Abstract

Multivariate correlation analysis plays an important role in various fields such as statistics, economics, and big data analytics. In this paper, we propose a pair of measures, the unsigned multivariate correlation coefficient (UMCC) and the unsigned multivariate incorrelation coefficient (UMIC), to measure the strength of correlation and incorrelation (lack of correlation) among multiple variables. The absolute value of Pearson’s correlation coefficient is a special case of UMCC for two variables. Based on the proposed UMIC, a compact formula for linear decomposition is also presented in this paper. The experiment results show that the proposed UMCC is an effective measure for multivariate correlation, and a new explanation of determinant is also made from the view of multivariate correlation.

Key words: Unsigned multivariate correlation coefficient (UMCC), Unsigned multivariate incorrelation coefficient (UMIC), Correlation matrix, Linear decomposition.

1. INTRODUCTION

Correlation analysis is a statistical subject which studies linear relationship and the “strength” of linear relationship among variables. It has been widely applied not only in statistics but also in almost all fields of science [1].

The quantitative method is the main research strategy for linear correlation analysis, in which the strength of correlation among variables is measured by a statistic called correlation coefficient (CC). Pearson’s correlation coefficient is a well-known CC. For two non-zero-variance random variables a and b, Pearson’s correlation coefficient between a and b is defined as

$$\rho_{ab} = \frac{\sigma_{ab}}{\sigma_a \sigma_b},$$

where $\sigma_a$ and $\sigma_b$ are the standard deviations of a and b, respectively, and $\sigma_{ab}$ is the covariance between a and b. $\rho_{ab} \in [-1, 1]$ and its absolute value $|\rho_{ab}|$ can be used to measure the strength of correlation between a and b.
Pearson’s correlation coefficient can only describe the linear relationship between two random variables. However, lots of applications, such as data dimensionality reduction, principal component analysis, and multiple linear regression, need CC to measure the strength of correlation among multiple variables. These applications usually select several variables from a number of variables to make the selected variables have the minimum correlation while maintaining enough information.

The development of information technology and big data analytics increases the importance of multivariate correlation analysis. Unfortunately, there was no compact formulation to define and measure the multivariate correlation until now, and people have to estimate the strength of multivariate linear correlation by the indirect methods such as partial correlation.

In this paper, an unsigned multivariate correlation coefficient (UMCC) and an unsigned multivariate incorrelation coefficient (UMIC) are proposed. The proposed UMCC and UMIC can be used to measure the strength of multivariate correlation and linear irrelevance. Many properties of them are introduced in the paper. For example, both the proposed UMCC and UMIC belong to an interval [0, 1]; The sum of the square of UMCC and the square of UMIC for the same variables is 1; The value of UMCC for multiple non-zero-variance random variables achieves the maximum value 1 if and only if these variables are linear dependent, and achieves the minimum value 0 if and only if these variables are perpendicular to each other; The value of UMCC for multiple variables is not less than that for part of them; If the number of variables is the same as their dimension, their UMIC then equals to the absolute value of the determinant of the square matrix whose row or column vectors are the standardized vectors of these variables.

In addition, based on the proposed multivariate UMIC, a compact and interesting formula of UMIC between a target vector and its linear decomposition is presented for the linear decomposition problem. The formula shows that if some vectors are selected from a vector set to match the target vector by a linear combination of them, these selected vectors should have small correlation while maintaining enough information of the target vector.

2. UMCC FOR THREE VARIABLES

We denote by $a'$ the standardized vector of non-zero-variance vector $a$:

$$a' = \frac{a - \mu a 1}{||a - \mu a 1||}.$$
where $\mu_a$ is the mean of the elements in $a$, $||a - \mu_a1||$ is the length of $a - \mu_a1$, and $1$ is the vector whose entries are all ones.

The sign of mutual direction for two variables can be judged by whether the angle between them is larger than 90. However, there is no the mutual direction for multiple variables. Therefore, we define UMCC and UMIC are both the non-negative values.

**Definition 1** For three $n$-dimensional non-zero-variance variables $a$, $b$, and $c$, $n \geq 3$, if $\rho_{ab}$, $\rho_{bc}$, and $\rho_{ac}$ are Pearson’s correlation coefficients between $a$ and $b$, between $b$ and $c$, and between $a$ and $c$, respectively, then the unsigned correlation coefficient $r_{abc}$ among $a$, $b$, and $c$ is defined as

$$r_{abc}^2 = \rho_{ab}^2 + \rho_{bc}^2 + \rho_{ac}^2 - 2\rho_{ab}\rho_{bc}\rho_{ac}.$$  \hspace{1cm} (2)

Some properties of $r_{abc}^2$ are listed as below.

**Property 2.1** $0 \leq r_{abc}^2 \leq 1$

Proof: Let $a^\prime$, $b^\prime$, and $c^\prime$ are the standardized vectors of $a$, $b$, and $c$, respectively. Dragomir had shown that \cite{2}

$$(a^\prime, b^\prime) - (a^\prime, c^\prime)(c^\prime, b^\prime) = (a^\prime - (a^\prime, c^\prime)c^\prime, b^\prime - (b^\prime, c^\prime)c^\prime),$$

according to Schwarz’s inequality,

$$(a^\prime - (a^\prime, c^\prime)c^\prime, b^\prime - (b^\prime, c^\prime)c^\prime)^2 \leq ||a^\prime - (a^\prime, c^\prime)c^\prime||^2 ||b^\prime - (b^\prime, c^\prime)c^\prime||^2$$

$$= [||a^\prime||^2 - (a^\prime, c^\prime)^2][||b^\prime||^2 - (b^\prime, c^\prime)^2].$$

Hence,

$$[(a^\prime, b^\prime) - (a^\prime, c^\prime)(c^\prime, b^\prime)]^2 \leq [1 - (a^\prime, c^\prime)^2][1 - (b^\prime, c^\prime)^2].$$  \hspace{1cm} (3)

Expand and simplify this inequality, we have $r_{abc}^2 \leq 1$.

