September 4, 2018

Abstract Suppose the ground field to be algebraically closed and of characteristic different from 2 and 3. All Heisenberg Lie superalgebras consist of two super versions of the Heisenberg Lie algebras, $\mathfrak{h}_{2m,n}$ and $\mathfrak{ba}_n$ with $m$ a nonnegative integer and $n$ a positive integer. The space of a “classical” Heisenberg Lie superalgebra $\mathfrak{h}_{2m,n}$ is the direct sum of a superspace with a non-degenerate anti-supersymmetric even bilinear form and a one-dimensional space of values of this form constituting the even center. The other super analog of the Heisenberg Lie algebra, $\mathfrak{ba}_n$, is constructed by means of a non-degenerate anti-supersymmetric odd bilinear form with values in the one-dimensional odd center. In this paper, we study the cohomology of $\mathfrak{h}_{2m,n}$ and $\mathfrak{ba}_n$ with coefficients in the trivial module by using the Hochschild-Serre spectral sequences relative to a suitable ideal. In characteristic zero case, for any Heisenberg Lie superalgebra, we determine completely the Betti numbers and associative superalgebra structure for their cohomology. In characteristic $p > 3$ case, we determine the associative superalgebra structures for the divided power cohomology of $\mathfrak{ba}_n$ and we also make an attempt to determine the cohomology of $\mathfrak{h}_{2m,n}$ by computing it in a low-dimensional case.

Keywords Heisenberg Lie superalgebra; divided cohomology; Hochschild-Serre spectral sequence

0. Introduction

The theory of Lie superalgebras and Lie supergroups has many applications in various areas of physics and cohomology is an important tool in the modern mathematics and theoretical physics (for example, see [GM, M, WLS]). One may find many studies on Lie superalgebra cohomology and its application in the literature (for example, see [G1, G2, GL, Leb1, LLS]).

For a given Lie superalgebra, generally speaking, it is not easy to determine the Betti numbers, superalgebra structures of cohomology, and so on. We should mention that the cohomology space with coefficients in the trivial module for a Lie superalgebra possesses a natural associative superalgebra structure arising from the cup product of the corresponding cochain space [Lei, M]. A standard fact is that such an associative superalgebra is graded-supercommutative (for a definition, see Section 1) for a Lie superalgebra with nontrivial odd part and is supercommutative for a Lie algebra. The present paper aims to determine explicitly the Betti numbers and associative superalgebra structures of the cohomology spaces with coefficients in the trivial module for a class of nilpotent Lie superalgebras—Heisenberg Lie superalgebras, over an algebraically closed field of characteristic different from 2 and 3.

Not as in the super case, for Heisenberg Lie algebras, one has obtained many conclusions on cohomology with coefficients in the trivial module. Santharoubane [Sa] studied the cohomology of Heisenberg Lie algebras and gave a description of cocycles, coboundaries and cohomology spaces over a field of characteristic zero. Sköldberg [Sk] calculated Betti numbers, which are dimensions of $n$-cohomology spaces, for Heisenberg Lie algebras over a field of characteristic two. Cairns and Jambor [CJ] extended Sköldberg’s work [Sk] to the case of arbitrary prime characteristic.

1. Heisenberg Lie Superalgebras

Throughout this paper, the ground field $\mathbb{F}$ is algebraically closed and of characteristic $p \neq 2, 3$. A Heisenberg Lie superalgebra is by definition a two-step nilpotent Lie superalgebra with 1-dimensional center [RSS]. Note that, over a non-algebraically closed field, there are several equivalence classes of non-degenerate symmetric bilinear forms on a given space. To simplify our life, we assume in this paper the ground field $\mathbb{F}$ is algebraically closed. In this case, all finite dimensional Heisenberg Lie superalgebras split precisely into two types $h_{2m,n}$ and $ba_n$, where $0 \leq m \in \mathbb{Z}$ and $1 \leq n \in \mathbb{Z}$, described as follows (we write the even basis elements first separated from the odd ones by a vertical bar):

- $h_{2m,n}$ having a basis \( \{z; x_1, \ldots, x_m, x_{m+1}, \ldots, x_{2m} \mid y_1, \ldots, y_n\} \) with non-zero
brackets of basis elements (in particular, $z$ spans the even center):

$$[x_i, x_{m+i}] = z, \ [y_j, y_j] = z$$

for any $1 \leq i \leq m$ and $1 \leq j \leq n$.

- $\mathfrak{b}a_n$ having a basis $\{x_1, \ldots, x_n | y_1, \ldots, y_n; z\}$ with non-zero brackets of basis elements (in particular, $z$ spans the odd center):

$$[x_i, y_i] = z$$

for any $1 \leq i \leq n$.

A Heisenberg Lie superalgebra can be realized to a subalgebra of Lie superalgebras of (odd) contact vector fields, which is precisely the negative part with respect to a certain natural grading [Leb2]. We should also note that Heisenberg Lie superalgebras correspond to Heisenberg supergroups, on which one find certain recent work (for example, see [BGT, CKN, T]).

The cochain space forms a graded-supercommutative superalgebra—an analog of the polynomial algebra. We will first describe the natural superalgebra structures on the cohomology spaces $H^\bullet(\mathfrak{h}_{2m,n})$ and $H^\bullet(\mathfrak{b}a_n)$ in case of characteristic zero. We know that the polynomial algebra has a divided power analog in the modular case, so does the cochain space. For Lie algebras, this phenomenon does not exist, since the graded-supercommutative superalgebra structure of cochain is generated by purely odd elements. Then, we will determine the superalgebra structure on the divided cohomology space $DPH^\bullet(\mathfrak{b}a_n)$ when $p > 3$. For the classical Heisenberg Lie superalgebra $\mathfrak{h}_{2m,n}$, we make an attempt by determining the superalgebra structures on the divided cohomology space $DPH^\bullet(\mathfrak{h}_{2m,n})$ for $m = 0, 1$ and $n = 1$. A complete description $DPH^\bullet(\mathfrak{h}_{2m,n})$ is beyond the scope of the present paper.

Our study is facilitated by the Hochschild-Serre spectral sequence, of which limit term is $E_3$ for Heisenberg Lie superalgebras (see Theorems 3.1, 3.2 and 4.1 and their proofs).

