi' \). Of course, the same equation holds for the unrefined limit, \( \phi \). Accordingly, define the curve \( h : C(h) \to \mathcal{B} \) as

\[
    h := \hat{f}_1 \circ \pi_1 \circ \phi .
\]

We have that \( \pi_i \circ \phi : C(h) \to C(\hat{f}_i) \) is a degree 1, genus-and-end-preserving holomorphic map onto the domain of some curve \( f'_i \) topologically indistinguishable from \( f_i \), and that \( h = \hat{f}_2 \circ \pi_2 \circ \phi \). If this degree 1 holomorphic map is not an isomorphism, there must be some component of the nodal curve \([C(h)]\) sent to a single point in some \([C(\hat{f}_i)]\), and this component must be a sphere with one or two special points. Moreover, this component must be sent to a single point in \([\mathcal{B}]\), so it must be collapsed to a single point in \([C(\hat{f}_1) \times C(\hat{f}_2)]\), because curves in both \( \hat{f}_i \) are stable. This collapsed component contradicts the fact that \( \phi : C(h) \to C(\hat{f}_1) \times C(\hat{f}_2) \) is stable. Therefore, \( \pi_i \circ \phi \) defines an isomorphism \( h \to f' \). As the curves \( f'_1 \) and \( f'_2 \) are isomorphic, and topologically indistinguishable from \( f_1 \) and \( f_2 \), it follows that \( f_1 \) and \( f_2 \) are topologically indistinguishable, and \([M_{st}^\ast]_{top}\) is Hausdorff, as required.

In [28] we prove in many situations that \( \mathcal{M}(\mathcal{B}) \to \mathcal{B}_0 \) is proper when \( \mathcal{M} \) is restricted to connected components of \( M_{st}(\mathcal{B}) \). In [28], this properness was stated as every sequence of holomorphic curves in a connected component of \( M_{st}^\ast \) over a convergent sequence in \( \mathcal{B}_0 \) must have a subsequence that converges in \( C^\infty \). The next lemma allows us to conclude that such sequential compactness implies compactness.

**Lemma 5.18.** \( M_{st}^\ast \) is a countable union of strata, each with a metric which induces the subspace topology on any sequentially compact subset of \([M_{st}^\ast]_{top}\). So any sequentially compact subspace of \([M_{st}^\ast]_{top}\) is a countable union of metrizable strata.
Proof:
For a stable curve $f$, restricting any core family $\hat{f}$ containing $f$ to the set of curves in $f$ with the same image in $[F(\hat{f})]$ gives a family, $\hat{f}$, of curves topologically indistinguishable from $f$. This family $\hat{f}$ has the property that any connected family of curves $h$ topologically indistinguishable from $f$ admits exactly $G$ maps into $\hat{f}$, where $G$ is the subgroup of the automorphism group of $f$ preserving the image of $f$ in $[F(\hat{f})]$. Any two such $f \to \hat{f}$ are canonically isomorphic.

For this lemma, stable curves $f_1$ and $f_2$ will be in the same stratum if there exists an invertible map $\phi: C(f_1) \to C(f_2)$ such that the following diagram commutes

\[
\begin{array}{ccc}
C(f_1) & \phi \to & C(f_2) \\
\downarrow & & \downarrow \\
F(\hat{f}_1) & \to & F(\hat{f}_2)
\end{array}
\]

and such that $\hat{f}_1 = \phi \circ \hat{f}_2$. For $f_1$ and $f_2$ to be indistinguishable, we need $\phi$ to be holomorphic, and we need that the maps $f_1$ and $f_2 \circ \phi$ coincide. The strata of $[C(\hat{f})] = [C(f)]$ corresponding to vertices of $C(f)$ are punctured Riemann surfaces. If such a stratum is stable, it has a canonical complete hyperbolic metric, and we can therefore measure the size of $\partial \phi$ using the metric on the domain and codomain. Define $|\partial \phi|_\infty$ to be the supremum of $|\partial \phi|$ over all these stable strata. On any unstable stratum, we assume that $\phi$ is holomorphic.

Choose a metric on $B$, and let $d(x, y)$ be the distance in this metric between any two points $x$ and $y$ with the same tropical part in $B$. Then, for any two stable curves $f_1$ and $f_2$ in the same stratum, define

\[
d(f_1, f_2) := \inf_{\phi} \left( \sup_{x \in C(f_1)} \text{dist}(\hat{f}_1(x), \hat{f}_2 \circ \phi(x)) + |\partial \phi|_\infty + |\partial \phi^{-1}|_\infty \right)
\]

where the infimum is over all invertible maps $\phi$ such that (17) commutes and such that $\phi$ is holomorphic on unstable components. This $d(\cdot, \cdot)$ is symmetric, non-negative, and satisfies the triangle inequality. It remains to check that there are only countably many strata, and that $d(\cdot, \cdot)$ induces the subspace topology on any sequentially compact subset.

Claim 5.19. Let $X$ be a sequentially compact substack of $\mathcal{M}^s$, and let $h_i$ be a sequence of curves in $X$. If $d(h_i, f)$ converges to 0, then $h_i$ converges in $C^\infty\frac{\Delta}{G}$ to $f$.

To prove Claim 5.19 it suffices to prove that every subsequence of $\{h_i\}$ has a subsequence converging to $f$. By assumption, each subsequence of $\{h_i\}$ must converge to some stable curve in $C^\infty\frac{\Delta}{G}$, so without losing generality, we may assume that $h_i$ converge to some stable curve $h$, and using Lemma 2.52 we can assume that $h_i$ converge to $h$ within a family of curves $h$. It remains to show that $h$ is topologically equivalent to $f$. Choose a core family $\hat{f}/G$ containing $f$. Each neighborhood of $\hat{f}$ in $\hat{f}$ contains curves with all complex structures close to $\hat{f}$, so there exists a sequence of holomorphic maps $\phi_i: C(h_i) \to C(\hat{f})$ which are holomorphic isomorphisms onto fibers of $C(\hat{f}) \to F(\hat{f})$ converging in $[F(\hat{f})]$ to the image of $f$ such that

\[
\text{dist}(h, \hat{f} \circ \phi_i)
\]

converges to 0. Arguing, using Lemma 5.18 as in the proof of Lemma 5.17 implies that $h$ is topologically equivalent to $f$, completing the proof of Claim 5.19.

Note that Claim 5.19 also implies that $d(f, h) = 0$ if and only if $f$ and $h$ are topologically indistinguishable, so $d(\cdot, \cdot)$ is nondegenerate, and defines a metric on our stratum of $[\mathcal{M}^s_{\text{top}}]$. 

70 BRETT PARKER
Claim 5.20. If a sequence of stable curves $f_i$ are in the same stratum as $f$, and $f_i$ converges to $f$, then $\lim_{i \to \infty} d(f_i, f) = 0$.

To prove Claim 5.20, choose a core family $(\mathcal{O}, f/G, \Phi)$ containing $f$. As $f_i$ converges to $f$, $f_i$ (and therefore $\hat{f}_i$) is eventually contained in $\mathcal{O}$, and the image of $\Phi f_i$ converges to the image of $f$ in $[F(\hat{f})/G]$. Condition 2 of Definition 5.1 implies that, after passing to a subsequence, we can assume that $\hat{f}/G \circ \Phi f_i^{+1}$ is a $\mathbb{R}$-deformation of $\hat{f}_i$, and therefore these two stable curves are in the same stratum of $\mathcal{M}^{st}$. Use $\hat{f}_i' \in \hat{f}$ for some choice of curve in $f$ isomorphic to this $\mathbb{R}$-deformation of $\hat{f}_i$, so that the image of $f_i'$ converges to $f$ in $\hat{f}$. By assumption, $f_i$ and $f_i'$ are in the same stratum of $\mathcal{M}^{st}$ as $f$, and therefore $F(\hat{f})$ is isomorphic to $f_i'$, so the tropical part of the strata of $F(\hat{f})$ containing these $\hat{f}$ and $f_i'$ must have the same dimension. As the image of $f_i'$ also converges to the image of $f$ in $F(\hat{f})$, this implies that $f_i'$ and $f$ must be in the same stratum of $F(\hat{f})$. On a neighborhood of $C(f)$ within this stratum, $C(\hat{f}) \to F(\hat{f})$ is isomorphic to $\mathbb{R}^n \times C(f) \to \mathbb{R}^n \times F(\hat{f})$ (where the complex structure on fibers may vary smoothly with the $\mathbb{R}^n$ coordinates). Projecting out the $\mathbb{R}^n$-direction, we obtain isomorphisms $\phi_i : C(\hat{f}_i) \to C(\hat{f})$ which we can use to verify that $d(f_i, f)$ converges to 0.

Claims 5.10 and 5.20 along with lemmas 5.14 and 5.21 imply that $d(\cdot, \cdot)$ induces the subspace topology on any sequentially compact subset of a stratum of $[\mathcal{M}^{st}]$. We must now check that $\mathcal{M}^{st}$ has only countably many strata.

Claim 5.21. Two stable curves $f$ and $h$ are in the same stratum of $\mathcal{M}^{st}$ if and only if there exists a strata-preserving homeomorphism $\mathcal{B} : [C(f)] \to [C(h)]$ such that

- for each stratum $s$ of $[C(f)]$, $[h]$ sends $b(s)$ to the stratum of $[\mathcal{B}]$ containing $[f](s)$; and
- Note that 0-dimensional strata of $[C(f)]$ correspond to edges of $C(f)$. If $s$ corresponds to an internal edge, then a neighborhood of $s \subset [C(f)]$ is homeomorphic to two disks joined at the origin. An orientation of this edge corresponds to a choice of one of these disks, so $b$ induces a bijection between oriented edges $e \subset C(f)$ and oriented edges $b(e) \subset C(h)$. We have that $f(e)$ and $b(b(e))$ are in the same stratum of $\mathcal{B}$ so we can compare their derivatives $\alpha_e$ and $\alpha_{b(e)}$, which are integral vectors. The last condition on our homeomorphism is that $\alpha_e = \alpha_{b(e)}$.

Up to homeomorphism, there are only countably many nodal curves with marked points. Moreover, each $C(f)$ only has finitely many strata, and $\mathcal{B}$ has at most countably many strata, and each stratum only has countably many integral vectors. So, Claim 5.21 implies that $\mathcal{M}^{st}$ has countably many strata, and to finish the proof of Lemma 5.18 we need only prove Claim 5.21.

Let us identify $F(\hat{f})$ using Remark 3.3 of [27], but simplifying using that $\mathcal{B}$ is basic. For each vertex $v$ of $C(\hat{f})$, let the polytope $P_v$ be the closure of the stratum $P_v^o$ of $\mathcal{B}$ containing $v$. There is a natural map $A_v : F(\hat{f}) \to P_v^o$ given by evaluating $\hat{f}$ on the stratum of $C(\hat{f})$ containing $v$. Moreover, for each internal edge $e$ of $C(\hat{f})$, there is a natural map $l_e : F(\hat{f}) \to (0, \infty)$ that records the length of the edges of fibers of $C(\hat{f}) \to F(\hat{f})$ corresponding to $e$. Remark 3.3 of [27] tells us that $\prod A_v \prod l_e$ is a $\mathbb{Z}$-affine embedding of $F(\hat{f})$ in $\prod P_v^o \times (0, \infty)^k$, where $f$ has $k$ internal edges, and tells us that this embedding is onto a sub-polytope cut out by $\mathbb{Z}$-affine equations. In this case, the $\mathbb{Z}$-affine equations are also very easy to
describe: Orient an internal edge of \( F(\bar{f}) \), so that it has a well-defined derivative \( \alpha_e \), and is attached at its beginning to a vertex \( v_1 \) and at its end to a vertex \( v_2 \). Note that polytopes \( P_v \) are faces of the polytope \( P_e \) containing the image of \( e \). Then, for any \( x \in F(\bar{f}) \),
\[
A_{v_1}(x) + l_e(x)\alpha_e = A_{v_2}(x)
\]
and such equations for all internal edges \( e \) are all the equations that cut out \( F(\bar{f}) \) as a sub-polytope of \( \prod_v P_v \times (0, \infty)^k \). As described in Remark 3.3 of [27], \( C(\tilde{f}) \) and \( \tilde{f} \) is also determined by this construction. In particular, given points \( A_v(x) \in P_v \) and lengths \( l_e(x) \) satisfying these equations, there is a unique tropical curve that is a continuous deformation of \( \bar{f} \) with these edge lengths and vertices at the chosen positions in \( P_v \), and this curve is the fiber of \( \bar{f} \) over \( x \in F(\bar{f}) \). From this construction, what we need is the following: given a homeomorphism between \( C(f) \) and \( [C(h)] \) satisfying the conditions of Claim 5.21, we there is an isomorphism between \( \tilde{f} \) and \( \tilde{h} \), and in particular an isomorphism \( \phi: C(\bar{f}) \rightarrow C(\bar{h}) \) such that \( \tilde{h} \circ \phi = \tilde{f} \).

By choosing a different curve in \( \tilde{h} \) if necessary, we can now reduce to the case \( f \) and \( h \) have the same tropical part, so \( \phi \) sends \( C(f) \) to \( C(h) \subset C(\bar{h}) \). The local model for edges of curves depends only on their length, so there exists a holomorphic isomorphism \( \phi_0 \) from a neighborhood of the edges of \( C(f) \) to a neighborhood of the edges of \( C(h) \) such that the tropical part of \( \phi_0 \) agrees with \( \phi \). We can choose a smooth representative of our homeomorphism \( \phi: [C(f)] \rightarrow [C(h)] \) that agrees with \( \phi_0 \) on a neighborhood of all special points in \( [C(f)] \). There is then a unique smooth isomorphism \( C(f) \rightarrow C(h) \) with smooth part \( b \) and tropical part \( \tilde{b} \). Moreover, this isomorphism extends uniquely to an isomorphism \( \phi: C(\tilde{f}) \rightarrow C(\tilde{h}) \) with tropical part \( \tilde{b} \). This \( \phi \) is the isomorphism required to show that \( \tilde{f} \) and \( h \) are in the same stratum of \( \mathcal{M}^{st}(B) \), which concludes the proof of Claim 5.21 and Lemma 5.18.

Corollary 5.22. Any sequentially compact substack \( \mathcal{X} \) of \( \mathcal{M}^{st} \) is compact.

Proof:

Any countable open cover \( \mathcal{U}_k \) of \( \mathcal{X} \) must have a finite subcover. If not, we could choose a sequence of curves \( f_i \) in \( \mathcal{X} \) such that \( f_i \) is not in \( \mathcal{U}_k \) for all \( j \leq i \). Then Lemma 5.15 implies that no subsequence of would converge to a curve in \( \mathcal{X} \), contradicting the assumption that \( \mathcal{X} \) is sequentially compact. To show that \( \mathcal{X} \) is compact, we therefore only need to show that every open cover of \( \mathcal{X} \) has a countable sub cover. Lemma 5.18 implies that the subspace \( \mathcal{X}_{top} \subset [\mathcal{M}^{st}_{top}] \) is a countable union of metrizable strata. Each metrizable stratum admits a countable subcover, because metric spaces are second countable, therefore \( \mathcal{X} \) also admits a countable subcover.

\[ \square \]

Lemma 5.23. Suppose that any sequence of holomorphic curves in a connected component of \( \mathcal{M}^{st}(B) \) over a convergent sequence in \( B_0 \) has a subsequence that converges in \( C^{\infty, \mathbb{Q}} \).

If \( G/\mathcal{O} \) is a core family for the open substack \( \mathcal{O} \) of \( \mathcal{M}^{st}(B) \), and \( f \) is a holomorphic curve in \( f \), there exists a continuous function \( \rho: \mathcal{O} \rightarrow \mathbb{R} \) such that \( \rho(f) = 1 \), and such that any holomorphic curve in the closure (within \( \mathcal{M}^{st}(B) \)) of \( \{ \rho > 0 \} \) is contained in \( \mathcal{O} \).

Proof:
Roughly speaking, this lemma holds because weak convergence of holomorphic curves to \( f \) — detected by continuous functions on \( \mathcal{O} \) — automatically implies \( C^\infty_\Delta \) convergence.

Choose a family of metrics on the fibers of \( \hat{\mathcal{B}} \to B_0 \), and use \( \text{dist}(x, y) \) to denote the distance between two points in \( \mathcal{B} \) using this metric. Recall that Definition 5.1 tells us that given any family of curves \( \hat{h} \in \mathcal{O} \), there is a canonical fiberwise-holomorphic map

\[
\begin{array}{rcl}
\mathcal{C}(\hat{h}) & \xrightarrow{\Phi^-_h} & \mathcal{C}(\hat{f})/G \\
\downarrow & & \downarrow \\
\mathbf{F}(\hat{h}) & \xrightarrow{\Phi_h} & \mathbf{F}(\hat{f})/G
\end{array}
\]

and that composing this map with the map \( \hat{f}/G : \mathcal{C}(\hat{f})/G \to \hat{\mathcal{B}} \) gives another family of curves

\[
\hat{f}/G \circ \Phi^{+1}_h : \mathcal{C}(\hat{h}) \to \hat{\mathcal{B}}
\]

which is a deformation of \( \hat{h} \), so \( \text{dist}(\hat{h}(x), \hat{f}/G \circ \Phi^{+1}_h(x)) \) is bounded and a continuous function on \( \mathcal{C}(\hat{f}) \).

Choose a proper \( C^\infty_\Delta \) function \( r_0 : \mathbf{F}(\hat{f})/G \to [0, \infty) \) equal to 0 only on the \( G \)-orbit of \( f \), (and curves with the same smooth part) — so \( r(p_i) \to 0 \) implies \( p_i \) converges to \( f \in \mathbf{F}(\hat{f}) \) or some \( G \)-translate of \( f \). For any family of curves \( \hat{h} \) in \( \mathcal{O} \) define

\[
r : \mathbf{F}(\hat{h}) \to [0, \infty)
\]

as

\[
r(h) := \sup_{x \in \mathcal{C}(h)} \text{dist}(h(x), \hat{f}/G \circ \Phi_h(x)) + r_0(\Phi_h)
\]

Clearly, \( r(h) \) depends only on \( h \), and for each family \( \hat{h} \) in \( \mathcal{O} \), \( r : \mathbf{F}(\hat{h}) \to [0, \infty) \) is continuous, so \( r \) defines a continuous map

\[
r : \mathcal{O} \to [0, \infty).
\]

Claim 5.24. There exists an \( \epsilon > 0 \) such that any holomorphic curve in the closure within \( \mathcal{M}^{st} \) of \( \{ r < \epsilon \} \) must be contained in \( \mathcal{O} \).

To prove Claim 5.24 suppose to the contrary that there exists a sequence of holomorphic curves \( \{ h_i \} \) not in \( \mathcal{O} \) such that for all \( \epsilon \), \( \{ h_i \} \) is eventually contained in the closure of the substack where \( r < \epsilon \). It follows that the image of \( h_i \) in \( B_0 \) converges, and \( \{ h_i \} \) is eventually contained in a connected component of \( \mathcal{M}^{st} \).

Our assumption on the properness of the map \( \mathcal{M} \to B_0 \) then implies that some subsequence of \( \{ h_i \} \) converges in \( C^\infty_\Delta \) to a stable holomorphic curve \( h \).

As \( \mathcal{O} \) is open, our holomorphic curve \( h \) must not be in \( \mathcal{O} \). On the other hand, for all \( \epsilon \), \( h \) is in the closure of the substack of \( \mathcal{O} \) where \( r < \epsilon \). We shall achieve a contradiction by showing that this implies that \( h \) and \( f \) are topologically indistinguishable.

Lemma 5.14 implies that there is a sequence of curves \( \{ f_i \} \) in \( \mathcal{O} \) converging in \( C^\infty_\Delta \) to \( h \), and such that \( r(f_i) \) converges to 0. Lemma 2.52 implies that, by passing to a subsequence, we may assume that \( f_i \) converge to \( h \) within some \( C^\infty_\Delta \) family \( \hat{h} \) containing \( h \).

As \( r_0 \circ \Phi_{f_i} \) converges to 0, the images of \( \mathcal{C}(f_i) \) in \( \mathcal{C}(\hat{f})/G \) converge to \( \mathcal{C}(f) \).

By a judicious choice of resolution of the \( G \)-fold ambiguity of the map \( \Phi_{f_i}^{+1} \), we obtain inclusions \( \mathcal{C}(f_i) \to \mathcal{C}(\hat{f}) \) converging to \( \mathcal{C}(f) \) which we shall again call \( \Phi_{f_i}^{+1} \). Applying Lemma 5.15 as in the proof of Lemma 5.17 then gives a stable
holomorphic curve $\phi$ in $C(\hat{h}) \times C(\hat{f})$ with image in $C(h') \times C(f')$ for curves $h'$ and $f'$ topologically indistinguishable from $h$ and $f$, and such that
\[ \text{dist} (\hat{h} \circ \phi, \hat{f} \circ \phi) = 0 \],
so $\hat{h} \circ \phi = \hat{f} \circ \phi$. As in the proof of Lemma 5.17, the stability of $\phi$, $h'$ and $f'$ implies that $\hat{h} \circ \phi$ is isomorphic to $h'$ and $\hat{f} \circ \phi$ is isomorphic to $f'$, so $h$ and $f$ are topologically indistinguishable. This completes the proof of Claim 5.24.

We now have that there exists some $\epsilon$ so that all holomorphic curves in the closure of \( \{ r > \epsilon \} \) are contained in $O$. To complete the proof of our lemma, all we need to do is compose $r$ with a cut off function equal to $1$ at 0 and vanishing outside of an $\epsilon$–neighborhood of 0. The resulting continuous function $\rho: O \rightarrow [0,1]$ is $1$ at $f$ and has the property that any holomorphic curve in the closure of \( \{ \rho > 0 \} \) is contained in $O$. This completes the proof of Lemma 5.23.

□

6. Locally representing the moduli stack of solutions to $\bar{\partial}f \in V$

The goal of this section is to prove Theorem 6.8 — for a simply-generated subsheaf $V$ of $Y$ transverse to $\bar{\partial}$ at a holomorphic curve $f$, the moduli stack of curves $f'$ with $\bar{\partial}f' \in V(f')$, is locally represented by $\hat{f}/G$, where $\hat{f}$ is a family of curves containing $f$ and $G$ is a finite group of automorphisms.

Proposition 6.1 below is a way of locally representing the moduli stack of holomorphic parametrized by the domain of a particular family of holomorphic curves. This proposition is then used in Lemma 6.4 to prove that an arbitrary simply-generated subsheaf $V$ may be parametrized by a family of curves. With $V$ written in this special form, the results of [31] imply Theorem 6.8.

**Proposition 6.1.** Given any family of holomorphic curves $\hat{f}$ in $\hat{B}$ containing a given curve $f$, there exists a $C^\infty$ family of curves $\hat{f}^*$ in $\hat{B}$ satisfying the following properties:

1. There is an inclusion $\iota: \hat{f} \rightarrow \hat{f}^*$ and a map
\[ C(\hat{f}^*) \xrightarrow{\psi} C(\hat{f}) \]
\[ F(\hat{f}^*) \rightarrow F(\hat{f}) \]
that is a holomorphic isomorphism restricted to each fiber. Moreover $C(\iota)$ and $\psi$ are related so that $C(\hat{f}^*)$ is isomorphic to a vectorbundle over $C(\hat{f})$ with projection $\psi$ and zero section $C(\iota)$.