**Property 2.2** $r_{abc}^2 = 1$ if and only if variables $a$, $b$, and $c$ are on the same plane.

Proof: Only one less-than-equal sign appears in the proof of the right side of Property 2.1. The condition for the equality to hold in Schwarz’s inequality is that if and only if
\( \mathbf{a}' - (\mathbf{a}', \mathbf{c}')\mathbf{c}' \) and \( \mathbf{b}' - (\mathbf{b}', \mathbf{c}')\mathbf{c}' \) are linearly dependent. Hence, two coefficients \( \lambda_1 \) and \( \lambda_2 \) exist to hold

\[
\lambda_1 (\mathbf{a}' - (\mathbf{a}', \mathbf{c}')\mathbf{c}') + \lambda_2 (\mathbf{b}' - (\mathbf{b}', \mathbf{c}')\mathbf{c}') = 0,
\]

then we have

\[
\lambda_1 \mathbf{a}' + \lambda_2 \mathbf{b}' + (-\lambda_1 (\mathbf{a}', \mathbf{c}') - \lambda_2 (\mathbf{b}', \mathbf{c}'))\mathbf{c}' = 0. \tag{4}
\]

This property was firstly proposed by Garnett [3].

**Property 2.3** \( r_{abc}^2 = 0 \) if and only if variables \( \mathbf{a}, \mathbf{b}, \) and \( \mathbf{c} \) are perpendicular to each other.

**Proof:** The sufficiency is obviously true.

Necessity: From the proof of left side of Property 2.1 we have

\[
\begin{align*}
    r_{abc}^2 &\geq (|\rho_{ab}| - |\rho_{bc}|)^2 + \rho_{ac}^2, \\
    r_{abc}^2 &\geq (|\rho_{ac}| - |\rho_{bc}|)^2 + \rho_{ab}^2.
\end{align*}
\]

Hence, if \( r_{abc}^2 = 0 \), we have \( \rho_{ab} = \rho_{bc} = \rho_{ac} = 0 \).

**Property 2.4** For two given non-zero-variance variables \( \mathbf{a} \) and \( \mathbf{b} \), if \( \mathbf{a} \) and \( \mathbf{b} \) are not linear dependent, \( r_{abc}^2 \) gets the biggest value 1 if and only if the third non-zero-variance variable \( \mathbf{c} \) lies on the plane spanned by \( \mathbf{a} \) and \( \mathbf{b} \), and \( r_{abc}^2 \) gets the smallest value \( \rho_{ab}^2 \) if and only if \( \mathbf{c} \) is perpendicular to the plane spanned by \( \mathbf{a} \) and \( \mathbf{b} \).

**Proof:** The first half part of Property 2.4 can be directly obtained from Property 2.2.

In the second part, we have

\[
r_{abc}^2 = (\rho_{bc} - \rho_{ab}\rho_{ac})^2 + (1 - \rho_{ab}^2)\rho_{ac}^2 + \rho_{ab}^2. \tag{5}
\]

To minimize \( r_{abc}^2 \), the first two parts should equal to zero. We obtain \( \rho_{bc} = \rho_{ac} = 0 \) and \( r_{abc}^2 = \rho_{ab}^2 \).

**Property 2.5** For two given non-zero-variance variables \( \mathbf{a} \) and \( \mathbf{b} \), if \( \rho_{bc} \) is fixed, \( \pi_{ab} \) is the plane spanned by \( \mathbf{a} \) and \( \mathbf{b} \), \( \pi_{bc} \) is the plane spanned by \( \mathbf{b} \) and \( \mathbf{c} \), and the angle between \( \pi_{ab} \) and \( \pi_{bc} \) is \( \theta \), \( \theta \in [0^0, 90^0] \), then \( r_{abc}^2 \) is a continuous and strictly monotone decreasing function of angle \( \theta \).

**Proof:** We only consider the 3-dimensional space spanned by \( \mathbf{a}, \mathbf{b}, \) and \( \mathbf{c} \). Suppose \( \alpha, \beta, \) and \( \gamma \) are the angles between \( \mathbf{a} \) and \( \mathbf{b} \), between \( \mathbf{b} \) and \( \mathbf{c} \), and between \( \mathbf{a} \) and \( \mathbf{c} \), respectively. There are many cases for different location relationships of \( \mathbf{a}, \mathbf{b}, \) and \( \mathbf{c} \). For example, when \( \pi_{ab} = \pi_{bc} \), if \( \alpha + \beta \leq \pi \), \( \gamma = \alpha + \beta \) or \( \gamma = |\alpha - \beta| \); if \( \alpha + \beta > \pi \), \( \gamma = 2\pi - (\alpha + \beta) \).
Figure 1. A case of the position relationship among the variables $a$, $b$, and $c$ are displayed when $a$, $b$, and $\rho_{bc}$ are fixed. Angles $\alpha$, $\beta$, and $\gamma$ are the angles between $a$ and $b$, between $b$ and $c$, and between $a$ and $c$, respectively. Points $C'$, $C_1$, and $C_2$, and the points set $\hat{C}$ are all on the extended line of possible locus of vector $c$.

or $\gamma = |\alpha - \beta|$. Here a proof of the case shown in Figure 1 is provided, the proofs in other cases can be similarly obtained.

If $OA$, $OB$, and $OC$ have the same direction vectors with variables $a$, $b$, and $c$, respectively. As shown in Figure 1, Points $C'$, $C_1$, and $C_2$, and the points set $\hat{C}$ are all on the extended line of possible locus of vector $c$. $AB \perp b$, $\pi_{bc} \perp \pi_{ab}$, $C_1 B \perp b$, $C_2 \in \pi_{ab}$, $C_2 B \perp b$, $\hat{C} = \{P|P \in \lambda c, PB \perp b, \pi/2 \leq \angle PBA \leq \pi, \lambda > 0\}$, $BC' \perp c$. According to Cosine Theorem, if $C \in \hat{C}$ we have

$$\rho_{ac} = \cos \gamma = \frac{||OA||^2 + ||OC||^2 - ||AC||^2}{2||OA|| ||OC||}$$

$$||AC||^2 = ||AB||^2 + ||BC||^2 - 2 ||AB|| ||BC|| \cos \angle ABC.$$$$\theta + \angle ABC = \pi$$

If point $A$ is fixed, then $||OA||, ||OC||, ||AB||, and ||BC||$ are all fixed. Hence, $\rho_{ac}$ is a continuous and strictly monotone increasing function of $\theta$ with $\theta \in [0, \pi/2]$.

