EXPLICIT SMOOTHED PRIME IDEALS THEOREMS UNDER GRH

LOÏC GRENIÉ AND GIUSEPPE MOLTENI

Abstract. Let $\psi_K$ be the Chebyshev function of a number field $K$. Let $\psi_K^{(1)}(x) := \int_0^x \psi(t) \, dt$ and $\psi_K^{(2)}(x) := 2 \int_0^x \psi_K^{(1)}(t) \, dt$. We prove under GRH (Generalized Riemann Hypothesis) explicit inequalities for the differences $|\psi_K^{(1)}(x) - \frac{x^2}{2}|$ and $|\psi_K^{(2)}(x) - \frac{x^3}{3}|$. We deduce an efficient algorithm for the computation of the residue of the Dedekind zeta function and a bound on small-norm prime ideals.

1. Introduction

For a number field $K$ we denote

- $n_K$ its dimension,
- $\Delta_K$ the absolute value of its discriminant,
- $r_1$ the number of its real places,
- $r_2$ the number of its imaginary places,
- $d_K := r_1 + r_2 - 1$.

Moreover, throughout this paper $p$ denotes a maximal ideal of the integer ring $\mathcal{O}_K$ and $N_p$ its absolute norm. The von Mangoldt function $\Lambda_K$ is defined on the set of ideals of $\mathcal{O}_K$ as $\Lambda_K(I) = \log N_p$ if $I = p^m$ for some $p$ and $m \geq 1$, and is zero otherwise. Moreover, the Chebyshev function $\psi_K$ and the arithmetical function $\tilde{\Lambda}_K$ are defined via the equalities

$$\psi_K(x) := \sum_{3 \leq \mathfrak{a} \subseteq \mathcal{O}_K \atop N_\mathfrak{a} \leq x} \Lambda_K(\mathfrak{a}) =: \sum_{n \leq x} \tilde{\Lambda}_K(n).$$

In 1979, Oesterlé announced [19] a general result implying under the Generalized Riemann Hypothesis that

$$(1.1) \quad |\psi_K(x) - x| \leq \sqrt{x} \left( \frac{\log x}{\pi} + 2 \right) \log \Delta_K + \left( \frac{\log^2 x}{2\pi} + 2 \right) n_K$$

$\forall x \geq 1,$

but its proof has never appeared. The stronger bound with $\log x$ substituted by $\frac{1}{2} \log x$ has been proved by the authors [8] for $x \geq 100$.

The function $\psi_K(x)$ is the first member of a sequence of similar sums $\psi_K^{(m)}(x)$ which are defined for every $m \in \mathbb{N}$ as

$$\psi_K^{(0)}(x) := \psi_K(x) \quad \psi_K^{(m)}(x) := m \int_0^x \psi_K^{(m-1)}(u) \, du = \sum_{n \leq x} \tilde{\Lambda}_K(n)(x - n)^m.$$
and are smoothed versions of $\psi_K(x)$. They could be studied using (1.1) via a partial summation formula, but a direct attack via the integral identities

\begin{equation}
\psi^{(m)}_K(x) = \frac{-m!}{2\pi i} \int_{2-i\infty}^{2+i\infty} \frac{c_K(s)}{s(s+1)\cdots(s+m)} x^s \, ds \quad \forall x \geq 1, \forall m \geq 0
\end{equation}

(see Section 4) produces better results, as a consequence of the better decay that the kernel in the integral has for $m \geq 1$ with respect to the case $m = 0$. In fact, the absolute integrability of the kernel allows us to apply the Cauchy integral formula to quickly obtain that

\begin{align}
\psi^{(1)}_K(x) &= \frac{x^2}{2} - \sum_{\rho} \frac{x^{\rho+1}}{\rho(\rho+1)} - x r_K + R_{(1)}^{(1)}(x), \\
\psi^{(2)}_K(x) &= \frac{x^3}{3} - \sum_{\rho} \frac{2x^{\rho+2}}{\rho(\rho+1)(\rho+2)} - x^2 r_K + 2xr'_K - r''_K + R_{(2)}^{(2)}(x),
\end{align}

and analogous formulas for every $m \geq 3$, where $\rho$ runs on the set of nontrivial zeros for $\zeta_K$, the constants $r_K$, $r'_K$ and $r''_K$ are defined in (3.8) below and the functions $R_{(1)}^{(m)}(x)$ in Lemma 3.3. These representations show that the main term for the difference $\psi^{(m)}_K(x) - \frac{x^m}{m}$ comes from the sum on nontrivial zeros. Assuming the Generalized Riemann Hypothesis we have the strongest horizontal localization on zeros but we lack any sharp vertical information. Thus we are in some sense forced to estimate the sum with $x^{m+1/2} \sum_{\rho} |\rho(\rho+1)\cdots(\rho+m)|^{-1}$, and the problem here is essentially producing good bounds for this sum. To estimate this type of sums, we use the following method. Let $Z$ be the set of imaginary parts of the nontrivial zeros of $\zeta_K$, counted with their multiplicities, and let

\begin{align*}
f(s, \gamma) := \operatorname{Re} \left( \frac{2}{s - \left( \frac{1}{2} + i\gamma \right)} \right), \\
fg(s) := \sum_{\gamma \in Z} f(s, \gamma).
\end{align*}

The sum converges to the real part of a meromorphic function with poles at the zeros of $\zeta_K$. Let $g$ be a non-negative function. Suppose we have a real measure $\mu$ supported on a subset $D \subseteq \mathbb{C}$ such that

\begin{equation}
g(\gamma) \leq \int_D f(s, \gamma) \, d\mu(s), \quad \forall \gamma \in \mathbb{R},
\end{equation}

then under moderate conditions on $D$ and $\mu$ we have

\begin{equation}
\sum_{\gamma \in Z} g(\gamma) \leq \int_D \sum_{\gamma \in Z} f(s, \gamma) \, d\mu(s) = \int_D \sum_{\gamma \in Z} f(s, \gamma) \, d\mu(s) = \int_D f_K(s) \, d\mu(s).
\end{equation}

To ensure the validity of the estimate it is sufficient to have $D$ on the right of the line $\operatorname{Re}(s) = \frac{1}{2} + \varepsilon$ for some $\varepsilon > 0$ and $\mu$ of bounded variation. The interest of the method comes from the fact that, using the functional equation of $\zeta_K$, one can produce a formula for $f_K$ independent of the zeros (see (5.7)).

The aforementioned idea works very well for certain $g$ corresponding to $m = 1$ and 2 above, allowing us to prove the explicit formulas for $\psi^{(1)}_K(x)$ and $\psi^{(2)}_K(x)$ given in Theorem 1.1. Other applications of this idea can be found in [8] and [9].
Theorem 1.1. (GRH) For every $x \geq 3$, when $K \neq \mathbb{Q}$ we have

\[
\left| \psi_K^{(1)}(x) - \frac{x^2}{2} \right| \leq x^{3/2}(0.5375 \log \Delta_K - 1.0355 n_K + 5.3879) + (n_K - 1)x \log x + x(1.0155 \log \Delta_K - 2.1041 n_K + 8.3419) + \log \Delta_K - 1.415 n_K + 4,
\]

\[
\left| \psi_K^{(2)}(x) - \frac{x^3}{3} \right| \leq x^{5/2}(0.3526 \log \Delta_K - 0.8212 n_K + 4.4992) + (n_K - 1)x^2(\log x - \frac{1}{2}) + x^2(1.0155 \log \Delta_K - 2.1041 n_K + 8.3419) + 2x(\log \Delta_K - 1.415 n_K + 4) + \log \Delta_K - 0.9151 n_K + 2,
\]

while for $\mathbb{Q}$ the bounds become

\[
\left| \psi_{\mathbb{Q}}^{(1)}(x) - \frac{x^2}{2} \right| \leq 0.0462 x^{3/2} + 1.838 x,
\]

\[
\left| \psi_{\mathbb{Q}}^{(2)}(x) - \frac{x^3}{3} \right| \leq 0.0015x^{5/2} + 1.838x^2.
\]

The method can be easily adapted to every $m \geq 3$, but depends on several parameters that we have to set in a proper way to get an interesting result, and whose dependence on $m$ is not clear. As a consequence it is not evident that the bounds for each $m \geq 3$ will be as good as the cases $m = 1$ and 2, despite the fact that our computations for $m = 3$ and 4 show that it should be possible. Moreover, the applications we will show in the next section essentially do not benefit from any such extension, the cases $m = 1$ and 2 giving already the best conclusions (see Remark 1.3 below). Thus we have decided not to include the cases $m = 3$ and 4 in the paper.

Remark 1.2. Integrating (1.4) for $\gamma \in \mathbb{R}$ we find that, if $D$ is in the $\text{Re } s > \frac{1}{2}$ half of the plane, then

\[
\mu(D) \geq \frac{1}{2\pi} \int_{\mathbb{R}} g(\gamma) \, d\gamma.
\]

The measure $\mu(D)$ will end up as the main coefficient of $\log \Delta_K$ in our inequalities. This means that the coefficient of $\log \Delta_K$ that we can obtain with this method is necessarily greater than $\frac{1}{2\pi} \int_{\mathbb{R}} g(\gamma) \, d\gamma$.

Finally, we notice that our method is not limited to upper-bounds, since if we change $\leq$ to $\geq$ in Inequality (1.4), then Inequality (1.5) gives a lower bound. For an application see Remark 1.4 below.

A file containing the PARI/GP [21] code we have used for a set of computations is available at the following address: [http://users.mat.unimi.it/users/molteni/research/psi_m_GRH/psi_m_GRH_data.gp](http://users.mat.unimi.it/users/molteni/research/psi_m_GRH/psi_m_GRH_data.gp)

**Notation.** $\lfloor x \rfloor$ denotes the integral part of $x$; $\gamma$ denotes the imaginary part of the nontrivial zeros, but in some places it will denote also the Euler-Mascheroni constant, the actual meaning being clear from the context.