### 2. Cohomology and Divided Power Cohomology

For a detailed description of superalgebras, the reader is referred to [E, M]. Let $T(V)$ be the tensor algebra of a superspace $V = V_0 \bigoplus V_1$. Then $T(V)$ is an associative superalgebra with a $\mathbb{Z}_2$-grading induced by the $\mathbb{Z}_2$-grading of $V$. Note that $T(V)$ has also a $\mathbb{Z}$-grading structure given by setting $\|v\| = 1$ for any $v \in V$. Hereafter $\|x\|$ denotes the $\mathbb{Z}$-degree of a $\mathbb{Z}$-homogeneous element $x$ in a $\mathbb{Z}$-graded superspace. Let $J(V)$ denote the two-sided ideal of $T(V)$ generated by all elements of form

$$u \otimes v + (-1)^{|u||v|} v \otimes u, \quad u, v \in V.$$

Hereafter $|x|$ denotes the parity of a $\mathbb{Z}_2$-homogeneous element $x$ in a superspace. Note that the ideal $J(V)$ is both $\mathbb{Z}_2$-graded and $\mathbb{Z}$-graded. By definition, the
super-exterior algebra is the quotient algebra of $T(V)$ by $J(V)$, denoted by

$$\bigwedge V = T(V)/J(V).$$

Then $\bigwedge V$ is graded-supercommutative in the following sense: A $\mathbb{Z}$-graded associative superalgebra $A$ is said to be graded-supercommutative, if for any $a, b \in A$,

$$ab = (-1)^{|a||b|}(-1)^{|a||b|}ba.$$

Note that the dimension of $k$-homogeneous subspace of the super-exterior algebra with $r$ even generators and $s$ odd generators, denoted by $d_k(r,s)$, is

$$\sum_{i=0}^{k} \binom{r}{k-i} \binom{s+i-1}{i}.$$

Over a field of characteristic zero, cohomology of Lie superalgebra $\mathfrak{g}$ is defined by applying the Sign Rule to the corresponding definition for Lie algebras (for example, see [F, Lei, M]). Let $\mathfrak{g}$ be a Lie superalgebra and denote by $\mathfrak{g}^*$ the dual superspace of $\mathfrak{g}$. Then $\bigwedge^* \mathfrak{g}^* = \bigoplus_{i \in \mathbb{Z}} \bigwedge^i \mathfrak{g}^*$ with the differential $d$ induced by the dual of the Lie superalgebra bracket map, $\bigwedge^1 \mathfrak{g}^* \longrightarrow \bigwedge^2 \mathfrak{g}^*$, becomes a cochain complex, which is isomorphic to the ordinary cochain complex. In Section 2, we determine the cohomology of complex $(\bigwedge^* \mathfrak{g}^*, d)$ for Heisenberg Lie superalgebras in characteristic 0 case.

Over a field of prime characteristic $p > 3$, we introduce the definition of divided power cohomology of Lie superalgebra $\mathfrak{g}$. The reader is refereed to [BGLL] for further detailed information. Fix two $n$-tuples of positive integers $\underline{t} = (t_1, t_2, \ldots, t_n)$ and $\pi = (\pi_1, \pi_2, \ldots, \pi_n)$, where $\pi_i = p^{t_i}$. Let

$$\mathfrak{A}(m, n; \underline{t}) = \text{span}_{\mathbb{F}} \{ u^{(\alpha)} | \alpha \in \mathfrak{A}(m, n; \underline{t}) \}$$

where

$$\mathfrak{A}(m, n; \underline{t}) = \left\{ \alpha = (\alpha_1, \ldots, \alpha_{m+n}) \in \mathbb{N}^{m+n} \middle| \begin{array}{l} \alpha_i = 0 \text{ or } 1, 1 \leq i \leq m; \\ \alpha_{m+i} < \pi_i, 1 \leq i \leq n \end{array} \right\}.$$

The space $\mathfrak{A}(m, n; \underline{t})$ is $\mathbb{Z}_2 \times \mathbb{Z}$-graded by letting $|u^{(\alpha)}| = \alpha_{m+1} + \cdots + \alpha_{m+n}$ and $\|u^{(\alpha)}\| = \alpha_1 + \cdots + \alpha_{m+n}$. Then

$$\mathfrak{A}(m, n; \underline{t}) = \bigoplus_{i=0}^{m-n+\sum_{k=1}^{n} p^k} \mathfrak{A}_i(m, n; \underline{t}).$$

Moreover, $\mathfrak{A}(m, n; \underline{t})$ is an associative superalgebra with multiplication

$$u^{(\alpha)} u^{(\beta)} = \lambda(\alpha, \beta) \left( \frac{\alpha + \beta}{\alpha} \right) u^{(\alpha+\beta)}; \quad (2.1)$$
where
\[
\lambda(\alpha, \beta) = \left( \prod_{i=1}^{m} \min(1, 2 - \alpha_i - \beta_i) \right) (-1)^{\sum_{i=1}^{m-n} \sum_{k=m+1}^{m+n} \beta_i \alpha_k} \sum_{1 \leq j < k \leq m} \beta_j \alpha_k,
\]
\[
\left( \alpha + \beta \right) = \prod_{i=1}^{m+n} \left( \frac{\alpha_i + \beta_i}{\alpha_i} \right).
\]

For \( \varepsilon_i = (\delta, \ldots, \delta_{m+n}) \), we know that \( u^{(\alpha)} = u^{(\alpha_1 \varepsilon_1)} \cdots u^{(\alpha_{m+n} \varepsilon_{m+n})} \), and write \( \xi_i \) for \( u^{(\varepsilon_i)} \), \( 1 \leq i \leq m + n \). We call \( \mathfrak{A}(m, n; \mathfrak{L}) \) the super-divided power algebra with variables \( \{ \xi_1, \ldots, \xi_m \mid \xi_{m+1}, \ldots, \xi_{m+n} \} \). From Eq. (2.2), we obtain that
\[
\xi_i \xi_j = (-1)^{||\xi_i||||\xi_j||} \xi_j \xi_i.
\]

Moreover, \( \mathfrak{A}(m, n; \mathfrak{L}) \) is graded-supercommutative. Note that our superalgebra \( \mathfrak{A}(m, n; \mathfrak{L}) \) is not isomorphic to the (super)algebra of divided power mentioned in [BLL], p. 248, which is supercommutative.

Suppose \( V \) is a module of Lie superalgebra \( g \), and \( \mathfrak{A}(V; \mathfrak{L}) := \mathfrak{A}(m, n; \mathfrak{L}) \) is the super-divided power algebra with variables \( \{ v_1, \ldots, v_m \mid v_{m+1}, \ldots, v_{m+n} \} \) which is a fixed basis of \( V \). Then \( \mathfrak{A}(V; \mathfrak{L}) \) has a natural \( g \)-module structure by defining
\[
g.1 = 0, \quad g.u^{(\alpha)} = \sum_{i=1}^{m+n} (-1)^{\alpha_1 + \cdots + \alpha_{i-1} + |v_i|} u^{(\alpha_1 + \cdots + \alpha_{i-1})} (g.v_i) u^{(\alpha-\varepsilon_i)}, \quad g \in g.
\]

Now consider the dual module \( g^* \) of the adjoint module of \( g \). Then \( \mathfrak{A}(g^*; \mathfrak{L}) \) is a \( g \)-module with respect to the module action indicated above. Fix an ordered basis of \( g \)
\[
\{ x_1, \ldots, x_m \mid x_{m+1}, \ldots, x_{m+n} \}, \quad (2.2)
\]
and write
\[
\{ x_1^*, \ldots, x_m^* \mid x_{m+1}^*, \ldots, x_{m+n}^* \}
\]
for the dual basis. For simplibility, write \( x_i^{(a)} \) for \( u^{(a \varepsilon_i)} \), where \( 0 \leq a \in \mathbb{Z}, 1 \leq i \leq m + n \).