When $\pi_{ab} \perp \pi_{bc}$, we have $c_1 \perp \triangle ABC'$ in Figure 1. Then

$$\rho_{ac} = \frac{OC'}{OA} = \frac{OC'O'B}{OB/OA} = \rho_{ab}\rho_{bc}$$

Moreover, $r_{abc}^2$ can be rewritten as following:

$$r_{abc}^2 = (\rho_{ac} - \rho_{ab}\rho_{bc})^2 + (\rho_{ab}^2 + \rho_{bc}^2 - \rho_{ab}\rho_{bc})$$ (6)
Hence, $r_{abc}^2$ is a continuous and strictly monotone decreasing function of $\rho_{ac}$ when $\rho_{ac} \leq \rho_{ab}/\rho_{bc}$. Because $\rho_{ac}$ is a continuous and strictly monotone increasing function of $\theta$, Property 2.5 is true.

3. INNER PRODUCT-DETERMINANT EQUATION

If $a'$ and $b'$ are the standardized vectors of $a$ and $b$, respectively, Pearson’s correlation coefficient between $a$ and $b$ is then the inner product between $a'$ and $b'$.

UMCC for three variables can also be expressed by inner product according to Definition 1.

In this section, we focus on an identical relation between inner product and a determinant group, which we call the inner product-determinant equation (IPD equation).

For $n$-dimensional variables $a_1, a_2, \ldots, a_m$, $a_i = (a_{i1}, a_{i2}, \ldots, a_{in})$, $i = 1, 2, \ldots, m, m \leq n$, we denote

$$[a(m)|j_1, j_2, \ldots, j_m] = \begin{bmatrix} a_{1j_1} & a_{1j_2} & \cdots & a_{1j_m} \\ a_{2j_1} & a_{2j_2} & \cdots & a_{2j_m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{mj_1} & a_{mj_2} & \cdots & a_{mj_m} \end{bmatrix},$$

where $1 \leq j_1 < j_2 < \cdots < j_m \leq n$.

According to Cauchy-Binet formula [4], we have the following lemma:

**Lemma 1** For $n$-dimensional variables $a_1, a_2, \ldots, a_m$, $a_i = (a_{i1}, a_{i2}, \ldots, a_{in})$, $i \in \{1, 2, \ldots, m\}$, $m \leq n$, if $M$ is the inner product matrix of these variables,

$$M = \begin{bmatrix} (a_1, a_1) & (a_1, a_2) & \cdots & (a_1, a_m) \\ (a_2, a_1) & (a_2, a_2) & \cdots & (a_2, a_m) \\ \vdots & \vdots & \ddots & \vdots \\ (a_m, a_1) & (a_m, a_2) & \cdots & (a_m, a_m) \end{bmatrix},$$

then we have

$$\det(M) = \sum_{j_1 < j_2 < \cdots < j_m} (\det[a(m)|j_1, j_2, \ldots, j_m])^2, \quad (7)$$

where $j_1, j_2, \ldots, j_m \in \{1, 2, \ldots, n\}$.

Proof: According to Cauchy-Binet formula, for the matrixes $A = [a_1^T, a_2^T, \ldots, a_m^T]$ and $A^T$, we have

$$\det(A^T A) = \sum_{j_1 < j_2 < \cdots < j_m} (\det[a(m)|j_1 < j_2 < \cdots < j_m])^2.$$
Because $A^T A = M$, this lemma is true.

We denote by $\Gamma$ the circular inner product

$$\Gamma(a_{k_1}, a_{k_2}, \ldots, a_{k_p}) = (a_{k_1}, a_{k_2}) (a_{k_2}, a_{k_3}) \cdots (a_{k_{p-1}}, a_{k_p}) (a_{k_p}, a_{k_1}).$$  \hspace{1cm} (8)$$

For some variables, all the permutations of them which can generate the same inner product or circular inner product are regarded as the same inner-product-permutation, then the inner product-determinant equation can be rewritten as following:

**Inner product-Determinant Equation** For $n$-dimensional variables $a_1, a_2, \ldots, a_m$, $m \leq n$, the inner-product-determinant equation is

$$\sum_{\pi} 2^{|\pi_1|} (-1)^{m-|\pi|} \prod_{\pi_1} |a_{s_i}|^2 \prod_{\pi_2} (a_i, a_j)^2 \prod_{\pi_3} \Gamma(a_{k_1}, a_{k_2}, \ldots, a_{k_p})$$

$$= \sum_{j_1 < j_2 < \cdots < j_m} (\text{det}[a(m)][j_1, j_2, \cdots, j_m])^2,$$  \hspace{1cm} (9)$$

where $\pi$ runs through the list of all partitions of $\{a_1, a_2, \ldots, a_m\}$ with only consider the inner-product-permutation, and the subsets in each partition $\pi$ are divided into three classes: If one subset only contains one variable, then this subset belongs to the first class $\pi_1$, and the self-inner product of the variable appears in the formula of the partition; If one subset contains two variables, then this subset belongs to the second class $\pi_2$, and the square of mutual inner product between the two variables appears in the formula of the partition; The others belong to the third class $\pi_3$, and the circular inner product for each subset in $\pi_3$ appears in the formula of the partition; The number of subsets in a partition $\pi$ and $\pi_3$ are $|\pi|$ and $|\pi_3|$, respectively.

Proof: In fact, each partition $\pi$ in the inner product-determinant equation is corresponding to one item in the expansion of the determinant of the inner product matrix. By considering the inversion number and the symmetry of inner product matrix, the above equation can be easily obtained.

If the number of subsets in each $\pi_1$ and $\pi_2$ are $|\pi_1|$ and $|\pi_2|$, respectively, then $|\pi_1| + |\pi_2| + |\pi_3| = |\pi|$. Moreover, the subsets in $\pi_3$ are not the standard sets because the inner-product-permutation is involved.

The inner product-determinant equation has a set-partition-based form, which is similar to the joint cumulant equation [5][6].