**Acknowledgements.** Special thanks go to Alberto Perelli and Karim Belabas for their valuable remarks and comments, and to Michael Rubinstein, who provided the authors the zeros for many Dirichlet $L$-functions. We are very grateful to the referee for her/his suggestions which greatly improved the presentation.
2. Applications

Small prime ideals. The bound in (1.1) can be used to prove that $\psi_K(x) > 0$ when $x \geq 4(\log \Delta_K \log^2 \log \Delta_K + 5n_K + 10)^2$. This fact, without explicit constants, was already mentioned by Lagarias and Odlyzko [10] who also gave an argument to remove the double logarithm of the discriminant and hence proving the existence of an absolute constant $c$ such that $\psi_K(x) > 0$ whenever $x \geq c \log^2 \Delta_K$. Later Oesterlé [19] announced that $c = 70$ works conditionally (see also [23 Th. 5]). More recently, Bach [1 Th. 4] proved (assuming GRH, again) that the class group of $K$ is generated by ideals whose norm is bounded by $12 \log^2 \Delta_K$ and by $(4 + o(1)) \log^2 \Delta_K$ when $\Delta_K$ tends to infinity (see also [4]). This proves the claim with $c = 12$, and $c = 4$ asymptotically. A different approach of Bach and Sorenson [3] proves that for any abelian extension of number fields $E/K$ with $E \neq \mathbb{Q}$ and every $\sigma \in \text{Gal}(E, K)$ there are degree-one primes $p$ in $K$ such that $\left[ \frac{E/K}{p} \right] = \sigma$ with $Np \leq (1 + o(1)) \log^2 \Delta_E$, where the “little-$o$” function is explicit but decays very slowly. As a consequence of the work of Lanzouli, Li and Soundararajan [11 Cor. 1.2] one can take $1 + o(1) = \left( \frac{(q \log q)}{\log \Delta_K} \right)^2$ in the case of the cyclotomic extension $\mathbb{K} = \mathbb{Q}[q]$ of $q$-th roots of unity.

The case $E = K$ of the aforementioned result of Bach and Sorenson implies that there exists a degree-one prime below $(1 + o(1)) \log^2 \Delta_K$. Using the bounds for $\psi_K^{(1)}(x)$ and $\psi_K^{(2)}(x)$ in Theorem 1.1 we reach a similar conclusion with the “little-$o$” function substituted by an explicit and quite small constant.

Corollary 2.1. (GRH) For every $\kappa \geq 0$, there are more than $\kappa$ degree-one prime ideals $p$ with $Np \leq (L_K + \sqrt[8]{8\kappa \log(L_K + \sqrt{\kappa \log \kappa})})^2$, where $L_K := 1.075(\log \Delta_K + 13)$ (with $\sqrt{\kappa \log \kappa} = 0$ for $\kappa = 0$).

Remark. The same argument, but this time based on bounds for $\psi_K^{(2)}(x)$, $\psi_K^{(3)}(x)$ and $\psi_K^{(4)}(x)$, produces a small improvement on the previous corollary, giving the same conclusion but with $L_K := 1.075(\log \Delta_K + c)$ for a suitable constant $c$ which can be explicitly computed. The improvement is due to the fact that the main constants 0.3526 and 0.5375 appearing in Theorem 1.1 satisfy $1.075 = 3 - 0.3526 < 2 - 0.5375 = 1.075$. Actually, no further improvement is possible with our technique (see Remark 4.3). In our opinion this very small improvement is unworthy of a detailed exposition: the interested reader will be able to prove it following the proof of Corollary 2.1 in Section 5.

Let $\partial_K = \prod_p p^{e_p}$ be the decomposition of the different ideal of $K$. We have $c_p = e(p) - 1$ when $p$ is tamely ramified and $c_p \geq e(p)$ when $p$ is wildly ramified. If $p$ is above an odd prime then $\log Np \geq \log 3$ hence $c_p \log Np \geq \log 3$. If $p$ is above 2, then either it is wildly ramified and $c_p \geq e(p) \geq 2$ or it is tamely ramified and $c_p = e(p) - 1 \geq 2$ (by definition of tame ramification). We thus have $c_p \log Np \geq \log 3$ in all cases. This in turn means that the number of ramifying ideals is at most $\frac{\log Np}{\log 3} \leq \log \Delta_K$. We deduce immediately the following

Corollary 2.2. (GRH) For every $\kappa \geq 0$, there are more than $\kappa$ unramified degree-one prime ideals $p$ with $Np \leq (L_K + \sqrt[8]{8\kappa' \log(L_K + \sqrt{\kappa' \log \kappa'})})^2$, where $\kappa' = \kappa + \log \Delta_K$ and $L_K := 1.075(\log \Delta_K + 13)$.

Remark. If $K/Q$ is a Galois extension, then the prime ideals in Corollary 2.2 are totally split, i.e. $[K/Q]_p = \text{id}$. 

Let \( \mathbb{K} := \mathbb{Q}[q] \) be the cyclotomic field of \( q \)-th roots of unity. Let \( p \) be the largest prime divisor of \( q \) and write \( q =: p^r q' \) with \( p \) and \( q' \) coprime. There is a ramified prime ideal of degree one if and only if \( p \equiv 1 \pmod{q'} \), this condition being trivially true when \( q' = 1 \), i.e. when \( q \) is a prime power. In that case there are \( \varphi(q') \) ramified primes of degree one and their norm is \( p \). Therefore, there is necessarily a prime congruent to 1 (mod \( q \)) below the bound of Corollary 2.1 with \( \kappa = \varphi(q') \). A second prime congruent to 1 modulo \( q \) is produced setting \( \kappa = \varphi(q') + \varphi(q) \). Comparing \( L_\kappa \) and \( \varphi(q) \log q \) we get the following explicit result.

**Corollary 2.3. (GRH)** For every \( q \geq 5 \) there are at least two primes which are congruent to 1 modulo \( q \) and \( \leq 1.2(\varphi(q) \log q)^2 \).

**Proof.** We know that \( \log \Delta_\kappa = \varphi(q) \log q - \varphi(q) \sum_{p|q} \frac{\log p}{p-1} \) (see [26] Prop. 2.17), so that \( L_\kappa \leq 1.075 \varphi(q) \log q \) for every \( q > e^{13} \) (and when \( q > 32 \) if \( q \) is not a prime). Define \( q =: p^r q' \) as above. As observed, we take \( \kappa = \varphi(q') + \varphi(q) \) in Corollary 2.1.

Notice that, if \( q' \neq 1 \), then \( p \geq 3 \) thus \( \varphi(q') = \frac{\varphi(q)}{(p-1)\cdot p^{r-1}} \leq \frac{1}{2} \varphi(q) \), while if \( q' = 1 \) the same inequality holds as soon as \( q \geq 3 \). This proves that \( \kappa \leq \frac{3}{2} \varphi(q) \) holds for every \( q \geq 3 \).

Since \( \log \Delta_\kappa \geq \frac{1}{2} \varphi(q) \log q \) for \( q \geq 7 \), one has \( \varphi(q) \leq 4L_\kappa / (2L_\kappa) \). Thus \( \kappa \leq 6L_\kappa / \log(2L_\kappa) \) when \( q \geq 7 \). With this upper bound, for \( L_\kappa \geq 1.3 \cdot 10^5 \), we get

\[
1.075^2 \cdot \left(1 + \frac{1}{L_\kappa} \sqrt{8 \kappa \log(L_\kappa + \sqrt{8 \kappa \log(\kappa)^2}} \right) \leq 1.2.
\]

If \( \varphi(q) \geq 24000 \), we have \( L_\kappa \geq 1.075 \left(\frac{1}{2} \varphi(q) \log \varphi(q) + 13 \right) \geq 1.3 \cdot 10^5 \). For \( q \geq 510510 = 2 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot 13 \cdot 17 \), looking separately the cases where \( q \) as at least 7 or less than 7 distinct prime factors, we see that \( \varphi(q) \geq 92160 \geq 24000 \). This proves the claim for \( q \geq 510510 \). Then, the explicit computation for \( q < 510510 \) of the bound in Corollary 2.1 shows that it is \( \leq 1.2(\varphi(q) \log q)^2 \) for every \( q > 4373 \); this proves the claim for \( 4373 < q < 510510 \). A direct search shows that two primes \( p = 1 \pmod{q} \) and \( p \leq 1.2(\varphi(q) \log q)^2 \) exist also in the range \( 5 \leq q \leq 4373 \).