Next let us introduce the differential. Suppose \( a^i_{kl} \), \( 1 \leq i, k, l \leq m + n \) are the structure constants of \( g \) with respect to the basis \( \{ 2.2 \} \). Let \( d : \mathfrak{A}(g^*; \mathfrak{L}) \rightarrow \mathfrak{A}(g^*; \mathfrak{L}) \) be the linear operator defined by
\[
d(1) = 0,
\]
\[
dx_i^* = \sum_{1 \leq k < l \leq m+n} (-1)^{|x_i^*|} a^i_{kl} x_k^* x_l^* - \sum_{m+1 \leq k \leq m+n} a^i_{k} x_k^* x^*_k, \quad 1 \leq i \leq m + n,
\]
\[
d(u^{(\alpha)}) = \sum_{j=1}^{m+n} (-1)^{|u^{(\alpha)}|} a^{(\alpha)}_{j} d(x_j^*) u^{(\alpha-\varepsilon_j)}, \quad \alpha \in \mathfrak{A}(m, n; \mathfrak{L}).
\]
Then \( d \) is a \( g \)-module homomorphism and
\[
\|d\| = 1; \quad |d| = 0; \quad d^2 = 0;
\]
\[
d(u^{(\alpha)}u^{(\beta)}) = d(u^{(\alpha)})u^{(\beta)} + (-1)^{|u^{(\alpha)}|}u^{(\alpha)}d(u^{(\beta)}).
\]
Recall that the divided power cohomology of Lie superalgebra \( g \), denoted by \( DPH^\bullet(g) \), is defined by the cochain complex \((\mathfrak{A}(g^*; t), d)\) (see [BGLL]).

A useful tool to compute the cohomology of Lie superalgebras is the Hochschild-Serre spectral sequence relative to an ideal \( I \triangleleft g \):
\[
E_2^{k,s} = H^k(g/I, H^s(I)) \Rightarrow H^{k+s}(g).
\]  
(2.3)

For Heisenberg Lie superalgebra \( g = h_{2m,n} \) or \( ba_n \), we are concentrate with the ideal \( I = \mathbb{F}z \). Notice that \( g/I \) is abelian and the action of \( g/I \) on \( I^* \) is trivial. Thus
\[
H^k(g/I, H^s(I)) = \bigwedge^k(g/I)^* \otimes \bigwedge^s(I)^*.
\]

### 3. Characteristic Zero

Throughout this section the ground field \( \mathbb{F} \) is assumed to be of characteristic zero.

#### 3.1. Main Results

Let \( \mathfrak{g}_{2m,n} \) be the associative superalgebra with \( 2m + n \) homogeneous generators
\[
\{\xi_1, \ldots, \xi_{2m} \mid \eta_1, \ldots, \eta_n\}
\]
and defining relations with \( 0 \leq i, j \leq 2m, \ 1 \leq k, s \leq n, \)
\[
\xi_i\xi_j + \xi_j\xi_i = 0; \quad \xi_i\eta_k + \eta_k\xi_i = 0; \quad \eta_k\eta_s - \eta_s\eta_k = 0; \quad \sum_{i=1}^{m} \xi_i\xi_{m+i} - 2^{-1} \sum_{i=1}^{n} \eta_i\eta_i = 0.
\]  
(3.1)  
(3.2)

Then \( \mathfrak{g}_{2m,n} \) is \( \mathbb{Z} \)-graded by letting \( \|\xi_i\| = \|\eta_k\| = 1. \)

Let \( \mathfrak{g}_n \) be the associative superalgebra with \( 2n \) homogeneous generators
\[
\{\xi_1, \ldots, \xi_n \mid \eta_1, \ldots, \eta_n\}
\]
and defining relations, for \( 0 \leq i, j \leq n, \)
\[
\xi_i\xi_j + \xi_j\xi_i = 0; \quad \xi_i\eta_j + \eta_j\xi_i = 0; \quad \eta_k\eta_j - \eta_j\eta_k = 0; \quad \sum_{k=1}^{n} \eta_k\xi_k = 0.
\]  
(3.3)  
(3.4)
Similarly, $\mathfrak{G}_n$ is $\mathbb{Z}$-graded by letting $\|\xi_i\| = \|\eta_j\| = 1$.

From Eqs. (3.1)–(3.4) we know that $G_{2m,n}$ and $G_n$ are just the quotient algebras of super-exterior algebras with variables $\{\xi_1, \ldots, \xi_{2m} | \eta_1, \ldots, \eta_n\}$ and $\{\xi_1, \ldots, \xi_n | \eta_1, \ldots, \eta_n\}$ modulo the ideals generated by the elements $\sum_{i=1}^{m} \xi_{i+1} - 2^{-1} \sum_{i=1}^{n} \eta_i \eta_i$ and $\sum_{k=1}^{n} \xi_k \eta_k$, respectively.

Let $\mathcal{V}$ be an infinite-dimensional superspace with a $\mathbb{Z}_2$-homogeneous basis $\{v_i | i \in \mathbb{Z}^+\}$ with $\|v_i\| = \bar{i}$. View $\mathcal{V}$ as a $\mathbb{Z}$-graded associative superalgebra with trivial multiplication and a $\mathbb{Z}$-grading structure given by $\|v_i\| = n + i$.

The superalgebra structures and Betti numbers for the cohomology of Heisenberg Lie superalgebras are formulated as follows:

**Theorem 3.1.** As a $\mathbb{Z}$-graded superalgebra, $H^*(\mathfrak{h}_{2m,n})$ is isomorphic to $\mathfrak{G}_{2m,n}$. In particular,

$$\dim H^k(\mathfrak{h}_{2m,n}) = d^k(2m, n) - d^{k-2}(2m, n).$$

**Theorem 3.2.** As $\mathbb{Z}$-graded superalgebras, $H^*(\mathfrak{ba}_n)$ is isomorphic to the direct sum of superalgebras $\mathfrak{G}_n \oplus \mathcal{V}$. In particular,

$$\dim H^k(\mathfrak{ba}_n) = d^k(n, n) - d^{k-2}(n, n)$$

$$+ \sum_{i=2}^{k-2} (-1)^{i-1}(d^{k-2i}(n, n) - \delta_{k-2i,n}) + \sum_{i=1}^{k-1} \delta_{k-i,n} + \delta_{k-2,n}.$$ 

**3.2. Proof**

We first consider the Heisenberg Lie superalgebra $\mathfrak{h}_{2m,n}$.