2. There exists an open neighborhood $O$ of $(\text{id}, f)$ in the moduli stack of $C^\infty$\-curves in $C(\hat{f}) \times B$, such that every family $(\psi', \hat{h})$ of holomorphic curves in $O$ has a unique map to $(\psi, \hat{f}^*)$ — so $\hat{h}$ is a family of holomorphic curves in $B$ and $\psi'$ is fiberwise-holomorphic-isomorphism map $\psi': C(\hat{h}) \rightarrow C(\hat{f})$, and there exists a unique map $\hat{h} \rightarrow \hat{f}^*$ such that the following diagram commutes.

\[ \begin{array}{ccc}
C(\hat{h}) & \xrightarrow{\hat{h}} & B \\
\downarrow^{\psi'} & & \downarrow^{f^*} \\
C(\hat{f}) & \xleftarrow{\psi} & C(\hat{f}^*)
\end{array} \]
Suppose furthermore that $\hat{\mathcal{B}}$ has a group, $G_0$, of automorphisms and that there is a group $G_0 \times G$ of automorphisms of $C(\hat{f}) \rightarrow F(\hat{f})$ such that $\hat{f}$ is $G$–invariant and $G_0$–equivariant. Then $f^*$ may be constructed so that $C(f^*) \rightarrow F(f^*)$ has a group $G_0 \times G$ of automorphisms, $\psi$ and $\iota$ are $G_0 \times G$–equivariant, and $f^*$ is $G$–invariant and $G_0$–equivariant.

**Remark 6.2.** The intersection of $\bar{\partial}\hat{f}^*$ with 0 should be regarded as representing the moduli space of holomorphic curves close to $\hat{f}$ and parametrized by $C(\hat{f}) \rightarrow F(\hat{f})$.

In the case when $G_0 \times G$ is nontrivial, \{\(f' \in \hat{f}^* \text{ such that } \bar{\partial}f' = 0\)\}/$G_0 \times G$ should be regarded as representing the moduli stack of holomorphic curves in $\hat{B}/G_0$ parametrized by $C(f)/ (G_0 \times G)$. The point of Proposition 6.1 is that this moduli stack is locally represented as a finite quotient of a subset of a finite-dimensional $C^\infty$ family of curves.

**Proof:**

We prove the equivariant case. Using a $G_0$–invariant, smooth, $J$–preserving connection on $T_{vert}\hat{B}$, we may construct a $G_0 \times G$–invariant trivialization $(F, \phi)$ to associate to $\hat{f}$. More precisely, define the map $F: f^*T_{vert}\hat{B} \rightarrow \hat{B}$ by exponentiating using our invariant connection (and reparametrizing in a $G_0 \times G$–equivariant way to ensure injectivity of $TF$ restricted to any vertical tangent space), and define $\phi: F^*T_{vert}\hat{B} \rightarrow \hat{f}^*T_{vert}\hat{B}$ using parallel transport, along a straight line homotopy, using our connection. Such a $F$ is $G$–invariant and $G_0 \times G$–equivariant, and $\phi$ is $G_0 \times G$–equivariant. Using such a trivialization, $\bar{\partial}: X^\infty\hat{\mathcal{L}}(f) \rightarrow \mathcal{Y}(\hat{f})$ is $G_0 \times G$–equivariant.

Given any family of curves $\hat{h}$ in $\hat{B}$ and a fiberwise-holomorphic-isomorphism map $\psi'$ so long as $\hat{f} \circ \psi'$ is close enough to $\hat{h}$, the trivialization associated with $\hat{f}$ allows us to uniquely factor $\hat{h}$ as $F$ composed with a map

\[
\nu_h: C(\hat{h}) \rightarrow f^*T_{vert}\hat{B}
\]

so that the following diagram commutes.

\[
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{\psi'} & C(\hat{f}) \\
\downarrow & & \downarrow \\
F(\hat{h}) & \xrightarrow{\nu_h} & F(\hat{f})
\end{array}
\]

Choose some $G_0 \times G$–invariant collection of marked-point sections $\{s_i\}$ of $C(\hat{f}) \rightarrow F(\hat{f})$ so that $D\bar{\partial}$ restricted to sections of $f^*T_{vert}\hat{B}$ vanishing at these extra marked points is injective. We shall use this injectivity with Theorem 3.6 to modify an extension, $f_0^*$, of $\hat{f}$ to contain all relevant holomorphic curves. Construct the domain
of \( \hat{f}_0^* \) as the following pullback.

\[
\begin{array}{ccc}
C(\hat{f}_0^*) & \longrightarrow & C(\hat{f}) \\
\downarrow & & \downarrow \\
\oplus_i (s_i \circ \hat{f})^* T_{vert} \hat{B} & \longrightarrow & F(\hat{f})
\end{array}
\]

(19)

Note that \( C(\hat{f}_0^*) \) has a natural \( G_0 \times G \)-action so that the above diagram is \( G_0 \times G \)-equivariant. Pull back the sections \( s_i \) to give a \( G_0 \times G \)-invariant collection of sections \( \{ s_i^* \} \) of \( C(\hat{f}_0^*) \longrightarrow F(\hat{f}_0^*) \).

Now, construct \( \hat{f}_0^* \) so that \( \hat{f}_0^* \) factors as a \( G_0 \times G \)-equivariant map \( \nu \) to \( \hat{f}^* T_{vert} \hat{B} \) followed by \( F \), so that the 5 inner loops in the following diagram commute,

\[
\begin{array}{ccc}
C(\hat{f}_0^*) & \xrightarrow{\nu} & \hat{f}^* T_{vert} \hat{B} & \xrightarrow{F} & \hat{B} \\
\downarrow \vert \hat{s}_i^* & & \downarrow \vert \hat{s}_i & & \downarrow \vert \hat{s}_i \\
F(\hat{f}_0^*) & \xleftarrow{s} & C(\hat{f}) & \xrightarrow{G} & F(\hat{f})
\end{array}
\]

and so that, if \( C(\hat{f}_0^*) \) is considered as a vectorbundle over \( C(\hat{f}) \), \( \nu \) is a map of vectorbundles, and \( \nu \circ s_i^* : \oplus (s_i \circ \hat{f})^* T_{vert} \hat{B} \longrightarrow (s_i \circ \hat{f})^* T_{vert} \hat{B} \) is projection onto the \( i \)th factor.

Our fiberwise-holomorphic-isomorphism map \( \psi' : C(\hat{h}) \longrightarrow C(\hat{f}) \) has a natural lift to a fiberwise-holomorphic-isomorphism map \( \psi'' : C(\hat{h}) \longrightarrow C(\hat{f}_0^*) \). First define a map

\[
x_{\hat{h}} : C(\hat{h}) \longrightarrow \oplus_i (s_i \circ \hat{f})^* T_{vert} \hat{B}
\]

by evaluating the section \( \nu_{\hat{h}} \) from equation (18) at the image of each section \( s_i \) using the following composition.

\[
\begin{array}{ccc}
C(\hat{h}) & \longrightarrow & F(\hat{h}) \\
\downarrow x_{\hat{h}} & & \downarrow (\psi')^* s_i \\
C(\hat{h}) & \xrightarrow{\nu_{\hat{h}}} & C(\hat{f}_0^*) \\
\downarrow s_i & & \downarrow (s_i \circ \hat{f})^* T_{vert} \hat{B}
\end{array}
\]

Then, the following diagram commutes.

\[
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{\psi'} & C(\hat{f}) \\
\downarrow x_{\hat{h}} & & \downarrow \\
\oplus_i (s_i \circ \hat{f})^* T_{vert} \hat{B} & \longrightarrow & F(\hat{f})
\end{array}
\]
As \( C(\hat{f}^*_h) \) is defined by the pullback diagram \([10]\) there is an induced map

\[
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{\psi''} & C(\hat{f}^*_0) \\
\downarrow & & \downarrow \\
F(\hat{h}) & \xrightarrow{\partial_i(s_i \circ \hat{f})^* T_{\text{vert}} \hat{B}} & \hat{B}
\end{array}
\]

which is a holomorphic isomorphism on each fiber because \( \psi' \) factorizes as \( \psi'' \) composed with the fiberwise-holomorphic-isomorphism map \( C(\hat{f}^*_0) \rightarrow C(\hat{f}) \). Roughly speaking, this lift, \( \psi'' \), of \( \psi' \) is determined by the condition that \( \hat{h} \) agrees with \( f^*_0 \circ \psi'' \) when restricted to the pullback under \( \psi' \) of the sections \( s_i \).

Let us define \( \nu'_h \) analogously to \( \nu_h \), using \( \psi'' \) in place of \( \psi' \). Pull back our constructed trivialization (or construct another trivialization using the same connection) to give a \((G_0 \times G)\)-invariant trivialization associated to our new family \( \hat{f}^*_h \). Again, call this trivialization \((\mathcal{F}, \phi)\). As before we may use this trivialization to factorize \( \hat{h} \) as follows:

\[
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{\nu'_h} & (\hat{f}^*_0)^* T_{\text{vert}} \hat{B} \\
\downarrow & & \downarrow \\
C(\hat{f}^*_0) & \xrightarrow{\psi''} & \hat{B}
\end{array}
\]

where \( \nu'_h \) is uniquely determined by the commutativity of the above diagram and the condition that it must vanish on the image of the sections \( s_i \).

Let us modify \( \hat{f}^*_0 \) using Theorem 3.6 in order to obtain a family containing all relevant holomorphic curves. At \( f \in f^*_0 \), \( D\partial \) is injective restricted to sections of \( f^* T_{\text{vert}} \hat{B} \) vanishing on marked points corresponding to the sections \( s_i \). Theorem 3.8 implies that we may choose a \( G_0 \times G \)-invariant, finite-dimensional sub-vectorbundle \( V \) of \( \mathcal{Y}(\hat{f}^*_0) \) so that the pre-obstruction model \((\hat{f}^*_0, V)\) has \( D\partial : X^\infty \mathcal{Y}(f) \rightarrow \mathcal{Y}(f) \) complementary to \( V(f) \). We may then apply Theorem 4.6 to \((f^*_0, V)\) to obtain a unique section \( \nu \) of \((f^*_0)^* T_{\text{vert}} \hat{B}\) defined near \( f \) and vanishing on the image of all \( s_i \) so that \( \partial \nu \) is a section of \( V \). (Without losing generality, we can assume that \( \nu \) is defined on all of \( f^*_0 \).) Below, we shall show that the modified family \( f^* := F \circ \nu \) has the properties required by our proposition.

**Claim 6.3.** There exists a neighborhood \( \mathcal{O} \) of \((id, f)\) in \( \mathcal{M}^*(C(\hat{f}) \times \hat{B}) \) such that, if a family of holomorphic curves \( \hat{h} \) is in \( \mathcal{O} \), then \( \nu'_h \) is the pullback of \( \nu \) under the following diagram:

\[
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{\nu'_h} & (\hat{f}^*_0)^* T_{\text{vert}} \hat{B} \\
\downarrow & & \downarrow \\
C(\hat{f}^*_0) & \xrightarrow{\psi''} & \hat{B}
\end{array}
\]

To prove Claim 6.3, we may choose any neighborhood \( \mathcal{O} \) of \((id, f)\) so that

1. the construction of \( \nu'_h \) makes sense for all \( \hat{h} \) in this neighborhood, and
2. so that for any individual curve \( h \in \mathcal{O} \), \( \nu'_h \) is in (the restriction of) the neighborhood \( O \) of \( 0 \in X^\infty (\hat{f}^*) \) on which the uniqueness statement of Theorem 3.7 applies.

As \( \nu'_h \) is natural and this second condition is an open condition on any family for which \( \nu'_h \) is defined, Lemma 2.8 implies that it is an open condition, so we can
construct such an open neighborhood by choosing a neighborhood on which the first condition applies then restricting using the second condition. For any family of holomorphic curves \( \hat{h} \) in \( \mathcal{O} \), the uniqueness statement from Theorem 3.6 gives that \( \nu_{\hat{h}} = \nu \circ \psi'' \). This completes the proof of Claim 6.3.

Claim 6.3 implies that for \( \hat{h} \in \mathcal{O} \), \( \hat{h} = F(\nu) \circ \psi'' \).

Letting \( \hat{f}^* := F(\nu) \), our map \( \psi'' \) therefore gives us the required unique map \( \hat{h} \rightarrow \hat{f}^* \) so that the following diagram commutes.

\[
\begin{array}{ccc}
C(\hat{h}) & \xrightarrow{h} & \hat{B} \\
\downarrow \psi' & & \downarrow \hat{f}^* \\
C(\hat{f}) & \xleftarrow{\psi} & C(\hat{f}^*)
\end{array}
\]

Because the map \( \partial \colon X^\infty \mathcal{Y}(\hat{f}_0^*) \rightarrow \mathcal{Y}(\hat{f}_0^*) \) is defined using our \( G_0 \times G \)-invariant trivialization, it is \( G_0 \times G \)-equivariant and \( V \) is \( G_0 \times G \)-invariant. Therefore, the unique solution \( \nu \) to \( \partial \nu \in V \) must also be \( G_0 \times G \)-equivariant. As the map \( F \) from our trivialization is \( G_0 \)-equivariant and \( G \)-invariant, our family \( \hat{f}^* \) is \( G_0 \)-equivariant and \( G \)-invariant as required.

\[\Box\]

We wish to study the moduli stack of solutions to \( \partial \hat{f} \in V(\hat{f}) \) where \( V \) is a simply-generated subsheaf of \( \mathcal{Y} \) in the sense of Definition 2.71. The next lemma shows that any such \( V \) can locally be parametrized by a family of curves \( \hat{f}_1/G \) that is a vectorbundle over a core family \( \hat{f}_0/G \). We shall use this result to apply the analysis from [31].

**Lemma 6.4.** If \( V \) is a rank–1 simply-generated subsheaf of \( \mathcal{Y} \), defined on a neighborhood (within \( M^\bullet \)) of a holomorphic curve \( f \) (with at least one smooth component), then there exists a neighborhood \( \mathcal{O} \) of \( f \) in \( M^\bullet \), a core family \( (\hat{f}_0/G, \{s_i\}) \) for \( \mathcal{O} \), and a \( G \)-invariant family of curves, \( \hat{f}_1 \) in \( \mathcal{O} \), together with a fiberwise-holomorphic map

\[
\begin{array}{ccc}
\mathcal{O}^+ & \phi_{\hat{f}_1} & \mathcal{C}(\hat{f}_1)/G \\
\downarrow & & \downarrow \\
\mathcal{O} & \phi_{\hat{f}_0} & \mathcal{F}(\hat{f}_1)/G
\end{array}
\]

such that the following holds:

1. There exists a locally-free rank–1 \( G \)-invariant sheaf, \( V_1 \), of \( C^\infty(\mathcal{F}(\hat{f}_1)) \)-modules on \( \mathcal{F}(\hat{f}_1) \) which is a subsheaf of \( \Gamma(0,1)(T^*_\text{vert} \mathcal{C}(\hat{f}_1) \otimes T^*_\text{vert} \hat{B}) \) and which pulls back to give \( V \) on \( \mathcal{O} \). (See Definition 2.70 for pulling back in this sense.)

2. \( \hat{f}_0 \) is a \( G \)-invariant sub-family of \( \hat{f}_1 \), and there is a \( G \)-equivariant map

\[
\psi \colon \hat{f}_1 \rightarrow \hat{f}_0
\]

which is a projection in the sense that it is the identity on \( \hat{f}_0 \subset \hat{f}_1 \), and \( \mathcal{C}(\hat{f}_1) \) is isomorphic to a vectorbundle over \( \mathcal{C}(\hat{f}_0) \) with the given projection.

---

63In other words, for \( U \subset \mathcal{F}(\hat{f}_1) \) a sufficiently small open subset in the standard topology on the exploded manifold \( \mathcal{F}(\hat{f}_1) \), the restriction, \( V_1(U) \) of \( V_1 \) to \( U \) is a free, \( C^\infty(\mathcal{U}) \)-module of rank \( n \).
and zero section. Moreover, $\psi$ has the property that the core family map to $C(\hat{f}_0)/G$ factorizes as

$$\Phi_0^{+1} : O^{+1} \xrightarrow{\Phi_0^{+1}} C(\hat{f}_1)/G \xrightarrow{C(\psi)} C(\hat{f}_0)/G$$

$$\xrightarrow{\Phi_1^{+1}} C(\hat{f}_1)/G \xrightarrow{C(\psi)} C(\hat{f}_0)/G$$

$O \xrightarrow{\Phi} F(\hat{f}_1)/G \xrightarrow{\Phi} F(\hat{f}_0)/G$

(3) For $t \in [0, 1]$, the subspace $((1 - t)D\bar{\partial} + tD\bar{\partial}^G)^{-1}(V(f)) \subset T_fM_{st}^* \cdot \hat{B}$ does not contain the image of any nonzero sections of $f^*T_{vert}\hat{B}$ vanishing at the image of the marked point sections $\{s_i\}$.

**Proof:**

Together with Remark 5.2, Proposition 5.12 implies that there is some $C^{\infty,1}$ core family $(\hat{f}/G, \{s_i\})$ containing $f$. As indicated by Proposition 5.12 and Theorem 3.8, we can construct $\hat{f}$ with enough marked point sections $s_i$ so that $((1 - t)D\bar{\partial} + tD\bar{\partial}^G)^{-1}(V(f))$ contains no nonzero sections of $f^*T_{vert}\hat{B}$ vanishing on the images of the $s_i$. This will ensure that condition 3 holds.

From the definition of a core family, there exists an open neighborhood $O \subset M_{st}$ of $\hat{f}$ with a fiberwise-holomorphic map

$$\xrightarrow{\Phi_0^{+1}} C(\hat{f})/G_1$$

in the sense of Definition 2.50. The definition of a simply-generated subsheaf $V$ of $\mathcal{Y}$, Definition 2.71, implies that if $O$ is small enough, there is also a fiberwise-holomorphic map

$$\xrightarrow{\Theta_0^{+1}} \hat{A}/G_0$$

$$\xrightarrow{\Theta} \hat{X}/G_0$$

and sections $v_1, \ldots, v_n$ of $\Gamma^{(0,1)}(T^{*}_{vert}\hat{A} \otimes T_{vert}\hat{B})$ pulling back to generate $V$.

In particular, there is a $G_0$–bundle $\hat{f}^{\times G_0} \rightarrow \hat{f}$ with a $G_0$–equivariant, fiberwise-holomorphic map

$$\Theta^{+1} : C(\hat{f}^{\times G_0}) \rightarrow \hat{A}.$$  

Definition 2.50 implies that the action of $G_1$ on $\hat{f}$ lifts to an action of $G_1$ on $\hat{f}^{\times G_0}$ and the family $\Theta^{+1} : C(\hat{f}^{\times G_1}) \rightarrow C(\hat{f}^{\times G_0})$ making the map $\Theta^{+1} : C(\hat{f}^{\times G_1}) \rightarrow \hat{A}$ a $G_1$–invariant and $G_0$–equivariant map. The group $G$ from the statement of this lemma is $G_1 \times G_1$, and the core family $\hat{f}_0$ is $\hat{f}^{\times G_0}$, with the lift of the sections $\{s_i\}$ from $\hat{f}$. Because the stacks $C(\hat{f})/G_1$ and $C(\hat{f}^{\times G_0})/G$ are equivalent, $\Phi$ is equivalent to a fiberwise

---

64The image under the map from the short exact sequence defining $T_fM_{st}^* \cdot \hat{B}$.
holomorphic map as below.

\[ \begin{array}{cccc}
\mathcal{O}'^1 & \xrightarrow{\Phi^+} & \mathcal{C}(f^{xG_0})/G & \xrightarrow{=} \mathcal{C}(\hat{f})/G_1 \\
\downarrow & & \downarrow & \\
\mathcal{O} & \xrightarrow{\Phi_0} & \mathcal{F}(f^{xG_0})/G & \xrightarrow{=} \mathcal{F}(\hat{f})/G_1 \\
\end{array} \]

Unpacking definitions, \( \Phi \) applied to \( \hat{h} \) is a \( G_1 \)-bundle \( \hat{h}^{xG_1} \to \hat{h} \) and a \( G_1 \)-equivariant, fiberwise holomorphic map \( \Phi^{+1}(\hat{h}): \mathcal{C}(\hat{h}^{xG_1}) \to \mathcal{C}(\hat{f}) \). Then, pulling back the \( G_1 \)-equivariant \( G_0 \)-bundle \( \mathcal{C}(\hat{f}^{xG_0}) \to \mathcal{C}(\hat{f}) \) gives a \( G_1 \)-equivariant \( G_0 \)-bundle over \( \mathcal{C}(\hat{h}^{xG_1}) \), and hence a \( G_1 \times G_0 \) bundle \( \hat{h}^{xG_1 \times G_0} \to \hat{h} \) such that the following is a \( G_1 \times G_0 \)-equivariant fiber-product diagram.

\[ \begin{array}{ccc}
\mathcal{C}(\hat{h}^{xG_1 \times G_0}) & \xrightarrow{\Phi^{+1}_0(\hat{h})} & \mathcal{C}(\hat{f}^{xG_0}) \\
\downarrow & & \downarrow \\
\mathcal{C}(\hat{h}^{G_1}) & \xrightarrow{\Phi^{+1}(\hat{h})} & \mathcal{C}(\hat{f}) \\
\end{array} \]

We can also use \( \Phi \) to extend \( \Theta \) to a fiberwise holomorphic map

\[ \begin{array}{ccc}
\mathcal{O}'^1 & \xrightarrow{\Theta^{+1}_0} & \hat{\mathcal{A}}/(G_0 \times G_1) \\
\downarrow & & \downarrow \\
\mathcal{O} & \xrightarrow{\Theta_1} & \hat{\mathcal{X}}/(G_0 \times G_1) \\
\end{array} \]

where \( G_1 \) acts trivially on \( \mathcal{A} \) and \( \mathcal{X} \). In particular, for \( \hat{h} \) a family in \( \mathcal{O} \), let \( \hat{h}^{xG_1} \to \hat{h} \) be the \( G_1 \)-bundle from \( \Phi \), and let \( \hat{h}^{xG} \to \hat{h}^{xG_1} \) be the \( G_1 \)-equivariant \( G_0 \)-bundle produced by applying \( \Theta \) to \( \hat{h}^{xG_1} \). Then \( \hat{h}^{xG} \to \hat{h}^{xG_1} \) is a \( G_0 \times G \)-bundle and hence a \( G \)-bundle. Given any map \( \psi: \hat{g} \to \hat{h} \), we also get a map of \( G \)-bundles \( \psi^G: \hat{g}^G \to \hat{h}^G \). To complete the definition of \( \Theta_1 \), the \( G_0 \times G_1 \)-invariant fiberwise-holomorphic map \( \Theta^{+1}_1(\hat{h}) = \Theta^{+1}(\hat{h}^{xG_1}) \).