**Remark.** We can repeat the proof of the previous corollary in a more general setting. Letting \( \kappa = \varphi(q') + (k-1)\varphi(q) \) one can prove that, when \( q > e^{13} \), there are at least \( k \) primes congruent to 1 modulo \( q \) and smaller than

\[
((1.075 + 0.02 \sqrt{k \log k}) \varphi(q) \log q)^2.
\]

**Computing the residue of \( \zeta_\kappa \).** An explicit form for the remainder of the formula for any \( \psi_\kappa^{(m)} \) gives a way to compute within a prefixed error any quantity which can be written as a Dirichlet series in the von Mangoldt function of the field. Among these, the computation of the logarithm of the residue of \( \zeta_\kappa \) with an error lower than \( \frac{1}{2} \log 2 \) is a particularly important problem, being an essential step of Buchmann’s algorithm [6] for the computation of the class group and the regulator of the ring of integral elements in \( \mathbb{K} \). The representation

\[
\log \zeta_\kappa(s) - \log \zeta(s) = \sum_{n=2}^{\infty} \frac{\Lambda_\kappa(n) - \Lambda_Q(n)}{n^s \log n}
\]

holds true uniformly in \( \text{Re}(s) \geq 1 \) by Landau’s and de la Vallée–Poussin’s estimates for the remainder terms of \( \psi_\kappa(x) \) and \( \psi_Q(x) \). Hence, a simple way to compute the residue is

\[
\log \text{res}_s \zeta_\kappa(s) = \lim_{s \to 1} [\log \zeta_\kappa(s) - \log \zeta(s)] = \sum_{n=2}^{\infty} \frac{\Lambda_\kappa(n) - \Lambda_Q(n)}{n \log n}.
\]
Here, truncating the series at a level \( N \) and using the partial summation formula one gets

\[
\log \text{res}_{\zeta_K}(s) = \sum_{n \leq N} (\tilde{\Lambda}_K(n) - \Lambda_Q(n)) (f(n) - f(N)) + R(N)
\]

with \( f(x) := (x \log x)^{-1} \) and

\[
R(N) := -\int_N^{+\infty} (\psi_K(x) - \psi_Q(x)) f'(x) \, dx.
\]

Moving the absolute value into the integral and using (1.1) yields

\[
|R(N)| \leq c \sqrt{N} \log \Delta_K + n_K \log N
\]

for an explicit constant \( c \). This procedure can already be used to compute the residue, but a substantial improvement has been obtained by Bach [2] and very recently announced by Belabas and Friedman [5]. They propose different approximations to \( \log \text{res}_{\zeta_K}(s) = 1 - \zeta_K(s) \) with a remainder term which is essentially estimated by \( c \log \Delta_K \sqrt{N \log N} \), with \( c = 8.33 \) in Bach’s work and \( c = 2.33 \) in the one of Belabas and Friedman. The presence of the extra \( \log N \) in the denominator and the small multiplicative constant in their formulas represent a strong boost to the computation, but this is achieved at the cost of some complexities in the proofs and in the implementation of the algorithm.

Using Theorem (1.1) after a further integration by parts of Equation (2.1) we get the same result with a simpler approach and already smaller constants. Even stronger results are available in Section 6. The following corollary is a part of Corollary 6.1.

\[\text{Corollary 2.4. (GRH) For } N \geq 3, \text{ we have}\]

\[
\log \text{res}_{\zeta_K}(s) = \sum_{n \leq N} (\tilde{\Lambda}_K(n) - \Lambda_Q(n)) (f(n) - f(N) - (n - N) f'(N)) + R^{(1)}(N)
\]

with

\[
|R^{(1)}(N)| \leq \alpha^{(1)}_K \left( \frac{\frac{5}{2} + y}{\sqrt{N} \log N} + \frac{3}{4} E_1 \left( \frac{1}{2} \log N \right) \right) + \beta^{(1)}_K \frac{2 + 3y}{N} + \gamma^{(1)}_K \frac{2y + y^2}{N} + \delta^{(1)}_K \frac{y + y^2}{N^2},
\]

\[f(x) := (x \log x)^{-1}, \ y := (\log N)^{-1}, \ E_1(x) := \int_1^{+\infty} e^{-xt} t^{-1} \, dt \text{ and} \]

\[
\alpha^{(1)}_K = 0.5375 \log \Delta_K - 1.0355 n_K + 5.4341, \quad \beta^{(1)}_K = n_K - 1, \quad \gamma^{(1)}_K = 1.0155 \log \Delta_K - 2.1041 n_K + 10.1799, \quad \delta^{(1)}_K = \log \Delta_K - 1.415 n_K + 4.
\]

The \( E_1 \) function satisfies the double inequality \( 1 - 1/x \leq xe^{-x} E_1(x) \leq 1 \) for every \( x > 0 \). Thus this strategy produces an error bounded essentially by \( 2.15 \log \Delta_K \sqrt{N \log N} \): this means that our algorithm is in \( N \) of the same order of Bach’s and Belabas–Friedman’s results with a smaller constant. Moreover, the negative coefficient for the contribution of the degree has the interesting side effect that, for fixed discriminant, the complexity actually decreases for increasing degree.

As shown in Tables 4 and 5 below, in practice Corollary 2.4 improves on Belabas and Friedman’s procedure by a factor of about 3, and in some ranges even by a factor of 10.
3. Preliminary inequalities

For \( \Re(s) > 1 \) we have
\[
-\frac{\zeta_K'(s)}{\zeta_K(s)} = \sum_p \sum_{m=1}^{\infty} \log(p)(Np)^{-ms},
\]
which in terms of standard Dirichlet series reads
\[
-\frac{\zeta_K'(s)}{\zeta_K(s)} = \sum_{n=1}^{\infty} \tilde{\Lambda}_K(n)n^{-s}
\]
observing that \( \tilde{\Lambda}_K(n) = \sum_{p|f} \log N_p \) if \( n = p^k \)
and otherwise, where \( f_p \) is the residual degree of \( p \). The formula for \( \tilde{\Lambda}_K(n) \) shows that \( \tilde{\Lambda}_K(n) \leq nK\Lambda(n) \) for every integer \( n \), so that immediately we get
\[
0 < -\frac{\zeta_K'(s)}{\zeta_K(s)} \leq -nK\frac{\zeta_K'(s)}{\zeta_K(s)} \forall s > 1.
\]

Let
\[
\Gamma_K(s) := \left[ \pi^{-\frac{s+1}{2}} \Gamma\left(\frac{s+1}{2}\right) \right]^{r_2} \left[ \pi^{-\frac{s}{2}} \Gamma\left(\frac{s}{2}\right) \right]^{r_1+r_2}
\]
and
\[
\xi_K(s) := s(s-1)\Delta_K^{-s/2}\Gamma_K(s)\zeta_K(s).
\]
The functional equation for \( \zeta_K \) then reads
\[
\xi_K(1-s) = \xi_K(s).
\]

Since \( \xi_K(s) \) is an entire function of order 1 and does not vanish at \( s = 0 \), one has
\[
\xi_K(s) = e^{A_K+B_Ks} \prod_{\rho} \left(1 - \frac{s}{\rho}\right)e^{s/\rho}
\]
for some constants \( A_K \) and \( B_K \), where \( \rho \) runs through all the zeros of \( \xi_K(s) \). These are precisely the zeros \( \rho = \beta + i\gamma \) of \( \zeta_K(s) \) for which \( 0 < \beta < 1 \) and are the so-called “nontrivial zeros” of \( \zeta_K(s) \). From now on \( \rho \) will denote a nontrivial zero of \( \zeta_K(s) \). We recall that the zeros are symmetric with respect to the real axis, as a consequence of the fact that \( \zeta_K(s) \) is real for \( s \in \mathbb{R} \).

Differentiating \((3.3)\) and \((3.5)\) logarithmically we obtain the identity
\[
\frac{\zeta_K'(s)}{\zeta_K(s)} = B_K + \sum_{\rho} \left(\frac{1}{s-\rho} + \frac{1}{\rho}\right) - \frac{1}{2} \log \Delta_K - \left(\frac{1}{s} + \frac{1}{s-1}\right) - \frac{\Gamma'_K(s)}{\Gamma_K(s)}.
\]

Stark \cite[Lemma 1]{Stark} proved that the functional equation \((3.4)\) implies that \( B_K = -\sum_{\rho} \Re(\rho^{-1}) \) (see also \cite[Ch. XVII, Th. 3.2]{Iwaniec}), and that once this information is available one can use \((3.3)\) and the definition of the gamma factor in \((3.2)\) to prove that the function
\[
f_K(s) := \sum_{\rho} \Re(\frac{2}{s-\rho})
\]
can be computed via the alternative representation
\[
f_K(s) = 2 \Re \frac{\zeta_K'(s)}{\zeta_K(s)} + \log \frac{\Delta_K}{\pi^nK} + \Re\left(\frac{2}{s} + \frac{2}{s-1}\right) + (r_1+r_2) \Re \frac{\Gamma'_K(s)}{\Gamma_K(s/2)} + r_2 \Re \frac{\Gamma'_K(s+1/2)}{\Gamma(s+1/2)}.
\]
Using (3.3), (3.4) and (3.6) one sees that
\[
\zeta_K'(s) = \begin{cases} 
\frac{r_1 + r_2 - 1}{s} + r_K + O(s) & \text{as } s \to 0 \\
\frac{r_2}{s+1} + r'_K + O(s+1) & \text{as } s \to -1 \\
\frac{r_1 + r_2}{s+2} + r''_K + O(s+2) & \text{as } s \to -2,
\end{cases}
\]
where
\[
(3.9a) \quad r_K = B_K + 1 - \frac{1}{2} \log \frac{\Delta_K}{\pi^{n_K}} + \frac{r_1 + r_2}{2} \Gamma'(1) - \frac{r_2}{2} \Gamma\left(\frac{1}{2}\right),
\]
\[
(3.9b) \quad r'_K = -\frac{\zeta_K'}{\zeta_K}(2) - \log \frac{\Delta_K}{\pi^{n_K}} - \frac{n_K \Gamma'(3)}{2} - \frac{n_K \Gamma'(1)}{2},
\]
\[
(3.9c) \quad r''_K = -\frac{\zeta_K''}{\zeta_K}(3) - \log \frac{\Delta_K}{\pi^{n_K}} - \frac{n_K \Gamma'(2)}{2} - \frac{n_K \Gamma'(3)}{2}.
\]

In order to prove our results we need explicit bounds for \(B_K, r_K, r'_K\) and \(r''_K\) and for some auxiliary functions.

