# LARGE SUBPOSETS WITH SMALL DIMENSION 

BENJAMIN REINIGER* AND ELYSE YEAGER

#### Abstract

Dorais asked for the maximum guaranteed size of a dimension $d$ subposet of an $n$-element poset. A lower bound of order $\sqrt{n}$ was found by Goodwillie. We provide a sublinear upper bound for each $d$. For $d=2$, our bound is $n^{0.8295}$.

## 1. Introduction

Given a family of posets $\mathcal{F}$, let $\operatorname{ex}^{*}(P, \mathcal{F})$ denote the size of the largest induced subposet of $P$ that does not contain any member of $\mathcal{F}$ as an induced subposet. Similarly, $\operatorname{ex}(P, \mathcal{F})$ is the size of the largest induced subposet of $P$ that does not contain a member of $\mathcal{F}$ as a not-necessarily-induced subposet. These can be seen as poset analogues of the relative Turán numbers of families of graphs (in some host graph). We write $\operatorname{ex}^{*}(P,\{Q\})$ as simply $\operatorname{ex}^{*}(P, Q)$. Let ex* $(n, \mathcal{F})$ denote the minimum of $\operatorname{ex}^{*}(P, \mathcal{F})$ over all $n$-element posets $P$. In other words, $\operatorname{ex}^{*}(n, \mathcal{F})$ is the maximum $k$ such that every $n$-element poset $P$ has an $\mathcal{F}$-free subposet of size at least $k$. Let $B_{n}$ be the boolean lattice of dimension $n$ and $A_{n}$ an antichain on $n$ points.

Then $\operatorname{ex}^{*}\left(P, B_{1}\right)$ is just the width of $P$ and $\operatorname{ex}^{*}\left(P, A_{2}\right)$ is the height of $P$. The function $\operatorname{ex}\left(B_{n}, B_{2}\right)$ is heavily studied as the maximum size of a "diamond-free" family of sets. In the literature, $\operatorname{ex}\left(B_{n}, P\right)$ is denoted $\mathrm{La}(n, P)$, and $\operatorname{ex}^{*}\left(B_{n}, P\right)$ is denoted $\mathrm{La}^{\sharp}(n, P)$ or $\mathrm{La}^{*}(n, P)$.

In this note we are concerned with finding large subposets of small dimension. Hence we let $\mathcal{D}_{d}$ denote the family of posets of dimension at least $d$, and ask
Question 1.1. What is $\mathrm{ex}^{*}\left(n, \mathcal{D}_{d+1}\right)$ ?
In other words, what is the largest size of a dimension $d$ subposet we are guaranteed to find in an $n$-element poset? (Note that when $d=1, A_{n}$ shows that $\operatorname{ex}^{*}\left(n, \mathcal{D}_{d+1}\right)=1$. We henceforth assume $d>1$.) This question was originally posed by F. Dorais [2], whose aim was to eventually understand the question for infinite posets [1]. Goodwillie [4] proved that $\operatorname{ex}^{*}\left(n, \mathcal{D}_{d+1}\right) \geq \sqrt{d n}$ by considering the width of $P$ : if $w(P) \geq \sqrt{d n}$, then a maximum antichain is a large subposet of dimension 2 ; if $w(P) \leq \sqrt{d n}$, then by Dilworth's theorem the union of some $d$ chains has $\geq \sqrt{d n}$ elements, and this has dimension at most $d$.

We provide a sublinear upper bound by considering the lexicographic power of standard examples. Theorem 2.1 finds the extremal number for lexicographic powers, and Corollary 2.2 applies this to $\operatorname{ex}^{*}\left(n, \mathcal{D}_{3}\right)$. For other $d$, Table 1 provides upper bounds on $\operatorname{ex}^{*}\left(n, \mathcal{D}_{d+1}\right)$.

## 2. Main theorem

Given a poset $P$ and positive integer $k$, let $P^{k}$ denote the lexicographic order on $k$-tuples of elements of $P$.

Theorem 2.1. Let $P$ be a poset, $\mathcal{F}$ a family of posets, $k$ a positive integer, and let $n=|P|^{k}=\left|P^{k}\right|$. Then $\operatorname{ex}^{*}\left(|P|^{k}, \mathcal{F}\right) \leq \operatorname{ex}^{*}\left(P^{k}, \mathcal{F}\right) \leq n^{\log _{|P|}\left(\mathrm{ex}^{*}(P, \mathcal{F})\right)}$.

Proof. Let $S$ be a maximum $\mathcal{F}$-free subposet of $P^{k}$ (so $|S|=\operatorname{ex}^{*}\left(P^{k}, \mathcal{F}\right)$ ). For $i \leq k+1$ and each $i$-tuple $\alpha$, let

$$
\begin{aligned}
S_{\alpha} & =\{s \in S: \alpha \text { is an initial segment of } s\} \\
Q(\alpha) & =\{p \in P:(\alpha, p) \text { is an initial segment of some } s \in S\} .
\end{aligned}
$$

Then each $Q(\alpha)$ is an induced subposet of $S$, under any of the maps that assign to $p \in P$ an element $s \in S$ with initial segment $(\alpha, p)$. Since $S$ is $\mathcal{F}$-free, so is $Q(\alpha)$, hence $|Q(\alpha)| \leq \operatorname{ex}^{*}(P, \mathcal{F})$.