**Proof of Theorem 3.1.** We use the Hochschild-Serre spectral sequence relative to the ideal $I = \mathbb{F}z$ [see Eq. (2.3)]. For $k \in \mathbb{Z}$, we have

$$E_2^{k,0} = \bigwedge (\mathfrak{h}_{2m,n}/\mathbb{F}z)^*; \quad E_2^{k,1} = \bigwedge (\mathfrak{h}_{2m,n}/\mathbb{F}z)^* \bigotimes (\mathbb{F}z)^*;$$

$$E_2^{k,s} = 0, \quad s \neq 0, 1.$$ 

Moreover,

$$E_\infty^{k,s} = E_3^{k,s}, \quad s = 0 \text{ or } 1; \quad E_\infty^{k,s} = 0, \quad \text{otherwise.}$$

Thus it is sufficient to consider the mapping

$$d_2^{k,1} : \bigwedge (\mathfrak{h}_{2m,n}/\mathbb{F}z)^* \bigotimes (\mathbb{F}z)^* \longrightarrow \bigwedge (\mathfrak{h}_{2m,n}/\mathbb{F}z)^*$$

$$d_2^{k,1}(f \otimes z^*) = dz^* \wedge f, \quad f \in \bigwedge (\mathfrak{h}_{2m,n}/\mathbb{F}z)^*,$$
Cohomology of Heisenberg Lie superalgebras

where

\[ dz^* = \sum_{i=1}^{m} x_i^* \wedge x_{m+i}^* - 2^{-1} \sum_{i=1}^{n} y_i^* \wedge y_i^* \]

can be viewed as an element in \( \bigwedge^2 (h_{2m,n}/Fz)^* \). From a direct computation, we have \( \ker d_2^{k,1} = 0 \). Then we obtain that

\[ E_3^{k,0} = \bigwedge^k (h_{2m,n}/Fz)^*/ \left( dz^* \wedge \bigwedge^{k-2} (h_{2m,n}/Fz)^* \right); \quad E_3^{k,1} = 0. \]

Thus, \( H^k(h_{2m,n}) = \bigwedge^k (h_{2m,n}/Fz)^*/ \left( dz^* \wedge \bigwedge^{k-2} (h_{2m,n}/Fz)^* \right) \). The proof is complete.

Next we consider the Heisenberg Lie superalgebra \( ba_n \). For an odd element \( w^* \), write \((w^*)^l\) for \( w^* \wedge \cdots \wedge w^* \in \bigwedge^l ba_n^* \). For \( ba_n \) with \( 1 \leq n \in \mathbb{Z} \), put

\[ X_n^* = x_1^* \wedge \cdots \wedge x_n^*. \]

Following from a standard computation, we obtain that

\[ dz^* = \sum_{j=1}^{n} x_j^* \wedge y_j^*; \quad dz^* \wedge dz^* = 0, \]

and then we can view \( dz^* \) as an element in \( \bigwedge^2 (ba_n/Fz)^* \).

**Lemma 3.3.** Suppose \( \alpha \in \bigwedge^k (ba_n/Fz)^* \), \( 0 \leq k \in \mathbb{Z} \), and \( \alpha \wedge dz^* = 0 \). Then

\[ \alpha = \beta \wedge dz^* + \delta_{k,n} \lambda X_n^* , \]

for some \( \beta \in \bigwedge^{k-2} (ba_n/Fz)^* \) and \( \lambda \in F \).

**Proof.** The conclusion is trivial for \( k = 0 \) and so we assume that \( k \geq 1 \). To show the conclusion, we use induction on \( n \). When \( n = 1 \), we may assume that

\[ \alpha = \lambda y_1^{*k-1} \wedge x_1^* + \mu y_1^{*k}, \quad \lambda, \mu \in F. \]

Since \( \alpha \wedge dz^* = 0 \), we have \( \mu = 0 \). Then \( \alpha = -\lambda y_1^{*k-2} \wedge x_1^* \wedge y_1^* + \delta_{k,1} \lambda X_1^* \). Now, we may assume that \( n > 1 \). Notice that

\[ x_n^* \wedge \sum_{j=1}^{n} x_j^* \wedge y_j^* = x_n^* \wedge \sum_{j=1}^{n-1} x_j^* \wedge y_j^*. \quad (3.5) \]
Suppose
\[ \alpha = \alpha_0 + \alpha_1 \wedge x_n^* + \sum_{i=1}^{k} \gamma_i \wedge y_n^i + \sum_{i=1}^{k-1} \zeta_i \wedge y_n^{i+1} \wedge x_n^*, \]
where \( \alpha_0 \in \bigwedge^k (\mathfrak{ba}_{n-1}/\mathbb{F}z)^* \), \( \alpha_1 \in \bigwedge^{k-1} (\mathfrak{ba}_{n-1}/\mathbb{F}z)^* \), \( \gamma_i \in \bigwedge^{k-1} (\mathfrak{ba}_{n-1}/\mathbb{F}z)^* \) and \( \zeta_i \in \bigwedge^{k-1} (\mathfrak{ba}_{n-1}/\mathbb{F}z)^* \). Note that \( |\alpha_0| = |\alpha_1| = |\alpha| \) and \( |\gamma_i| = |\zeta_i| = |\alpha| + i \). The condition \( \alpha \wedge dz^* = 0 \) implies that
\begin{align*}
\alpha_1 \wedge x_n^* \wedge \sum_{j=1}^{n-1} x_j^* \wedge y_j^* &= 0, 
(3.6) \\
\zeta_1 \wedge y_n^* \wedge x_n^* \wedge \sum_{j=1}^{n-1} x_j^* \wedge y_j^* + \alpha_0 \wedge x_n^* \wedge y_n^* &= 0, 
(3.7) \\
\sum_{i=2}^{k-1} \zeta_i \wedge y_n^{i-1} \wedge x_n^* &+ \sum_{j=1}^{n-1} \gamma_i \wedge y_n^i \wedge x_n^* \wedge y_n^* = 0. 
(3.8)
\end{align*}

From Eq. (3.6), we have \( \alpha_1 \wedge \sum_{j=1}^{n-1} x_j^* \wedge y_j^* = 0 \), which implies that, for \( \mathfrak{ba}_{n-1} \), \( \alpha_1 \wedge dz^* = 0 \). Applying the inductive hypothesis, we may assume that
\[ \alpha_1 = \beta_1 \wedge \sum_{j=1}^{n-1} x_j^* \wedge y_j^* + \delta_{k-1,n-1} \lambda X_{n-1}^*, \]
for some \( \beta_1 \in \bigwedge^{k-2} (\mathfrak{ba}_{n-1}/\mathbb{F}z)^* \) and \( \lambda \in \mathbb{F} \). From Eq. (3.7), we have
\[ \zeta_1 \wedge \sum_{j=1}^{n-1} x_j^* \wedge y_j^* = -\alpha_0. \]
(3.10)

From Eq. (3.8), we have
\begin{align*}
\gamma_k &= \gamma_{k-1} = 0, 
(3.11) \\
\sum_{i=2}^{k-1} \zeta_i \wedge y_n^{i-1} \wedge \sum_{j=1}^{n-1} x_j^* \wedge y_j^* &= - \sum_{i=1}^{k-2} \gamma_i \wedge y_n^i. 
(3.12)
\end{align*}

By Eqs. (3.5), (3.9)–(3.12), we have
\[ \alpha = (\beta_1 \wedge x_n^* - \sum_{i=1}^{k-1} \zeta_i \wedge y_n^i) \wedge \sum_{j=1}^{n} x_j^* \wedge y_j^* + \delta_{k,n} \lambda X_n^*. \]