For three $n$-dimensional variables $a$, $b$, and $c$, $n \geq 3$, there are 6 cases of inner products in total, and they are $(a, a)$, $(b, b)$, $(c, c)$, $(a, b)$, $(a, c)$, and $(b, c)$. From Lemma 1, the IPD equation for three variables can be obtained as following:
Corollary 1 For three $n$-dimensional variables $a$, $b$, and $c$, $n \geq 3$, the inner product-determinant equation is as following:

\[
|a|^2 |b|^2 |c|^2 + 2(a, b)(b, c)(a, c) - |a|^2 (b, c)^2 - |b|^2 (a, c)^2 - |c|^2 (a, b)^2 = \sum_{i<j<k} (\det[a, b, c|i, j, k])^2,
\]

where $i, j, k \in \{1, 2, \cdots, n\}$.

Similarly, IPD equation for two variables is listed below.

Corollary 2 For two $n$-dimensional variables $a$ and $b$, $n \geq 2$, the inner product-determinant equation is

\[
|a|^2 |b|^2 - (a, b)^2 = \sum_{i<j} (\det[a, b|i, j])^2,
\]

where $i, j \in \{1, 2, \cdots, n\}$.

4. CORRELATION MEASURES FOR MULTIPLE VARIABLES

According to Corollary 1 and the definition of UMCC for three variables, if $a^\prime$, $b^\prime$, and $c^\prime$ are the standardized vectors of $a$, $b$, and $c$, respectively, we have

\[
r_{abc}^2 = 1 - \sum_{i<j<k} (\det[a^\prime, b^\prime, c^\prime|i, j, k])^2.
\]

Similarly, the square of Pearson’s correlation coefficient between $a$ and $b$ can be obtained from Corollary 2:

\[
\rho_{ab}^2 = 1 - \sum_{i<j} (\det[a^\prime, b^\prime|i, j])^2.
\]

Inspired by the above formulas of $r_{abc}^2$ and $\rho_{ab}^2$, we define the multivariate correlation coefficient as following:

Definition 2 For $n$-dimensional non-zero-variance variables $a_1, a_2, \cdots, a_m$, $2 \leq m \leq n$, if $a'_i$ is the standardized vector of $a_i$, $i \in \{1, 2, \cdots, m\}$, then the unsigned correlation coefficient $r_{a_1a_2 \cdots a_m}$ among $a_1, a_2, \cdots, a_m$ is defined as

\[
r_{a_1a_2 \cdots a_m}^2 = 1 - \sum_{j_1<j_2<\cdots<j_m} (\det[a'(m)|j_1, j_2, \cdots, j_m])^2,
\]

where $j_1, j_2, \cdots, j_m \in \{1, 2, \cdots, n\}$.

According to Definition 2, for two non-zero-variance variables $a$ and $b$, $r_{ab} = |\rho_{ab}|$. Then we can see that the sum of the squares of the determinant group is a coupling part of
the proposed UMCC. We define the coupling part as the multivariate incorrelation coefficient (UMIC), which can be used to measure linear irrelevance among variables:

**Definition 3** For \( n \)-dimensional non-zero-variance variables \( \mathbf{a}_1, \mathbf{a}_2, \cdots, \mathbf{a}_m, 2 \leq m \leq n \), if \( \mathbf{a}_i' \) is the standardized vector of \( \mathbf{a}_i, i \in \{1, 2, \cdots, m\} \), the unsigned multivariate incorrelation coefficient (UMIC) \( \omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_m} \) among \( \mathbf{a}_1, \mathbf{a}_2, \cdots, \) and \( \mathbf{a}_m \) is defined as

\[
\omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_m}^2 = \sum_{j_1 < j_2 < \cdots < j_m} (\det[\mathbf{a}'(m)[j_1, j_2, \cdots, j_m]])^2,
\]

where \( j_1, j_2, \cdots, j_m \in \{1, 2, \cdots, n\} \).

A lemma exists for UMIC as following:

**Lemma 2** For \( n \)-dimensional variables \( \mathbf{a}_1, \mathbf{a}_2, \cdots, \mathbf{a}_m, \mathbf{a}_{m+1}, 2 \leq m + 1 \leq n \), if \( \mathbf{a}_i' \) is the standardized vector of \( \mathbf{a}_i, i = 1, 2, \cdots, m, m+1 \), we have

\[
\omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_m}^2 - \omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_{m+1}}^2 = \sum_{J_{m-1}} \left( \sum_{J_{m+1}} (-1)^{g(p:J_{m-1})} a_{m+1,p}^2 \det[\mathbf{a}'(m)[p, J_{m-1}]]^2 \right),
\]

where \( J_{m-1} = \{j_1, j_2, \cdots, j_{m-1}\}, j_1 < j_2 < \cdots < j_{m-1}, j_1, j_2, \cdots, j_{m-1} \in \{1, 2, \cdots, n\} \), and \( g(p : S) \) is the number of elements which are larger than \( p \) in the set \( S \).

**Proof:** Let \( J_m = \{j_1, j_2, \cdots, j_m\}, j_1 < j_2 < \cdots < j_m, j_1, j_2, \cdots, j_m \in \{1, 2, \cdots, n\} \), and \( J_{m+1} = \{j_1, j_2, \cdots, j_m, j_{m+1}\}, j_1 < j_2 < \cdots < j_{m+1}, j_1, j_2, \cdots, j_m, j_{m+1} \in \{1, 2, \cdots, n\} \).

\[
\omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_{m+1}}^2 = \sum_{J_{m+1}} (\det[\mathbf{a}'(m+1)[J_{m+1}]]^2
\]

\[
= \sum_{J_{m+1}} \left\{ \sum_{J_{m-1}} (a_{m+1,p}^2 \det[\mathbf{a}'(m)[J_{m+1}\setminus p]])
\]

\[
+ \sum_{l,p \in J_{m+1}, l \neq p} [2(-1)^{g(l:J_{m+1})}(a_{l+1,p}^2 \det[\mathbf{a}'(m+1)[J_{m+1}\setminus l]])]ight\}.
\]