We want to combine our fiberwise holomorphic maps to obtain a single fiberwise holomorphic map \( (\Phi_0, \Theta_1); \) for this, we must equate the domains, \( \mathcal{C}(\hat{h}^{xG_1 \times G_0}) \) of \( \Phi^{+1}_0(\hat{h}) \), and \( \mathcal{C}(\hat{h}^{xG_0}) \) of \( \Theta^{+1}_1(\hat{h}) \).

**Claim 6.5.** Assuming \( \mathcal{O} \) is small enough (by replacing \( \mathcal{O} \) with a smaller neighborhood of \( \hat{f}_0/G \) if necessary) the following is true. For all \( \hat{h} \) in \( \mathcal{O} \), there is a canonical \( G_0 \times G_1 \)-equivariant map \( \alpha_{h}: \hat{h}^{xG} \to \hat{h}^{xG_1 \times G_0} \). Moreover, given a map \( \beta: \hat{g} \to \hat{h} \), the following diagram commutes

\[ \begin{array}{ccc}
\hat{h}^{xG} & \xrightarrow{\beta^{xG}} & \hat{h}^{xG} \\
\downarrow_{\alpha_{\hat{h}}} & & \downarrow_{\alpha_{\hat{h}}} \\
\hat{g}^{xG_1 \times G_0} & \xrightarrow{\beta^{xG_1 \times G_0}} & \hat{h}^{xG_1 \times G_0} \\
\end{array} \]

To prove Claim 6.5, consider first the special case of a family \( \hat{h} \) with a map \( \psi: \hat{h}^{xG_1} \to \hat{f} \) such that \( \mathcal{C}(\psi) = \Phi^{+1}(\hat{h}) \). Then, recalling the definition of \( \mathcal{C}(\hat{h}^{xG_1 \times G_0}) \) as a fiber product, we define \( \alpha_{\hat{h}}: \hat{h}^{xG_1 \times G_0} \to \hat{h}^{xG} \) to be the unique
map such that the following diagram commutes.

\[
\begin{array}{c}
\mathcal{C}(\hat{h}^{\times G_1}) \\
\downarrow \Phi_{\hat{h}}^+(\hat{h}) \\
\mathcal{C}(\hat{h}^{\times G_1} \times \mathcal{G}_0) \\
\downarrow \Phi_{\hat{h}}^+(\hat{h}) \\
\mathcal{C}(\hat{h}^{\times G_1}) \\
\end{array}
\]

More generally, by choosing \( \mathcal{O} \) small enough, we can assume that \( \Phi^+1(\hat{h}) \) is an isomorphism on each fiber. Remark 5.3 implies that if \( \mathcal{O} \) is small enough, there is a canonical homotopy \( \hat{h}_t \) of \( \hat{h} \) within \( \mathcal{O} \) to a family of curves \( \hat{h}_1 \) with a map \( \psi: \hat{h}_1^{\times G_1} \to \hat{f} \) such that \( \mathcal{C}(\psi) = \Phi^+1(\hat{h}) \) and such that \( \Phi^+1(\hat{h}_t) \) is independent of \( t \). As argued above, we get a canonical map \( \alpha_{\hat{h}_t}: \hat{h}_1^{\times G_1} \times \mathcal{G}_0 \to \hat{h}_1^{\times G} \). This map extends uniquely along our homotopy \( \hat{h}_t \) to define \( \alpha_{\hat{h}}: \hat{h}^{\times G_1} \times \mathcal{G}_0 \to \hat{h}^{\times G} \). Any map \( \beta: \hat{g} \to \hat{h} \) extends uniquely to \( \beta_t: \hat{g}_t \to \hat{h}_t \) along the homotopy from Remark 5.3 so it follows that the diagram from Claim 6.5 commutes.

With Claim 6.5 proved, we now have a fiberwise-holomorphic map \((\Phi_0, \Theta_1)\)

\[
\begin{array}{c}
\mathcal{O} \times \mathcal{G}_1^+ \xrightarrow{(\Phi_0, \Theta_1)^+1} (\mathcal{C}(\hat{f}^{\times G_1}) \times \hat{A})/G \\
\mathcal{O} \xrightarrow{(\Phi_0, \Theta_1)} (\mathcal{F}(\hat{f}^{\times G_1}) \times \hat{X})/G
\end{array}
\]

which associates to a family \( \hat{h} \) in \( \mathcal{O} \) the \( G \)-bundle \( \hat{h}^{\times G} \) and the \( G \)-equivariant map \((\Phi_0, \Theta_1)^+1(\hat{h}): \mathcal{C}(\hat{h}^{\times G}) \to \mathcal{C}(\hat{f}_0) \times \hat{A} \) defined as

\[
(\Phi_0, \Theta_1)^+1(\hat{h}) = \left( \Phi_{\hat{h}}^+(\hat{h}) \circ \mathcal{C}(\alpha_{\hat{h}}), \Theta_1^+1(\hat{h}) \right).
\]

So, for any family \( \hat{h} \) in \( \mathcal{O} \), \( (\Phi_0, \Theta_1)^+1(\hat{h}) \) is a \( G \)-equivariant family of holomorphic curves in \( \mathcal{C}(\hat{f}_0) \times \hat{A} \) with \( \mathcal{C}(\hat{h}^{\times G}) \).

Use Proposition 6.1 to extend the family of holomorphic curves \( \Theta^+1(\hat{f}): \mathcal{C}(\hat{f}_0) \to \hat{A} \) to a \( G_1 \)-invariant and \( G_0 \)-equivariant family of curves \( \Theta^+1(\hat{f})^* \) in \( \hat{A} \) with a map \( \psi: \mathcal{C}(\Theta^+1(\hat{f})^*) \to \mathcal{C}(\hat{f}_0) \) so that, given any family of curves \( \hat{h} \) close enough to \( f \), the family of holomorphic curves \( (\Phi_0, \Theta_1)^+1(\hat{h}) \) in \( \mathcal{C}(\hat{f}_0) \times (\hat{A}) \) has a unique map

\[
(20)\quad \psi^*_h : (\Phi_0, \Theta_1)^+1(\hat{h}) \to (\psi, \Theta^+1(\hat{f})^*)
\]

in \( \mathcal{M}^s(\mathcal{C}(\hat{f}_0) \times \hat{A}) \). As this map is unique and both families of curves are \( G \)-equivariant, \( \psi^*_h \) must also be \( G \)-equivariant. If necessary, replace \( \mathcal{O} \) with a smaller open neighborhood of \( f \) so that the above property holds for all families \( \hat{h} \) in \( \mathcal{O} \). Note that given any map \( \beta: \hat{h} \to \hat{g} \),

\[
(21)\quad \mathcal{C}(\psi^*_h) = \mathcal{C}(\psi) \circ \mathcal{C}(\beta^{\times G})
\]

**Definition 6.6.** Define the family of curves \( \hat{f}_1 \) in \( \mathcal{O} \) to be the pullback of \( \hat{f}_0 := \hat{f}^{\times G} \) under the map \( \psi: \mathcal{C}(\Theta^+1(\hat{f})^*) \to \mathcal{C}(\hat{f}_0) \), so \( \mathcal{C}(\hat{f}_1) = \mathcal{C}(\Theta^+1(\hat{f})^*) \), and

\[
\hat{f}_1 = \hat{f}_0 \circ \psi.
\]
Note that $G$ still acts as a group of automorphisms of $\hat{f}_1$. Now, define our fiberwise holomorphic map $\Phi_1$:

$$\mathcal{O} \xrightarrow{\Phi_1^{-1}} C(\hat{f}_1)/G$$

as follows: $\Phi_1$ applied to $\hat{h}$ is the $G$–bundle $\hat{h}^G \rightarrow \hat{h}$, together with the $G$–equivariant fiberwise-holomorphic map

$$\Phi_1^{-1}(\hat{h}) := C(\psi_{\hat{h}}): C(\hat{h}^G) \rightarrow C(\hat{f}_1).$$

Equation (21) ensures that $\Phi_1$ satisfies Definition 2.50. Note also that $\psi \circ \Phi_0^{-1}(\hat{h}) = \Phi_0^{-1}$, so we have verified condition 2 of our lemma.

Recall from Definition 6.7 that $C(\hat{f}_1) = C(\Theta^{-1}(\hat{f})^*)$, and $\Theta^{-1}(\hat{f})^*$ is a $G_1$–invariant, and $G_0$–equivariant family of curves in $A$.

Accordingly, we get a maps of stacks

$$C(\hat{f}_1) \xrightarrow{\Theta^{-1}(\hat{f})^*} A \xrightarrow{\Phi_1^{-1}} \mathcal{F}(\hat{f}_1) \xrightarrow{\Theta^{-1}(\hat{f})^*} \mathcal{X}$$

Claim 6.7. $\Theta^{-1}(\hat{f})^* \circ \Phi_1^{-1} = \Theta_1^{-1}$.

Proving Claim 6.7 is a matter of tracing back through our definitions (which have been chosen so that this is a strict equality.) Let us apply these maps to $\hat{h}$. First, applying $\Phi_1^{-1}$, we get a $G$–bundle $\hat{h}^G \rightarrow \hat{h}$ with a map $C(\psi_{\hat{h}}): C(\hat{h}^G) \rightarrow C(\hat{f}_1) = C(\Theta^{-1}(\hat{f})^*)$. The definition of $\psi_{\hat{h}}$ above equation (20) then implies that $\Theta^{-1}(\hat{f})^* \circ \Phi_1^{-1}(\hat{h}) = \Theta_1^{-1}(\hat{h})$.

With the help of Claim 6.7, we shall now examine how to parametrize our obstruction bundle $V$ using $\hat{f}_1$. The map

$$(\Theta^{-1}(\hat{f})^*, \text{id}): C(\hat{f}_1) \times \hat{B} \rightarrow \hat{A} \times \hat{B}$$

pulls back the sections $v_1, \ldots, v_n$ of $\Gamma(0,1)(T^*_\text{vert}\hat{A} \otimes T^*_\text{vert}\hat{B})$ to $G_1$–equivariant sections

$$(\Theta^{-1}(\hat{f})^*)^* v_1, \ldots, (\Theta^{-1}(\hat{f})^*)^* v_n$$

of $\Gamma(T^*_\text{vert}C(\hat{f}_1) \otimes T^*_\text{vert}\hat{B})$. Because $\Theta^{-1}(\hat{f})^*$ is not fiberwise holomorphic everywhere, these sections may not be in $\Gamma(0,1)$, so we take their projection $((\Theta^{-1}(\hat{f})^*)^* v_i)^{(0,1)}$ to $\Gamma(0,1)$. (This projection does not affect our section on the image of $\Phi_1^{-1}(\hat{h})$, because $\Theta^{-1}(\hat{f})^*$ is fiberwise holomorphic there.)

Given any family $\hat{h}$ in $\mathcal{O}$, Claim 6.7 implies that

$$(\Phi_1^{-1}(\hat{h}), \hat{h}^G)^* ((\Theta^{-1}(\hat{f})^*)^* v_i)^{(0,1)} = (\Theta_1^{-1}, \hat{h}^G)^* v_i$$

So, the map

$$(\Phi_1^{-1}(\hat{h}), \hat{h}^G): C(\hat{h}^G) \rightarrow C(\hat{f}_1) \times \hat{B}$$
pulls back these sections to $G_1$–equivariant sections
\[(\Theta_1^{1+}(\bar{h}), \bar{h}^{xG})^* \nu_1, \ldots, (\Theta_1^{1+}(\bar{h}), \bar{h}^{xG})^* \nu_n\]
of $\mathcal{Y}(\bar{h}^{xG})$. Because $\Theta_1^{1+}(\bar{h}) = \Theta^{1+}(\bar{h}^{xG_1})$ these $G_1$–equivariant sections are the same as those obtained using $\Theta^{1+}$ applied to $\bar{h}^{xG_1}$.

\[(\Theta_1^{1+}(\bar{h}), \bar{h}^{xG})^* \nu_i = (\Theta^{1+}(\bar{h}^{xG_1}), \bar{h}^{xG})^* \nu_i\]

So, these sections of $\mathcal{Y}(\bar{h}^{xG})$ are linearly independent at every curve in $\bar{h}^{xG}$ and generate $V(\bar{h}^{xG})$.

In other words, the pullback of $((\Theta^{1+}(\hat{f})^*)^* \nu_i)^{(0,1)}$ generate $V$ on $\mathcal{O}$. As the sheaf of $C^\infty_-(\mathcal{X})$–modules over $\mathcal{X}$ generated by $\nu_1, \ldots, \nu_n$ is $G_0$–invariant and the map $\Theta^{1+}(\hat{f})^*$ is $G_1$–invariant and $G_0$–equivariant, the sheaf of $C^\infty_-(\mathcal{F})$–modules over $\mathcal{F}(\hat{f})$ generated by $((\Theta^{1+}(\hat{f})^*)^* \nu_i)^{(0,1)}$ is $G$–invariant. As the pullback of $((\Theta^{1+}(\hat{f})^*)^* \nu_i)^{(0,1)}$ to any curve in $\mathcal{O}$ are linearly independent, restricted to a neighborhood of the image of $\mathcal{O}$ in $\mathcal{F}(\hat{f})$, the sheaf $V_1$ generated by $((\Theta^{1+}(\hat{f})^*)^* \nu_i)^{(0,1)}$ is free and $n$–dimensional.

Therefore, by restricting $\hat{f}_1$ to a $G$–invariant neighborhood of the image of $\mathcal{O}$, $((\Theta^{1+}(\hat{f})^*)^* \nu_i)^{(0,1)}$ generate an $n$–dimensional $G$–invariant vector bundle $V_1$ pulling back to give $V$ on $\mathcal{O}$.

We are ready to prove our main theorem on the local structure of the moduli stack of holomorphic curves. The statement uses definitions 2.44, 2.45, 2.46, 2.47, 2.49 and 2.56.

Theorem 6.8. Let $V$ be a simply-generated subsheaf of $\mathcal{Y}$, defined on an open substack of $\mathcal{M}^{st}_*$ such that, for some holomorphic curve $f$, $V(f)$ is transverse to $\partial \mathcal{O}$: $T_f \mathcal{M}^{st}_*(\bar{\mathcal{B}}) \to \mathcal{Y}(f)$. Then there exists an open neighborhood $\mathcal{O} \subset \mathcal{M}^{st}_*$ of $f$ and a family of curves $\hat{f}$ in $\mathcal{M}^{st}_*$ with automorphism group $G$ such that $\hat{f}/G$ represents the substack $\partial^{-1}V \subset \mathcal{O}$ consisting of curves $g$ in $\mathcal{O}$ with the property that $\partial g \in V(g)$.

Moreover, the map

\[T_f \hat{f}: T_f \mathcal{F}(\hat{f}) \to T_f \mathcal{M}^{st}_*(\bar{\mathcal{B}})\]
is injective and has image $D \partial^{-1}V(f) \subset T_f \mathcal{M}^{st}_*(\bar{\mathcal{B}})$.

Proof:

We shall prove the easy case, in which the domain of $f$ is $\mathcal{T}$, separately in Lemma 7.6. For the rest of this proof, assume that the domain of $f$ has at least one smooth component, so we may use Lemma 6.4 to construct a core family $(\mathcal{F}_0/G, \{s_i\})$ for an open neighborhood $\mathcal{O}$ of $f$ and a $G$–invariant extension $\hat{f}_1$ of $f_0$ for parametrizing $V$ in the sense of Lemma 6.4. In particular, there is a $G$–invariant sub-bundle $V_1$ of $\Gamma^{(0,1)} \left( T_{\text{vert}} \mathcal{C}(\hat{f}_1) \otimes T_{\text{vert}} \bar{\mathcal{B}} \right)$ so that, given any family of curves $\hat{h}$ in $\mathcal{O}$, there is a $G$–bundle $\hat{h}^{xG} \to \hat{h}$ and a lift of the core-family map $\Phi_0^{1+}(\hat{h})$: $\mathcal{C}(\hat{h}^{xG}) \to \mathcal{C}(\hat{f}_1)$ to another $G$–equivariant map

\[
\begin{array}{ccc}
\mathcal{C}(\hat{h}^{xG}) & \xrightarrow{\Phi_0^{1+}(\hat{h})} & \mathcal{C}(\hat{f}_1) \\
\downarrow & & \downarrow \\
\mathcal{F}(\hat{h}^{xG}) & \xrightarrow{\Phi_1(\hat{h})} & \mathcal{F}(\hat{f}_1)
\end{array}
\]
such that the pullback of $V_1$ using $(\Phi_1^{1+}(\hat{h}), \hat{h}^{xG})$ is $V(\hat{h}^{xG})$. 

Definition 6.9. Consider $V_1$ as a vector bundle over $F(\hat{f}_1)$. Let $\hat{f}_2$ be the family of curves defined using the following pullback diagram:

\[
\begin{array}{c}
\xymatrix{ 
C(\hat{f}_2) \ar[r]^r \ar[d] & C(\hat{f}_1) \ar[r]^f & \hat{B} \\
F(\hat{f}_2) = V_1 \ar[r] & F(\hat{f}_1) 
}
\end{array}
\]

We will regard $\hat{f}_1$ as the subfamily of $\hat{f}_2$ corresponding to the zero section of the bundle $V_1 \to F(\hat{f}_1)$.

There is a $G$–equivariant tautological section $\theta$ of $\Gamma^{(0,1)} \left( T_{\text{vert}}^* C(\hat{f}_2) \otimes T_{\text{vert}}^* \hat{B} \right)$ defined as follows: A point $(f', v)$ in $F(\hat{f}_2)$ corresponds to a curve $f'$ in $\hat{f}_1$ and a vector $v \in V(f')$. By the definition of $V_1$, this $v$ is also in $\Gamma^{(0,1)} \left( T^* C(f') \otimes T_{\text{vert}} \hat{B} \right)$, and we can pull this section back using the isomorphism $r$. So,

\[
\theta(f', v) := r^* v .
\]

This tautological section has the following property: given any family of curves $\hat{h}$ in $\mathcal{O}$ and a section $\theta_{\hat{h}}$ of $V(\hat{h})$, the canonical map $\Phi_{\hat{h}}(\hat{h}) : C(\hat{h}^{\times G}) \to C(\hat{f}_1)$ lifts uniquely to a canonical $G$–equivariant map $\psi_{\theta_{\hat{h}}}$ such that such that the following diagram commutes

\[
\begin{array}{c}
\xymatrix{ 
C(\hat{h}^{\times G}) \ar[r]_{\psi_{\theta_{\hat{h}}}} \ar[d] & C(\hat{f}_1) \ar[r]^f & \hat{B} \\
F(\hat{h}^{\times G}) \ar[r] & F(\hat{f}_2) \ar[r] & F(\hat{f}_1) 
}
\end{array}
\]

and such that

\[
(\psi_{\theta_{\hat{h}}}, \hat{h}^{\times G})^* \theta = \theta_{\hat{h}}
\]

where we have abused notation slightly on the right to identify $\theta_{\hat{h}}$ with its pullback to $\mathcal{Y}(\hat{h}^{\times G})$ using the $G$–bundle map $\hat{h}^{\times G} \to \hat{h}$. Given a map $\alpha : \hat{g} \to \hat{h}$, the uniqueness of $\psi_{\theta_{\hat{h}}}$ implies that the following diagram commutes.

\[
\begin{array}{c}
\xymatrix{ 
C(\hat{h}^{\times G}) \ar[r]_{\psi_{\theta_{\hat{h}}}} \ar[d] & C(\hat{f}_1) \ar[d] \\
C(\hat{g}^{\times G}) \ar[r]_{\psi_{\alpha \ast \theta_{\hat{h}}}} \ar[u]_{C(\alpha^{\times G})} & C(\hat{f}_2) \ar[u]_{C(\hat{g}^{\times G})} 
}
\end{array}
\]

A particular case of interest is when $\theta_{\hat{h}} = \partial \hat{h}$, when we obtain a canonical $G$–equivariant map

\[
\Phi_{\hat{h}}(\hat{h}) := \psi_{\partial \hat{h}} : C(\hat{h}^{\times G}) \to C(\hat{f}_2) .
\]

This map only works when $\partial \hat{h}$ is a section of $V(\hat{h})$, but for such $\hat{h}$ we get another fiberwise holomorphic map, $\Phi_2$. 

Definition 6.10. Define the fiberwise holomorphic map

\[
(\bar{\partial}^{-1}V)^{+1} \xrightarrow{\Phi_{2}^{+1}} \mathbb{C}(\hat{f}_{2})/G
\]

\[
\bar{\partial}^{-1}V \xrightarrow{\Phi_{2}} \mathbb{F}(\hat{f}_{2})/G
\]

as follows. To \( \hat{h} \in \bar{\partial}^{-1}V \subset \mathcal{O} \), associate the same \( G \)-bundle \( \hat{h}^{xG} \rightarrow \hat{h} \) as for the maps \( \Phi_{1} \) and \( \Phi_{0} \) (along with the same \( G \)-bundle maps \( \psi^{xG} : \hat{g}^{xG} \rightarrow \hat{h}^{xG} \) for morphisms \( \psi : \hat{g} \rightarrow \hat{h} \)). Then define

\[
\Phi_{2}^{+1}(\hat{h}) := \psi_{\partial \hat{h}} : \mathbb{C}(\hat{h}^{xG}) \rightarrow \mathbb{C}(\hat{f}_{2})
\]

Given any map \( \alpha : \hat{g} \rightarrow \hat{h} \), the pullback \( \alpha^{*}\partial \hat{h} = \partial \hat{g} \), so the commutative diagram \([24]\) implies that

\[
\Phi_{2}^{+1}(\hat{g}) = \Phi_{2}^{+1}(\hat{h}) \circ \mathbb{C}(\alpha^{xG})
\]

so \( \Phi_{2} \) satisfies Definition \([2.50]\).

Close to \( f \), the image of \( \Phi_{2}^{+1} \) will be a sub family \( \mathbb{C}(\hat{f}_{3}) \subset \mathbb{C}(\hat{f}_{2}) \). In what follows, we modify \( \hat{f}_{2} \) to a family \( \mathcal{F}(\nu) : \mathbb{C}(\hat{f}_{2}) \rightarrow \mathcal{B} \) such that the restriction of \( \mathcal{F}(\nu) \) to \( \mathbb{C}(\hat{f}_{3}) \) is a family, \( \hat{f}_{3} \), in \( \bar{\partial}^{-1}V \).

Recall that \( \hat{f}_{1} \) is the pullback of \( \hat{f}_{0} \), and \( \hat{f}_{2} \) is the pullback of \( \hat{f}_{1} \). Therefore, the sections \( \{s_{i}\} \) of \( \mathbb{C}(\hat{f}_{0}) \rightarrow \mathcal{F}(\hat{f}_{0}) \) pull back to sections \( \{s_{i}'\} \) of \( \mathbb{C}(\hat{f}_{2}) \rightarrow \mathcal{F}(\hat{f}_{2}) \). As the set of sections \( \{s_{i}\} \) is \( G \)-invariant and the maps \( f_{2} \rightarrow f_{1} \rightarrow f_{0} \) are \( G \)-equivariant, the set of sections \( \{s_{i}'\} \) is \( G \)-invariant.