**Lemma 3.1.** \(B_K\) is real, negative, and under GRH we have
\[
|B_K| \leq 0.5155 \log \Delta_K - 1.2432n_K + 9.3419.
\]

**Proof.** We know that \(-B_K = \sum \rho \text{Re} \left(\frac{1}{\zeta}\right) = \sum \rho \frac{\text{Re}(\rho)}{|\rho|^2}\), which is positive. The upper bound will be proved in next section. \(\square\)

**Lemma 3.2.** (GRH) We have
\[
|r_K| \leq 1.0155 \log \Delta_K - 2.1042n_K + 8.3423,
\]
\[
|r'_K| \leq \log \Delta_K - 1.415n_K + 4,
\]
\[
|r''_K| \leq \log \Delta_K - 0.9151n_K + 2.
\]

**Proof.** Substituting the values \(-\Gamma'(\frac{1}{2}) = \gamma + 2 \log 2, \quad -\Gamma'(1) = \gamma\) in (3.9a) we get
\[
(3.10) \quad r_K = B_K - \frac{1}{2} \log \Delta_K + (\log \pi + \gamma) \frac{n_K}{2} + r_2 \log 2 + 1.
\]

By Lemma 3.1 we get
\[
r_K \leq -\frac{1}{2} \log \Delta_K + (\gamma + \log 2\pi) \frac{n_K}{2} + 1 \leq -\frac{1}{2} \log \Delta_K + 1.2076n_K + 1
\]
and
\[
r_K \geq -(0.5155 \log \Delta_K - 1.2432n_K + 9.3423) - \frac{1}{2} \log \Delta_K + (\log \pi + \gamma) \frac{n_K}{2} + 1
\]
\[
\geq -1.0155 \log \Delta_K + 2.1042n_K - 8.3423.
\]

The (opposite of the) lower bound for \(r_K\) gives the upper bound for \(|r_K|\), since the explicit bounds for the discriminant in terms of the degree proved by Odlyzko (see [13, 15, 16, 18] and Table 3 in [14]) show that the difference
\[
(3.11) \quad 1.0155 \log \Delta_K - 2.1042n_K + 8.3423 - \left(-\frac{1}{2} \log \Delta_K + 1.2076n_K + 1\right)
\]
\[
= 1.5155 \log \Delta_K - 3.3118n_K + 7.3423
\]
is always positive (use the entry $b = 1.3$ in [14 Tab. 3]).

The bounds for $r'_K$ and $r''_K$ are proved with a similar argument. By (3.9b) and the identities $-\Gamma(\frac{1}{2}) = \gamma + 2\log 2 - 2$, $-\Gamma'(1) = \gamma$ we have

$$r'_K = -\frac{\zeta'(2)}{\zeta K} - \log \Delta_K + (\log 2\pi + \gamma - 1)n_K.$$ 

By (3.1) we have

$$r'_K \leq -\log \Delta_K + \left( -\frac{\zeta'(2)}{\zeta} + 2\pi + \gamma - 1 \right)n_K \leq -\log \Delta_K + 1.9851n_K$$

and

$$r'_K \geq -\log \Delta_K + (\log 2\pi + \gamma - 1)n_K \geq -\log \Delta_K + 1.415n_K \geq -\log \Delta_K + 1.415n_K - 4.$$ 

The lower bounds for the discriminant prove that the inequality

$$\log \Delta_K - 1.415n_K + 4 - (\log \Delta_K + 1.9851n_K) = 2\log \Delta_K - 3.4001n_K + 4 \geq 0$$

is true for $n_K \geq 5$ (entry $b = 1$ in [14 Tab. 3]). Using the “megrez” number field tables [20] we find that (3.12) has only two exceptions for fields of equation $x^2+x+1$ and $x^4-x^3-x^2+x+1$. We numerically compute the value of $r'_K$ for these two fields and we find that indeed $|r'_K| \leq \log \Delta_K - 1.415n_K + 4$.

Finally, by (3.9c)

$$r''_K = -\frac{\zeta'(3)}{\zeta K} - \log \Delta_K + \left( \log 2\pi + \gamma - \frac{3}{2} \right)n_K$$

and thus

$$r''_K \leq -\log \Delta_K + \left( -\frac{\zeta'(3)}{\zeta} + 2\pi + \gamma - \frac{3}{2} \right)n_K \leq -\log \Delta_K + 1.08n_K$$

and

$$r''_K \geq -\log \Delta_K + (\log 2\pi + \gamma - \frac{3}{2})n_K \geq -\log \Delta_K + 0.9151n_K \geq -\log \Delta_K + 0.9151n_K - 2.$$ 

The lower bounds for the discriminant prove that the inequality

$$\log \Delta_K - 0.9151n_K + 2 - (\log \Delta_K + 1.08n_K) = 2\log \Delta_K - 1.9951n_K + 2 \geq 0$$

is true for all $n_K$ (entry $b = 0.6$ in [14 Tab. 3]).

\textbf{Lemma 3.3.} For $x \geq 1$ let

$$f_{1,1}^{(1)}(x) := \sum_{r=1}^{\infty} \frac{x^{1-2r}}{2r(2r-1)}, \quad f_{2,1}^{(1)}(x) := \sum_{r=2}^{\infty} \frac{x^{2-2r}}{(2r-1)(2r-2)},$$

$$f_{1,2}^{(2)}(x) := \sum_{r=2}^{\infty} \frac{x^{2-2r}}{r(2r-1)(2r-2)}, \quad f_{2,2}^{(2)}(x) := \sum_{r=1}^{\infty} \frac{x^{1-2r}}{(2r+1)r(2r-1)},$$

and

$$R_{r_1,r_2}^{(1)}(x) := -d_K x(log x - 1) + r_2(log x + 1) - (r_1 + r_2)f_{1,2}^{(1)}(x) - r_2f_{2,1}^{(1)}(x),$$

$$R_{r_1,r_2}^{(2)}(x) := -d_K x^2 \left( \log x - \frac{3}{2} \right) + 2r_2 x \log x - (r_1 + r_2) \left( \log x + \frac{3}{2} \right) + (r_1 + r_2)f_{1,2}^{(2)}(x) + r_2f_{2,2}^{(2)}(x).$$
If \( x \geq 3 \) then

\[
|R_{r_1,r_2}^{(1)}(x)| \leq (n_K - 1)x \log x + \delta_{n_K,1} \frac{0.5097}{x},
\]

\[
|R_{r_1,r_2}^{(2)}(x)| \leq (n_K - 1)x^2(\log x - \frac{1}{2}) + \delta_{n_K,1}(\log x + 2)
\]

where \( \delta_{n_K,1} \) is 1 if \( n_K = 1 \) and 0 otherwise.

**Proof.** We have

\[
f_1^{(1)}(x) = \frac{1}{2} \left[ x \log(1 - x^{-2}) + \log \left( \frac{1 + x^{-1}}{1 - x^{-1}} \right) \right],
\]

\[
f_2^{(1)}(x) = 1 - \frac{1}{2} \left[ \log(1 - x^{-2}) + x \log \left( \frac{1 + x^{-1}}{1 - x^{-1}} \right) \right],
\]

\[
f_1^{(2)}(x) = \frac{3}{2} - \frac{1}{2} (x^2 + 1) \log(1 - x^{-2}) - x \log \left( \frac{1 + x^{-1}}{1 - x^{-1}} \right),
\]

\[
f_2^{(2)}(x) = -x + x \log(1 - x^{-2}) + \frac{1}{2} (x^2 + 1) \log \left( \frac{1 + x^{-1}}{1 - x^{-1}} \right),
\]

and the claims follow with elementary arguments. \( \square \)

### 4. PROOF OF THE THEOREM

When \( m \geq 1 \) the equality in (1.2) follows by the Dirichlet series representation of \( \zeta_K(s) \) and the special integrals

\[
\frac{m!}{2\pi i} \int_{2-i\infty}^{2+i\infty} y^{s+m} \prod_{u=0}^{m}(s+u) \, ds = \begin{cases} (y - 1)^m & \text{if } y > 1 \\ 0 & \text{if } 0 < y \leq 1 \end{cases} \quad \forall m \geq 1.
\]

The case \( m = 0 \) is more complicated but well known (see [10]). Equalities (1.3a, 1.3b) come from the Cauchy residue theorem, using the identities

\[
\frac{x^{s+1}}{s(s+1)} = \begin{cases} \frac{x}{s} + x \log x - x + O(s) & \text{as } s \to 0 \\ -\frac{x}{s+1} - \log x - 1 + O(s+1) & \text{as } s \to -1, \end{cases}
\]

\[
\frac{x^{s+2}}{s(s+1)(s+2)} = \begin{cases} \frac{x^2}{2s} + \frac{x^2}{2} \log x - \frac{3}{2} x^2 + O(s) & \text{as } s \to 0 \\ -\frac{x}{s+1} - x \log x + O(s+1) & \text{as } s \to -1 \\ \frac{1}{2(s+2)} + \frac{1}{2} \log x + x + O(s+2) & \text{as } s \to -2, \end{cases}
\]

and the definitions of \( r_K, r_K' \) and \( r_K'' \) in (3.8) and of \( R_{r_1,r_2}^{(m)}(x) \) in Lemma 3.3. They show that

\[
\left| \psi^{(1)}_{K'}(x) - \frac{x^2}{2} \right| \leq x^{3/2} \sum \frac{1}{|\rho(\rho + 1)|} + |x r_K - r_K' - R^{(1)}_{r_1,r_2}(x)|,
\]

\[
\left| \psi^{(2)}_{K'}(x) - \frac{x^3}{3} \right| \leq x^{5/2} \sum \frac{2}{|\rho(\rho + 1)(\rho + 2)|} + |x^2 r_K - 2x r_K' + r_K'' - R^{(2)}_{r_1,r_2}(x)|.
\]

For \( Q \), we observe that \( |x r_Q - r_Q' - R^{(1)}_{1,0}(x)| \leq x \log 2\pi \) and \( |x^2 r_Q - 2x r_Q' + r_Q'' - R^{(2)}_{1,0}(x)| \leq x^2 \log 2\pi \). For generic \( K \) these terms are estimated with the sums of the absolute values, and \( |r_K|, |r_K'|, |r_K''| \) and \( |R^{(j)}_{r_1,r_2}(x)| \) have already been estimated in Lemmas 3.2 and 3.3. We
thus only need a bound for \( \sum_{\rho} |\rho(\rho + 1)|^{-1} \) and \( \sum_{\rho} |\rho(\rho + 1)(\rho + 2)|^{-1} \). It is easy to check that
\[
(4.1) \quad \sum_{\rho} \frac{1}{|\rho(\rho + 1)|} \leq \frac{2}{3} f_K\left(\frac{3}{2}\right) \quad \text{and} \quad \sum_{\rho} \frac{1}{|\rho(\rho + 1)(\rho + 2)|} \leq \frac{4}{15} f_K\left(\frac{3}{2}\right).
\]

A bound comes from the estimation \( f_K\left(\frac{3}{2}\right) \leq \log \Delta_K - (\gamma + \log 8\pi - 2) n_K + \frac{16}{3} \), which is the case \( a = 1/2 \) of Lemma 5.6 in \([1]\) and of Lemma 4.6 in \([3]\), but we can do better.