The proof is complete.
Proof of Theorem 3.2. From Eq. (2.3) with the ideal $I = \mathbb{F}z$, we know that for $k \in \mathbb{Z}$, $0 \leq i \leq k$,

$$E_{2}^{k-i,i} = \bigwedge^{k-i}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^* \bigotimes (\mathbb{F}z^*)^i.$$

We consider the mapping

$$d_{2}^{k-i,i} : \bigwedge^{k-i}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^* \bigotimes (\mathbb{F}z^*)^i \longrightarrow \bigwedge^{k-i+2}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^* \bigotimes (\mathbb{F}z^*)^{i-1},$$

$$d_{2}^{k-i,i}(f \otimes (z^*)^i) = if \wedge dz^* \otimes (z^*)^{i-1}, f \in \bigwedge^{k-i}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^*.$$

From Lemma 3.3, we obtain that

$$E_{3}^{k,0} = \bigwedge^{k}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^*/\left(\bigwedge^{k-2}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^* \wedge dz^*\right);$$

$$E_{3}^{k-i,i} \cong \delta_{k-i,n}X_n^* \otimes (z^*)^i, \ 0 < i < k;$$

$$E_{3}^{0,k} = 0.$$

Moreover,

$$E_{4}^{k-i,i} = E_{3}^{k-i,i}, \ 0 \leq i \leq k.$$

Then, we have

$$H^k(\mathfrak{b}\mathfrak{a}_n) = \bigwedge^{k}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^*/\left(\bigwedge^{k-2}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^* \wedge dz^*\right) \bigoplus \bigoplus_{i=1}^{k-1} \delta_{k-i,n}X_n^* \otimes (z^*)^i.$$

Thus, $H^*(\mathfrak{b}\mathfrak{a}_n) \cong \mathfrak{S}_n \bigoplus \mathcal{Y}$ as superalgebras.

To compute the dimension of $H^k(\mathfrak{b}\mathfrak{a}_n)$, we consider the following mapping: for any $k \in \mathbb{Z}$,

$$\psi_k : \bigwedge^{k}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^* \longrightarrow \bigwedge^{k+2}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^*, \ \alpha \mapsto \alpha \wedge dz^*.$$

We claim

$$\dim \ker \psi_k = \sum_{i=1}^{\lfloor \frac{k}{2} \rfloor} (-1)^{i-1} \left( \dim \bigwedge^{k-2i}(\mathfrak{b}\mathfrak{a}_n/\mathbb{F}z)^* - \delta_{k-2i,n} \right) + \delta_{k,n}.$$
In fact, we can use induction on \( k \) and assume that \( k \geq 1 \). When \( k = 1 \), for \( \alpha \in \ker \psi_k \subset \Lambda^1(ba_n/Fz)^* \), from Lemma 3.3, we obtain that

\[
\alpha = \delta_{1,n} \lambda X_1^*.
\]

Then \( \dim \ker \psi_1 = \delta_{1,n} \). When \( k \geq 2 \), notice that \( X_n^* \in \ker \psi_n \). From Lemma 3.3, we obtain that

\[
\dim \ker \psi_k = \dim \im \psi_{k-2} + \delta_{k,n} = \dim \Lambda^{k-2}(ba_n/Fz)^* - \dim \ker \psi_{k-2} + \delta_{t,n}.
\]

Then the claim holds. From Eq. (3.13) we have

\[
\dim H^k(ba_n) = \dim \Lambda^{k}(ba_n/Fz)^* - \dim \Lambda^{k-2}(ba_n/Fz)^*
\]

\[
+ \dim \ker \psi_{k-2} + \sum_{i=1}^{k-1} \delta_{k-i,n}.
\]

The proof is complete. \( \square \)

4. Characteristic \( p > 3 \)

Throughout this section the ground field is assumed to be of characteristic \( p > 3 \). Put \( \delta_a = 1 \) when \( a \equiv 0 \pmod{p} \) and \( \delta_a = 0 \) otherwise.

4.1. Divided Power Cohomology of \( ba_n \)

In this section, we will determine the divided power cohomology of Heisenberg Lie superalgebra \( ba_n \). Fix an \( n + 1 \)-tuples of positive integers \( \underline{t} = (t_1, t_2, \ldots, t_{n+1}) \).

Let \( \mathfrak{G}_n \) be the super-divided power algebra with variables

\[
\{\xi_1, \ldots, \xi_n \mid \eta_1, \ldots, \eta_n\}
\]

and defining relations

\[
\sum_{i=1}^{n} \eta_i \xi_i = 0.
\]

Then, \( \mathfrak{G}_n \) is \( \mathbb{Z} \)-graded by letting \( ||\xi_i|| = ||\eta_j|| = 1 \). We know that \( \mathfrak{G}_n \) is just the quotient algebra of the super-divided power algebra with variables \( \{\xi_1, \ldots, \xi_n \mid \eta_1, \ldots, \eta_n\} \) modulo the ideal generated by the elements \( \sum_{i=1}^{n} \xi_i \eta_i \).
Cohomology of Heisenberg Lie superalgebras

Let \( \mathcal{V} \) be a \( 2^n p^{\sum_i t_i n - n} (p^{n+1} - 1) \)-dimensional superspace with a \( \mathbb{Z}_2 \)-homogeneous basis
\[
\left\{ \frac{a_{i_1}, \ldots, a_{i_s}, a_{i_1}, \ldots, a_{i_{n-s}}}{} \right\}_{\frac{1 \leq i_1 < \cdots < i_s \leq n}{1 \leq j \leq p^{n+1}-1}, \frac{0 \leq s \leq n, 0 \leq a_i \leq p^{i+1}-1, 1 \leq k \leq s}{1 \leq i_k \leq p^{i-1}, 1 \leq k < n - s}}.
\]
where \( \left\| \frac{a_{i_1}, \ldots, a_{i_s}, a_{i_1}, \ldots, a_{i_{n-s}}}{} \right\| = a_1 + \cdots + a_n - n + s + j \). View \( \mathcal{V} \) as a \( \mathbb{Z} \)-graded associative superalgebra with the trivial multiplication and the \( \mathbb{Z}_2 \)- graded divided power cohomology \( DPH^* (\mathfrak{b}_n) \).