Choose a \( G \)-invariant trivialization \((\mathcal{F}, \Phi)\) to associate to \( \hat{f}_{2} \), and use this trivialization and \( \theta \) to define a simple perturbation of \( \bar{\partial} \)

\[
\bar{\partial}' : X^{\infty}(\hat{f}_{2}) \rightarrow \mathcal{Y}(\hat{f}_{2})
\]

\[
\bar{\partial}'(\nu) := \bar{\partial}\nu - \Phi((id, \mathcal{F}(\nu))^{*}\theta)
\]

as in Example \([5.3]\) where \( \theta \) is the tautological section from \([24]\). Note that \( \bar{\partial}' \) is a \( G \)-equivariant map.

Recall, from Lemma \([5.4]\) that we can choose \((\hat{f}_{0}/G, \{s_{i}\})\) so that \( D\bar{\partial} \) is injective when restricted to sections of \( \mathcal{F}^{T_{\text{vert}}\mathcal{B}} \) vanishing at the image of \( \{s_{i}\} \). As \( \theta \) vanishes on \( \mathbb{C}(f) \subset \mathbb{C}(\hat{f}_{2}) \), \( D\bar{\partial}' \) is also injective when restricted to sections of \( \mathcal{F}^{T_{\text{vert}}\mathcal{B}} \) vanishing at the image of \( \{s_{i}\} \). The space \( X^{\infty}(\hat{f}) \) is the space of these sections vanishing on the image of \( \{s_{i}\} \). We may therefore choose a \( G \)-invariant obstruction bundle \( V_{2} \) over \( f_{2} \) such that

\[
D\bar{\partial}' : X^{\infty}(\hat{f}) \rightarrow \mathcal{Y}(f)
\]

has image complementary to \( V_{2} \). Note that \( V_{2} \) need not have anything to do with \( V \).

Apply Theorem \([5.6]\) to \((\hat{f}_{2}, V_{2})\) to obtain a unique section \( \nu \) in \( X^{\infty}(\hat{f}_{2}) \) defined in a neighborhood of \( f \) in \( \hat{f}_{2} \) such that \( \bar{\partial}'\nu \) is a section of \( V_{2} \). The uniqueness part of Theorem \([5.6]\) and the fact that \( \bar{\partial}' \) is \( G \)-equivariant imply that \( \nu \) is \( G \)-equivariant.

If necessary, reduce the size of \( \mathcal{O} \) so that every curve in \( \mathcal{O} \) is isomorphic to some curve in \( \mathcal{F}(\mathcal{O}) \) where \( \mathcal{O} \) is the neighborhood referred to in Theorem \([5.6]\). Remark \([5.3]\) implies that this is possible because \((f_{0}/G, \{s_{i}\})\) is a core family. Then, we have the following.

Claim 6.11. Suppose that \( \hat{h} \) is a family in \( \bar{\partial}^{-1}V \subset \mathcal{O} \). Then

\[
\hat{h}^{xG} = \mathcal{F}(\nu) \circ \Phi_{2}^{+1}(\hat{h})
\]

and \( \bar{\partial}'\nu = 0 \) on the image of \( \Phi_{2}(\hat{h}) \).
To prove Claim 6.11 it suffices to consider the case of a single curve $h$. We have that $h^{*}\bar{G} = \mathcal{F}(\nu)\circ \Phi_{2}^{1}(h)$ for some section $\nu$ in the neighborhood $O$ from Theorem 3.6. Using (25), we get $(\Phi_{2}^{1})^{*}\theta = \partial h^{*}\bar{G}$, so $\Phi_{2}(h)\partial \nu = 0$, so $\partial \nu$ vanishes on the image of $\Phi_{2}(h)$. The uniqueness statement from Theorem 3.6 then implies that $\nu$ and $\nu$ must coincide on the image of $\Phi_{2}(h)$. Therefore, $h^{*}\bar{G} = \mathcal{F}(\nu)\circ \Phi_{2}^{1}(h)$, as required for Claim 6.11.

Claim 6.12. $\partial \nu$ is transverse to the $0$-section of $V_{2}$ at the curve $f$ in $\hat{f}_{2}$.

To prove Claim 6.12 above, we need the condition that $D\partial: T_{f}\mathcal{M}_{\mathcal{B}}^{*}(\mathcal{B}) \rightarrow \mathcal{Y}(f)$ is transverse to $V$. This transversality and Lemma 2.6 imply that, given any element $\nu_{0}$ of $V_{2}(f)$, there exists a family $\hat{h}$ parametrized by $\mathbb{R}$ and containing $f$ at 0, and a section $\theta_{\hat{h}}$ of $V(\hat{h})$ so that the derivative at $0$ of $\partial \hat{h} - \theta_{\hat{h}}$ is $\nu_{0}$. Recall that the tautological section $\theta$ of $\Gamma_{\vert}(T_{\text{vert}}^{*}\mathcal{C}(\hat{f}_{2}) \otimes T_{\text{vert}}\mathcal{B})$ is defined so that there exists a canonical lift of the $G$-equivariant map $\Phi_{1}^{1}(\hat{h}): \mathcal{C}(\hat{h}^{*}\bar{G}) \rightarrow \mathcal{C}(\hat{f}_{1})$ to a map

$$\psi_{\theta_{\hat{h}}}: \mathcal{C}(\hat{h}^{*}\bar{G}) \rightarrow \mathcal{C}(\hat{f}_{2})$$

such that

$$\psi_{\hat{h}}^{*}\theta = \theta_{\hat{h}}$$

— or more accurately, $\psi_{\theta_{\hat{h}}}^{*}\theta$ is equal to the lift of $\theta_{\hat{h}}$ to $V(\hat{h}^{*}\bar{G})$. We may then express $\hat{h}^{*}\bar{G}$ using the trivialization $(\mathcal{F}, \Phi)$ associated to $\hat{f}_{2}$, so there is a section $\nu_{\hat{h}^{*}\bar{G}}$ of $\psi_{\hat{h}}^{*}\hat{f}_{2}T_{\text{vert}}\mathcal{B}$ such that $\hat{h}^{*}\bar{G} = \mathcal{F}(\psi_{\hat{h}}^{*}\nu_{\hat{h}^{*}\bar{G}})$. The map $\psi_{\theta_{\hat{h}}}$ is constructed so that

$$\partial \nu_{\hat{h}^{*}\bar{G}} = \Phi(\partial \hat{h} - \theta_{\hat{h}}).$$

In particular, $\partial \nu_{\hat{h}^{*}\bar{G}}$ is zero at 0 and has first derivative equal to $\nu_{0}$. Theorem 3.6 implies that there is a unique section $\nu_{\hat{h}^{*}\bar{G}}^{*}$ of $\psi_{\hat{h}}^{*}\hat{f}_{2}T_{\text{vert}}\mathcal{B}$ such that $\partial \nu_{\hat{h}^{*}\bar{G}}^{*} = \nu_{\hat{h}^{*}\bar{G}}$, and Corollary 3.7 implies that that $\nu_{\hat{h}^{*}\bar{G}}^{*}$ and $\nu_{\hat{h}^{*}\bar{G}}$ are equal to first order at 0. It follows that the derivative at 0 of $\partial \nu_{\hat{h}^{*}\bar{G}}^{*}$ is equal to $\nu_{0}$. The uniqueness part of Theorem 3.6 implies that $\nu_{\hat{h}^{*}\bar{G}}^{*} = \psi_{\hat{h}}^{*}\nu_{\hat{h}}^{*}$, so $\nu_{0}$ must be in the image of the derivative of $\partial \nu$ at the curve $f$ in $\hat{f}_{2}$. As this argument holds for any $\nu_{0}$ in $V_{2}(f)$, it follows that $\partial \nu$ is transverse to 0 at $f = 0$, and the proof of Claim 6.12 is complete.

With Claim 6.12 complete, we may shrink $\hat{f}_{2}$ to an open subfamily (and shrink $\mathcal{O}$ to a smaller open substack accordingly) until we may assume that $\partial \nu$ is transverse to 0, and $D\partial$ is transverse to $V_{2}$ at $\nu$.

Definition 6.13. Let $\hat{f}_{3}$ be the subfamily of $\mathcal{F}(\nu)$ given by the intersection of $\partial \nu$ with 0.

So $\nu: \hat{f}_{3} \rightarrow \mathcal{F}(\nu)$ is a sub family with $\partial \hat{f}_{3} \subset V(\hat{f}_{3})$, and $C(\nu): C(\hat{f}_{3}) \rightarrow C(\hat{f}_{2}) = C(\mathcal{F}(\nu))$ is also a sub family. Moreover,

$$\partial \hat{f}_{3} = (C(\nu), \hat{f}_{3})\theta$$

where $\theta$ is the tautological section from (22).

Claim 6.14. For any family $\hat{h}$, and map $k: C(\hat{h}) \rightarrow C(\hat{f}_{1})$, there exists at most one map $\psi: \hat{h} \rightarrow \hat{f}_{3}$ such that

$$r \circ C(\psi) = k$$

where $r: C(\hat{f}_{3}) \rightarrow C(\hat{f}_{1})$ is the restriction of the map $r$ in Definition 6.9 to the subfamily $C(\hat{f}_{3}) \subset C(\hat{f}_{2})$. 

In fact, equation (26) implies that curves over the fiber of \( F(f_3) \to F(f_1) \) over different points in \( F(f_3) \subset F(f_2) = V_1 \) can’t be isomorphic, because \( \bar{\rho} \) of these curves is determined by the map to \( V_1 \). As \( \psi \) is determined by \( r \circ C(\psi) = k \) and \( F(\psi): F(\hat{h}) \to F(f_3) \), Claim 6.14 follows.

The uniqueness property of \( \nu \) implies that \( \hat{f}_3 \) is a \( G \)-invariant family of curves. Claim 6.14 gives that our fiberwise holomorphic map \( \Phi^1_{+1} \) has image in \( C(f_3) \subset C(f_2) \), and also implies that this fiberwise holomorphic map can be regarded as a map of stacks

\[
\Psi: \bar{\rho}^{-1} V \to \hat{f}_3/G
\]

so that \( \Psi(\hat{h}) \) is the \( G \)-bundle \( \hat{h}^G \to \hat{h} \) with the \( G \)-equivariant map \( \Psi(\hat{h}): \hat{h}^G \to \hat{f}_3 \) such that \( C(\Psi(\hat{h})) = \Phi^1_{+1} (\hat{h}) \). As with \( \Phi_2 \) and \( \Phi_1 \), \( \Psi \) sends the morphism \( \alpha: \hat{g} \to \hat{h} \) to the map \( \alpha^G: \hat{g}^G \to \hat{h}^G \) of \( G \)-bundles.

Claim 6.14 implies that this map \( \Psi(\hat{h}): \hat{h}^G \to \hat{f}_3 \) is also the unique map with the property that \( \Phi^1_{+1} (\hat{h}) \) factorizes as follows:

\[
\begin{array}{ccc}
C(\hat{h}^G) & \xrightarrow{C(\Psi(\hat{h}))} & C(\hat{f}_3) \\
\downarrow{\Phi^1_{+1} (\hat{h})} & & \downarrow{r} \\
C(\hat{f}_3) & \xrightarrow{\Phi^1_{+1} (\hat{f})} & C(\hat{f}_1)
\end{array}
\]

so \( \Phi^1_{+1} (\hat{h}) = r \circ C(\Psi(\hat{h})) \), where \( r \) appears in Definition 6.9.

We have not proved — and it is not true — that \( \hat{f}_3/G \) represents \( \bar{\rho}^{-1} V \subset O \). We must restrict \( \hat{f}_3 \) to a sub-family to achieve this. Moreover, the maps \( \Phi^1_{+1} \) and \( r \) do not coincide on \( C(f_3) \). Roughly speaking, the family \( \hat{f} \subset \hat{f}_3 \) we are looking for is the subfamily where \( r \) and \( \Phi^1_{+1} (f_3) \) coincide.

The fiberwise holomorphic map \( \Phi_1 \) applied to \( \hat{f}_3 \) gives a \( G \)-fold cover \( \hat{f}_3^G \) of \( \hat{f}_3 \) and a map

\[
\Phi^1_{+1} (\hat{f}_3): C(\hat{f}_3^G) \to C(\hat{f}_1).
\]

For \( O \) small enough, and \( \hat{f}_1 \) restricted accordingly, we may assume that \( \hat{f}_3^G \) consists of \( |G| \) copies of \( \hat{f}_3 \), so \( \Phi^1_{+1} (\hat{f}_3) \) above consists of \( |G| \) maps \( C(\hat{f}_3) \to C(\hat{f}_1) \). Both \( \hat{f}_3 \) and \( \hat{f}_1 \) have a canonical inclusion of the curve \( f \). The fact, from Lemma 6.14, that the core family map to \( C(f_3) \) factorizes through \( \Phi^1_{+1} (f_3) \) implies that exactly one of these maps \( C(f_3) \to C(\hat{f}_1) \) must be the identity on \( C(f) \). There is therefore a unique lift

\[
l: \hat{f}_3 \to \hat{f}_3^G
\]

(or section of the \( G \)-bundle \( \hat{f}_3^G \to \hat{f}_3 \)) such that the map

\[
\phi_1 := \Phi^1_{+1} (\hat{f}_3) \circ l: C(\hat{f}_3) \to C(\hat{f}_1)
\]

is the identity on \( C(f) \).

As \( \hat{f}_3^G \to \hat{f}_3 \) is a \( G \) bundle, and the \( G \)-action on \( \hat{f}_3 \) lifts to an action on this \( G \)-bundle, there is an action of \( G \times G \) on \( \hat{f}_3^G \) such that \( \Phi^1_{+1} (\hat{f}_3) \) is invariant under the first factor and equivariant under the second factor, and the bundle map \( \hat{f}_3^G \to \hat{f}_3 \) is equivariant under the first factor and invariant under the second factor. The lift \( l: \hat{f}_3 \to \hat{f}_3^G \) is \( G \)-equivariant when the diagonal action of \( G \) is used on \( \hat{f}_3^G \), so the map \( \phi_1 \) is \( G \)-equivariant.

The map \( \phi_1 \) has the following important property:

\[
\phi_1 \circ C(\Psi(h)) = \Phi^1_{+1} (\hat{h})
\]
The two factorizations of $\Phi_1^+(h): C(h^{\times G}) \to C(\hat{f}_3)$ from (28) and (31) imply that the map $\Psi(h): h^{\times G} \to \hat{f}_3$ has image in the subset of $C(f_3)$ where $r$ and $\phi_1$ coincide. These two maps $r$ and $\phi_1$ are not the same, but they do coincide after projecting to $C(f_0)$. Recall from Lemma 5.4 that $\Phi_1^+(h)$ followed by the projection $C(f_1) \to C(f_0)$ is the core-family map $\Phi_0^+(h)$ to $f_0$. The map $r$ followed by projection to $C(f_0)$ and quotiented by $G$ is also the stack version of the core-family map $(\Phi_0^+)_{\hat{f}_2}: C(\hat{f}_2) \to C(\hat{f}_0)/G$. Definition 5.1 part 3 implies that this core-family map is the same for $\hat{f}_2$ and its deformation $F(\nu)$, so the restriction of $r$ to $C(f_3)$ followed by a quotient by $G$ is also the stack version of the core-family map $(\Phi_0^+)_{\hat{f}_3}: C(\hat{f}_3) \to C(\hat{f}_0)/G$. As both $r$ and $\phi_1$ are the identity on the canonical inclusion of $f$ in $\hat{f}_3$, the step of taking a quotient by $G$ is not necessary, and the following diagram commutes:

$$
\begin{array}{ccc}
C(\hat{f}_3) & \xrightarrow{\phi_1} & C(\hat{f}_1) \\
\downarrow & & \downarrow \\
C(f_1) & \longrightarrow & C(f_0)
\end{array}
$$

Claim 6.15. At the curve $f$ in $\hat{f}_3$, the map

$$(r, \phi_1): C(f_3) \to C(\hat{f}_1) \times_{C(f_0)} C(\hat{f}_1)$$

is transverse to the diagonal section of $C(\hat{f}_1) \times_{C(f_0)} C(\hat{f}_1) \to C(f_0)$.

To prove Claim 6.15 recall that there is an inclusion of $\hat{f}_1$ into $\hat{f}_2$ on which the tautological section $\theta$ from (22) is 0. The inverse image, $\hat{g}$, of $f$ under the map $\hat{f}_1 \to f_0$ is holomorphic. Therefore, $\nu$ is 0 on the image of $\hat{g}$ in $\hat{f}_2$, so there is an inclusion $\hat{g} \to f_3 \subset F(\nu)$ lifting the inclusion $g \to f_1$. As every curve in $\hat{g}$ is isomorphic to $f$, $\phi_1$ restricted to $C(\hat{g})$ is constant. On the other hand, $r$ restricted to $C(\hat{g})$ is an isomorphism onto the fiber of $C(\hat{f}_1) \to C(f_0)$ over $C(f)$, therefore $(r, \phi_1)$ is transverse to the diagonal at $f$ as required.

By restricting $\hat{f}_3$ to a possibly smaller neighborhood $O$ of $f$, Claim 6.15 implies that we may assume that $(r, \phi_1)$ is transverse to the diagonal.

Definition 6.16. Let $\hat{f}$ be the restriction of $\hat{f}_3$ to the inverse image of the diagonal under $(r, \phi_1): C(\hat{f}_3) \to C(\hat{f}_1) \times_{C(f_0)} C(\hat{f}_1)$.

As the diagonal and $(r, \phi_1)$ are $G$–equivariant, $\hat{f}$ is a $G$–invariant family.

As noted above, (28) and (31) imply that $\Psi: \hat{f}_3/G \to \hat{f}/G$ has image in the substack where $r$ and $\phi_1$ coincide, so we have a map $\Psi: \hat{f}_3/G \to \hat{f}/G$. In the following claims, we prove that $\hat{f}/G$ represents this moduli stack of curves with $\hat{\partial}$ in $V$.

Claim 6.17. The fiber product $\hat{f} \times_{\hat{f}/G} \hat{f}$ is represented by $\Psi(\hat{f})$ in the following sense. Given a family $h$ in $O$ with two maps $\alpha, \beta: h \to \hat{f}$, there exists a unique map $\psi_{\alpha, \beta}: h \to \hat{f}^{\times G}$ such that the following diagram commutes

$$
\begin{array}{cccc}
h & \xrightarrow{\alpha} & \hat{f} \\
\downarrow & & \downarrow & \psi_{\alpha, \beta} \\
\hat{f} & \leftrightarrow & \hat{f}^{\times G}
\end{array}
$$

where $\pi: \hat{f}^{\times G} \to \hat{f}$ is the $G$–bundle from $\Psi$. 
To prove Claim 6.17, we will construct an equivariant lift \( l' : \hat{f} \rightarrow \hat{f}^{\times G} \) such that both \( \pi \circ l' \) and \( \Psi(f) \circ l' \) are the identity. In particular, \( l' \) is the pullback of the lift \( l : \hat{f}_3 \rightarrow \hat{f}_3^{\times G} \) from (29) using the inclusion \( i : \hat{f} \hookrightarrow \hat{f}_3 \).

\[
\begin{array}{ccc}
\hat{f}^{\times G} & \xrightarrow{\pi^{\times G}} & \hat{f}_3^{\times G} \\
\downarrow \downarrow \downarrow & & \downarrow \downarrow \downarrow \\
\hat{f} & \xrightarrow{i} & \hat{f}_3 
\end{array}
\]

From Definition 2.50, we have

\[
\Phi_1^+(\hat{f}_3) \circ C(l^{\times G}) = \Phi_1^+(\hat{f})
\]

so (30) implies that

\[
\Psi(\hat{f}) \circ (\Phi_1^+(\hat{f}_3)) = \Phi_1^+(\hat{f})
\]

From (28), we also have that \( r \circ C(\Psi(\hat{f})) = \Phi_1^+(\hat{f}) \), and Definition 6.16 implies that \( \phi_1 \) and \( r \) coincide restricted to \( C(\hat{f}_3) \), so

\[
r \circ C(\Psi(\hat{f})) \circ C(l') = r
\]

and Claim 6.14 then implies that \( \Psi(\hat{f}) \circ l' \) is the identity. By construction, \( l' \) is also a section of the \( G \)-bundle \( \pi : \hat{f}^{\times G} \rightarrow \hat{f} \), so \( l' \) allows us to identify \( \hat{f}^{\times G} \) with \( \hat{f} \times G \), where \( l'(f) = (f, \text{id}) \), \( \pi(f, g) = f \), and \( \Psi(\hat{f})(f, g) = g \ast f \).

Assume without loss of generality that \( \hat{h} \) is connected. Given maps \( \alpha \) and \( \beta \) from \( \hat{h} \) into \( \hat{f} \), we get two sections \( \alpha \ast l' \) and \( \beta \ast l' \) of the \( G \)-bundle \( \hat{h}^{\times G} \rightarrow \hat{h} \), and hence a unique element \( g_{\alpha, \beta} \in G \) such that \( g_{\alpha, \beta} \ast (\beta \ast l') = \alpha \ast l' \). Then there is a map \( \psi_{\alpha, \beta} : \hat{h} \rightarrow \hat{f}^{\times G} = \hat{f} \times G \) such that the required diagram commutes. In particular,

\[
\psi_{\alpha, \beta}(\hat{h}) = (\beta, g_{\alpha, \beta})
\]

As \( G \) does not act trivially on any curve in \( \hat{f} \), it follows that \( \psi_{\alpha, \beta} \) is the unique map such that the required diagram commutes. This completes the proof of Claim 6.17.

Claim 6.18. For \( \hat{h} \) a family in \( \partial^{-1}V \cap \mathcal{O} \), the fiber product \( \hat{h} \times_{\mathcal{O}} \hat{f} \) is represented by \( \hat{h} \xrightarrow{\psi(h)} \hat{f} \).

So, given \( \alpha : \hat{g} \rightarrow \hat{f} \) and \( \beta : \hat{g} \rightarrow \hat{h} \), we must prove that there exists a unique map \( \psi_{\alpha, \beta} : \hat{g} \rightarrow \hat{h}^{\times G} \) such that the following diagram commutes.

\[
\begin{array}{ccc}
\hat{g} & \xrightarrow{\alpha} & \hat{f} \\
\downarrow \beta & \downarrow \psi_{\alpha, \beta} & \downarrow \psi(h) \\
\hat{h} & \xleftarrow{\beta} & \hat{h}^{\times G}
\end{array}
\]

Without losing generality, we can assume that \( \hat{g} \) is connected and small enough that it maps into a subfamily of \( \hat{h} \) over which the \( G \)-bundle \( \hat{h}^{\times G} \rightarrow \hat{h} \) is trivial, so there are exactly \( |G| \) lifts of \( \beta \), permuted by the action of \( G \) on this \( G \)-bundle. Moreover, Claim 6.17 implies that there are exactly \( |G| \) maps \( \hat{g} \rightarrow \hat{f} \), permuted by the action of \( G \) on \( \hat{f} \). As \( \Psi(\hat{h}) \) is \( G \)-equivariant, it follows that there is exactly one lift \( \psi_{\alpha, \beta} \) of \( \beta \) such that \( \Psi(h) \circ \psi_{\alpha, \beta} = \alpha \). Claim 6.18 follows.