**Lemma 4.1. (GRH)** We have
\[
\sum_{\rho} \frac{1}{|\rho(\rho + 1)|} \leq 0.5375 \log \Delta_K - 1.0355 n_K + 5.3879,
\]
\[
\sum_{\rho} \frac{1}{|\rho(\rho + 1)(\rho + 2)|} \leq 0.1763 \log \Delta_K - 0.4106 n_K + 2.2496.
\]

For the Riemann zeta function the conclusions improve to
\[
\sum_{\rho} \frac{1}{|\rho(\rho + 1)|} \leq 0.0462, \quad \sum_{\rho} \frac{1}{|\rho(\rho + 1)(\rho + 2)|} \leq 0.00146.
\]

**Proof.** We apply the method we have described in the introduction with real \( s \), so \( f(s, \gamma) = 4(2s - 1)/((2s - 1)^2 + 4\gamma^2) \). We choose \( D = \{ s_j : j = 1, 2, \ldots \} \) with \( s_j := 1 + j/2 \), and \( \mu \) compactly supported on \( D \). For the first claim let \( g(\gamma) := 4/((1 + 4\gamma^2)(9 + 4\gamma^2))^{1/2} \), so that \( \sum_{\rho} |\rho(\rho + 1)|^{-1} = \sum_{\gamma} g(\gamma) \). Condition (1.4) indicates that we must prove
\[
(4.2) \quad g(\gamma) \leq F(\gamma) := \sum_j a_j f(s_j, \gamma) \quad \forall \gamma \in \mathbb{R}
\]
for suitable \( a_j \). Recalling that \( f_K(s) = \sum_{\gamma} f(s, \gamma) \), Inequality (1.5) gives
\[
(4.3) \quad \sum_{\rho} \frac{1}{|\rho(\rho + 1)|} \leq \sum_j a_j f_K(s_j),
\]
which generalizes (4.1). From (4.3) and (3.7), and once (4.2) is proved, we obtain a bound for \( \sum_{\rho} |\rho(\rho + 1)|^{-1} \). The final coefficient of \( \log \Delta_K \) will then be the sum of all \( a_j \), thus we are interested in linear combinations for which this sum is as small as possible. We choose the support of \( \mu \) such that the \( s_j \) appearing in (4.2) are those with \( 1 \leq j \leq 2q \) for a suitable integer \( q \). Let \( \Upsilon \subset (0, \infty) \) be a set with \( q - 1 \) numbers. We require:

1. \( g(\gamma) = F(\gamma) \) for all \( \gamma \in \{0\} \cup \Upsilon \),
2. \( g'(\gamma) = F'(\gamma) \) for all \( \gamma \in \Upsilon \),
3. \( \lim_{\gamma \to \infty} \gamma^2 g(\gamma) = \lim_{\gamma \to \infty} \gamma^2 F'(\gamma) \).

This produces a set of \( 2q \) linear equations for the \( 2q \) constants \( a_j \). The first conditions impose a double contact between \( g \) and \( F \) in all the points of \( \Upsilon \). This means that \( g \) will almost certainly not cross \( F \) at these points. With a little bit of luck, \( F \) will be always above \( g \) ensuring (4.2). We chose \( q := 40 \) and \( \Upsilon := \{ v^i - v + 1 : 1 \leq i \leq q - 1 \} \) for \( v := 1.21 \). Finally, with an abuse of notation we took for \( a_j \) the solution of the system, rounded above to \( 10^{-7} \); this produces the numbers in Table 9. Then, using Sturm’s algorithm, we prove that the
values found actually give an upper bound for \( g \), so that (4.3) holds with such \( a_j \)'s. These constants verify

\[
\sum a_j = 0.53747 \ldots, \quad \sum a_j \left( \frac{2}{s_j} + \frac{2}{s_j - 1} \right) \leq 5.3879, \tag{4.4}
\]

\[
\sum a_j \Gamma' \left( \frac{s_j}{2} \right) \leq -0.6838, \quad \sum a_j \Gamma' \left( \frac{s_j + 1}{2} \right) \leq -0.1567.
\]

Moreover, the sum \( \sum_j a_j \zeta'(s_j) \) is negative. Indeed we write it as

\[- \sum_n \tilde{\Lambda}_K(n)S(n) \quad \text{with} \quad S(n) := \sum_j \frac{a_j}{n^s} \]

and, since the signs of the \( a_j \)'s alternate, we can easily prove that the sum in pairs \( \frac{a_j}{n^s} + \frac{a_{j+1}}{n^s} \), \( \ldots, \frac{a_{2n-1}}{n^s} + \frac{a_{2n}}{n^s} \) are positive for \( n \geq 26500 \). Then we check numerically that \( S(n) > 0 \) also for \( n \leq 26500 \). The result now follows from (3.7), (4.3) and (4.4).

For the second inequality, let \( g(\gamma) := 8/(1 + 4\gamma^2)(9 + 4\gamma^2)(25 + 4\gamma^2)^{1/2} \), so that \( \sum_\rho |\rho(\rho + 1)(\rho + 2)|^{-1} = \sum_j g(\gamma) \). We use \( s_j \) with \( 1 \leq j \leq 2q - 1 \), \( q := 20 \), \( \Upsilon := \{ v^i - v + 0.75: 1 \leq i \leq q - 1 \} \), keeping \( v = 1.21 \), and the conditions

1. \( g(\gamma) = F(\gamma) \) for all \( \gamma \in \{0\} \cup \Upsilon \),
2. \( g'(\gamma) = F'(\gamma) \) for all \( \gamma \in \Upsilon \).

We take for \( a_j \) the solution of the system, rounded above to \( 10^{-7} \): this produces the numbers in Table 7. We check their validity using Sturm’s algorithm as before. We then have

\[
\sum_\rho \frac{1}{|\rho(\rho + 1)(\rho + 2)|} \leq \sum_j a_j f_\xi(s_j) \tag{4.5}
\]

where the constants \( a_j \) verify

\[
\sum_j a_j = 0.17629 \ldots, \quad \sum_j a_j \left( \frac{2}{s_j} + \frac{2}{s_j - 1} \right) \leq 2.2496, \tag{4.6}
\]

\[
\sum_j a_j \Gamma' \left( \frac{s_j}{2} \right) \leq -0.3130, \quad \sum_j a_j \Gamma' \left( \frac{s_j + 1}{2} \right) \leq -0.1047,
\]

\[
\sum_j a_j \zeta'(s_j) \leq 0.
\]

As before, we prove the last inequality noticing that it is \(- \sum_n \tilde{\Lambda}_K(n)S(n) \) with \( S(n) := \sum_j \frac{a_j}{n^s} \), and that each \( S(n) \) is positive since this is true for \( n \leq 16800 \) (numerical test) and since the sums in pairs \( \frac{a_j}{n^s} + \frac{a_{j+1}}{n^s} \), \( \ldots, \frac{a_{2n-1}}{n^s} + \frac{a_{2n}}{n^s} \) and the last summand \( \frac{a_{2n+1}}{n^{2n+1}} \) are positive for \( n \geq 16800 \). The result now follows from (3.7), (4.5) and (4.6).

For the Riemann zeta function we proceed as in the general case, but now using the numerical value of \( \sum_j a_j f_\xi(s_j) \).

\[\square\]

**Remark 4.2.** For the Riemann zeta function one has \( \sum_{|\gamma| \geq T} |\rho|^{-2} \leq 10^{-5} \) when \( T \geq 400000 \) (by partial summation, using \[22\] Th. 19) or \[25\] Cor. 1), thus the value of \( \sum_\rho |\rho(\rho + 1)|^{-1} \)
correct up to the fifth digit can be obtained summing the first \( 7 \cdot 10^5 \) zeros. The computation
produces the number $0.0461(1)$. In a similar way, \( \frac{1}{T} \sum_{|\gamma| \leq T} |\rho|^{-2} \leq 10^{-10} \) when \( T \geq 200000 \), thus the value of \( \sum_{\rho} (\rho(p+1)(\rho+2)^{-1} \) correct up to the tenth digit can be obtained summing the first \( 3 \cdot 10^6 \) zeros. The computation produces the number $0.001439963(2)$. In both cases the bounds in Lemma 4.1 essentially agree with the actual values.