The first part can be rewritten as

\[
\sum_{J_{m+1}} \sum_{p=J_1}^{J_{m+1}} (a_{m+1,p}^2 \det[\mathbf{a}'(m)[J_{m+1}\setminus p]]) = \sum_p a_{m+1,p}^2 \sum_{J_m} \det[\mathbf{a}'(m)[J_m]]
\]

\[
= \sum_p a_{m+1,p}^2 \sum_{J_m} \det[\mathbf{a}'(m)[J_m]]
\]

\[
= \sum_p a_{m+1,p}^2 (\omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_m}^2 - \sum_{p \in J_m} \omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_m}^2)
\]

\[
= \sum_p a_{m+1,p}^2 (\omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_m}^2 - \sum_{p \in J_m} \omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_m}^2)
\]

\[
= \omega_{\mathbf{a}_1 \mathbf{a}_2 \cdots \mathbf{a}_m}^2 - \sum_{p \in J_{m-1}} \sum_{J_{m-1}} \det[\mathbf{a}'(m)[J_{m-1}]],
\]
and the second part can be rewritten as

\[
\sum_{J_{m+1}} \sum_{l, p \in J_{m+1}} \sum_{l \neq p} \{2(-1)^{g(l; J_{m+1})+g(p; J_{m+1})} a_{m+1, l}^l a_{m+1, p}^p \det[a'(m)|J_{m+1}\setminus l] \det[a'(m)|J_{m+1}\setminus p] \}
\]

\[
= 2 \sum_{l \neq p} a_{m+1, l}^l a_{m+1, p}^p \sum_{J_{m+1}} \{(-1)^{g(l; J_{m+1})+g(p; J_{m+1})} \det[a'(m)|J_{m+1}\setminus l] \det[a'(m)|J_{m+1}\setminus p] \}
\]

\[
= 2 \sum_{l \neq p} a_{m+1, l}^l a_{m+1, p}^p \sum_{J_{m-1}} \{(-1)^{g(l; J_{m-1})+g(p; J_{m-1})+1} \det[a'(m)|p, J_{m-1}] \det[a'(m)|l, J_{m-1}] \}
\]

\[
= -2 \sum_{J_{m-1}} \sum_{l \neq p} \{(-1)^{g(p; J_{m-1})} a_{m+1, l}^l a_{m+1, p}^p \det[a'(m)|p, J_{m-1}] \det[a'(m)|l, J_{m-1}] \}.
\]

Hence, we have

\[
\omega^2_{a_1 a_2 \cdots a_m a_{m+1}} = \omega^2_{a_1 a_2 \cdots a_m a_{m+1}} - \phi(a'(m + 1)),
\]

and \(\phi(a'(m + 1))\) can be expressed as

\[
\phi(a'(m + 1)) = \sum_{J_{m-1}} \sum_{p \notin J_{m-1}} a_{m+1, p}^p \det[a'(m)|p, J_{m-1}] \]

\[
+2 \sum_{J_{m-1}} \sum_{l \neq p} \{(-1)^{g(p; J_{m-1})} a_{m+1, l}^l \det[a'(m)|p, J_{m-1}] \}
\]

\[
= \sum_{J_{m-1}} \sum_{p \notin J_{m-1}} \{(-1)^{g(p; J_{m-1})} a_{m+1, p}^p \det[a'(m)|p, J_{m-1}] \}.
\]

The proposed unsigned multivariate correlation coefficient and unsigned incoherence coefficient have some important properties, several of which are discussed below.

**Property 4.1** If \(r_{a_1 a_2 \cdots a_m}\) and \(\omega_{a_1 a_2 \cdots a_m}\) are UMCC and UMIC for non-zero-variance random variables \(a_1, a_2, \cdots, a_m\), respectively, and \(r_{a_1 a_2 \cdots a_{m-1}}\) and \(\omega_{a_1 a_2 \cdots a_{m-1}}\) are UMCC and UMIC for \(a_1, a_2, \cdots, a_{m-1}\), respectively, then

\[
r^2_{a_1 a_2 \cdots a_m} \geq r^2_{a_1 a_2 \cdots a_{m-1}}
\]

\[
\omega^2_{a_1 a_2 \cdots a_m} \leq \omega^2_{a_1 a_2 \cdots a_{m-1}}
\]

Property 4.1 can be directly obtained from Lemma 2. It shows that the value of UMCC is not less than that for part of them.

**Property 4.2**

\[
0 \leq r^2_{a_1 a_2 \cdots a_m} \leq 1
\]

\[
0 \leq \omega^2_{a_1 a_2 \cdots a_m} \leq 1
\]

\[10\]
Proof: According to Definition 3 we have $\omega_{a_1a_2\cdots a_m}^2 \geq 0$. From Property 4.1, $\omega_{a_1a_2\cdots a_m}^2 \leq \cdots \leq \omega_{a_i a_j}^2 = 1 - \rho_{a_i a_j}^2 \leq 1$, $i \neq j$, $i, j \in \{1, 2, \cdots, m\}$. Because $r_{a_1a_2\cdots a_m}^2 + \omega_{a_1a_2\cdots a_m}^2 = 1$, we have $0 \leq r_{a_1a_2\cdots a_m}^2 \leq 1$.

**Property 4.3** $r_{a_1a_2\cdots a_m}^2 = 1$ if and only if variables $a_1, a_2, \cdots, a_m$ are linear dependence.

Proof:

Sufficiency: If $a_1, a_2, \cdots, a_m$ are linear dependence, $\det[a'(m)|j_1, j_2, \cdots, j_m] = 0$ for all cases of $j_1 < j_2 < \cdots < j_m, j_1, j_2, \cdots, j_m \in \{1, 2, \cdots, n\}$.

Necessity: We denote by $\hat{\mathbf{a}}_j = (a_{1j}, a_{2j}, \cdots, a_{mj})^T$ the $j$th column vector of the matrix $[a(m)|1, 2, \cdots, n]$, $j = 1, 2, \cdots, n$. Suppose $\{j_1, j_2, \cdots, j_m\}$ exists to make $\text{rank}\{\hat{\mathbf{a}}_{j_1}, \hat{\mathbf{a}}_{j_2}, \cdots, \hat{\mathbf{a}}_{j_m}\} = m$, then $\det[a(m)|j_1, j_2, \cdots, j_m] \neq 0$ and $r_{a_1a_2\cdots a_m}^2 < 1$. Hence, if $r_{a_1a_2\cdots a_m}^2 = 1$ we have $\text{rank}\{\hat{\mathbf{a}}_1, \hat{\mathbf{a}}_2, \cdots, \hat{\mathbf{a}}_n\} \leq m - 1$. Because the row rank equals to the column rank of the same matrix, we have

$$\text{rank}\{a_1, a_2, \cdots, a_m\} = \text{rank}\{\hat{\mathbf{a}}_1, \hat{\mathbf{a}}_2, \cdots, \hat{\mathbf{a}}_n\} \leq m - 1.$$

**Property 4.4** $r_{a_1a_2\cdots a_m}^2 = 0$ if and only if variables $a_1, a_2, \cdots, a_m$ are perpendicular to each other.