Claim 6.19. The stack \( \partial^{-1}V \subset \mathcal{O} \) is represented by \( \hat{f}/G \) in the sense of Definition 2.29. Moreover, the map \( \Phi_X \) from Definition 2.19 is an inverse to the map \( \Psi : \partial^{-1}V \rightarrow \hat{f}/G \). 
By definition, \( \Psi(\hat{h}) \) is a \( G \)-bundle \( \hat{h}^\ast G \to \hat{h} \) with a \( G \)-equivariant map to \( \tilde{f} \), and \( \Phi_X(\Psi(\hat{h})) = \hat{h} \). Similarly for a morphism, \( \alpha \) in \( \partial^{-1}V \), \( \Phi_X(\Psi(\alpha)) = \alpha \). So, \( \Phi_X \circ \Psi \) is the identity. To prove Claim 6.19 it remains to construct a 2-isomorphism \( \eta \) from the identity to \( \Psi \circ \Phi_X \).

Consider a family in \( \hat{f}/G \); this is a \( G \)-bundle \( \hat{h}' \to \hat{h} \) internal to \( O \) and a \( G \)-equivariant map \( \alpha : \hat{h}' \to \hat{f} \) (call this family \( \alpha \)). We have \( \Phi_X(\alpha) = \hat{h} \), so \( \Psi(\Phi_X(\alpha)) \) is the \( G \)-bundle \( \hat{h}^\ast G \to h \) with the \( G \)-equivariant map \( \Psi(\hat{h}) : \hat{h}^\ast G \to \tilde{f} \). We want an isomorphism \( \eta_\alpha \) from \( \alpha \) to \( \Psi(\hat{h}) \), or an isomorphism of \( G \)-bundles \( \eta_\alpha : \hat{h}' \to \hat{h}^\ast G \) such that the following diagram commutes.

\[
\begin{array}{ccc}
\hat{h}' & \xrightarrow{\alpha} & \tilde{f} \\
\downarrow{\eta_\alpha} & & \downarrow{\Psi(\hat{h})} \\
\hat{h} & & \hat{h}^\ast G
\end{array}
\]

In fact, Claim 6.18 implies that there is a unique map \( \eta_\alpha \) such that the above diagram commutes. Claim 6.17 implies that \( \eta_\alpha \) must be \( G \)-equivariant, so \( \eta_\alpha \) is the required isomorphism of \( G \)-bundles. Moreover, Claim 6.18 implies that given any map \( \psi' \) of \( G \)-bundles, the following diagram commutes:

\[
\begin{array}{ccc}
\hat{g}' & \xrightarrow{\psi'G} & \hat{h}' \\
\downarrow{\eta_\alpha} & & \downarrow{\alpha} \\
\hat{g} & \xrightarrow{\psiG} & \hat{h}
\end{array}
\]

so \( \eta \) defines a natural transformation. This completes the proof of Claim 6.19.

To complete the proof of our theorem, we must still verify that \( T_f \tilde{f} : T_f \mathbf{F}(\tilde{f}) \to D\partial^{-1}V(f) \) is a bijection.

The following claim allows us to think of \( \mathbf{C}(\tilde{f}) \) as embedded in both \( \mathbf{C}(\hat{f}_1) \) and \( \mathbf{C}(\hat{f}_0) \). It implies that any \( G \)-invariant section of \( V(\tilde{f}) \) may be extended to a global section of \( V \) defined on a neighborhood of \( \tilde{f} \) in \( M^s_{\mathbb{R}} \), and similarly any \( G \)-invariant, \( C^\infty_\mathbb{L} \) function of \( \mathbf{F}(\tilde{f}) \) may be extended to a \( G \)-invariant, \( C^\infty_\mathbb{L} \) function defined on a neighborhood of \( \tilde{f} \) in \( M^s_{\mathbb{R}} \).

**Claim 6.20.** The maps

\[
\phi_1 : \mathbf{C}(\tilde{f}) \to \mathbf{C}(\hat{f}_1)
\]

and

\[
\mathbf{C}(\tilde{f}) \xrightarrow{\phi_1} \mathbf{C}(\hat{f}_1) \to \mathbf{C}(\hat{f}_0)
\]

are embeddings in a neighborhood of \( f \).

To prove Claim 6.20 note that \( \mathbf{F}(\hat{f}_1) \to \mathbf{F}(\hat{f}_2) \) is an embedding, locally defined by transverse vanishing of some \( C^\infty_\mathbb{L} \) functions. (This was proved in Claim 6.12) \( \mathbf{C}(\tilde{f}) \subset \mathbf{C}(\hat{f}_1) \) is defined as the subset where \( r \) and \( \phi_1 \) agree. These maps are proved to be transverse in Claim 6.13. As required by Lemma 6.4 part 2 \( \mathbf{C}(\hat{f}_1) \to \mathbf{C}(\hat{f}_0) \) is isomorphic to a vectorbundle. The maps \( r \) and \( \phi_1 \) agree after composition with the map \( \mathbf{C}(\hat{f}_1) \to \mathbf{C}(\hat{f}_0) \), therefore \( \mathbf{F}(\tilde{f}) \subset \mathbf{F}(\hat{f}_2) \) is also an embedding locally defined by the transverse vanishing of some \( C^\infty_\mathbb{L} \) functions.

As \( \mathbf{F}(\hat{f}_2) \) is isomorphic to a vectorbundle over \( \mathbf{F}(\hat{f}_1) \), and \( \mathbf{F}(\hat{f}_1) \) is isomorphic to a vectorbundle over \( \mathbf{F}(\hat{f}_0) \), to finish Claim 6.20 it now suffices to prove that
the derivative of the map \( F(\hat{f}) \rightarrow F(\hat{f}_0) \) is injective at \( f \). Let \( v \) be a vector in \( T_f F(\hat{f}) \) sent to 0 in \( T_f F(\hat{f}_0) \). As this map \( F(\hat{f}) \rightarrow F(\hat{f}_0) \) corresponds to the core-family map, it follows that \( v \) must equal a section of \( f^* T_{\text{vert}} B \) vanishing on the extra marked points \( \{s_i\} \) in the definition of the core family \( \hat{f}_0 \). Lemma [2.63] specifies that \( D\bar{\partial}^{-1} V(f) \) does not contain any nonzero such vector, but \( D\bar{\partial}(v) \) must be in \( V(f) \) because \( \bar{\partial} f \) is a section of \( V(f) \). It follows that the image of \( v \) in \( T_f \mathcal{M}^\psi \) is 0. In particular, \( D\bar{\partial}(v) = 0 \), therefore \( v \) is tangent to \( F(\hat{f}_1) \subset F(\hat{f}_2) \).

The projection of \( T_f F(\hat{f}_2) \) onto \( T_f F(\hat{f}_1) \) comes from the map \( r \), which coincides on \( T_f F(\hat{f}) \subset T_f F(\hat{f}_2) \) with \( \phi_1 \). As \( \phi_1 \) comes from a fiberwise-holomorphic map \( \Phi_1 \) of a neighborhood of \( f \) in \( \mathcal{M}^\psi \), Lemma [2.64] implies that the map \( T_f F(\hat{f}) \rightarrow T_f F(\hat{f}_1) \) factors through \( T_f \mathcal{M}^\psi \), therefore the image of \( v \) in \( T_f F(\hat{f}_1) \) must be zero. As we have already established that \( v \) is tangent to \( T_f F(\hat{f}_1) \), it follows that \( v \) is the zero vector in \( T_f F(\hat{f}) \) and the map \( T_f F(\hat{f}) \rightarrow T_f F(\hat{f}_0) \) is injective.

It follows that, on some neighborhood of \( f \) in \( F(\hat{f}) \), the map \( F(\hat{f}) \rightarrow F(\hat{f}_0) \) is an embedding, locally defined by the transverse vanishing of some \( C_{\infty,L}^1 \) functions. As \( F(\hat{f}_1) \rightarrow F(\hat{f}_0) \) is isomorphic to a vectorbundle, the same holds for the map \( F(\hat{f}) \rightarrow F(\hat{f}_1) \). This completes the proof of Claim [6.20]

To complete the proof of Theorem [6.8] it remains to prove the following:

**Claim 6.21.** The map

\[
T_f \hat{f} : T_f F(\hat{f}) \rightarrow T_f \mathcal{M}^\psi(B)
\]

is injective, and has image

\[
D\bar{\partial}^{-1} (V(f)) \subset T_f \mathcal{M}^\psi(B).
\]

To prove Claim [6.21], note that Claim [6.20] gives that the map \( T_f F(\hat{f}) \rightarrow T_f F(\hat{f}_0) \) is injective. As this map comes from the core family map \( \Phi_0 \) to \( C(\hat{f}_0)/G \), Lemma [2.64] implies that it factors through \( T_f \mathcal{M}^\psi \), therefore \( T_f F(\hat{f}) \) injects into \( T_f \mathcal{M}^\psi \).

So far, we have seen that \( T_f \hat{f} : T_f F(\hat{f}) \rightarrow T_f \mathcal{M}^\psi \) is injective. Obviously, \( T_f F(\hat{f}) \) has image contained inside \( D\bar{\partial}^{-1} (V(f)) \), so it remains to show that the image of \( T_f F(\hat{f}) \) contains \( D\bar{\partial}^{-1} (V(f)) \). Given any vector \( v \) in \( D\bar{\partial}^{-1} (V(f)) \), Lemma [2.63] implies that there exists a family \( \hat{h} \) of curves in \( O \) parametrized by \( \mathbb{R} \), such that \( \hat{h} \) is the curve over 0, and the derivative of \( \hat{h} \) at 0 is \( v \). There therefore exists a section \( \theta_{\hat{h}} \) of \( V(\hat{h}) \) so that \( \bar{\partial} \hat{h} - \theta_{\hat{h}} \) is tangent to the zero-section at 0. Then there exists a map \( \psi_{\hat{h}} : C(h) \rightarrow C(f) \) and a section \( \nu_{\hat{h}} \) of \( (f_2 \circ \psi_{\hat{h}})^* T_{\text{vert}} B \) vanishing on the inverse image of the marked point sections \( \{s_i\} \) so that \( \hat{h} = F(\nu_{\hat{h}}) \) and \( \bar{\partial} \nu_{\hat{h}} \) is tangent to the zero-section at 0. The uniqueness part of Theorem [5.4] then implies that, close to 0, there exists a section \( \nu'_{\hat{h}} \) for which \( \bar{\partial} \nu'_{\hat{h}} = 0 \), and Corollary [6.7] implies that \( \nu'_{\hat{h}} \) is tangent to \( \nu_{\hat{h}} \) at 0. The uniqueness part of Theorem [5.4] implies that \( \nu'_{\hat{h}} = (\psi_{\hat{h}})^* \nu \), so \( \hat{h} \) is tangent at 0 to the family \( \hat{f}_3 \) at \( f \). This proves that the image of \( T_f \hat{f}_3 : T_f F(\hat{f}_3) \rightarrow T_f \mathcal{M}^\psi \) contains \( D\bar{\partial}^{-1} (V(f)) \), so the image of \( T_f \hat{f} \) also contains \( D\bar{\partial}^{-1} (V(f)) \), because \( \Psi(\hat{f}_3) \) maps a \( G \)-bundle over \( \hat{f}_3 \) into \( f \), and represents the \( G \)-quotient map when restricted to \( f \subset \hat{f}_3 \). It follows that \( T_f \hat{f} : T_f F(\hat{f}) \rightarrow D\bar{\partial}^{-1} (V(f)) \) is a bijection.

This completes the proof of Claim [6.21] and Theorem [6.8].

\( \square \)
7. Construction of an Embedded Kuranishi Structure

Throughout this section, we assume that the map \( \mathcal{M} \to \mathcal{B}_0 \) is proper when restricted to any connected component of \( \mathcal{M}^{st} \) in the sense that any sequence of holomorphic curves in \( \mathcal{M} \) over a compact subset of \( \mathcal{B}_0 \) has a subsequence that converges in \( C^\infty \) — this compactness property for the moduli stack of holomorphic curves is proved for many targets \( \mathcal{B} \) in [28], and Definition 2.58 implies that the same property holds for \( \mathcal{M}_* \subset \mathcal{M}^{st}_* \). We need this assumption to use Lemma 5.23 and to construct our Kuranishi charts to give a locally finite cover of \( \mathcal{M} \) or \( \mathcal{M}_* \).

Before beginning the construction, we need an analogue of Lemma 5.23 to apply to \( \mathcal{M}^{st}_* \) so that we can shrink open substacks of \( \mathcal{M}^{st}_* \) appropriately.

**Lemma 7.1.** Given any holomorphic curve \( f \) in \( \mathcal{M}^{st}_* \) and open neighborhood \( \mathcal{U} \subset \mathcal{M}^{st}_* \), there exists an open neighborhood \( \mathcal{O} \subset \mathcal{U} \) of \( f \) and a \( C^\infty \) function \( \rho: \mathcal{O} \to [0,1] \) so that \( \rho(f) = 1 \), and any holomorphic curve in the closure (within \( \mathcal{M}^{st}_* \)) of \( \{ \rho > 0 \} \) is contained in \( \mathcal{O} \).

**Proof:**
Use \( \pi: \mathcal{M}^{st}_* \to \mathcal{M}^{st} \) for the map forgetting decorations. Theorem 6.8 implies that we may choose a neighborhood \( \mathcal{O}_1 \) of the undecorated \( \pi(f) \) in \( \mathcal{M}^{st} \) so that the moduli stack of holomorphic curves in \( \mathcal{O}_1 \) is represented by some substack of \( \hat{f}/G \), and Claim 6.20 implies that \( \hat{f}/G \) embeds into a core family \( f_0/G \) for \( \mathcal{O}_1 \). Definition 2.58 implies that the lift \( (\pi^*\hat{f})/G \) of \( \hat{f}/G \) to \( \mathcal{M}^{st}_* \) contains the moduli stack of holomorphic curves in the inverse image \( \pi^{-1}\mathcal{O}_1 \) of \( \mathcal{O}_1 \) within \( \mathcal{M}^{st}_* \). Remark 5.2 then implies that the lift \( (\pi^*f_0)/G \) of \( f_0/G \) is a core family for \( \pi^{-1}\mathcal{O}_1 \). Note that this means that any \( G \)-invariant \( C^\infty \) function on \( \pi^*\hat{f} \) may be extended to a \( G \)-invariant \( C^\infty \) function on \( \pi^{-1}\mathcal{O}_1 \). Lemma 6.23 implies that there exists an open neighborhood \( \mathcal{O}_2 \subset \mathcal{O}_1 \) of the undecorated \( \pi(f) \) such that every holomorphic curve in the closure of \( \mathcal{O}_2 \) within \( \mathcal{M}^{st} \) is contained in \( \mathcal{O}_1 \). Choose a \( C^\infty \) function \( \rho: \pi^{-1}\mathcal{O}_1 \to [0,1] \) to be equal to 1 at \( f \), and to have compact support when restricted to the intersection of \( \pi^{-1}\mathcal{O}_1 \) with \( \mathcal{U} \cap \pi^{-1}\mathcal{O}_2 \). The restriction of \( \rho \) to \( \mathcal{O} := \mathcal{U} \cap \pi^{-1}\mathcal{O}_2 \) satisfies the required property. \( \square \)

**Lemma 7.2.** Let \( \mathcal{O} \) be an open neighborhood of a holomorphic curve \( f \in \mathcal{M}^{st}_* \) with a \( C^\infty \) submersion
\[
\Phi: \mathcal{O} \to X
\]
to an exploded manifold or orbifold \( X \). Then, there exists an open neighborhood \( \mathcal{U} \) of \( f \in \mathcal{M}^{st}_* \), and, on \( \mathcal{U} \), a simply-generated complex subsheaf \( V \) of \( \mathcal{Y} \) so that
\begin{enumerate}
  \item \( V \) is strongly transverse to \( \partial \) at all holomorphic curves in \( \mathcal{U} \),
  \item and, at any holomorphic curve \( f' \) in \( \mathcal{U} \), \( D\partial \) restricted to the kernel of \( T_{f'}\Phi \) is strongly transverse to \( V(f) \), so for any \( t \in [0,1] \)
  \[
  T_{f'}\Phi \left( \left( (1-t)D\partial + tD\partial \right)^{-1}(V(f')) \right) = T_{f(f')}X
  \]
\end{enumerate}
Suppose further that there is a finite collection of open substacks \( \mathcal{U}_i \) of \( \mathcal{M}^{st}_* \) on which are defined simply-generated subsheaves \( V_i \) of \( \mathcal{Y} \), and for each \( \mathcal{U}_i \) there is a chosen substack \( \mathcal{C}_i \subset \mathcal{U}_i \), closed within \( \mathcal{M}^{st}_* \). Then \( V \) may be modified so that, in addition to the above conditions, for any holomorphic curve \( f' \) in \( \mathcal{C}_i \cap \mathcal{U}_i \), the intersection of \( V(f') \) and \( V(f') \) is \( 0 \).

\[\text{Note that lemmas 5.14 and 2.53 imply that a substack of } \mathcal{M}^{st} \text{ is compact if and only if it is sequentially compact. The existence of core families make } \mathcal{M}^{st} \text{ relatively tame, but more general stacks are non-Hausdorff in nastier ways than exploded manifolds, so the correct definition of a proper map of stacks is probably stronger than the inverse image of compact substacks being compact.}\]
Proof:
If \( f \) has domain \( T \), this lemma follows from Lemma 7.6 and the observations that precede it on page 97. Going forward, we assume that the domain of \( f' \) is not \( T \).

Remark 5.2 together with Proposition 5.12 gives that there exists an open neighborhood \( U \) of \( f \) in \( \mathcal{M}^* \) and a core family \( f/G \) for \( U \) containing \( f \). Theorem 5.8 implies that there exists a finite-dimensional subspace of \( Y(f) \) strongly transverse to \( \mathcal{D} \) in the sense of Definition 2.7.3. As the codimension of \( \ker T_f \Phi \subset T_f \mathcal{M}^* \) is finite, we can also construct our finite dimensional subspace of \( Y \) to be strongly transverse to \( D \overline{\partial} \) restricted to \( \ker T_f \Phi \). We may also assume that \( G \) preserves \([f]\) within \([F(f)]\). Then, as \( \mathcal{Y}(f) \) only depends on the smooth part of \( f \), the action of \( G \) on \([f]\) gives a \( G \)-action on \( \mathcal{Y}(f) \). As this \( G \)-action on \( \mathcal{Y}(f) \) is complex, we may choose a finite-dimensional, complex, \( G \)-invariant subspace \( V(f) \) of \( \mathcal{Y}(f) \), strongly transverse to \( \mathcal{D} \) when restricted to \( \ker T_f \Phi \).

There exists a complex basis \( \{v_1(f), \ldots, v_n(f)\} \) for \( V(f) \) so that the action of \( g \in G \) in this basis is given by a \( n \times n \) complex matrix \( A_g \). Let us extend \( v_i \) and this action. As the inclusion \( C(f) \rightarrow C(\hat{f}) \) is an isomorphism onto a fiber of \( C(\hat{f}) \), Remark 5.8 implies that there exist sections \( v'_i \) of \( \Gamma^{0,1}(\mathcal{T}_{\text{vert}} C(\hat{f}) \otimes T_{\text{vert}} \mathcal{B}) \), considered as a sheaf of \( \mathbb{C} \)-modules, such that the pullback of \( v'_i \) to \( Y(f) \) is \( v_i(f) \). If \( v' \) indicates the vector with components \( v'_i \), then define

\[
v := \sum_{g \in G} A_g^{-1} g * v'.
\]

Note that

\[
g * v = A_g v
\]

so the sheaf of \( \mathcal{C}^\infty_{\text{vert}}(F(\hat{f}), \mathbb{C}) \)-modules generated by the components of \( v \) is \( G \)-invariant. Restricted to \( C(f) \), \( g * v' = A_g v' \), so the pullback of the \( i \)-th component of \( v \) to \( Y(f) \) is \(|G| v_i(f) \). It follows that the complex subsheaf, \( V \) of \( Y \), generated by the pullback of this sheaf of \( \mathcal{C}^\infty_{\text{vert}}(F(\hat{f}), \mathbb{C}) \)-modules is equal to \( V(f) \) at \( f \), and is simply generated on some neighborhood \( \mathcal{U} \) of \( f \).

We have chosen \( V \) so that \( V(f) \) is strongly transverse to \( D \partial \) restricted to \( \ker T_f \Phi \). Such strong transversality will also hold at all holomorphic curves in a neighborhood of \( f \): Theorem 6.3 states that, if \( U \) is small enough, the moduli stack \( \hat{\mathcal{D}}^{-1} V \subset U \) is represented by the quotient of some family \( \hat{f} \) of curves by an automorphism group \( G' \). Theorem 5.6 then implies that, at all holomorphic curves \( f' \) in a neighborhood of \( f \) in \( \hat{f}' \), \( V \) is strongly transverse to \( D \partial \) restricted to \( \ker T_{f'} \Phi \); see also Lemma 8.7. In particular, as \( T_f \Phi \) is surjective, this is equivalent to requiring that \( V(f') \) is strongly transverse to \( D \partial \), and that

\[
T_f \Phi(((1-t)D \partial + t D \partial \mathcal{C})^{-1} V(f')) = T_{\Phi(f')} X.
\]

It remains to prove that \( V \) may be modified so that, for any holomorphic curve \( h \) in \( C_t \), \( V(h) \cap V_t(h) = 0 \). For applications of this lemma, it is important that the domain \( \mathcal{U} \) of definition of this modified \( V \) does not depend on \( \mathcal{U}_t \) and \( V_t \). Choose our \( \mathcal{U} \) so that the stack of holomorphic curves in the closure, \( \overline{\mathcal{U}} \), of \( \mathcal{U} \), is compact, and so that \( V \) is still defined and satisfies the required transversality conditions on a larger neighborhood \( \mathcal{U}' \) containing all such holomorphic curves — Lemma 7.1 implies that such a reduction of the size of \( \mathcal{U}' \) is possible. We shall use \( \hat{f}/G \) to indicate the core family for this larger \( \mathcal{U}' \).

Recall that \( V \) is pulled back from a \( G \)-invariant complex subsheaf of \( \Gamma^{0,1}(\mathcal{T}_{\text{vert}} C(\hat{f}) \otimes T_{\text{vert}} \mathcal{B}) \). This subsheaf is a sheaf of \( \mathcal{C}^\infty_{\text{vert}}(F(\hat{f}), \mathbb{C}) \)-modules, but there is also an
action of $C^\infty(\mathcal{C}(\hat{f}) \times \hat{B}, \mathbb{C})$ by multiplication on $\Gamma^{(0,1)}(T_{\text{vert}}^* \mathcal{C}(\hat{f}) \otimes T_{\text{vert}}^* \mathcal{B})$. Multiplication by any $G$–invariant, $C^*$–valued, function $m$ on $\mathcal{C}(\hat{f}) \times \hat{B}$ sends $V$ to some other complex, simply-generated subsheaf $mV$ of $\mathcal{Y}$.