**Remark 4.3.** Let \( g_m(\gamma) := \prod_{n=0}^{m} n + \frac{1}{2} + i\gamma \). As observed in Remark 1.2, \( \sum a_j \geq \frac{1}{2\pi} \int_{0}^{T} g_1(\gamma) d\gamma \geq 0.53659 \) in the first case, and \( \sum a_j \geq \frac{1}{2\pi} \int_{0}^{T} g_2(\gamma) d\gamma \geq 0.1759 \) in the second case. These are the best coefficients of \( \log \Delta_K \) we can get from our method. Thus, what we get in Lemma 4.1 are close to the best. Moreover, for a generic \( m \geq 1 \) one gets

\[
\left| \psi^{(m)}(x) - \frac{x^{m+1}}{m+1} \right| \leq m! \frac{x^{m+1/2}}{m+1} \sum g_m(\gamma) + \text{lower order terms}
\]

and we need an upper bound of \( \sum g_m(\gamma) \). If we could follow the argument proving Lemma 4.1 for general \( m \) we would get a sequence \( a_j \) (a different sequence for every \( m \)) necessarily satisfying the lower bound \( \sum a_j \geq \frac{1}{2\pi} \int_{0}^{T} g_m(\gamma) d\gamma \). Since \( \int_{0}^{T} g_m(\gamma) d\gamma \sim \frac{\sqrt{m}}{m+1} \int_{0}^{T} \Gamma(\frac{1}{2} + i\gamma) d\gamma \) when \( m \) tends to infinity, in this way we cannot produce an upper-bound for \( \psi^{(m)}(x) - \frac{x^{m+1}}{m+1} \) with a coefficient for \( \log \Delta_K \) better than \( \frac{x^{m+1/2}}{2\sqrt{m}} + o(1) \int_{0}^{T} \Gamma(\frac{1}{2} + i\gamma) d\gamma \).

Iterating \( m \) times the partial summation for the logarithm of the residue of \( \zeta_K \) we get a remainder term which, in its main part, is controlled by \( 2(m+1)! \sum a_j \), so that it tends to infinity as \( \frac{\sqrt{m}}{m+1} \int_{0}^{T} \Gamma(\frac{1}{2} + i\gamma) d\gamma \): this proves that one cannot expect to improve the algorithm for the residue simply increasing \( m \). A closer look at the sequence \( (m+1)! \int_{0}^{T} g_m(\gamma) d\gamma \) shows that it attains its minimum exactly when \( m = 2 \), so that our formulas are already the best we can produce.

**Proof of Lemma 3.7.** We still follow the method described in the introduction. We use \( s_j = 1 + j/2 \) as in Lemma 4.1. Let \( g(\gamma) := 2/(1 + 4\gamma^2) \), so that \( |B_K| = \sum g(\gamma) \). Then using Sturm’s algorithm we see that \( g(\leq) \leq \sum_{j=1}^{10} a_j f(s_j, \gamma) \) for every \( \gamma \in \mathbb{R} \), when the constants \( a_j \) have the values in Table 8. As for Lemma 4.1 the numbers \( a_j \) have been generated imposing a double contact at the points in \( \Upsilon := \{0.84, 2.04, 4.01, 9.61\} \), the equality at \( \gamma = 0 \) and the asymptotic equality for \( \gamma \to \infty \). With these constants we have

\[
\begin{align*}
\sum a_j &= 0.51543 \ldots, \\
\sum a_j \Gamma' \left( \frac{s_j}{2} \right) &\leq -1.0094, \\
\sum a_j \frac{\zeta_K}{\zeta_K} (s_j) &\leq 0,
\end{align*}
\]

where the last inequality follows by noticing once again that it is \( -\sum \hat{\Lambda}_K(n) S(n) \) with \( S(n) := \sum a_{n} \), and that each \( S(n) \) is positive (for \( n < 150 \) by numerical test, and for every \( n \geq 150 \) because the sums in pairs \( \frac{a_1}{n^2} + \frac{a_2}{n^2}, \ldots, \frac{a_9}{n^2} + \frac{a_{10}}{n^2} \) are positive). The result now follows from (3.7) and (4.7).
Remark 4.4. The best coefficient of \( \log \Delta_K \) we can get from our argument is \( \frac{1}{2} \). Moreover, trying to find a lower bound, we can prove \( |B_K| \geq 0.4512 \log \Delta_K - 5.2554n_K + 5.2784 \). Unfortunately this bound is not sufficiently strong to produce anything useful for our purposes, thus we do not include its proof.

5. PROOF OF COROLLARY 2.1

Proof of the case \( \kappa = 0 \). We write

\[
\psi_K^{(1)}(x) = \sum_{p, m} \log(Np)(x - Np^m)
\]
as \( S_1 + S_2 \), where \( S_1 \) is the contribution to \( \psi_K^{(1)}(x) \) coming from the primes in the statement, and \( S_2 \) is the complementary term. Thus

\[
S_1 := \sum_{p \text{ prime}} \log Np \sum_{p^m \leq x} (x - Np^m) = \sum_{p \leq x} \left( \sum_{p|p} 1 \right) \log p \sum_{p^m \leq x} (x - p^m)
\]
and

\[
S_2 := \sum_{p \not\text{ prime}} \log Np \sum_{p^m \leq x} (x - Np^m) = \sum_{p \leq x} \sum_{p^m \leq \sqrt{x}} f_p \log p \sum_{p^m \leq x} (x - p^m/f_p),
\]
where \( f_p \) is the residual degree of the prime ideal \( p \). The definition of \( S_2 \) shows that

\[
S_2 \leq \sum_{p \leq x} \sum_{p^m \leq \sqrt{x}} f_p \log p \sum_{p^m \leq x} (x - p^m) \leq n_K \sum_{p \leq x} \log p (x - p^m)
\]

\[
= n_K \sum_{n \leq \sqrt{x}} A(n)(x - n^2) = n_K (2\sqrt{x} \psi_Q^{(1)}(\sqrt{x}) - \psi_Q^{(2)}(\sqrt{x}))
\]

\[
\leq n_K \left( \frac{2}{3} x^{3/2} + 2\sqrt{x} \psi_Q^{(1)}(\sqrt{x}) - \frac{x}{2} \right) + \left| \psi_Q^{(2)}(\sqrt{x}) - \frac{x^{3/2}}{3} \right|
\]

(5.1)

Thus, in order to prove that \( S_1 \) is positive it is sufficient to verify that \( \psi_K^{(1)}(x) \) is larger than the function appearing on the right in (5.1), which can be estimated using the upper bounds for \( Q \) and the lower bound for \( \psi_K^{(1)}(x) \) in Theorem 1.1. After some simplifications the inequality is reduced to

\[
\sqrt{x} \geq \mathcal{L}_K = 1.075(\log \Delta_K + 13) > A
\]
where

\[
A := 2(0.5375 \log \Delta_K - 1.0355n_K + 5.3879) + 2(n_K - 1) \frac{\log x}{\sqrt{x}}
\]

\[
+ \frac{2}{\sqrt{x}}(1.0155 \log \Delta_K - 2.1041n_K + 8.3419) + \frac{2}{x^{3/2}}(\log \Delta_K - 1.415n_K + 4)
\]

\[
+ 2n_K \left( \frac{2}{3} + \frac{0.0939}{x^{1/4}} + \frac{5.514}{x^{1/2}} \right).
\]

After some rearrangements the inequality \( \mathcal{L}_K > A \) becomes
Proof of the general case. Let \( A \) be the set of all degree-one prime ideals in \( \mathcal{O}_K \). Thus the term \( S_1 \) appearing in the decomposition of \( \psi_K^{(1)}(x) \) as \( S_1 + S_2 \) in the proof of the case \( \kappa = 0 \) reads

\[
S_1 = \sum_{p \leq x} \delta_{p \in A} \log Np \sum_{m \mid m \leq x} (x - Np^m)
\]

where \( \delta_{p \in A} \) is 1 if \( p \in A \) and 0 otherwise. With two applications of the Cauchy–Schwarz inequality we get

\[
S_1 \leq \left( \sum_{p \leq x} \delta_{p \in A} \right)^{1/2} \cdot \left( \sum_{p \leq x} \log^2 Np \left( \sum_{m \mid m \leq x} (x - Np^m) \right)^2 \right)^{1/2}
\]

\[
\leq \left( \sum_{p \leq x} \delta_{p \in A} \right)^{1/2} \cdot \left( \sum_{p \leq x} \log^2 Np \left( \frac{\log x}{\log Np} \sum_{m \mid m \leq x} (x - Np^m)^2 \right) \right)^{1/2}
\]

\[
\leq \left( \sum_{p \leq x} \delta_{p \in A} \right)^{1/2} \cdot \sqrt{\log x} \left( \sum_{p \leq x} \log Np \sum_{m \mid m \leq x} (x - Np^m)^2 \right)^{1/2}
\]

\[
= \left( \sum_{p \leq x} \delta_{p \in A} \right)^{1/2} \cdot \sqrt{\log x} \psi_K^{(2)}(x).
\]

Thus, in order to have \( \sum_{p \leq x} \delta_{p \in A} \) it is sufficient to have \( S_1 > \sqrt{\kappa \log x} \psi_K^{(2)}(x) \), i.e.