**Theorem 4.1.** There exists a graded-supercommutative superalgebra isomorphism between \(\mathcal{V} \) and \(\mathfrak{b}_n \ltimes \mathcal{V}\) which is the semidirect sum of superalgebras with the following multiplication
\[
\eta^{(ap)}_{i_1, \ldots, i_s,j} \left\{ \frac{a_{i_1}, \ldots, a_{i_s}, a_{i_1}, \ldots, a_{i_{n-s}}}{} \right\} = (-1)^{a p \delta_{i \not\in \{ i_1, \ldots, i_s \}}} \left( \frac{a + a_i \cdot p - 1}{a p} \right) \left\{ \frac{a_{i_1}, \ldots, a_{i_s}, a_{i_1}, \ldots, a_{i_{n-s}}}{} \right\}.
\]
To prove this theorem, we make the following preparations. Let
\[
\left\{ x_1^*, \ldots, x_n^* \left| y_1^*, \ldots, y_n^* ; z^* \right. \right\}
\]
be the dual basis of the basis \(\left\{ x_1, \ldots, x_n \left| y_1, \ldots, y_n ; z \right. \right\}\) of \(\mathfrak{b}_n\). Notice that
\[
dz^* = \sum_{i=1}^n x_i^* y_i^* ; \quad \dz^* \dz^* = 0 ;
\]
\[
x_n^* \sum_{i=1}^n x_i^* y_i^* = x_n^* \sum_{i=1}^{n-1} x_i^* y_i^* ; \quad \text{(4.1)}
\]
\[
y_n^*(a p - 1) \sum_{i=1}^n x_i^* y_i^* = y_n^*(a p - 1) \sum_{i=1}^{n-1} x_i^* y_i^* , \quad 1 \leq a \in \mathbb{Z} . \quad \text{(4.2)}
\]
We can view \(\dz^*\) as an element in \(\mathfrak{A}_2((\mathfrak{b}_n/\mathbb{F}_2)^* ; t)\). For \(0 \leq q \leq n\) and \(0 \leq k \in \mathbb{Z}\), put
\[
V^k_{q,n} = \text{span}_k \left\{ x_{i_1}^* \cdots x_{i_q}^* y_{i_1}^* (a_{i_1} p) \cdots y_{i_q}^* (a_{i_q} p) y_{j_1}^* (a_{j_1} p - 1) \cdots y_{j_{n-q}}^* (a_{j_{n-q}} p - 1) \left| (a_1 + \cdots + a_n) p - n + 2q = k, a_{i_k} \geq 0, \quad s \in \mathbb{T} ; a_{i_k} \geq 1, t \in \mathbb{T} ; j_{1 \leq j \leq n-q} \right. \right\}.
\]
Lemma 4.2. Suppose $\alpha \in \mathfrak{A}_k((\mathfrak{ba}_n/Fz)^*; \mathcal{L})$, $0 \leq k \in \mathbb{Z}$, and $\alpha dz^* = 0$. Then

$$\alpha = \beta dz^* + \sum_{i=0}^{n} \delta'_{k+n-2i} \varepsilon^{k}_{i,n}$$

for some $\beta \in \mathfrak{A}_{k-2}((\mathfrak{ba}_n/Fz)^*; \mathcal{L})$ and $\varepsilon^{k}_{i,n} \in V^{k}_{i,n}$.

Proof. The conclusion is trivial for $k = 0$ and then we assume that $k \geq 1$. We use induction on $n$. When $n = 1$, we may assume that $\alpha = \lambda y_1^{(k-1)} x_1^* + \mu y_1^{(k)}$ with $\lambda, \mu \in \mathbb{F}$.

Since $\alpha dz^* = 0$, we have $\lambda = 0$. We consider the following cases:

Case 1: $k + 1 \equiv 0 \pmod{p}$. Note that $k - 1 \equiv 0 \pmod{p}$ for $p > 3$. Then $\alpha = \beta dz^* + \mu y_1^{(k)}$

where $\beta = -\frac{\lambda}{k-1} y_1^{(k-2)} \in \mathfrak{A}_{k-2}((\mathfrak{ba}_1/Fz)^*; \mathcal{L})$ and $y_1^{(k)} \in V^k_{0,1}$.

Case 2: $k + 1 \not\equiv 0 \pmod{p}$. Then $\mu = 0$. When $k - 1 \equiv 0 \pmod{p}$, we have $\alpha = \lambda y_1^{(k-1)} x_1^* \in V^k_{1,1}$.

When $k - 1 \not\equiv 0 \pmod{p}$, we have $\alpha = \beta dz^*$, where $\beta = -\frac{\lambda}{k-1} y_1^{(k-2)} \in \mathfrak{A}_{k-2}((\mathfrak{ba}_1/Fz)^*; \mathcal{L})$.

Thus, the conclusion holds.

Now, we may assume that $n > 1$. Suppose

$$\alpha = \alpha_0 + \alpha_1 x_1^* + \sum_{i=1}^{k} \gamma_i y_n^{(i)} + \sum_{i=1}^{k-1} \zeta_i y_n^{(i)} x_n^* ,$$

where $\alpha_0 \in \mathfrak{A}_k((\mathfrak{ba}_{n-1}/Fz)^*; \mathcal{L})$, $\alpha_1 \in \mathfrak{A}_{k-1}((\mathfrak{ba}_{n-1}/Fz)^*; \mathcal{L})$, $\gamma_i \in \mathfrak{A}_{k-i}((\mathfrak{ba}_{n-1}/Fz)^*; \mathcal{L})$ and $\zeta_i \in \mathfrak{A}_{k-i-1}((\mathfrak{ba}_{n-1}/Fz)^*; \mathcal{L})$. Note that $|\alpha_0| = |\alpha_1| = |\alpha|$ and $|\gamma_i| = |\zeta_i| = |\alpha| + i$. 
The condition $\alpha dz^* = 0$ implies that

$$\alpha_1 \sum_{j=1}^{n-1} x_j^* y_j^* = 0,$$

$$\gamma_i \sum_{j=1}^{n-1} x_j^* y_j^* = 0, \quad 1 \leq i \leq k, \quad (4.4)$$

$$\alpha_0 = -\zeta_1 \sum_{j=1}^{n-1} x_j^* y_j^*, \quad (4.5)$$

$$\gamma_i = (-1)^{i+1}(i+1)\zeta. \sum_{j=1}^{n-1} x_j^* y_j^*, \quad 1 \leq i \leq k - 1, \quad i + 1 \equiv 0 \pmod{p}, \quad (4.6)$$

$$\zeta_{i+1} \sum_{j=1}^{n-1} x_j^* y_j^* = 0, \quad 1 \leq i \leq k - 2, \quad i + 1 \equiv 0 \pmod{p}, \quad (4.7)$$

$$\gamma_k = \gamma_{k-1} = 0. \quad (4.8)$$

From Eqs. (4.3), (4.4), and (4.7) we obtain that, for $\mathfrak{A}((\mathfrak{ba}_{n-1}/\mathbb{F}z)^*; \ell), 1 \leq i \leq k - 2, 2 \leq m \leq k - 1, \quad i, q \equiv 0 \pmod{p},$

$$\alpha_1 dz^* = \gamma_i dz^* = \zeta_q dz^* = 0.$$  

Applying the inductive hypothesis, we may assume that

$$\alpha_1 = \theta \sum_{j=1}^{n-1} x_j^* y_j^* + \sum_{l=0}^{n-1} \delta_{k+n-2l-2}^{k-1} \epsilon_{l,n-1}^{k-1}, \quad (4.9)$$

$$\gamma_i = \eta_i \sum_{j=1}^{n-1} x_j^* y_j^* + \sum_{l=0}^{n-1} \delta_{k+n-2l-i-1}^{k-1} \sigma_{l,n-1}^{k-1}, \quad (4.10)$$

$$\zeta_q = \xi_q \sum_{j=1}^{n-1} x_j^* y_j^* + \sum_{l=0}^{n-1} \delta_{k+n-2l-q-2}^{k-q-1} \tau_{l,n-1}^{k-q-1}, \quad (4.11)$$

where

$$\theta \in \mathfrak{A}_{k-3}((\mathfrak{ba}_{n-1}/\mathbb{F}z)^*; \ell), \quad \epsilon_{l,n-1}^{k-1} \in V_{l+1,n}^{k-1};$$

$$\eta_i \in \mathfrak{A}_{k-i-2}((\mathfrak{ba}_{n-1}/\mathbb{F}z)^*; \ell), \quad \sigma_{l,n-1}^{k-i} \in V_{l,n-1}^{k-i};$$

$$\xi_q \in \mathfrak{A}_{k-q-3}((\mathfrak{ba}_{n-1}/\mathbb{F}z)^*; \ell), \quad \tau_{l,n-1}^{k-q-1} \in V_{l,n-1}^{k-q-1}.$$  