Proof:

$$r_{a_1a_2\cdots a_m}^2 = 0 \iff \omega_{a_1a_2\cdots a_m}^2 = 1$$

According to Properties 1 and 2, we can obtain

$$1 = \omega_{a_1a_2\cdots a_m}^2 \leq \cdots \leq \omega_{a_i a_j}^2 \leq 1$$

Hence, for arbitrary $i, j \in 1, 2, \cdots, m, i \neq j$, we have $\omega_{a_i a_j}^2 = 1$ and $r_{a_i a_j}^2 = \rho_{a_i a_j}^2 = 0$.

**Property 4.5** If variables $a_1, a_2, \cdots, a_{m-1}$ are not linear dependent, $r_{a_1a_2\cdots a_m}^2$ then gets the biggest value 1 if and only if variable $a_m$ lies on the hyperplane spanned by $a_1, a_2, \cdots, a_{m-1}$, and $r_{a_1a_2\cdots a_m}^2$ gets the smallest value $r_{a_1a_2\cdots a_m}^2$ if and only if $a_m$ is perpendicular to the hyperplane spanned by $a_1, a_2, \cdots, a_{m-1}$.

Proof: The first half is true according to Property 4.3. Now we prove the second part.

According to Lemma 2, we have

$$r_{a_1a_2\cdots a_m}^2 - r_{a_1a_2\cdots a_{m-1}}^2 = \sum_{J_{m-2}} \left( \sum_{p \notin J_{m-2}} (-1)^{g(p,J_{m-2})} a_{m,p} (a'(m-1)|p, J_{m-2}) \right)^2$$
Denote the determinant \( \det(\tilde{\i}; J_{m-2}) \) as

\[
\det(\tilde{\i}; J_{m-2}) = \det([a_1', a_2', \ldots, a_{m-1}' \mid a_m'][J_{m-2}]).
\]

Then we have

\[
\sum_{p \notin J_{m-2}} (-1)^{g(p; J_{m-2})} a_{m,p}' \det[a'(m - 1)|p, J_{m-2}]
\]

\[
= \sum_{p \notin J_{m-2}} (-1)^{i+1} a_{i,p}' \det(\tilde{\i}; J_{m-2})
\]

\[
= \sum_{i} (-1)^{i+1} \det(\tilde{\i}; J_{m-2}) \sum_{p \notin J_{m-2}} a_{m,p}' a_{i,p}'
\]

\[
= \sum_{i} (-1)^{i+1} \det(\tilde{\i}; J_{m-2})(\sum_{p} a_{m,p}' a_{i,p}' - \sum_{p \notin J_{m-2}} a_{m,p}' a_{i,p}')
\]

\[
= \sum_{i} (-1)^{i+1} \det(\tilde{\i}; J_{m-2})(a_i'; a_m') - \sum_i (-1)^{i+1} \det(\tilde{\i}; J_{m-2}) \sum_{p=j_1}^{j_{m-2}} a_{m,p}' a_{i,p}'
\]

The first part of the above equation is a formula of the inner product. The second part can be simplified as

\[
\sum_{i} (-1)^{i+1} \det(\tilde{\i}; j_1, j_2, \ldots, j_{m-2}) \sum_{p=j_1}^{j_{m-2}} a_{m,p}' a_{i,p}'
\]

\[
= \det \left[ \begin{array}{cccc}
\sum_{p=j_1}^{j_{m-2}} a_{m,p}' a_{i,p}' & a_{1,j_1}' & a_{1,j_2}' & \cdots & a_{1,j_{m-2}}' \\
\sum_{p=j_1}^{j_{m-2}} a_{m,p}' a_{i,p}' & a_{2,j_1}' & a_{2,j_2}' & \cdots & a_{2,j_{m-2}}' \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\sum_{p=j_1}^{j_{m-2}} a_{m,p}' a_{i,p}' & a_{m-1,j_1}' & a_{m-1,j_2}' & \cdots & a_{m-1,j_{m-2}}'
\end{array} \right] = 0
\]

Hence,

\[
\sum_{p \notin J_{m-2}} (-1)^{g(p; J_{m-2})} a_{m,p}' \det[a'(m - 1)|p, J_{m-2}]
\]

\[
= \sum_{i=1}^{m-1} (-1)^{i+1} \det(\tilde{\i}; J_{m-2})(a_i'; a_m').
\]

Then \( \gamma^2_{a_1 a_2 \cdots a_{m-1}} \) gets the minimum value \( r^2_{a_1 a_2 \cdots a_{m-1}} \) if and only if

\[
\sum_{i=1}^{m-1} (-1)^{i+1} \det(\tilde{\i}; j_1, j_2, \ldots, j_{m-2})(a_i'; a_m') = 0 \quad (17)
\]

holds for all possible \( \{j_1, j_2, \ldots, j_{m-2}\} \) and \( \i \).
Because variables $a_1, a_2, \ldots, a_{m-1}$ are not linear dependent, $J_{m-1} = \{j_1, j_2, \ldots, j_{m-1}\}$ exists to make the rank of $[a'(m-1)|J_{m-1}]$ equal to $m - 1$. Then $[a'(m-1)|J_{m-1}]$ is an invertible matrix and its adjoint matrix is also an invertible matrix. Each row of the adjoint matrix of $[a'(m-1)|J_{m-1}]$ is just the linear coefficients of one equation in the above equation. Finally, we obtain $(a'_i, a'_m) = 0, i = 1, 2, \ldots, m - 1$.

According to Lemma 1 and Definition 3, if the number of variables is the same as their dimension, we have the following corollary, which gives a new explanation of determinant from the view of multivariate correlation.

**Corollary 3** For $n$-dimensional non-zero-variance random variables $a_1, a_2, \ldots, a_n$, $a_i = (a_{i1}, a_{i2}, \ldots, a_{im})$, if $a'_i$ is the standardized vector of $a_i$, $i \in \{1, 2, \ldots, n\}$, and $A$ is the square matrix whose row vectors are $a'_1, a'_2, \ldots, a'_n$, respectively, then we have

$$\omega^2_{a_1, a_2, \ldots, a_m} = (\text{det}(A))^2. \quad (18)$$

This corollary gives a new explanation of determinant that if the row or column vectors of a matrix are all standardized, then the absolute value of the determinant of the matrix depicts the linear irrelevance of these standardized vectors.