\[
\psi_K^{(1)}(x) > S_2 + \sqrt{\kappa \log x} \psi_K^{(2)}(x).
\]
Recalling the upper bound (5.1) for $S_2$ and Theorem 1.1 (with $K \neq \mathbb{Q}$), for the previous inequality it is sufficient to have

$$\sqrt{x} > A + 2\sqrt{\kappa B \log x}$$

where $A$ is given in (5.2) and

$$B := \frac{1}{3} + \frac{1}{\sqrt{x}}(0.3526 \log \Delta_K + 0.8212n_K + 4.4992) + (n_K - 1)\frac{1}{x}(\log x - \frac{1}{2})$$

$$+ \frac{1}{x}(1.0155 \log \Delta_K - 2.1041n_K + 8.3419) + \frac{2}{x^2}(\log \Delta_K - 1.415n_K + 4)$$

$$+ \frac{1}{x^3}(\log \Delta_K - 0.9151n_K + 2).$$

We can take $\sqrt{x} = L_K + 2\sqrt{\kappa \log(L_K + \sqrt{\kappa \log \kappa})}$ with $L_K = 1.075(\log \Delta_K + 13)$, and under this hypothesis function $B$ is bounded by $2/3$. To prove it we notice that

$$\frac{1}{x}(\log x - \frac{1}{2}) \leq \frac{0.33}{\sqrt{x}}$$

because $\sqrt{x} \geq L_K \geq 15$. This remark and the assumption $n_K \geq 2$ show that $B$ is smaller than

$$B \leq \frac{1}{3} + \frac{1}{\sqrt{x}}(0.3526 \log \Delta_K + 3.6) + \frac{1}{x}(1.0155 \log \Delta_K + 4.2) + \frac{2}{x^2}(\log \Delta_K + 1.2)$$

$$+ \frac{1}{x^3}(\log \Delta_K + 0.2).$$

It is now easy to prove that this is smaller than $2/3$ for $\sqrt{x} \geq L_K$. Since $B \leq \frac{2}{3}$ we only need to prove that

$$\sqrt{x} > A + 2\sqrt{\frac{2}{3} \kappa \log x}.$$  

From the proof of Corollary 2.1 we already know that $L_K > A$. Thus the inequality holds when $\kappa = 0$ and for $\kappa > 0$ it is sufficient to verify that

$$(L_K + \sqrt{\kappa \log \kappa})^{3/2} \geq L_K + (8\kappa \log(L_K + \sqrt{\kappa \log \kappa}))^{1/2}$$

which holds true for every $L_K \geq 15$ and every $\kappa > 0$. \hfill \qed

6. Proof of Corollary 2.4 and Improvements

Starting with (2.1) and with, respectively, one and two further integrations by parts one gets

(6.1a) \hspace{1cm} \log_{s=1} \log \zeta_K(s) = \sum_{n \leq N} (\tilde{\Lambda}_K(n) - \Lambda_{\mathbb{Q}}(n))W^{(1)}(n, N) + R^{(1)}(N),

(6.1b) \hspace{1cm} \log_{s=1} \log \zeta_K(s) = \sum_{n \leq N} (\tilde{\Lambda}_K(n) - \Lambda_{\mathbb{Q}}(n))W^{(2)}(n, N) + R^{(2)}(N)

with the weights

$W^{(1)}(n, N) := f(n) - f(N) - (n - N)f'(N),$ 

$W^{(2)}(n, N) := f(n) - f(N) - (n - N)f'(N) - \frac{1}{2}(n - N)^2f''(N)$.
For (6.5b) we plug (6.6b) into (6.3b) and we use (A.1f–A.1j).

For (6.5a) we plug (6.6a) into (6.3a) and we use (A.1a–A.1d): the integrals apply here because the remainders satisfy

\[ |\mathcal{R}^{(1)}(N)| \leq \mathcal{R}_{\text{bas}}^{(1)}(N) \quad \text{and} \quad |\mathcal{R}^{(2)}(N)| \leq \mathcal{R}_{\text{bas}}^{(2)}(N) \quad \forall N \geq 3, \]

with

\[ R_{\text{bas}}^{(1)}(N) := \alpha_K^{(1)} \left( \frac{\frac{1}{2} + y}{\sqrt{N \log N}} \right) + \gamma_K^{(1)} \frac{2y + y^2}{N} + \beta_K^{(1)} \frac{3 + y^2}{N^2}. \]

\[ R_{\text{bas}}^{(2)}(N) := \alpha_K^{(2)} \left( \frac{\frac{3}{2} + \frac{11}{12} y + \frac{1}{2} y^2}{\sqrt{N \log N}} \right) + \frac{15}{16} E_1 \left( \frac{1}{2} \log N \right) + \beta_K^{(2)} \frac{3 + \frac{11}{2} y + \frac{3}{8} y^2}{N} + \gamma_K^{(2)} \frac{3y + \frac{5}{2} y^2 + y^3}{N^2} + \delta_K^{(2)} \frac{2y^2 + y^3}{N^3} + \eta_K^{(2)} \frac{2y^2 + y^3}{N^3}, \]

where \( E_1(x) := \int_1^{+\infty} e^{-xt} \, dt \) is the exponential integral, \( y := (\log N)^{-1} \) and

\[ \alpha_K^{(1)} = 0.5375 \log \Delta_K - 0.10355n_K + 5.4341, \quad \beta_K^{(1)} = n_K - 1, \]

\[ \gamma_K^{(1)} = 1.0155 \log \Delta_K - 2.1041n_K + 10.1799, \quad \delta_K^{(1)} = \log \Delta_K - 1.415n_K + 4, \]

\[ \alpha_K^{(2)} = 0.3526 \log \Delta_K - 0.8212n_K + 4.5007, \quad \beta_K^{(2)} = n_K - 1, \]

\[ \gamma_K^{(2)} = 1.0155 \log \Delta_K - 2.6041n_K + 10.6799, \quad \delta_K^{(2)} = 2 \log \Delta_K - 2.83n_K + 8, \]

\[ \eta_K^{(2)} = \log \Delta_K - 0.9151n_K + 2. \]

**Proof.** Suppose we have found constants \( \alpha_K^{(1)}, \ldots, \delta_K^{(1)} \) and \( \alpha_K^{(2)}, \ldots, \eta_K^{(2)} \) such that

\[ |\psi^{(1)}_K(x) - \psi^{(1)}_Q(x)| \leq \alpha_K^{(1)} x^{3/2} + \beta_K^{(1)} x \log x + \gamma_K^{(1)} x + \delta_K^{(1)}, \]

\[ |\psi^{(2)}_K(x) - \psi^{(2)}_Q(x)| \leq \alpha_K^{(2)} x^{5/2} + \beta_K^{(2)} x^2 \log x + \gamma_K^{(2)} x^2 + \delta_K^{(2)} x + \eta_K^{(2)}. \]

For (6.3a) we plug (6.6a) into (6.3a) and we use (A.1a–A.1d): the integrals apply here because \( f(x) = (x \log x)^{-1} \) is a completely monotone function, i.e. satisfies \((-1)^k f^{(k)}(x) > 0\) for every \( x > 1 \) and for every order \( k \).

For (6.3b) we plug (6.6b) into (6.3b) and we use (A.1b–A.1b).
Lemma 4.1. In this way we get in the inner part both of the integral and of the sum, and then apply the upper bound in Remark 2.4. This strategy produces algorithms where the errors \(|\mathcal{R}^{(1)}(N)|\) and \(|\mathcal{R}^{(2)}(N)|\) are bounded essentially by \(2.15 \frac{\log \Delta}{\sqrt{N \log N}}\), and \(2.116 \frac{\log \Delta}{\sqrt{N \log N}}\), respectively. The minimal \(N\) needed for Buchmann’s algorithm using Belabas and Friedman’s result and ours are compared in Table 4. Coming back to the remark below Corollary 2.4 this strategy produces algorithms where the errors \(|\mathcal{R}^{(1)}(N)|\) and \(|\mathcal{R}^{(2)}(N)|\) are bounded essentially by \(2.15 \frac{\log \Delta}{\sqrt{N \log N}}\), and \(2.116 \frac{\log \Delta}{\sqrt{N \log N}}\), respectively. The minimal \(N\) needed for Buchmann’s algorithm using Belabas and Friedman’s result and ours are compared in Table 4. 

The terms \(-x r_K\) and \(R^{(1)}_{r_1, r_2}(x)\) in (1.3a) and \(-x^2 r_K\) and \(R^{(2)}_{r_1, r_2}(x)\) in (1.3b) are generally of comparable size and opposite in sign for the typical values of \(x\) which are needed in this application; thus it is possible to improve the result by estimating the remainders in such a way as to keep these terms together. This remark produces the following corollary.

Corollary 6.2. (GRH) In Equations (6.1a) and (6.1b) the remainders satisfy

\[
|\mathcal{R}^{(1)}(N)| \leq \mathcal{R}^{(1)}_{\text{imp}}(N) \quad \text{and} \quad |\mathcal{R}^{(2)}(N)| \leq \mathcal{R}^{(2)}_{\text{imp}}(N) \quad \forall N \geq 3,
\]

where

\[
\mathcal{R}^{(1)}_{\text{imp}}(N) := \alpha_1^{(1)} \left( \frac{5 + y}{\sqrt{N \log N}} + \frac{3}{4} E_1 \left( \frac{1}{2 \log N} \right) \right) + \left( d_K + \frac{r_2}{4N} \right) \frac{y^2}{N} + \left| d_K \frac{2 + y - y^2}{N} + \left( r_K - r_Q \right) \frac{2y + y^2}{N} - r_2 \frac{1 + \frac{5}{2} y + y^2}{N^2} - \left( r_K' - r_Q' \right) \frac{y + y^2}{N^2} \right|,
\]

\[
\mathcal{R}^{(2)}_{\text{imp}}(N) := \alpha_2^{(2)} \left( \frac{33 + \frac{11}{2} y + y^2}{\sqrt{N \log N}} + \frac{15}{16} E_1 \left( \frac{1}{2 \log N} \right) \right) + \left( d_K + \frac{r_2}{4N} \right) \frac{y^2}{N} \left( 1 + \frac{5}{2N} \right) + \left| \frac{1}{2} d_K \frac{6 + 2y - \frac{9}{2} y^2 - 3y^3}{N} + \left( r_K - r_Q \right) \frac{6y + 5y^2 + 2y^3}{N} - 2r_2 \frac{3 + \frac{11}{2} y + 3y^2}{N^2} - 2 \left( r_K' - r_Q' \right) \frac{3y + 4y^2 + 2y^3}{N^2} + \frac{2 + \frac{20}{7} y + \frac{15}{2} y^2 + 3y^3}{N^3} + \left( r_K'' - r_Q'' \right) \frac{2y + 3y^2 + 2y^3}{N^3} \right|,
\]

and \(\alpha_1^{(1)}\) and \(\alpha_2^{(2)}\) are as in Corollary 6.1.