We have that

$$
\left|S_{\alpha}\right|=\sum_{p \in Q(\alpha)}\left|S_{(\alpha, p)}\right| \leq|Q(\alpha)| \cdot \max _{p \in Q(\alpha)}\left|S_{(\alpha, p)}\right| \leq \operatorname{ex}^{*}(P, \mathcal{F}) \cdot \max _{p \in Q(\alpha)}\left|S_{(\alpha, p)}\right|
$$

When $\omega$ is a $k$-tuple, $S_{\omega}$ is either $\{\omega\}$ or $\emptyset$. Hence we have, for $\alpha$ an $i$-tuple,

$$
\left|S_{\alpha}\right| \leq\left(\mathrm{ex}^{*}(P, \mathcal{F})\right)^{k-i}
$$

and in particular, for $\alpha$ the 0 -tuple,

$$
|S| \leq\left(\mathrm{ex}^{*}(P, \mathcal{F})\right)^{k}=|P|^{\log _{|P|}\left(\mathrm{ex}^{*}(P, \mathcal{F})^{k}\right)}=n^{\log _{|P|}\left(\mathrm{ex}^{*}(P, \mathcal{F})\right)}
$$

Corollary 2.2. For all sufficiently large $n$, $\operatorname{ex}^{*}\left(n, \mathcal{D}_{3}\right) \leq n^{0.8295}$.

Proof. Take $P=S_{m}$, the standard example on $2 m$ points, in the preceding theorem. It is easy to see that $\operatorname{ex}^{*}\left(S_{m}, \mathcal{D}_{3}\right)=m+2$. Hence the exponent on the family of posets obtained is $\log _{2 m}(m+2)$, which is minimized at $m=10$ with value approximately 0.82948 . This completes the proof when $n$ is a power of 20 .

Otherwise, write $n=\sum_{i=0}^{k} \alpha_{i}(20)^{i}$, each $\alpha_{i} \in\{0, \ldots, 19\}$. Then let $Q$ be the poset that is the disjoint union of $\alpha_{i}$ copies of $S_{10}^{i}$ for each $i$. A maximum dimension 2 subposet of $Q$ is precisely the union of maximum dimension 2 subposets of each
$S_{10}^{i}$. So

$$
\begin{aligned}
\operatorname{ex}^{*}\left(n, \mathcal{D}_{3}\right) & \leq \operatorname{ex}^{*}\left(Q, \mathcal{D}_{3}\right) \\
& =\sum_{i=0}^{k} \alpha_{i} \operatorname{ex}^{*}\left(S_{10}^{i}, \mathcal{D}_{3}\right) \\
& \leq \sum_{i=0}^{k} \alpha_{i}(20)^{0.82949 i} \\
& \leq\left(\sum_{i=0}^{k} \alpha_{i}\right)\left(\frac{\sum_{i=0}^{k} \alpha_{i}(20)^{i}}{\sum_{i=0}^{k} \alpha_{i}}\right)^{0.82949} \quad \text { (Jensen's inequality) } \\
& =\left(\sum_{i=0}^{k} \alpha_{i}\right)^{1-0.82949} n^{0.82949} \\
& \leq\left(19\left(\left\lfloor\log _{20} n\right\rfloor+1\right)\right)^{0.17051} n^{0.82949} \\
& <n^{0.8295}
\end{aligned}
$$

for sufficiently large $n$.
Essentially the same proof works for any $d$. We have for any $m$ and any $\epsilon>0$ that for sufficiently large $n$, $\operatorname{ex}^{*}\left(n, \mathcal{D}_{d+1}\right) \leq n^{\log _{2 m}(m+d)+\epsilon}$. Table 1 shows some values of $d$ with the minimizing $m$ and the minimum value of the exponent (rounded to the 5th decimal place).

$$
\begin{array}{rrl}
d & m & \log _{2 m}(m+d) \\
2 & 10 & 0.82948 \\
3 & 17 & 0.84953 \\
4 & 25 & 0.86076 \\
10 & 78 & 0.88663 \\
100 & 1169 & 0.92122
\end{array}
$$

TABLE 1. Values of $m$ that minimize $\log _{2 m}(m+d)$ for given $d$.

## 3. Remarks

There is still a rather large gap between the known lower and upper bounds for $\operatorname{ex}^{*}\left(n, \mathcal{D}_{d+1}\right)$. Any improvement to either the lower or upper bound would be interesting.

Given the interest in ex $\left(B_{n}, B_{2}\right)$, one may be interested in $\mathrm{ex}^{*}\left(B_{n}, \mathcal{D}_{d+1}\right)$ instead of $\mathrm{ex}^{*}\left(n, \mathcal{D}_{d+1}\right)$.
Question 3.1. What is $\operatorname{ex}^{*}\left(B_{n}, \mathcal{D}_{d+1}\right)$ ?
Lu and Milans (personal communication) have shown that $\mathrm{ex}^{*}\left(B_{n}, S_{d}\right) \leq(4 d+$ $C \sqrt{d}+\epsilon)\binom{n}{\lfloor n / 2\rfloor}$. Hence also $\operatorname{ex}^{*}\left(B_{n}, \mathcal{D}_{d}\right)=\Theta\left(\binom{n}{\lfloor n / 2\rfloor}\right)$. For small cases, we have computed that $\mathrm{ex}^{*}\left(B_{n}, \mathcal{D}_{3}\right)=1,4,7,12,20$ for $n=1,2,3,4,5$.

In 1974, Erdős [3] posed and partially answered the following question: given an $r$-uniform hypergraph $G_{r}(n)$ on $n$ vertices such that every $m$-vertex subgraph has
chromatic number at most $k$, how large can the chromatic number of $G_{r}(n)$ be? Using probability methods Erdős found a lower bound for ordinary graphs when $k=3$; that is, when every $m$-vertex subgraph has chromatic number at most 3 . Thinking of poset dimension as analogous to graph chromatic number, we ask:

Question 3.2. Given a poset $P$ with $n$ elements such that every m-element subposet has dimension at most d, how large can the dimension of $P$ be?