Lastly, if the variables in the inner product matrix $M$ are all standardized, the inner product matrix is then transformed into the correlation matrix. Correlation matrix is also a widely used feature in various fields. For $n$-dimensional non-zero-variance variables $a_1, a_2, \ldots, a_m, 2 \leq m \leq n$, if $\rho_{a_i a_j}$ is Pearson’s correlation coefficient between $a_i$ and $a_j$, $i, j \in \{1, 2, \ldots, m\}$, the correlation matrix $R$ of these variables is as following:

$$R = \begin{bmatrix}
1 & \rho_{a_1 a_2} & \cdots & \rho_{a_1 a_m} \\
\rho_{a_2 a_1} & 1 & \cdots & \rho_{a_2 a_m} \\
\vdots & \vdots & \ddots & \vdots \\
\rho_{a_m a_1} & \rho_{a_m a_2} & \cdots & 1
\end{bmatrix}.$$
The sum of $r^2_{a_1 a_2 \cdots a_m}$ and $\omega^2_{a_1 a_2 \cdots a_m}$ is 1:

\[
\omega^2_{a_1 a_2 \cdots a_m} = \det(R) \\
r^2_{a_1 a_2 \cdots a_m} + \omega^2_{a_1 a_2 \cdots a_m} = 1 .
\]

(19)

5. CORRELATION MEASURES FOR LINEAR DECOMPOSITION

For a group of $n$-dimensional vectors $\{v_1, v_2, \cdots, v_k\}$ and a target vector $y$, linear decomposition selects $m$ vectors from $\{v_1, v_2, \cdots, v_k\}$ to approximate the target $y$ by a linear combination of these selected vectors. Linear decomposition has lots of important applications such as linear regression, sparse coding, and portfolio in economics.

Without loss of generality, suppose the selected vectors are $v_1, v_2, \cdots, v_m$, and their linear combination is $x = \beta_1 v_1 + \beta_2 v_2 + \cdots + \beta_m v_m + o1$, where $1$ is the vector whose entries are all ones, and $\beta_i$ and $o$ are the coefficients of the linear combination, $i = 1, 2, \cdots, m$. Then the mean square error (MSE) between $x$ and $y$ is

\[
MSE(x, y) = \frac{1}{n} \| y - (\beta_1 v_1 + \beta_2 v_2 + \cdots + \beta_m v_m + o1) \|^2_2.
\]

(20)

Let the variances of the elements in $v_i, x,$ and $y$ are $\sigma^2_i, \sigma^2_x,$ and $\sigma^2_y$, respectively, the means of the elements in $v_i, x,,$ and $y$ are $\mu_i, \mu_x,$ and $\mu_y,$ respectively, and the covariances between $v_i$ and $y$, between $v_i$ and $v_j$, and between $x$ and $y$ are $\sigma_{iy}, \sigma_{ij},$ and $\sigma_{xy}$, respectively, $i, j = 1, 2, \cdots, m$. Then

\[
\sigma^2_x = \sum_i \beta_i \sum_j \beta_j \sigma_{ij} \\
\sigma_{xy} = \sum_i \beta_i \sigma_{iy}.
\]

To minimize the value of MSE between $x$ and $y$ by the least square method, we have

\[
\frac{\partial MSE(x, y)}{\partial o} = 0 \Rightarrow \mu_y = \hat{\beta}_1 \mu_1 + \hat{\beta}_2 \mu_2 + \cdots + \hat{\beta}_m \mu_m + \hat{o} \\
\frac{\partial MSE(x, y)}{\partial \beta_i} = 0 \Rightarrow \sum_j \hat{\beta}_j \sigma_{ij} = \sigma_{iy}
\]

where $\hat{\beta}_i$ and $\hat{o}$ are the estimates of $\beta_i$ and $o$, respectively, $i = 1, 2, \cdots, m$. Then we have

\[
MSE(\hat{x}, y) = \sigma^2_y - 2 \sigma_{\hat{x} y} + \sigma^2_{\hat{x}} \\
\sigma^2_{\hat{x}} = \sigma^2_{\hat{xy}}
\]

where $\hat{x} = \hat{\beta}_1 v_1 + \hat{\beta}_2 v_2 + \cdots + \hat{\beta}_m v_m + \hat{o}1$ is the estimated vector of the target $y$. 

14
Let $S = \begin{bmatrix}
\sigma_{11} & \sigma_{12} & \cdots & \sigma_{1m} \\
\sigma_{21} & \sigma_{22} & \cdots & \sigma_{2m} \\
\vdots & \vdots & \ddots & \vdots \\
\sigma_{m1} & \sigma_{m2} & \cdots & \sigma_{mm}
\end{bmatrix}$, $B = \begin{bmatrix}
\beta_1 \\
\beta_2 \\
\vdots \\
\beta_m
\end{bmatrix}$, and $S_y = \begin{bmatrix}
\sigma_{1y} \\
\sigma_{2y} \\
\vdots \\
\sigma_{my}
\end{bmatrix}$, then

$B = S^{-1}S_y$

$\det \begin{bmatrix}
S & S_y \\
S^T & \sigma_y^2
\end{bmatrix} = \det(S)(\sigma_y^2 - S^T S^{-1} S_y)$

Hence,

$MSE(\hat{x}, y) = \sigma_y^2 - \sigma_{\hat{x}y}^2 = \sigma_y^2 - S^T S^{-1} S_y = \sigma_y^2 \frac{\omega_{v_1v_2\cdots v_my}}{\omega_{v_1v_2\cdots v_m}}.$

For a given target vector $y$, $\sigma_y^2$ is kept invariant. Then we obtain an interesting equation:

$\min MSE(\hat{x}, y) \Leftrightarrow \min \frac{\omega_{v_1v_2\cdots v_my}}{\omega_{v_1v_2\cdots v_m}}$ \hspace{1cm} (21)

According to Eq. (21), these vectors selected from $\{v_1, v_2, \cdots, v_k\}$ should have small correlation while maintaining enough information of the target vector $y$. This conclusion fits well with our intuition.