Note that

$$\epsilon_{l+1,n} := \epsilon_{l,n}^{k-1} x_n^* \in V_{l+1,n}^{k}, \quad (4.12)$$

$$\delta_{k,n} := \sigma_{l,n-1}^{k-1} y_n^{(i-1)} \in V_{l,n}^{k}, \quad (4.13)$$

$$\tau_{l+1,n} := \tau_{l,n-1}^{k-1} y_n^{(q)} x_n^* \in V_{l+1,n}^{k}. \quad (4.14)$$
From Eqs. (4.1), (4.2), (4.5)–(4.14), we obtain that

$$\alpha = \beta dz^* + \sum_{i=0}^{n} \delta'_{k+n-2i} i^k$$

where

$$\beta = \sum_{i=0}^{k-2} (\delta'_{i+1} - 1)(i+1)^{-1} \zeta_{i+1} y_n^{* (i)} + \theta x_n^* + \sum_{i=1}^{k-2} \delta'_{i+1} y_i^* x_n^* - \sum_{i=2}^{k-1} \delta'_i y_n^{* (i)} x_n^*,$$

$$\varepsilon^k_{i,n} = \varepsilon_{i,n}^k + \sigma^k_{i,n} + \tau^k_{i,n}.$$

\[ \square \]

**Proof of Theorem 4.1.** From Eq. (2.3) with the ideal \( I = Fz \), we know that for \( k \in \mathbb{Z}, 0 \leq i \leq k \),

$$E^{k-i,i}_2 = \mathcal{A}_{k-i}((ba_n/Fz)^*; \ell) \bigotimes (Fz^{* (i)}).$$

We consider the mapping

$$d^{k-i,i}_2 : \mathcal{A}_{k-i}((ba_n/Fz)^*; \ell) \bigotimes (Fz^{* (i)}) \rightarrow \mathcal{A}_{k-i+2}((ba_n/Fz)^*; \ell) \bigotimes (Fz^{* (i-1)})$$

$$d^{k-i,i}_2 (f \otimes z^{* (i)}) = f dz^* \otimes z^{* (i-1)}, f \in \mathcal{A}_{k-i}((ba_n/Fz)^*; \ell).$$

From Lemma 4.2 similar to the proof of Theorem 3.2 we can obtain that

$$DPH^k(ba_n) = \mathcal{A}_k((ba_n/Fz)^*; \ell) / \mathcal{A}_{k-2}((ba_n/Fz)^*; \ell) d^* z^* \bigoplus \bigoplus_{1 \leq i \leq k-1, 0 \leq j \leq n} V^{k-i}_{j,n} \otimes z^{* (i)}.$$

Put

$$\varepsilon^k_{11, \ldots, 11, j} \varepsilon^k_{i1, \ldots, is} \varepsilon^{(a_1, \ldots, a_k, 1, \ldots, a_{n-s})} = x_{i1}^* \cdots x_{is}^* y_{11}^* (a_1, p, \ldots, y_{is}^* (a_k, 1, \ldots, y_{i1}^* (a_{n-s}, p-1) \otimes z^{*(j)} \in V^k_{s,n} \bigotimes Fz^{* (j)},$$

where \( \sum_{i=1}^{n} a_i p = n + 2s = k \). Notice that for \( \varepsilon^{(bk_1, \ldots, b_k, \ldots, b_{n-d})}_{k_1, \ldots, k_q} \in V^t_{d,n} \bigotimes Fz^{* (q)}, \)

$$\varepsilon_{11, \ldots, is} \varepsilon^{(a_1, \ldots, a_k, 1, \ldots, a_{n-s})} \varepsilon_{k_1, \ldots, k_q} \in \mathcal{A}((ba_n/Fz); \ell) dz^* \bigotimes Fz^{* (j+q)}.$$

For any \( i = 1, \ldots, n \), notice that

$$x^*_{i1} \varepsilon_{i1, \ldots, is} = 0, y^*_{i1} \varepsilon_{i1, \ldots, is} = 0,$$

$$y^*_{i1} \varepsilon^{(a_1, \ldots, a_k, 1, \ldots, a_{n-s})}_{i1, \ldots, is} = (-1)^{sap} \delta \varepsilon^{(a_1, \ldots, a_k, 1, \ldots, a_{n-s})}_{i1, \ldots, is} \in V^{k+ap}_{s,n} \bigotimes Fz^{* (j)}.$$
Then we have a graded-supercommutative superalgebra isomorphism

\[ DPH^*(\mathfrak{b}_a_n) \cong \mathcal{G}_n \ltimes \mathcal{V}. \]

The proof is complete.

\[ \square \]

### 4.2. Divided Power Cohomology of \( \mathfrak{h}_{2m,n} \) in low dimensions

For \( \mathfrak{h}_{2m,n} \), we only describe the superalgebra structure of \( DPH^*(\mathfrak{h}_{0,1}) \) and \( DPH^*(\mathfrak{h}_{2,1}) \). In this case, let \( t = t \) be a positive integer. Determine the divided power cohomology \( DPH^*(\mathfrak{h}_{2m,n}) \) with arbitrary \( m \) and \( n \) should be a more cumbersome and excruciating task. A complete description of \( DPH^*(\mathfrak{h}_{2m,n}) \) is beyond the scope of this paper.

#### Example 4.3.

Recall \( \mathfrak{h}_{0,1} = \text{span}_F \{ z \mid y \} \) with \([y, y] = z\). Note that

\[
dy^* = 0; \quad dz^* = -y^{*(2)}; \\
d(z^* y^{*(i)}) = -\left(\frac{i + 2}{2}\right)y^{*(i+2)}, \quad 1 \leq i \leq p^t - 1.
\]

Then we obtain that

\[
\ker d = \bigoplus_{i=0}^{p^t-1} Fy^{*(i)} \bigoplus_{i=0}^{p^t-1} (\delta'_{i+1} + \delta'_{i+2}) Fz^* y^{*(i)},
\]

and

\[
im d = \bigoplus_{i=0}^{p^t-1} (1 - \delta'_i - \delta'_{i-1}) Fy^{*(i)}.
\]

We construct following superalgebras in order to describe \( DPH^*(\mathfrak{h}_{0,1}) \). Let \( \mathcal{G}_{0,1} \) be a \( 2p^t - 1 \)-dimensional graded-supercommutative superalgebra with basis

\[
\{ l_0, m_0, \ldots, l_{p^t-1}, m_{p^t-1} \},
\]

where \( |l_i| = i \), \( ||l_i|| = ip \), \( |m_i| = i + 1 \), \( ||m_i|| = ip + 1 \) and multiplication

\[
l_i l_j = \left( \frac{(i + j)p}{ip} \right) l_{i+j}, \quad l_i m_j = \left( \frac{(i + j)p + 1}{ip} \right) m_{i+j}.
\]

Let \( \mathcal{U} \) be a \( 2p^t - 1 \)-dimensional \( \mathbb{Z} \)-graded superalgebra with \( \mathbb{Z}_2 \)-homogeneous basis

\[
\{ v_1, u_1, \ldots, v_{p^t-1}, u_{p^t-1} \},
\]
where \(|v_i| = i + 1, \|v_i\| = ip, \|u_i\| = 1, \|u_i\| = ip - 1,\) and trivial multiplication.