Consider a family $m_t$ of such $G$–invariant $C^*$–valued functions on $\mathcal{C}(\hat{f}) \times \hat{B}$ parametrized by $\mathbb{R}$ such that $m_0 = 1$. Then we may consider $(\hat{f} \times \mathbb{R}, G)$ to be a core family for $U' \times \mathbb{R}$ in $\mathcal{M}_{\text{vert}}^t(\hat{B} \times \mathbb{R})$, and $m_tV$ is a simply-generated complex subsheaf of $\mathcal{Y}$ on $U' \times \mathbb{R}$. If $m_tV$ satisfies the required transversality conditions at any holomorphic curve $h$, it satisfies these transversality conditions at all holomorphic curves in a neighborhood of $h$. As the required transversality conditions hold for all holomorphic curves in $U'$, and the set of holomorphic curves within $\mathcal{U}$ is compact and contained in $U'$, it follows that for some neighborhood $O$ of $0$ in $\mathbb{R}$, the required transversality conditions hold for all holomorphic curves in $\mathcal{U} \times O$.

Let $h$ be a holomorphic curve in $\mathcal{U} \cap \mathcal{M}$. Given any nonzero $v \in V(h)$, there exists some $G$–invariant function $m_v$ on $\mathcal{C}(\hat{f}) \times \hat{B}$ so that, if our holomorphic curve $h \in \mathcal{U}$, then

$$m_v v \notin V(h) \oplus V_i(h) .$$

It follows that for all curves $h'$ and $v' \in V(h')$ within a neighborhood of $(h, v)$ in $V(\hat{f}')$

$$m_v v' \notin V(h') \oplus V_i(h') .$$

The compactness of the set of holomorphic curves within $C_i \cap \mathcal{U}$ and the fact that $V$ is finitely generated then imply that there exists some $m$ so that for all holomorphic curves $h \in C_i$, and nonzero $v \in V(h)$,

$$mv \notin V(h) \oplus V_i(h) .$$

Then for $t > 0$ small enough,

$$e^{tm} v \notin \oplus V_i(h)$$

so $e^{tm} V(h) \cap \oplus V_i(h) = 0$ for all $h \in \mathcal{M} \cap \mathcal{U}$. As our transversality conditions also hold for $t$ small enough, it follows that $e^{tm} V$ is a modification of $V$ with the required properties for any $t > 0$ small enough.

We are now ready to construct the embedded Kuranishi structures from Definition 2.78.

**Theorem 7.3.** Suppose that the map $\mathcal{M} \rightarrow \mathcal{B}_0$ is proper when restricted to any connected component of $\mathcal{M}^t$. Then there exists an embedded Kuranishi structure on $\mathcal{M} \subset \mathcal{M}^t$. More generally, there exists an embedded Kuranishi structure on $\mathcal{M}^t \subset \mathcal{M}^t$.

Moreover, given any submersion $\Phi: \mathcal{M}^t \rightarrow \mathbb{X}$ where $\mathbb{X}$ is an exploded manifold or orbifold, all Kuranishi charts can be chosen $\Phi$–submersive in the sense of Definition 2.76.

This embedded Kuranishi structure may be chosen to include any countable, locally-finite, compatible collection of extendible $\Phi$–submersive Kuranishi charts $\{ (\mathcal{U}_k, V_k, \hat{f}_k/G_k) \}$.

**Proof:**

We prove the more general case, and construct an embedded Kuranishi structure on $\mathcal{M}^t \subset \mathcal{M}^t$. We are given a locally-finite, countable collection $\{ (\mathcal{U}_k, V_k, \hat{f}_k/G_k) \}$ of extendible, $\Phi$–submersive Kuranishi charts. Index these charts by negative integers $k$, leaving positive integers free for the rest of our Kuranishi charts. As specified in definitions 2.78 and 2.79 there are extensions

$$(\mathcal{U}_k, V_k, \hat{f}_k/G_k)$$
of \( \{\mathcal{U}_k, V_k, \hat{f}_k/G_k\} \) so that each pair of these extended Kuranishi charts are compatible, and \( \{\mathcal{U}_k^\rho\} \) is a locally-finite collection of substacks of \( \mathcal{M}^{i*} \). In particular, as specified by Definition 2.79, each holomorphic curve \( f \) has a neighborhood intersecting only finitely many \( \mathcal{U}_k^\rho \). Definition 2.79 gives that there is a continuous function \( \rho_k: \mathcal{U}_k^\rho \to (0, 1] \) such that \( \mathcal{U}_k = \{\rho_k > 0.5\} \subset \mathcal{U}_k^\rho \) and for any \( t > 0 \), any holomorphic curve in the closure (in \( \mathcal{M}^{i*} \)) of \( \{\rho_k > t\} \) is contained in \( \{\rho_k > 0.4\} \). We shall use the restriction of \( \{\mathcal{U}_k^\rho, V_k, \hat{f}_k/G_k\} \) to \( \{\rho_k > 0.4\} \) instead of our original extension. The above local finiteness implies that, for any holomorphic curve \( f \), there exists a neighborhood of \( f \) intersecting only finitely many \( \mathcal{U}_k^\rho \), and not intersecting \( \{\rho_k > 0.1\} \) if \( f \) is not in \( \mathcal{U}_k^\rho \).

Lemmas 7.2 and 7.1 imply that each holomorphic curve \( f \) has a neighborhood \( \mathcal{O} \) with a \( C^{\infty, 1} \) function \( \rho: \mathcal{O} \to [0, 1] \) so that

- all holomorphic curves in the closure of \( \{\rho > 0\} \) are contained in \( \mathcal{O} \),
- \( \rho(f) = 1 \),
- \( \mathcal{O} \) satisfies the conditions on \( \mathcal{U} \) within Lemma 7.2,
- \( \mathcal{O} \) intersects only finitely many \( \mathcal{U}_k^\rho \), and intersects \( \{\rho_k > 0.1\} \) only if \( f \) is in \( \mathcal{U}_k^\rho \).

Our assumption that \( \mathcal{M} \to \mathcal{B}_0 \) is proper restricted to each connected component of \( \mathcal{M}^{i*} \) and Corollary 5.22 implies \( \mathcal{M} \) admits an exhaustion by compact substacks and that these \( (\mathcal{O}, \rho) \) may be chosen so that there is a countable collection \( \{\mathcal{O}_i, \rho_i\} \) of them indexed by natural numbers so that the sets \( \{\rho_i > 0.5\} \subset \mathcal{O}_i \) cover \( \mathcal{M}^{i*} \). Let \( \rho \) intersect only finitely many \( \mathcal{O}_i \).

For each \( i \in \mathbb{N} \) in turn, the second part of Lemma 7.3 implies that on \( \mathcal{O}_i \), we may choose a simply-generated complex subsheaf \( V_i \) of \( \mathcal{Y} \) satisfying the transversality conditions of Lemma 7.3 so that, given any holomorphic curve \( f \in \mathcal{O}_i \), any \( V_k(f) \) with \( \rho_k \geq 0.1 \) and the \( V_j(f) \) with \( 0 < j \leq i \) and \( \rho_j \geq 0.1 \) are linearly independent — so, \( V_k(f) \oplus V_i(f) \subset \mathcal{Y}(f) \) has dimension \( \dim V_k(f) + \sum_{k,j} \dim V_j(f) \).

For any set \( A \) of negative integers, and nonempty \( I \subset \mathbb{N} \), define the sheaf

\[
V_{A,I} := \oplus_{k \in A} V_k \oplus_{i \in I} V_i
\]
on \cap_{k \in A} \mathcal{U}_k^\rho \cap_{i \in I} \mathcal{O}_i. (Recall that negative integers are indexing our already-constructed Kuranishi charts.) Because the \( V_k \) are subsheaves of each other, the maximum dimension that \( V_{A,I} \) can be is

\[
\dim V_{A,I} = \max_{k \in A} \dim V_k + \sum_{i \in I} \dim V_i.
\]

The substack on which the dimension of \( V_{A,I} \) is maximal is open; see Definition 2.88. Let \( \mathcal{O}_{A,I} \) denote this open substack. As noted above, \( \mathcal{O}_{A,I} \) is an open neighborhood of the holomorphic curves where \( \rho_j \geq 0.1 \) for \( j \in A \cup I \).

As we want to define compatible Kuranishi charts, we must determine where to use \( V_{A,I} \) carefully. In particular, we shall use \( V_{A,I} \) on an open substack \( \mathcal{O}_{A,I} \subset \mathcal{O}_{A,I} \) with the following properties:

1. If \( f \in \mathcal{O}_S \) and \( \rho_j(f) > 0.4 \), then \( j \in S \).
2. If \( f \in \mathcal{O}_S \) and \( \rho_j \) is not defined at \( f \), or \( \rho_j \leq 0.1 \), then \( j \notin S \).
3. \( \mathcal{O}_S \) intersects \( \mathcal{O}_S \), nontrivially only if \( S \subset S' \) or \( S' \subset S \).

We need to define \( \mathcal{O}_S \) satisfying the above for finite subsets \( S \subset \mathbb{Z} \) containing at least one natural number. Let \( n_S \) be the number of \( j' \) with \( \rho_{j'}(f) \geq 0.1 \) for some \( f \) so that \( \rho_{j'}(f) \geq 0.5 \) for some \( j' \in S \). We constructed \( \mathcal{O}_i \), so that \( n_S \) is finite. Now define \( \mathcal{O}_S \) to be the interior of the following stack:

\[
\mathcal{O}_S' := \left\{ \left( \min_{j \in S} 0.4, \min_{j \notin S} \rho_j \right) - \max_{j' \notin S} 0.1, \max_{j' \in S} \rho_{j'} \right\} > \frac{0.1}{n_S} \subset \mathcal{O}_S
\]
In the above, we set \( \rho_j \) to be 0 where it is not yet defined. As the \( \rho_j \) do not necessarily extend to be continuous functions on \( M^A_{\bullet} \), the above inequality does not necessarily define an open substack, and we must take \( \mathcal{O}'_S \) to be its interior — explicitly, we need to remove the closure of \( \{ \rho_j > .1 \} \) from \( \mathcal{O}'_S \) for all \( j' \notin S \). Each of the above required properties of \( \mathcal{O}'_S \) follows immediately for \( \mathcal{O}'_S \), and therefore they also hold for \( \mathcal{O}'_S \).

**Claim 7.4.** \( \{ \mathcal{O}'_S \} \) is an open cover of the holomorphic curves within \( M^A_{\bullet} \).

To prove Claim 7.4, we must show that each stable holomorphic curve \( f \) is in \( \mathcal{O}'_S \) for some \( S \). We already know that for some \( i \in \mathbb{N} \), \( p_i(f) > .5 \). There are at most \( n_i \) \( j \)'s such that \( \rho_i(f) \geq .1 \), therefore, there exists some set \( S \) containing \( i \) so that

\[
\min \left( 0.4, \min_{j \in S} \rho_j(f) \right) - \max \left( 0.1, \max_{j' \notin S} \rho_j(f) \right) \geq 0.3/n_i.
\]

As by definition, \( n_S \geq n_i \) when \( i \in S \), \( f \) is in \( \mathcal{O}'_S \). It remains to verify that \( f \) is in the interior of \( \mathcal{O}'_S \). If \( f \) was in the boundary of \( \mathcal{O}'_S \), then there would be some \( j' \) so that \( \rho_{j'} \) was not defined at \( f \), but \( f \) was in the closure of \( \{ \rho_{j'} > .1 \} \). One of our conditions on \( \rho_{j'} \) is that this is not possible for holomorphic curves \( f \), therefore no holomorphic curve \( f \) is in the boundary of \( \mathcal{O}'_S \). Therefore \( f \in \mathcal{O}'_S \) and Claim 7.4 is proved.

We can now construct our Kuranishi charts. Restricted to \( \mathcal{O}'_{A,U,I}, V_{A,I} \) is a simply-generated complex subsheaf of \( \mathcal{Y} \) strongly transverse to \( D\hat{\Phi} \) at all holomorphic curves. Theorem 6.4 then implies that each holomorphic curve \( f \) in \( \mathcal{O}'_{A,U,I} \) has an open neighborhood \( U \) on which \( D\hat{\Phi}^{-1}V_{A,I} \) is locally represented by some \( f/G \). For \( U \) small enough, \( (U, V_{A,I}, \hat{f}/G) \) is then a Kuranishi chart containing \( f \).

One of the transversality conditions from Lemma 7.2 is that, at holomorphic curves \( f \), \( D\hat{\Phi} \) restricted to \( \ker T_f \Phi \) is strongly transverse to \( V \) — this implies that, by choosing \( U \) small enough if necessary, we may assume that \( \hat{f} \) is \( \Phi \)-submersive in the sense of Definition 2.16.

Claim 6.20 implies that, if \( U \) is chosen small enough, \( \hat{f}/G \) is embedded in a core family for \( U \). It follows that there exists a continuous function, \( \rho: U \rightarrow [0,1] \), equal to 1 at \( f \), and with compact support on \( \hat{f}/G \). Lemma 7.1 implies furthermore that \( \rho \) may be chosen so that any holomorphic curve in the closure (within \( M^A_{\bullet} \)) of \( \{ \rho > 0 \} \) is contained in \( U \). Restricting \( (U, V_{A,I}, \hat{f}/G) \) to \( \{ \rho > .5 \} \) gives a Kuranishi chart with an extension to \( \{ \rho > 0 \} \). Condition 1 on \( \mathcal{O}'_{A,U,I} \) implies that all such charts are compatible, and condition 1 on \( \mathcal{O}'_{A,U,I} \) implies that any such chart is compatible with any of our original \( (U_k, V_k, \hat{f}_k/G_k) \) on the extension where \( p_k > .4 \).

Our properness assumption on \( M \rightarrow \mathbb{B}_0 \) together with Corollary 5.22 implies that the moduli stack of homomorphic curves within \( M^A_{\bullet} \) has an exhaustion by compact substacks, therefore we can choose a countable, locally-finite collection of extendible Kuranishi charts of the above type covering \( M_{\bullet} \). This collection of Kuranishi charts together with our original collection of Kuranishi charts is our required embedded Kuranishi structure.

---

**Corollary 7.5.** If \( M \rightarrow \mathbb{B}_0 \) is proper restricted to any connected component of \( M^A_{\bullet} \), then any two embedded Kuranishi structures on \( M_{\bullet}(\mathbb{B}) \) are homotopic: there exists an embedded Kuranishi structure on \( M_{\bullet}(\mathbb{B} \times \mathbb{R}) \) pulling back to the given embedded Kuranishi structures via the inclusions of \( \mathbb{B} \) over the points 0 and 1 in \( \mathbb{R} \).
Moreover, if there is a submersion
\[ \Phi: \mathcal{M}_t^i(\hat{B}) \to X \]
and the two original embedded Kuranishi structures are \( \Phi \text{–submersive,} \) then the homotopy may be chosen \( \Phi' \text{–submersive where} \Phi' \text{is the composition} \)
\[ \mathcal{M}_t^i(\hat{B} \times \mathbb{R}) \xrightarrow{\Phi'} \mathcal{M}_t^i(\hat{B}) \xrightarrow{\Phi} X \]

Proof:
Pull back the first embedded Kuranishi structure to a collection of Kuranishi charts over \( (-\infty, \frac{1}{3}) \) and pull back the second embedded Kuranishi structure to a collection of Kuranishi charts over \( (\frac{2}{3}, \infty) \). Together, these charts give a countable, locally finite, extendible collection of \( \Phi' \text{–submersive,} \) compatible Kuranishi charts on \( \mathcal{M}_t^i(\hat{B} \times \mathbb{R}) \).

Theorem \ref{thm:main} implies that we can expand this collection of Kuranishi charts to a \( \Phi' \text{–submersive embedded Kuranishi structure.} \)

\[ \square \]

7.1. The case of curves with domain \( T \).

Observe the following:

- If any curve in a connected family of curves \( \hat{f} \) has domain \( T \), then all curves in \( \hat{f} \) have domain \( T \).
- If any curve in a connected component of \( \mathcal{M}^t \) has domain \( T \), then all curves in that connected component have domain \( T \).
- If a curve \( f \) has domain \( T \), then \( f \) is holomorphic and \( \mathcal{V}(f) \) is trivial.
- As the smooth part of \( T \) is a single point, a curve \( f \) in \( \hat{B} \) with domain \( T \) is always contained in a single coordinate chart, and any curve in a neighborhood of \( f \) within \( \mathcal{M}^t \) is also contained in the same coordinate chart.
- Any coordinate chart on \( \hat{B} \) containing a stable curve \( f \) with domain \( T \) may be written in the form \( U \times T \) so that
  \[ f(\tilde{z}) = (u, e^{at} \tilde{z}^n) \]
  where \( u \in U \) and \( e^{at} \in \mathbb{C}^\times \mathbb{R} \) are constant, and \( n \) is a positive integer. All nearby curves \( f' \) will be in the same form, with different constants, but the same integer \( n \).

Lemma 7.6. If \( n \) is a positive integer, and \( U \) is a connected exploded manifold, the moduli stack \( \mathcal{X} \) of curves \( f \) in \( U \times T \) in the form
  \[ f(\tilde{z}) = (u, e^{at} \tilde{z}^n) \]
is represented\(^{66}\) by the quotient of the family of curves
  \[ U \times T \xrightarrow{(id, \tilde{z}^n)} U \times T \xrightarrow{\downarrow} U \]
by its automorphism group, \( \mathbb{Z}_n \).

\[ ^{66}\text{Definition} \ref{def:quotient} \]
Proof: Call this family of curves $\hat{f}_0$. The automorphism group of $\hat{f}_0$ is $\mathbb{Z}_n$, acting trivially on $U = F(\hat{f}_0)$, and acting by multiplying the $T$ fibers of $C(f_0)$ by $n$th roots of unity. To satisfy Definition 2.29, we must construct an inverse $\Psi: X \rightarrow f_0/\mathbb{Z}_n$ to the map $\Phi: f_0/\mathbb{Z}_n \rightarrow X$ from Definition 2.10.

Given any family $\hat{f}$ of curves in $X$, $\Phi(f)$ is some $\mathbb{Z}_n$–bundle $\hat{\pi}: \hat{\mathbb{Z}}_n \rightarrow \hat{\phi}$ with a $\mathbb{Z}_n$–equivariant map $\hat{\pi}: \hat{\mathbb{Z}}_n \rightarrow \hat{f}$. Define $C(\hat{\pi})$ to be the $n$–fold cover of $C(\hat{f})$ given by the fiber product

$$C(\hat{\pi}) := C(\hat{f}) \times_{\hat{f}_0} (U \times T)$$

and define $F(\hat{\pi})$ to be the fiber product of $\hat{f}$ with the inclusion of $U$ into $U \times T$ sending $u$ to $(u, \text{id})$.

$$F(\hat{\pi}) := C(\hat{f}) \times_{(\text{id}, 1_T)} U$$

The projection $U \times T \rightarrow U$ induces a map $C(\hat{\pi}) \rightarrow F(\hat{\pi})$ making $C(\hat{\pi}) \rightarrow F(\hat{\pi})$ the family of $T$s pulled back from the following diagram:

$$
\begin{array}{ccc}
C(\hat{\pi}) & \rightarrow & C(\hat{f}) \\
\downarrow & & \downarrow \\
F(\hat{\pi}) & \rightarrow & F(\hat{f})
\end{array}
$$

Then, pull back $\hat{f}_0$ via the map $C(\hat{\pi}) \rightarrow C(\hat{f})$ to define a family of curves $\hat{f}_0$ with maps to $\hat{f}$.

$$
\begin{array}{ccc}
\hat{\pi} & \rightarrow & \hat{f}_0 \\
\downarrow & & \downarrow \\
\hat{f} & \rightarrow & \hat{f}
\end{array}
$$

There are two actions of $\mathbb{Z}_n$ on $\hat{\mathbb{Z}}_n$, induced by multiplying fibers of $C(\hat{f})$ or $C(\hat{f}_0)$ by $n$th roots of unity. The map $\hat{\pi}: \hat{\mathbb{Z}}_n \rightarrow \hat{f}_0$ is invariant under the first action and equivariant under the second action, whereas the map $\hat{\mathbb{Z}}_n \rightarrow \hat{f}$ is equivariant under the first action and invariant under the second action. This second action makes $\hat{\pi}: \hat{\mathbb{Z}}_n \rightarrow \hat{f}$ a $\mathbb{Z}_n$–fold cover, so the above is equivalent to a family $\Psi(\hat{f})$ in the stack $\hat{f}_0/\mathbb{Z}_n$ from Definition 2.22.

Now suppose that $\hat{h} \rightarrow \hat{h}$ is a $\mathbb{Z}_n$–bundle over $\hat{h}$ with a map $\psi: \hat{h} \rightarrow \hat{f}$ and a $\mathbb{Z}_n$–equivariant map $\hat{h} \rightarrow \hat{f}_0$. The construction of $C(\hat{\pi})$ as a fiber product gives a unique map

$$\psi: \hat{h} \rightarrow \hat{\pi}$$

commuting with the maps to $\hat{f}$ and $\hat{f}_0$. This unique map $\psi$ must be $\mathbb{Z}_n$–equivariant because the action of $\mathbb{Z}_n$ on $C(\hat{f}_0)$ is free. It follows that $\psi$ defines a unique lift of $\psi$ to a morphism in the stack $f_0/\mathbb{Z}_n$. Defining $\Psi(\psi) = \psi$ gives a functor $\Psi: X \rightarrow f_0/\mathbb{Z}_n$.

Clearly, $\Phi_X \circ \Psi$ is the identity. Moreover if $\hat{f}' \rightarrow \hat{f}$ is any family in $\hat{f}/\mathbb{Z}_n$, id$\hat{f}'$ is a canonical isomorphism between $\hat{f}' \rightarrow \hat{f}$ and $\Psi \circ \Phi_X(\hat{f}' \rightarrow \hat{f})$, defining a $2$–isomorphism between $\Psi \circ \Phi_X$ and the identity. Therefore our moduli stack of curves is represented by $f_0/\mathbb{Z}_n$ as required. □
8. Relative complex structure and orientation of Kuranishi charts

Suppose that \((U,V,f/G)\) is a Kuranishi chart. At each holomorphic curve \(f\) in \(\hat f\), we will construct a canonical homotopy class of \(G\)-invariant complex structure on \(T_j F(\hat f)\) — or, in the case of a family of targets over \(B_0\), a complex structure on \(T_j F(\hat f)\mid_{B_0}\). On a neighborhood of the holomorphic curves in \(\hat f\), this defines a canonical orientation of \(F(\hat f)\) relative to \(B_0\).

Let us define this homotopy class of complex structures in a single Kuranishi chart. If \(f\) is holomorphic, \(T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}\) is complex, so \(\partial\bar\partial: T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}\to \mathcal{C}(f)\) has a complex-linear part, \(D\partial\bar\partial\). For a Kuranishi chart, \((U_i,V_i,f_i/G_i)\), containing \(f\), define

\[
K_{i,t}(f) := ((1 - t)D\partial\bar\partial + tD\partial\bar\partial)^{-1}(V_i(f)) \subset T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}.
\]

This \(K_{i,t}(f)\) for \(t \in [0,1]\) is a smooth family of sub-vectorspaces of \(T_j M^\bullet_{\mathcal{S}t}\) — because \(\partial\bar\partial\) is strongly transverse to \(V_i\), we can prove this using Theorem 3.8. At the start of our homotopy, Theorem 3.8 implies that \(K_{i,0}(f)\) is equal to \(T_j F(\hat f)\mid_{B_0}\). At the other end, \(K_{i,1}(f)\) is the inverse image of the complex vectorspace \(V_i(f)\) under a complex map, so it is a complex subspace of \(T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}\). Therefore, there is a canonical homotopy class of complex structure on \(K_{i,0}(f) = T_j F(\hat f)\mid_{B_0}\), namely, those complex structures homotopic to the complex structure on \(K_{i,1}(f)\). To check that the resulting relative orientation of Kuranishi charts is compatible, we must globalize this construction.