Let $r_{\hat{x}y}$ and $\omega_{\hat{x}y}$ are the unsigned bivariate correlation coefficient and the unsigned bivariate incorrelation coefficient between $y$ and its estimated vector $\hat{x}$, respectively, then we have

$r_{\hat{x}y}^2 = \rho_{\hat{x}y}^2 = \left(\frac{\sigma_{\hat{x}y}}{\sigma_{\hat{x}} \sigma_y}\right)^2 = \frac{\sigma_{\hat{x}y}^2}{\sigma_y^2} = 1 - \frac{\omega_{v_1v_2\cdots v_my}}{\omega_{v_1v_2\cdots v_m}}.$

Hence,

$\omega_{\hat{x}y} = \frac{\omega_{v_1v_2\cdots v_my}}{\omega_{v_1v_2\cdots v_m}}.$ \hspace{1cm} (22)

The above compact equation offers the relationship among the UMIC between the estimated linear decomposition $\hat{x}$ and the target vector $y$, the UMIC of these vector $v_1, v_2, \cdots, v_m, y$, and the UMIC of these vectors $v_1, v_2, \cdots, v_m$. It shows that the minimization of $MSE(x, y)$ is equivalent to the maximization of the MCC between $\hat{x}$ and $y$, which is kept the same with the unitary case [7].

Additionally, the coefficient of multiple determination [8] can also be simplified as

$R^2 = \frac{SSR}{SSTO} = \frac{\sigma_x^2}{\sigma_y^2} = \frac{\sigma_{\hat{x}y}^2}{\sigma_y^2} = r_{\hat{x}y}^2.$ \hspace{1cm} (23)
Figure 2. The curve of the absolute value of Pearson’s correlation coefficient against the angle $\gamma$ between two variables.

Hence, the coefficient of multiple determination is just the absolute value of Pearson’s correlation coefficient between the target vector and its estimated vector.

6. EXPERIMENT ANALYSIS

In this section, we take the case of three variables as an example to visually demonstrate the effectiveness of the proposed linear correlation coefficient.

6.1 Performance of the Proposed MCC

The variation of the absolute value of Pearson’s correlation coefficient with the angle $\gamma$ between two variables is shown in Figure 2. The correlation coefficient curve in Figure 2 approaches the line segments connecting the extreme-value points within the interval $[0^0, 90^0]$ and $[90^0, 180^0]$, which indicates Pearson’s correlation coefficient can effectively describe the relation between the strength of linear correlation and the angle $\gamma$.

For multiple variables, correlation coefficient changes with multiple angles in different spatial directions. We take the case of three variables as an example, if an angle $\alpha$ is fixed, then the relation of the other two angles $\beta$ and $\gamma$, and the correlation coefficient among three variables can be visually display in a 3D graph. Figure 3 shows four such graphs with different fixed angles $30^0$, $90^0$, $145^0$, and $160^0$, respectively. From Figure 3 we can see that these surfaces have similar structure but different depth, curvature, and top rectangles.

To further examine the synergistic effect of different spatial angles on the proposed UMCC, some vertical profile lines of the surfaces need to be analyzed. Because the surface of the proposed MCC against the angles $\beta$ and $\gamma$ is a symmetrical surface about the vertical direction of the two central axes and the central point of the top rectangle, we only need
Figure 3. Some surfaces of the unsigned correlation coefficient against the angles $\beta$ and $\gamma$ with the other angle $\alpha$ fixed as $30^0$, $90^0$, $145^0$, and $160^0$, respectively.

to consider parts of the vertical profile lines, and the profile lines for other symmetrical cases are kept the same or are the reflection of them. Figure 4 gives some profile lines with different vertical cutting lines. All the experiments show that the profile lines of the surfaces of the proposed UMCC against the angles $\beta$ and $\gamma$ approaches the line segments connecting the extreme-value points, which means that the proposed UMCC is an effective descriptor to measure the strength of multivariate correlation.

6.2 Contour Line and Geometrical Explanation of UMIC

As shown in Figure 3, a myriad of contour lines exist in the surface of multivariate UMCC. A simple example is that if the pairwise angles for three variables $a_1$, $b_1$, and $c_1$ are $45^0$, $45^0$, and $60^0$, respectively, and the pairwise angles for three variables $a_2$, $b_2$, and $c_2$ are $30^0$, $90^0$, and $90^0$, respectively, then the three variables $a_1$, $b_1$, and $c_1$ and the other
three variables $a_2$, $b_2$, and $c_2$ have the same value of UMCC. Some contour lines for three variables with the fixed angle $\alpha$ equal to $90^0$ and $140^0$ are shown in Figure 5.

In fact, the linear relation for multiple variables is closely tied with the parallelotope in multi-dimensional space. For example, the linear space structured by $m$ independent variables is the $m$-dimensional linear space, and the vector sum of the $m$ variables is the diagonal of the parallelogram formed by these variables in this $m$-dimensional space.

Barth had proposed that the determinant of a Gram matrix is the square of the volume of the parallelotope formed by the variables [9], and the correlation matrix is a special Gram matrix. According to Section 4 in this paper, the square of the proposed linear incorre-
Figure 5. Some contour lines with different unsigned correlation coefficients for three variables with fixed the angle $\alpha = 90^\circ$ and $\alpha = 140^\circ$, respectively.

Correlation coefficient is the determinant of correlation matrix. Hence, we have the following corollarys:

**Corollary 4** If $\omega_{a_1 a_2 \cdots a_m}$ is the linear incorrelation coefficient among multiple variables $a_1, a_2, \cdots, a_m$, then $\omega_{a_1 a_2 \cdots a_m}$ is the volume of the parallelootope formed by the vectors $a_1', a_2', \cdots, a_m'$, where $a_i'$ is the standardized vector of $a_i$, $i = 1, 2, \cdots, m$.

**Corollary 5** For spatial angles $\alpha_1, \alpha_2, \cdots, \alpha_m$, the linear incorrelation coefficient is the volume of the parallelootope formed by the unit vectors whose pairwise angles are $\alpha_1, \alpha_2, \cdots, \alpha_m$, respectively.

According to Corollary 5, the contour lines on the UMCC surface is the equal-volume line for different spatial angles.