Proof. By (6.2a) and the explicit formula (1.3a) we get

\[
|\mathcal{R}^{(1)}(N)| = \sum_{\rho} \frac{x^{\rho + 1}}{\rho(\rho + 1)} - \sum_{\rho} \frac{x^{\rho + 1}}{\rho(\rho + 1)} \left( r_K - r_Q \right) x + \left( r_K' - r_Q' \right) + R^{(1)}_{r_1, r_2}(x) - R^{(1)}_{1, 0}(x) \int_N^{+\infty} f''(x) \, dx.
\]

Here we isolate the part depending on the zeros. We estimate it by moving the absolute value in the inner part both of the integral and of the sum, and then applying the upper bound in Lemma 4.1. In this way we get

\[
|\mathcal{R}^{(1)}(N)| \leq \alpha_1^{(1)} \int_N^{+\infty} x^{3/2} |f''(x)| \, dx + \left| \int_N^{+\infty} \left( - \left( r_K - r_Q \right) x + \left( r_K' - r_Q' \right) + R^{(1)}_{r_1, r_2}(x) - R^{(1)}_{1, 0}(x) \right) f''(x) \, dx \right|
\]
where \( \alpha^{(1)}_K \) is the constant of Corollary 6.1. We apply then Equalities (A.1b–A.1c), thus getting

\[
|R^{(1)}(N)| \leq \frac{\alpha^{(1)}_K}{\sqrt{N}} (4y - 2y^2 + 12y^3) + \left| - \frac{r_K - r_Q}{N} (2y + y^2) + \frac{r'_K - r'_Q}{N^2} (y + y^2) + \int_{N}^{+\infty} \left( R^{(1)}_{r_1,r_2}(x) - R^{(1)}_{1,0}(x) \right) f''(x) \, dx \right|.
\]

Recalling the definition of functions \( f_j^{(1)}(x) \) and \( R^{(1)}_{r_1,r_2}(x) \) in Lemma 3.3, we have

\[
|R^{(1)}(N)| \leq \frac{\alpha^{(1)}_K}{\sqrt{N}} (4y - 2y^2 + 12y^3) + \left| \int_{N}^{+\infty} (d_K f_1^{(1)}(x) + r_2 f_2^{(1)}(x)) f''(x) \, dx \right| + \left| \frac{r_K - r_Q}{N} (2y + y^2) - \frac{r'_K - r'_Q}{N^2} (y + y^2) + \int_{N}^{+\infty} (d_K x (\log x - 1) - r_2 (\log x + 1)) f''(x) \, dx \right|.
\]

The part depending on \( f_j^{(1)} \) functions is estimated using the inequalities \( 0 < f_1^{(2)}(x) \leq 0.6x^{-1} \) and \( 0 < f_2^{(2)}(x) \leq 0.2x^{-2} \) for \( x \geq 3 \), the other integrals are computed via (A.1b–A.1c). After some computations one gets the bound \( |R^{(1)}(N)| \leq R^{(1)}_{\text{imp}}(N) \) with \( R^{(1)}_{\text{imp}}(N) \) given in (6.8).

The proof of (6.9) is similar using \( 0 < f_1^{(2)}(x) \leq 0.1x^{-2} \) and \( 0 < f_2^{(2)}(x) \leq 0.4x^{-1} \) for \( x \geq 3 \), and (A.1g–A.1l).

In order to apply the formulas in Corollary 6.2, we recall that

\[
r_Q = \log 2\pi \quad r'_Q = - \frac{\zeta'(2)}{\zeta(2)} + \gamma + \log 2\pi - 1 \quad r''_Q = - \frac{\zeta'(3)}{\zeta(3)} + \gamma + \log 2\pi - \frac{3}{2}
\]

(for \( r_Q \) see [7] Ch. 12), the other two are a direct consequence of (3.9b–3.9c), but we need also the parameters \( r_K, r'_K \) and \( r''_K \). They can be estimated as (see the proof of Lemma 6.2)

\begin{align*}
(6.10a) & \quad -1.0155 \log \Delta_K + 2.1042 n_K - 8.3419 \leq r_K \leq - \frac{1}{2} \log \Delta_K + 1.2076 n_K + 1 \\
(6.10b) & \quad - \log \Delta_K + 1.415 n_K \leq r'_K \leq - \log \Delta_K + 1.9851 n_K \\
(6.10c) & \quad - \log \Delta_K + 0.9151 n_K \leq r''_K \leq - \log \Delta_K + 1.08 n_K.
\end{align*}

Thus we can take the largest value that \( R^{(m)}_{\text{imp}} \) assumes when the parameters run in those ranges. To that effect, it is sufficient to consider the values of the term in the absolute value where \( r_K, r'_K \) and \( r''_K \) are replaced by the maximum and the minimum of their range. The results are summarized in Tables 2–5. Tables 2 and 3 show that in any case the improved estimate beats the plain bound by a quantity which largely depends on the quotient \( n_K/\log \Delta_K \), reaching a gain greater than 10% for \( R^{(1)} \) and 16% for \( R^{(2)} \) for some combinations. This behavior agrees with our motivations for the improved formulas: keeping together the quantities \( d_K + r_K y, r_2 + r'_K y \) (for non-totally real fields) and \( d_K + r''_K y \), which are \( \approx n_K - \log \Delta_K - \log N \) (times suitable multiple of \( N^{-1} \)), we take advantage of their cancellations which can be quite large for suitable values of \( n_K/\log \Delta_K \). Tables 4 and 5 show that the new algorithms improve Belabas–Friedman’s bound by a factor which is at least 3 and sometimes 10. Finally, Tables 4–5 show that in that range of discriminants and for degrees larger than 10 it is convenient to use \( R^{(2)}_{\text{imp}} \) instead of \( R^{(1)}_{\text{imp}} \).
We could improve the algorithm a bit further by using the relation

\[
  r_K = \sum_{n=1}^{+\infty} \frac{\tilde{\Lambda}_K(n) - \Lambda(n)}{n} - \log \Delta_K + (\gamma + \log 2\pi)n_K - \gamma,
\]

which follows combining the functional equations for \( \zeta_K \) and \( \zeta_Q \). In fact, truncating the series at a new level \( N' \) and estimating the remainder as in (6.1) via Theorem 1.1 we get an explicit formula which already for \( N' \approx 100 \) gives for \( r_K \) a range shorter than (6.10a). This computation takes only a small fraction of the total time needed for Buchmann’s algorithm, and the new range allows us to improve the \( N \) computed via \( R_{\text{imp}}^{(m)} \) by a quantity which in our tests has been generally around 1–2\%, and occasionally large as 5\%.

We can also compute \( r'_K \) and \( r''_K \) via (3.9b) and (3.9c), but their ranges (6.10b) and (6.10c) are already tight and in the formulas for \( R_{\text{imp}}^{(m)} \) these parameters appear only in terms which are several orders lower than the principal one, and no improvement comes from their computation.
Appendix A. Some integrals

We collect here a lot of computations and approximations of integrals that are used in Section 6; they can easily be proved by integration by parts. Recall that \( f(x) = (x \log x)^{-1} \), \( N \geq 3 \) and \( y = (\log N)^{-1} \). Thus

\[
 f(N) = \frac{y}{N}, \quad f'(N) = -\frac{y + y^2}{N^2}, \quad f''(N) = \frac{2y + 3y^2 + 2y^3}{N^3}.
\]

In the following \( \theta \) is a constant in \((0,1)\), with possibly different values in each occurrence. We have

\[
\begin{align*}
(A.1a) & \quad \int_N^{+\infty} x^{3/2} f''(x) \, dx = \frac{1}{\sqrt{N}}(\frac{5}{2}y + y^2) + \frac{3}{4} E_1 \left( \frac{1}{2} \log N \right) \\
(A.1b) & \quad \int_N^{+\infty} xf''(x) \, dx = \frac{1}{N}(2y + y^2) \\
(A.1c) & \quad \int_N^{+\infty} f''(x) \, dx = \frac{1}{N^2}(y + y^2) \\
(A.1d) & \quad \int_N^{+\infty} x \log x f''(x) \, dx = \frac{1}{N}(2 + 3y - \theta y^2) \\
(A.1e) & \quad \int_N^{+\infty} \log x f''(x) \, dx = \frac{1}{N^2}(1 + \frac{3}{2}y + \frac{\theta}{4}y^2) \\
(A.1f) & \quad \int_N^{+\infty} x^{5/2} f'''(x) \, dx = -\frac{1}{\sqrt{N}}(\frac{33}{4}y + \frac{11}{2}y^2 + 2y^3) - \frac{15}{8} E_1 \left( \frac{1}{2} \log N \right) \\
(A.1g) & \quad \int_N^{+\infty} x^2 f'''(x) \, dx = \frac{1}{N}(6y + 5y^2 + 2y^3) \\
(A.1h) & \quad \int_N^{+\infty} xf'''(x) \, dx = -\frac{1}{N^2}(3y + 4y^2 + 2y^3) \\
(A.1i) & \quad \int_N^{+\infty} f'''(x) \, dx = -\frac{1}{N^3}(2y + 3y^2 + 2y^3) \\
(A.1j) & \quad \int_N^{+\infty} x^2 \log x f'''(x) \, dx = \frac{1}{N}(-6 - 11y - 3y^2 + 2\theta y^2) \\
(A.1k) & \quad \int_N^{+\infty} x \log x f'''(x) \, dx = \frac{1}{N^2}(-3 - \frac{11}{2}y - 3y^2 - \frac{6}{4}y^2) \\
(A.1l) & \quad \int_N^{+\infty} \log x f'''(x) \, dx = \frac{1}{N^3}(-2 - \frac{11}{3}y - 3y^2 + \frac{2\theta}{9}y^2).
\end{align*}
\]