To globalize our construction, we will show that \(K_{i,t}\) may be regarded as a family of \(G_1\)-invariant, \(C^\infty\) sub-vectorbundles of \(T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}\) restricted to \(\{\partial f_i = 0\}\). Moreover, in Proposition 8.1 we show that \(K_{i,t}\) may be identified for all \(t\) in a way which is \(G_1\)-invariant, compatible with all inclusions \(K_{i,t} \subset K_{i,t'}\), constant on \(\mathbb{R}\)-nil vectors, and compatible with any chosen submersion \(\Phi: M^\bullet_{\mathcal{S}t} \to X\).

Let us first verify that we can keep the canonical structure on \(\mathbb{R}\)-nil vectors. The \(\mathbb{R}\)-nil vectors in \(T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}\) — the vectors acting trivially as derivations on \(C^\infty\) functions — form a complex-linear subspace of \(T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}\), in the kernel of \(D\partial\bar\partial\), and therefore always contained in \(K_{i,t}(f)\).

**Lemma 8.1.** Suppose that \(f\) is a holomorphic curve contained in \(\hat f\) and \(T_j F(\hat f) \to T_j M^\bullet_{\mathcal{S}t}\) is injective. Then the \(\mathbb{R}\)-nil vectors from \(T_j F(\hat f)\mid_{B_0}\) form a complex-linear subspace of \(T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}\) contained in the kernel of \(D\partial\bar\partial: T_j M^\bullet_{\mathcal{S}t}\mid_{B_0}\to \mathcal{C}(f)\).

**Proof:**

Without losing generality, we may restrict to the case that \([F(\hat f)]\) is a single point. As in this case each curve in \(\hat f\) is holomorphic, it follows that \(T_j F(\hat f)\mid_{B_0}\) is in the kernel of \(D\partial\bar\partial\). As we are dealing with tangent spaces relative to \(B_0\) in this lemma, it suffices to consider the case when \(B_0\) is a point, so we may talk of \(TM^\bullet_{\mathcal{S}t}(B)\) instead of \(TM^\bullet_{\mathcal{S}t}(B)\mid_{B_0}\).

There exists a unique complex structure \(j\) on \(C(f)\) extending the given fiberwise almost-complex structure. In particular, the (locally defined) fiberwise-holomorphic exploded functions on \(C(f)\) are always equal, in local coordinates, to some monomial times a holomorphic \(C^\infty\) function on the smooth part of the coordinate chart. These fiberwise-holomorphic exploded functions define a sheaf of holomorphic exploded functions on \(C(f)\) and give the canonical complex structure \(j\) on \(C(f)\). Also, there is a unique complex structure on \(F(\hat f)\), because the smooth part of \(F(\hat f)\) is a single point.

The map \(C(f) \to F(\hat f)\) is holomorphic. In fact, any fiberwise-holomorphic \(C^\infty\) map from \(C(f)\) to a complex exploded manifold must also be holomorphic with respect to this canonical complex structure \(j\), because any \(C^\infty\) map must be
holomorphic restricted to $\mathbb{R}$–nil vectors, and the tangent space of $C(\hat{f})$ is spanned by the vertical tangent space and $\mathbb{R}$–nil vectors. In particular, the map $\hat{f}$ is also $\mathbb{J}$–holomorphic.

We have established that $\hat{f}$ is a holomorphic family of curves. We shall now check that the map $T_\hat{f}\hat{f}: T_\hat{f}F(\hat{f}) \to T_{\hat{f}}M^*_\mathbb{J}$ is complex linear. Let $v$ be the lift of any vectorfield on $F(\hat{f})$ to vectorfield on $C(\hat{f})$. As $\mathbb{J}$ is integrable, calculation in $\mathbb{C}^n$ gives that

$$\mathbb{J} \circ L_{\mathbb{J}} = L_{\mathbb{J}} \circ \mathbb{J}.$$ 

As $\hat{f}$ is holomorphic, $Jd\hat{f}(v) = d\hat{f}(jv)$. In particular, the map $v \mapsto (L_{\mathbb{J}}d\hat{f}(v))$ is complex, so the map $T_\hat{f}F(\hat{f}) \to T_{\hat{f}}M^*_\mathbb{J}$ is complex linear.

\[ \square \]

The canonical homotopy class of complex structure on $T_\hat{f}F(\hat{f}) \otimes_{B_{\mathbb{J}}} B_{\mathbb{J}}$ gives a canonical homotopy class of complex structure on $TF(\hat{f}) \otimes_{B_{\mathbb{J}}} B_{\mathbb{J}}$ in a neighborhood of $\hat{f}$. To verify that this agrees with the canonical homotopy class of complex structure at other holomorphic curves in this neighborhood, we shall extend the definition of $K_{i,t}$ to all curves in a neighborhood of $\hat{f}$ in $\hat{f}$. As a first step, we modify $V_i$ off $\hat{f}$ to make later application of Theorem 3.8 easier.

**Lemma 8.2.** After restricting $\hat{f}$ to a neighborhood of $f$ if necessary, there exists a core family $(\hat{f}/G, \{s_l\})$ with

- an identification of $G$ with $G_i$ and a $G$–equivariant embedding $\hat{f}_i \to \hat{f}$

so that, for $t \in [0, 1]$, there is no nonzero section of $f^*T_{\text{vert}}B$ in $((1 - t)D\bar{\partial} + tD\partial\bar{F})^{-1}V_i(f)$ also vanishing on the image of all the sections $\{s_l\}$,

- and a locally free, $G$–invariant subsheaf $V'$ of $\Gamma^{(0,1)}(T_{\text{vert}}C(\hat{f}) \otimes T_{\text{vert}}B)$ with the same dimension as $V_i$, and pulling back to $\hat{f}_i$ (in the sense of Definition 2.70) to give $V_i(\hat{f}_i)$.

**Proof:**

After restricting $\hat{f}_i$ to a neighborhood of any holomorphic curve $f$ in $\hat{f}_i$, Claim 6.20 provides an equivariant, fiberwise-holomorphic embedding

$$\begin{array}{ccc}
C(\hat{f}_i) & \longrightarrow & C(\hat{f}_0) \\
\downarrow & & \downarrow \\
F(\hat{f}_i) & \longrightarrow & F(\hat{f}_0)
\end{array}$$

where, as specified by Lemma 6.4 part 3 $(\hat{f}_0/G, \{s_l\})$ is a core family containing $f$ with enough sections $\{s_l\}$ so that $((1 - t)D\bar{\partial} + tD\partial\bar{F})^{-1}V(f)$ contains no nonzero sections of $f^*T_{\text{vert}}B$ vanishing on the image of all $\{s_l\}$. The above map removes the $G$–fold ambiguity of the core family map $C(\hat{f}_i) \to C(\hat{f}_0)/G$, so $\hat{f}_i$ is equal to the above map composed with $\hat{f}_0$ followed by exponentiation of some section of $\hat{f}_0^*T_{\text{vert}}B$ vanishing on the image of the sections $\{s_l\}$. We may choose this section to be $G$–equivariant, and define $\hat{f}$ to be $f_0$ followed by exponentiation of this section. Now the above map corresponds to a $G$–equivariant embedding

$$\hat{f}_i \to \hat{f}$$

and $(\hat{f}/G, \{s_l\})$ is a core family satisfying the requirements of this lemma. In particular, as $\hat{f}_i \to \hat{f}$ is an embedding, we may choose a locally free subsheaf $V'$ of $\Gamma^{(0,1)}(T_{\text{vert}}C(\hat{f}) \otimes T_{\text{vert}}B)$ pulling back to give $V_i(\hat{f}_i)$, and with the same rank
as $V_t$, when considered as a sheaf of $C^\infty\Lambda(F(\tilde{f}))$–modules. We may also choose $V'$ to be $G$–invariant.

On a neighborhood of $\tilde{f}_t$, the pullback of $V'$ defines some subsheaf $V$ of $\mathcal{Y}$. Let us verify that $\tilde{\partial}^{-1}V = \partial^{-1}V_t$. For any family of curves $h$ in this neighborhood, consider the subset comprising curves $h$ in $\tilde{h}$ for which the dimension of $V(h)$ is equal to the rank of $V'$; this subset is open, and contains any curve isomorphic to $f$. Therefore, on a neighborhood of $f$, $V$ is simply generated in the sense of Definition 2.71. As $V(f) = V_t(f)$, $\tilde{\partial}$ is strongly transverse to $\mathcal{Y}(f)$, so we may apply Theorem 6.8 to see that, in a neighborhood of $f$, the moduli stack $\tilde{\partial}^{-1}V$ is represented by the quotient of a family of curves by a group of automorphisms. Theorem 6.8 also implies that this family of curves has the same dimension as $f_t$, therefore this moduli stack $\tilde{\partial}^{-1}V$ equals our original moduli stack $\partial^{-1}V_t$, represented by $\tilde{f}_t/G$ (restricted to a neighborhood of $f$ if necessary). We can therefore continue to define an extension of $\mathcal{K}_{i,t}(f)$ using $V$ instead of $V_t$.

To linearize $\partial$ at a non-holomorphic curve, we would need a connection on $\mathcal{Y}$. Instead, we linearize $\pi V \partial$, where $\pi_V$ is the projection

$$
\pi_V : \mathcal{Y} \to \mathcal{Y}/V .
$$

**Construction 8.3.** For any curve $f$ so that $\partial f \in V(f)$, define the linear map

$$
D\pi_V \partial : T_f \mathcal{M}^i_t \to \mathcal{Y}(f)/V(f)
$$

as follows: In light of Lemma 2.64, we need only construct $D\pi_V \partial$ on $T_f F(\tilde{f})$ for an arbitrary $C^\infty\Lambda$ family $f$ containing $\tilde{f}$. So long as this construction commutes with maps of families and gives a linear map, Lemma 2.64 implies that it defines a linear map from $T_f \mathcal{M}^i_t$. Choose a section $v$ of $V(\tilde{f})$ equal to $\partial f$ at $f$ in $\tilde{f}$. Then $\partial f_t - v$ is a section of $\mathcal{Y}(\tilde{f})$ vanishing at $f$, therefore its derivative at $f$ is a linear map

$$
T_f F(\tilde{f}) \to \mathcal{Y}(f) .
$$

Another choice of $v$ would change the above map by a linear map to $V(f)$. This derivative therefore gives a well defined linear map

$$
D\pi_V \partial : T_f F(\tilde{f}) \to \mathcal{Y}(f)/V(f) .
$$

As the above construction is compatible with maps of families, Lemma 2.64 implies that this construction gives a well defined linear map $T_f \mathcal{M}^i_t \to \mathcal{Y}(f)/V(f)$.

**Lemma 8.4.** On a neighborhood $U$ of all holomorphic curves in $\tilde{f}_i$, there exists a map of sheaves of $C^\infty\Lambda(F(\tilde{f}_i))$–modules over $F(\tilde{f}_i)$,

$$
D\pi_V \partial : T_{\tilde{f}_i} \mathcal{M}^i_t \to \mathcal{Y}(\tilde{f}_i)/V(\tilde{f}_i)
$$

restricting to each curve $f'$ in $U$ to be $D\pi_V \partial : T_{f'} \mathcal{M}^i_t \to \mathcal{Y}(f')/V(f')$.

**Proof:**

If such a map exists it is uniquely determined by its restriction to $T_{f'} \mathcal{M}^i_t$ for each $f'$ in $U$. We therefore need only construct such a map in a neighborhood of a holomorphic curve $f$ in $\tilde{f}_i$.

To globalize the definition of $D\pi_V \partial$, note that there exists a neighborhood of $f$ in $\mathcal{M}^i_t$ with a section $\theta$ of the sheaf $V$ such that $\theta(\tilde{f}_i) = \tilde{\partial} \tilde{f}_i$. In particular, as $f_i$ embeds into the core family $\tilde{f}$, the section $\tilde{\partial}$ of $\tilde{f}_i$ is the pullback of some section $\theta'$ of $V'$ over $F(f)$. As $\tilde{\partial}$ is $G$–invariant and the inclusion $f_i \to f$ is $G$–equivariant, averaging allows us to construct $\theta'$ to be $G$–invariant. The pullback of $\theta'$ to a neighborhood of $f$ defines a section $\theta$ of $V \subset \mathcal{Y}$. 

Given a section \( w \) of \( T_{\hat{f}_i}M^\bullet_{vert} \), Lemma 7.68 implies that there is a one-dimensional deformation \( \hat{f}_i \) of \( \hat{f}_i \) such that the \( t \)-derivative of \( \hat{f}_i \) at \( t = 0 \) is \( w \). The derivative of \( \partial f_t - \theta(f_t) \) at \( t = 0 \) is a section of \( \mathcal{I}(\hat{f}_i) \) that, when restricted to any curve \( f' \) in \( \hat{f}_i \) and followed by projection to \( \mathcal{Y}(f')/V(f') \), is equal to \( D\pi_V \partial w(f') \). So, given any \( C^\infty \) section \( w \) of \( T_{\hat{f}_i}M^\bullet_{vert} \), there exists a \( C^\infty \) section \( D\pi_V w \) of \( \mathcal{Y}(\hat{f}_i)/V(\hat{f}_i) \) restricting to each \( \mathcal{Y}(f')/V(f') \) to equal \( D\pi_V \partial w(f') \). As this characterization uniquely determines \( D\pi_V \partial w \), it follows that

\[
D\pi_V \partial: T_{\hat{f}_i}M^\bullet_{vert} \rightarrow \mathcal{Y}(\hat{f}_i)/V(\hat{f}_i)
\]

is a well-defined map of sheaves of \( C^\infty \) modules over \( \mathcal{F}(\hat{f}_i) \).

The quotient \( \mathcal{Y}(\hat{f}_i)/V(\hat{f}_i) \) has a canonical complex structure because, on \( \hat{f}_i \), \( V \) coincides with the complex sub-bundle \( V_i \). In order to talk of the complex-linear part \( (D\pi_V \partial)^{\mathbb{C}} \) of \( D\pi_V \partial \) restricted to \( T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \), we must choose a complex structure on \( T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \).

**Claim 8.5.** There exists a \( G_i \)-invariant complex structure \( J' \) on \( T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \) defined within a neighborhood \( U \) of \( f \) so that

- the restriction of this complex structure \( J' \) to any holomorphic curve \( f' \in U \) is the canonical complex structure on \( T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \);
- if \( X(\hat{f}_i) \) indicates the sheaf of \( C^\infty \) sections of \( \hat{f}_i^*T_{vert} \mathcal{B} \) vanishing on the image of the core-family sections \( \{s_i\} \) from Lemma 8.2, the inclusion \( X(\hat{f}_i) \hookrightarrow T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \) is complex.

**Proof:**

Recall that the sheaf \( T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \) is defined using the following short exact sequence:

\[
\Gamma(T_{vert}C(\hat{f}_i)) \rightarrow \Gamma^0(T_{vert}C(\hat{f}_i) \otimes T_{vert}^*C(\hat{f}_i)) \times \Gamma(\hat{f}_i^*T_{vert} \mathcal{B})
\]

The sheaf \( \Gamma^0(T_{vert}C(\hat{f}_i) \otimes T_{vert}^*C(\hat{f}_i)) \times \Gamma(\hat{f}_i^*T_{vert} \mathcal{B}) \) has a complex structure, but \( T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \) fails to have a canonical complex structure because the lefthand map above need not be complex. Below, we construct a complex structure on \( T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \) by splitting the above exact sequence with an inclusion of \( T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \) as a complex subsheaf of \( \Gamma^0(T_{vert}C(\hat{f}_i) \otimes T_{vert}^*C(\hat{f}_i)) \times \Gamma(\hat{f}_i^*T_{vert} \mathcal{B}) \).

Recall that we have \( \hat{f}_i \) embedded in a core family \( \hat{f} \), and that \( X(\hat{f}_i) \) indicates the sheaf of \( C^\infty \) sections of \( \hat{f}_i^*T_{vert} \mathcal{B} \) vanishing on the core-family sections \( \{s_i\} \). There is a canonical injective map \( X(\hat{f}_i) \hookrightarrow T_{\hat{f}_i}M^\bullet_{vert} |_{\mathcal{B}_0} \) with cokernel isomorphic to the pullback of \( T\mathcal{F}(\hat{f}_i) |_{\mathcal{B}_0} \) to \( \mathcal{F}(\hat{f}_i) \) (because \( (\hat{f}/G, \{s_i\}) \) is a core family.) This \( X(\hat{f}_i) \) is a complex subsheaf of \( \Gamma^0(T_{vert}C(\hat{f}_i) \otimes T_{vert}^*C(\hat{f}_i)) \times \Gamma(\hat{f}_i^*T_{vert} \mathcal{B}) \). Moreover, at our holomorphic curve \( f \), the inclusion \( X(f) \hookrightarrow T_fM^\bullet_{vert} |_{\mathcal{B}_0} \) is complex, and has finite-dimensional cokernel. So, there exists a \( G_i \)-invariant, locally-free, finite-rank, complex subsheaf \( W \) of \( \Gamma^0(T_{vert}C(\hat{f}_i) \otimes T_{vert}^*C(\hat{f}_i)) \times \Gamma(\hat{f}_i^*T_{vert} \mathcal{B}) \) which, restricted to \( f \), is a finite-dimensional vector space complementary to the direct sum of the image of \( \Gamma(TC(f)) \) with \( X(f) \).
Restricted to any other curve $f', W$ is complementary to the direct sum of the image of $\Gamma(T\mathcal{C}(f'))$ with $X(f')$ if and only if its image in $T_\partial F(f)'|_{\mathcal{B}_0}$ is surjective — this holds for all $f'$ in a neighborhood of $f$ in $f$. On this neighborhood the map $X(f_j) \oplus W \to T_\partial \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$ is an isomorphism, so we may use the complex structure from $X(f_j) \oplus W$ to give a $G_i$-invariant complex structure on $T_\partial \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$ in a neighborhood of $f$. For $f'$ holomorphic, this complex structure on $T_\partial \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$ agrees with the canonical one.

Remark 8.6. In the proof of Claim 8.3 above, we embedded $T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$ inside $\Gamma_0^1(T_{\text{vert}} \mathcal{C}(\hat{f}_i) \otimes T_{\text{vert}} \mathcal{C}(\hat{f}_i)) \times \Gamma(\hat{f}_i^* T_{\text{vert}} \mathcal{B})$. We may use this embedding to construct a metric on $T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$. Our embedding represents sections of $T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$ as sections of some vectorbundle over $\mathcal{C}(\hat{f}_i)$. So, we can choose a $C^\infty$ inner product $\langle \cdot , \cdot \rangle$ on this vectorbundle, and a $C^\infty$ fiberwise volume form $\theta$ on $\pi: \mathcal{C}(\hat{f}_i) \to F(\hat{f}_i)$ to define an inner product $\langle \cdot , \cdot \rangle$ on $T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$ as

$$\langle v, w \rangle = \pi(v) \theta(v, w) > 0 \theta$$

so, $\langle v, w \rangle$ is a $C^\infty$ function on $F(\hat{f}_i)$ with value at a point $p$ the integral of $\langle v, w \rangle > 0 \theta$ over the fiber of $\mathcal{C}(\hat{f}_i)$ over $p$ — the fact that $\langle v, w \rangle > 0$ is $C^\infty$ follows from Theorem 6.1 of [30].

With our chosen complex structure on $T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$, we can define the complex-linear part, $(\partial_{\pi V} \partial)^C$ of $\partial_{\pi V} \partial$. Use the following notation:

$$A_t := (1 - t)\partial_{\pi V} \partial + t(\partial_{\pi V} \partial)^C: T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0} \to \mathcal{Y}(\hat{f}_i)/V(\hat{f}_i)$$

Lemma 8.7. On a neighborhood of $f$ in $\hat{f}_i$,

$$\ker A_t \subset T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$$

is a one-dimensional family of finite-dimensional sub-vectorbundles of $T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$ — so, $\ker A_t$ is a one-dimensional family of locally-free, finite-rank subsheaves of $T_{\partial} \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$.

Proof:

We use notation from the proof of Lemma 8.4. Within the proof of Lemma 8.4 we constructed $\partial_{\pi V} \partial$ as the linearization of $(\partial - \theta)$ followed by projection to $\mathcal{Y}/V$. The section $\theta$ of $V$ is the pullback of a section $\theta'$ of $V'$ over $F(f)$. As $\hat{f}_i$ is a sub-family of $f$, we may restrict $\theta'$ to $F(\hat{f}_i)$ (and again call it $\theta'$).

Let $X(\hat{f}_i)$ denote the sheaf of $C^\infty$ sections of $\hat{f}_i^* T_{\text{vert}} \mathcal{B}$ vanishing on the pullback of the core-family sections $\{s_i\}$. After choosing a $G$-invariant trivialization for $\hat{f}_i$ in the sense of Definition 8.4, we may use $\theta'$ to get a simple perturbation $\tilde{\theta} := \partial - \theta': X(\hat{f}_i) \to \mathcal{Y}(\hat{f}_i)$ as in Example 8.5. Now apply Theorem 8.3 to the linearization of $\tilde{\theta}'$, and its linear homotopy to a complex operator — as allowed by Remark 8.3. Theorem 8.3 implies that there exists a vector sub-bundle $V$ of $\mathcal{Y}(\hat{f}_i)$ containing $V$ so that, on some neighborhood of $f$, $((1 - t)D\tilde{\theta}' + tD\tilde{\theta}^C)$ restricted to $X(\hat{f}_i)$ surjects onto $\mathcal{Y}(\hat{f}_i)/V$ for all $t$, and on this neighborhood, the inverse image of $W$ is a 1-dimensional family of vector sub-bundles of $X(\hat{f}_i)$. As $T_\partial \mathcal{M}_{\bullet}^{a|\mathcal{B}_0} / X(\hat{f}_i)$ is a finite-dimensional $C^\infty$ vectorbundle, the same holds for $((1 - t)D\tilde{\theta}' + tD\tilde{\theta}^C)$ with domain extended from $X(\hat{f}_i)$ to $T_\partial \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$. By our strong transversality assumption, this map restricted to $T_\partial \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$ is transverse to $V(f)$ for all $t$, therefore it follows that on some neighborhood of $f$, the inverse image of $V$ is a 1-dimensional family of finite-dimensional sub-vectorbundles of $T_\partial \mathcal{M}_{\bullet}^{a|\mathcal{B}_0}$, as required.
For any holomorphic curve $f'$ in $\hat{f}_i$, the complex structure on $T_f \mathcal{M}_{\bullet}^t \downarrow B_0$, chosen in Claim 8.5, agrees with the canonical complex structure, so the restriction of $\ker A_t$ to $f'$ is $K_{i,t}(f')$. Therefore, the kernel of $A_t$ is our extension of $K_{i,t}$ to a family of vectorbundles defined on a neighborhood of holomorphic curves within $\hat{f}_i$. Moreover, as $A_t$ is complex, $\ker A_t$ has a complex structure agreeing with the complex structure on $K_{i,t}(f')$. As our choice of complex structure on $T_f \mathcal{M}_{\bullet}^t \downarrow B_0$ was $G_t$-invariant, and $\partial \pi_t \bar{\partial}$ is intrinsically defined, $\ker A_t$ is a $G_t$-invariant family of vectorbundles on $T_f \mathcal{M}_{\bullet}^t \downarrow B_0$. We therefore have a canonical homotopy class of $G_t$-invariant complex structures on $\ker A_t$, restricting at any holomorphic curve $f'$ to our previously constructed one.