There exist a graded-supercommutative superalgebra isomorphism between \(\text{DPH}^\bullet(\mathfrak{h}_{0,1})\) and \(\mathcal{G}_{0,1} \times \mathcal{U}\) which is the semidirect sum of superalgebras with the multiplication

\[
l_{ij}v_j = \binom{(i + j)p - 1}{ip} v_{i+j}; \quad l_iu_j = \binom{(i + j)p - 2}{ip} u_{i+j};
\]

\[
m_{ij}v_j = \binom{(i + j)p - 1}{ip + 1} v_{i+j},
\]

where \(0 \leq i \leq p^{t-1} - 1, 1 \leq j \leq p^{t-1} - 1\).

**Example 4.4.** Recall \(\mathfrak{h}_{2,1} = \text{span}_F \{z, x_1, x_2 \mid y\}\) with \([x_1, x_2] = [y, y] = z\). Note that

\[
dx^* = dy^* = 0; \quad dz^* = x_1^*x_2^* - y^{(2)}.
\]

Then we obtain that \(\ker d\) is spanned by the following elements:

\[
x_i^*y^{(i)}, x_i^*y^{(i)}; \quad x_1^*x_2^*y^{(i)}, y^{(i)}, \quad 0 \leq i \leq p^t - 1;
\]

\[
\delta^i_{k+2} \left( \begin{array}{c} k \\ 2 \end{array} \right) y^{(k)} + x_i^*y^{(k-2)}z^*;
\]

\[
\delta^i_{k+1}x_1^*y^{(k-2)}z^* + \delta^i_{k+1}x_2^*y^{(k-2)}z^* + \delta^i_{k+1}x_1^*x_2^*y^{(k-2)}z^*;
\]

\[
\delta^i_{k+1}x_1^*y^{(k-2)}z^* = \delta^i_{k+1}x_2^*y^{(k-2)}z^* = \delta^i_{k+1}x_1^*x_2^*y^{(k-2)}z^*.
\]

By a direct computation we obtain that \(\text{DPH}^\bullet(\mathfrak{h}_{2,1})\) is spanned by

\[
y^{(ep+s)} , x_i^*x_j^*y^{(ep+s)} ;
\]

\[
x_i^*x_j^*y^{(kp+s-2)}z^* = \left( \begin{array}{c} kp + s - 2 \\ 2 \end{array} \right) y^{(kp+s-2)} + x_i^*x_j^*y^{(kp+s-4)}z^* ,
\]

where \(x_0 := 1\) and \(0 \leq i < j \leq 2, 0 \leq e \leq p^{t-1} - 1, 1 \leq k \leq p^{t-1} - 1, s = 0\) or 1.

We construct following surperalgebras to describe \(\text{DPH}^\bullet(\mathfrak{h}_{2,1})\).

Put \(\rho^{h,t}_{k,s} = \left( \binom{(k + h)p + s + t}{kp + s} \right)\) and \(\rho^{\ell,t}_h = \left( \binom{hp + t - 2}{2} \right), 0 \leq k, h \in \mathbb{Z}, s, t \in \mathbb{Z}.\) Let \(\mathcal{G}_{2,1}\) be an \(8p^{t-1}\)-dimensional graded-supercommutative superalgebra with basis

\[
\{f^{k,s}_{(0,0)}, f^{k,s}_1, f^{k,s}_2, f^{k,s}_{(1,1)} \mid 0 \leq k \leq p^{t-1} - 1, s = 0 \text{ or } 1\},
\]

where \(|f^{k,s}_{(i,j)}| = k + s\) and \(\|f^{k,s}_{(i,j)}\| = kp + s + i + j, (i, j) = (0, 0), (0, 1), (1, 0)\) or \((1, 1)\), with the multiplication

\[
f^{k,s}_{(i,j)}f^{h,t}_{(0,0)} = (\delta_{s+t,1} + \delta_{s+t,0})\rho^{h,t}_{k,s_{(i,j)}};
\]

\[
f^{k,s}_{(i,j)}f^{h,t}_{(0,1)} = (-1)^{k+s}(\delta_{s+t,1} + \delta_{s+t,0})\rho^{h,t}_{k,s_{(1,1)}}.
\]
Let $\mathcal{W}$ be an $(8p^t - 8)$-dimensional $\mathbb{Z}$-graded superalgebra with basis
\[ \{ w_{k,s}^{(0,0)}, w_{k,s}^{(0,1)}, w_{k,s}^{(1,0)}, w_{k,s}^{(1,1)} \mid 1 \leq k \leq p^t - 1, s = 0 \text{ or } 1 \}, \]
where $|w_{k,s}^{(i,j)}| = k + s$ and $\|w_{k,s}^{(i,j)}\| = kp + s - 1 + i + j$. (i, j) = (0, 0), (0, 1), (1, 0) or (1, 1), with trivial multiplication.

There exist a graded-supercommutative superalgebra isomorphism between $DPH^•(h_2, 1)$ and $G_2, 1 \ltimes \mathcal{W}$ which is the semidirect sum of superalgebras with the multiplication
\[
\begin{align*}
l_{k,s}^{(0,0)} w_{h,t}^{(0,0)} &= \rho_{h,t}^{k,s} (\delta_{s+t,0} + \delta_{s+t,1}) w_{(0,0)}^{k+h, s+t} + \delta_{s+t,2} w_{(1,1)}^{k+h, 0}; \\
l_{k,s}^{(i,j)} w_{h,t}^{(0,0)} &= (\delta_{s+t,0} + \delta_{s+t,1}) \rho_{h,t}^{k,s} w_{(i,j)}^{k+h, s+t}; \\
l_{k,s}^{(0,0)} w_{h,t}^{(i,j)} &= (\delta_{s+t,0} + \delta_{s+t,1}) \rho_{h,t}^{k,s} w_{(i,j)}^{k+h, s+t}.
\end{align*}
\]
where $0 \leq k \leq p^t - 1, 1 \leq h \leq p^t - 1, s, t = 0 \text{ or } 1 \text{ and } (i, j) = (0, 1), (1, 0) \text{ or } (1, 1)$.