Lemma 8.8. In a neighborhood of the holomorphic curves in $\hat{f}_i$, ker $A_0$ is $T_F(\hat{f}_i) \downarrow B_0$.

Proof: At holomorphic curves $f'$, Theorem 6.8 implies that $K_{i,0}(f')$ and ker $A_0(f')$ both equal $T_F(\hat{f}_i) \downarrow B_0$.

More generally, the fact that $\partial \hat{f}_i$ is a section of $V(\hat{f}_i)$ implies that the map $T_F(\hat{f}_i) \downarrow B_0 \rightarrow T_f \mathcal{M}_{\bullet}^t \downarrow B_0$ has image inside ker $A_0 = \ker D\pi_t \bar{\partial}$. As noted above, this $C^{\infty,1}$ map of finite-dimensional vectorbundles $T_F(\hat{f}_i) \downarrow G \rightarrow$ ker $A_0$ is an isomorphism at holomorphic curves $f'$. Therefore, it is an isomorphism in a neighborhood of these holomorphic curves.

We have now locally constructed an extension of $K_{i,t}$ to a family of $G_t$-equivariant vector sub-bundles ker $A_t \subset T_f \mathcal{M}_{\bullet}^t \downarrow B_0$. More generally, say $K_{i,t}'$ is an extension of $K_{i,t}$ if it is a family of $G_t$-equivariant vector sub-bundles of $T_f \mathcal{M}_{\bullet}^t \downarrow B_0$, so that, for any holomorphic curve $f$ in the domain of definition, $K_{i,t}'(f) = K_{i,t}(f)$. With these extensions, we can think of $K_{i,t}$ as a family of $G_t$-equivariant vectorbundles over $\{\partial \hat{f}_i = 0\}$. In particular, define a $C^{\infty,1}$ section of $K_{i,t}$ to be a section extending to a $C^{\infty,1}$ section of $\hat{T_f} \mathcal{M}_{\bullet}^t \downarrow B_0$. The following lemma implies that any such $C^{\infty,1}$ section of $K_{i,t}$ extends to a $C^{\infty,1}$ section of any extension $K_{i,t}'$ of $K_{i,t}$.

Lemma 8.9. Any section of $K_{i,t}$ extending to a $C^{\infty,1}$ section of $T_f \mathcal{M}_{\bullet}^t \downarrow B_0$ also extends to a $C^{\infty,1}$ section of any extension $K_{i,t}'$ of $K_{i,t}$.

Proof: Let us use the metric on $T_f \mathcal{M}_{\bullet}^t \downarrow B_0$, constructed in Remark 8.6. Given any $C^{\infty,1}$ section of $T_f \mathcal{M}_{\bullet}^t \downarrow B_0$, its orthogonal projection to $K_{i,t}'$ is a $C^{\infty,1}$ section of $K_{i,t}'$. In particular, any $C^{\infty,1}$ extension of a section of $K_{i,t}$ to $T_f \mathcal{M}_{\bullet}^t \downarrow B_0$ projects to a $C^{\infty,1}$ extension contained within $K_{i,t}'$.

Lemma 8.9 implies that the $C^{\infty,1}$ vectorbundle structure on $K_{i,t}$ induced by including $K_{i,t}$ inside $K_{i,t}'$ does not depend on the choice of extension $K_{i,t}'$ of $K_{i,t}$.

Definition 8.10. A $t$-trivialization of $K_{i,t}$ is a choice of $G_t$-equivariant identification of $K_{i,t}$ with $K_{i,0}$ for all $t$ which extends to a $C^{\infty,1}$ family of isomorphisms $K_{i,t}' \rightarrow K_{i,0}$ and which is the identity on the subspace of $\mathbb{R}$-nil vectors within $K_{i,t}$.

Given a submersion $\Phi: \mathcal{M}_{\bullet}^t \rightarrow X$, say that a $t$-trivialization is $\Phi$-submersive if the following diagram commutes:

$$
\begin{array}{ccc}
K_{i,t}(f) & \xrightarrow{T_f \Phi} & TX \\
\downarrow & & \downarrow \\
K_{i,0}(f) & \xrightarrow{T_f \Phi} & TX
\end{array}
$$
A \textit{t–trivialization} for an embedded Kuranishi structure, \{(U_i, V_i, \hat{f}_i/G_i)\}, is a choice of t–trivialization for \(K_{i,t}\) on \((U^2_i, V_i, \hat{f}^2_i/G_i)\) for all \(i\) such that, whenever there is an inclusion \(K_{i,t}(f) \hookrightarrow K_{j,t}(f)\), the following diagram commutes:

\[
\begin{array}{ccc}
K_{i,t}(f) & \longrightarrow & K_{j,t}(f) \\
\downarrow & & \downarrow \\
K_{i,0}(f) & \longrightarrow & K_{j,0}(f)
\end{array}
\]

\[
(1-t)D\nu_{\hat{f}_i} \partial + t(D\nu_{\hat{f}_j} \partial)^C \quad \text{on} \quad V_j/V_i
\]

Lemma \[\text{8.10}\] implies that the definition of a \textit{t–trivialization} is independent of the choice of extension \(K_{i,t}'\) of \(K_{i,t}\).

The most useful case of \(\Phi\)–submersive \textit{t–trivializations} is when \(\Phi\) is holomorphic in the sense of Definition \[\text{2.75}\]. The following proposition constructs a \(\Phi\)–submersive \textit{t–trivialization}.

**Proposition 8.11.** Given a holomorphic submersion \(\Phi: \mathcal{M}^t \rightarrow X\), and a \(\Phi\)–submersive embedded Kuranishi structure \(\{(U_i, V_i, \hat{f}_i/G_i)\}\) on \(\mathcal{M}_* \subset \mathcal{M}^t\), there exists a \(\Phi\)–submersive \textit{t–trivialization} of \(K_{i,t}\).

Such a \(t\)–trivialization can be chosen compatibly with a given \(t\)–trivialization defined on a neighborhood of a closed substack \(\mathcal{M}' \subset \mathcal{M}_*\) — our new \(t\)–trivialization will coincide with the given one when restricted to a (possibly smaller) neighborhood of \(\mathcal{M}'\).

**Proof:** The construction of a \(t\)–trivialization shall proceed by transfinite induction. In particular, we shall choose a well ordering of our Kuranishi charts, then construct our \(t\)–trivialization in this order. At each step we shall need to shrink the domain of definition a little, so we shall also need to specify more than one extension of each Kuranishi chart. We shall use the notation \(\hat{f}_i \subset \hat{f}_j^2\) to indicate that \(\hat{f}_j^2\) is an extension of \(\hat{f}_i\).

**Claim 8.12.** There is a well-ordering \(\prec\) of the Kuranishi charts such that \(j \prec i\) if \(\dim V_j < \dim V_i\), and such that, for any \(i\), there are only finitely many \(j\) with \(j \prec i\) and \(\dim V_j = \dim V_i\).

There are compatible extensions, \((U_{i,k}, V_i, \hat{f}_{i,k}/G_i)\) and \((U_{i,k}, V_i, \hat{f}_{i,k}/G_i)\), of \((U_i, V_i, \hat{f}_i/G_i)\) for all \(k \geq i\) so that

\[\hat{f}_{i,k} \subset \hat{f}_i \subset \hat{f}_{i,k}\]

whenever \(k > k'\),

and the intersection of \(\hat{f}_{i,k}\) for all \(k \geq i\) contains an extension of \(\hat{f}_i\).

As there are only a countable number of Kuranishi charts, they may be well-ordered as above. Embed our well-ordered set of indices into \((0, 3/8)\) as follows:

\[x_k := 3/8 - 2^{-\dim V_k - 2(1 + 1/(n_k + 2))}\]

where \(n_k\) is the number of indices \(j \leq k\) with \(\dim V_j = \dim V_k\). The only important property of \(x_k\) is that

\[x_k > \sup_{j < k} x_j\]

By definition, \((U_i, V_i, \hat{f}_i/G_i)\) is extendible, so there exists an extension \((U^2_i, V_i, \hat{f}^2_i/G_i)\) and a \(C^{\infty,1}\) map \(\rho: U^2_i \rightarrow [0, 1]\) satisfying the requirements of Definition \[\text{2.78}\] so that \(U_i\) is the substack where \(\rho > 1/2\). Then, define

\[U_{i,k} := \{\rho > x_k\} \subset U^2_i\]

and

\[U_{i,k} := \{\rho > x_k/2 + \sup_{j < k} x_j/2\} \subset U^2_i\].
These open substacks $U_{i,t}$ satisfy all the requirements of Claim 8.12 above.

For $j < i$, we only require compatibility between $K_{j,t}$ and $K_{i,t}$ on the intersection of $U_{j,i}$ with $U_{i,t}$. Similarly, when matching a given $t$-trivialization on a neighborhood of $M'$, our new $t$-trivialization need only agree with the given $t$-trivialization on $O$ — where $O$ is some fixed open neighborhood of $M' \subset M_s$ with closure contained in domain of definition of our given $t$-trivialization.

Let $f$ be a holomorphic curve in $f_{j,i}$. Suppose that, for $j < k < i$, we have a compatible choice of $t$-trivialization for all $K_{i,t}$ on $f_{j,k}$. We shall construct a $t$-trivialization of $K_{i,t}$ in a neighborhood of $f$ using the following three methods.

1. If $f$ is contained in $M'$, then there is already a given $t$-trivialization of $K_{i,t}$ compatible with our trivializations of $K_{j,t}$ for $j < i$ (by inductive assumption).

2. If $f$ is contained in $U_{j,i}$ for some $j < i$ but not in $M'$, proceed as follows: Without losing generality, assume that $V_j$ has the largest dimension so that $f$ is in $U_{j,i}$. We shall construct a $t$-trivialization of $K_{i,t}$ on some open subset of $f_{j,i} \cap U_{j,i}$ where we already have a $t$-trivialization of $K_{j,t} \subset K_{i,t}$.

   On a neighborhood of $f$, construct an extension $K'_{j,t}$ of $K_{i,t}$ using the complex structure on $T_{f_{j,i}}(M') \downarrow B_0$ from Claim 8.5 to construct a homotopy of $D\pi_V \partial$ to its complex-linear part, and letting $K'_{j,t}$ be the kernel. Because this complex structure is $G_t$-invariant, and there is a unique map $\tilde{f}_{j,i} \to f_{j,i}/G_t$ (defined in a neighborhood of $f$), we may pull this complex structure back to a complex structure on $T_{f_{j,i}}(M') \downarrow B_0$. Using this pulled back complex structure, construct an extension $K'_{j,t}$ of $K_{j,t}$ on a neighborhood of $f$ in $\tilde{f}_{j,i}$ with the property that $K'_{j,t} \subset K'_{i,t}$. In particular, construct $K'_{j,t}$ as the kernel of the following operator:

\[
A_t := (1 - t)D\pi_V \partial + t(D\pi_V \partial)^C: T_{f_{j,i}}(M') \downarrow B_0 \to \mathcal{Y}(\tilde{f}_{j,i})/V_j
\]

Note that $K'_{j,t}$ is defined using the analogous operator with $V_i$ in place of $V_j$. As $V_j \subset V_i$, and the same complex structure is used to define both $K'_{i,t}$ and $K'_{j,t}$, $K'_{j,t}(f') = A_t^{-1}(V_i/V_j)$, and $K'_{i,t} \subset K'_{j,t}$.

As our embedded Kuranishi structure is $\Phi$-submersive, $A_t$ restricted to the kernel of $T_f \Phi$ is surjective. $T_f \Phi: (K'_{j,t}(f') \to T_f X \downarrow X_s$ is surjective, and the same holds for all $f'$ in some neighborhood of $f$. It follows that

\[
K'_{j,t}(f')/K'_{i,t}(f') \xrightarrow{A_t} V_i/V_j
\]

and

\[
(\ker T_f \Phi \cap K'_{j,t}(f')) / (\ker T_f \Phi \cap K'_{i,t}(f')) \xrightarrow{A_t} V_i/V_j
\]

are both isomorphisms for $f'$ in a neighborhood of $f$.

Use the notation $(K'_{j,t})^\perp$ to denote the orthogonal complement of $\ker T_f \Phi \cap K'_{j,t}$ within $\ker T_f \Phi \cap K'_{i,t}$. (For this, use the equivariant metric from Remark 8.1.3) We may split $K'_{j,t}$ into $K'_{j,t} \oplus (K'_{j,t})^\perp$. On a neighborhood of $f$ in $\tilde{f}_{j,i}$, $A_t$ defines an isomorphism of vectorbundles as follows:

\[
A_t: (K'_{j,t})^\perp \to V_i/V_j
\]
Our $t$–trivialization of $K_{j,t}$ extends by definition to a $t$–trivialization of $K'_{j,t}$, which we may take to be $G_j$–equivariant. There is a canonical $G_j$–equivariant $t$–trivialization of $(K'_{j,t})^\perp$ so that the diagram

$$
\begin{array}{ccc}
(K'_{j,t})^\perp & \xrightarrow{A_t} & V_i/V_j \\
| & \downarrow{A_0} & \\
(K'_{j,0})^\perp & & \\
\end{array}
$$

commutes. The corresponding $G_j$–equivariant $t$–trivialization of $K'_{j,t}$ provides a locally defined, $G_i$–equivariant $t$–trivialization of the restriction of $K'_{i,t}$ to $(\bar{\partial}f_{i,i})^{-1}V_j$ with the property that the following diagram commutes

$$
\begin{array}{ccc}
K'_{j,t} & \xrightarrow{\Delta t} & V_i/V_j \\
| & \downarrow{A_0} & \\
K'_{j,0} & & \\
\end{array}
$$

As $\bar{\partial}f_{i,i}$ is transverse to $V_j$, we may extend the above $t$–trivialization to a $t$–trivialization of $K'_{i,t}$ in a neighborhood of $f$ within $\hat{f}_{i,i}$. The diagram above commutes for all holomorphic curves $f'$. As all $\mathbb{R}$–nil vectors in $T_f\mathcal{M}'\downarrow\mathcal{B}_0$ are contained in $K_{j,t}(f')$ and the $t$–trivialization of $K_{j,t}$ is constant on $\mathbb{R}$–nil vectors, the resulting $t$–trivialization of $K_{i,t}$ is constant on all $\mathbb{R}$–nil vectors.

As $(K'_{j,t})^\perp(f')$ is contained in the kernel of $T_{f'}\Phi$, the diagram

$$
\begin{array}{ccc}
K_{i,t}(f') & \xrightarrow{T_{f'}\Phi} & T_{\Phi(f')}X \\
| & \downarrow{T_{f'}\Phi} & \\
K_{i,0}(f') & & \\
\end{array}
$$

commutes for holomorphic curves $f'$.

So far we have constructed a $\Phi$–submersive $t$–trivialization of $K_{i,t}$ on a neighborhood of $f$ within $\hat{f}_{i,i}$, compatible with the $t$–trivialization of $K_{j,t}$. Given any $j' \prec i$ so that $\dim V_{j'} \leq \dim V_j$, the diagram

$$
\begin{array}{ccc}
K'_{j',t}(f') & \xrightarrow{(1-t)D\pi_{V_j}\delta + t(D\pi_{V_{j'}}\delta)^c} & V_j/V_{j'} \\
| & \downarrow{D\pi_{V_j}\delta} & \\
K_{j',0}(f') & & \\
\end{array}
$$

commutes whenever $K'_{j',t}(f')$ and $K_{j,t}(f')$ are both defined. It follows that our locally constructed $t$–trivialization of $K_{i,t}$ is automatically compatible with the $t$–trivialization of $K'_{j',t}(f')$. On the other hand, we have no reason to expect that our constructed $t$–trivialization is compatible with a $t$–trivialization of $K'_{j',t}$ if $\dim V_{j'} > \dim V_j$, and we also have no reason to expect compatibility with the already defined $t$–trivialization on a neighborhood of $\mathcal{M}'$.

(3) If $f$ is not contained in $\mathcal{M}'$ or $U_{j,i}$ for any $j \prec i$, then proceed as follows: On a neighborhood of $f$, choose an extension $K'_{j,i}$ of $K_{i,t}$. Choose a $G_i$–equivariant metric on $T_{\hat{f}_{i,i}}\mathcal{M}'\downarrow\mathcal{B}_0$ as in Remark 8.6. For all $f'$ in a
neighborhood of $f$ in $\hat{f}_{i,t}$. $T_f\Phi: K'_{i,t}(f') \longrightarrow T_{\Phi(f')}X|_{X_0}$ is surjective. We may therefore locally choose a $G_i$–equivariant splitting of $K'_{i,t}$

$$K'_{i,t} = (\ker T\Phi \cap K'_{i,t}) \oplus W$$

and a $G_i$–equivariant splitting of $T_{\hat{f}_{i,t}}M^{st}_i|_{B_0}$ as follows:

$$T_{\hat{f}_{i,t}}M^{st}_i|_{B_0} = (\ker T\Phi \cap T_{\hat{f}_{i,t}}M^{st}_i|_{B_0}) \oplus W$$

Denote by

$$\pi: T_{\hat{f}_{i,t}}M^{st}_i|_{B_0} \longrightarrow K'_{i,t}$$

the projection which in the above splittings is the orthogonal projection of $\ker T\Phi \cap T_{\hat{f}_{i,t}}M^{st}_i|_{B_0}$ to $\ker T\Phi \cap K'_{i,t}$ and the identity on $W$. As our splittings and our metric are $G_i$–equivariant projection.

To construct a $t$–trivialization of $K'_{i,t}$, define a connection in the $t$–direction of $K_{i,t}$ as follows. A section $\sigma_t$ of $K'_{i,t}$ for all $t$ may be viewed as a family of sections of $T_{\hat{f}_{i,t}}M^{st}_i|_{B_0}$. The derivative $\frac{d\sigma_t}{dt}$ is again a section of $T_{\hat{f}_{i,t}}M^{st}_i|_{B_0}$. Define

$$\nabla_t \sigma_t := \pi \left( \frac{d\sigma_t}{dt} \right).$$

Note that $\nabla_t f \sigma_t = \frac{d}{dt} \sigma_t + f \nabla_t \sigma_t$, so $\nabla_t$ defines a $G_i$–invariant connection in the $t$–direction on $K'_{i,t}$. Therefore parallel transport in the $t$ direction gives $G_i$–equivariant $t$–trivialization maps $K_{i,t,0} \longrightarrow K_{i,t}$. For holomorphic curves $f'$, $K_{i,t}(f)$ contains all $\mathbb{R}$–nil vectors, so our $t$–trivialization is the identity on these $\mathbb{R}$–nil vectors, as required. Notice too that if $\sigma_t$ is a section for which $T\Phi(\sigma_t)$ is independent of $t$, then $T\Phi(\nabla_t \sigma_t)$ is the zero section. It follows that our $t$–trivialization commutes with $T\Phi$, so the diagram

$$\begin{array}{ccc}
K_{i,t}(f') & \stackrel{T_f\Phi}{\longrightarrow} & TX \\
\downarrow & & \downarrow T_{\Phi(f')} \\
K_{i,0}(f') & \stackrel{T_{\Phi(f')}}{\longrightarrow} & TX
\end{array}$$

commutes.

The above three methods give a locally defined, $\Phi$–submersive $t$–trivialization of $K_{i,t}$ around every holomorphic curve in $\hat{f}_{i,t}$. As these $t$–trivializations have no reason to match up, we shall average them using a $G_i$–invariant partition of unity. In particular, given any finite collection of $t$–trivializations of $K_{i,t}$ defined in a neighborhood of $f$, we may extend them all to locally defined $t$–trivializations of some extension $K'_{i,t}$ of $K_{i,t}$. These $t$–trivializations correspond to connections on $K'_{i,t}$ in the $t$ direction, which may be averaged using a partition of unity to create another $t$–trivialization of $K'_{i,t}$. Note the following.

- The resulting averaged $t$–trivialization of $K_{i,t}$ does not depend on the choice of extension $K'_{i,t}$ used.
- As averaging $G_i$–invariant connections using a $G_i$–invariant partition of unity gives a $G_i$–invariant connection, the resulting $t$–trivialization of $K_{i,t}$ is $G_i$–invariant.
- A $t$–trivialization is $\Phi$–submersive if and only if, for each holomorphic curve $f$, the corresponding connection $\nabla_t$ satisfies the following property: if $\sigma_t$ is a section of $K_{i,t}(f)$ such that $T_f\Phi(\sigma_t)$ is constant, then $T\Phi(\nabla_t \sigma_t) = 0$. This property is preserved when we average connections satisfying it, so the resulting $t$–trivialization of $K_{i,t}$ is also $\Phi$–submersive.
• Averaging connections equal on a subspace produces a connection unchanged on the given subspace. It follows that our averaged $t$–trivialization is constant on $\mathbb{R}$–nil vectors.

• If all the original $t$–trivializations were compatible with a given $t$–trivialization of $K_{j,t} \subset K_{i,t}$, then the averaged $t$–trivialization is also compatible with the given $t$–trivialization. This follows because compatibility with the inclusion $K_{j,t} \subset K_{i,t}$ specifies what our connections must be when restricted to the subspace $K_{j,t}(f) \subset K_{i,t}(f)$, and the property of the isomorphism $K_{i,t}(f)/K_{j,t}(f) \to V_i/V_j$ being constant in our $t$–trivialization is also preserved by averaging.

Each holomorphic curve in the closure of $U_{j,i}$ is in $U_{j,\frac{i}{2}}$. As embedded Kuranishi structures are by definition locally finite, each holomorphic curve $f$ in $\check{f}_{i,t}$ has an open neighborhood in $\check{f}_{i,t}$ intersecting $U_{j,i}$ for $j < i$ only if $f \in U_{j,\frac{i}{2}}$. Either choose this open neighborhood contained in the domain of definition of our given $t$–trivialization, or not intersecting $O$, our chosen neighborhood of $\mathcal{M}'$. We may also choose this neighborhood of $f$ small enough so that the relevant method above for constructing a $t$–trivialization applies, and choose such a $t$–trivialization. Choose a $G_\mathcal{T}$–equivariant partition of unity on $F(\check{f}_{i,t})$ subordinate to the corresponding open cover of the holomorphic curves in $\check{f}_{i,t}$, and average our $t$–trivializations using this partition of unity.

As noted in the bullet points above, the corresponding $t$–trivialization is $G_\mathcal{T}$–equivariant, $\Phi$–submersive, agrees with the previously chosen trivialization on $O$, and for all $j < i$ is compatible with the $t$–trivialization of $K_{j,t}$ on $U_{j,i}$. By (transfinite) induction, we can choose such compatible $t$–trivializations on $\check{f}_{i,t}$ for all $i$. These define the required $t$–trivialization on our Kuranishi structure. □
