# LOCAL RAMSEY SPACES IN MATET FORCING EXTENSIONS AND FINITELY MANY NEAR-COHERENCE CLASSES 

HEIKE MILDENBERGER

#### Abstract

We introduce Gowers-Matet forcing with a finite sequence of pairwise non-isomorphic Ramsey ultrafilters over $\omega$, and with this forcing we settle the long-standing problem about the spectrum of numbers of near-coherence classes. We prove that for any finite $n \geq 1$, there is a forcing extension with exactly $n$ near-coherence classes of non-principal ultrafilters.

For evaluating the new forcing, we prove a strengthening of Gowers' theorem on colourings of $\mathrm{Fin}_{k}$.

## 1. Introduction

We connect two lines of research: The topic of whether special kinds of ultrafilters from the ground model have extensions of the same kind in a forcing extension by a Ramsey-theoretic forcing and the investigation of the possible numbers of nearcoherence classes. We answer Banakh's and Blass' question [1, Question 31] on the finite part of near-coherence spectrum.

On the existence of special ultrafilters: For ${ }^{\omega} \omega$-bounding forcings and $P$-points or even Ramsey ultrafilters the following is known: Kunen [27] proved that no Ramsey ultrafilter can be extended to a $P$-point after addition of any number of random reals at once, Shelah [37] constructed a model with no $P$-points, recently Chodounsky and Guzmán [16] proved that there are no $P$-points in the Silver model and that no $P$-point from the ground model can be extended in a Silver extension. On the other hand [41] and [20] proved that there are Milliken-Taylor ultrafilters

[^0]in the Sacks model, indeed, any Milliken-Taylor ultrafilter from the ground model is preserved. Blass [9] proved that the minimum and the maximum projection of a Milliken-Taylor ultrafilter are Ramsey ultrafilters.

In the case of forcings adding an unbounded real, Ketonen proved that $\mathfrak{d}=\mathfrak{c}$ implies the existence of a $P$-point, Canjar [15] proved the generic existence of Ramsey ultrafilters under $\operatorname{cov}(\mathcal{M})=\mathfrak{c}$ and Eisworth [17] proved the generic existence of a Milliken-Taylor ultrafilter with the Galvin-Glazer technique (see, e.g. 26]) under the same condition. We refer the reader to [10] for the definitions of the cardinal characteristics $\operatorname{cov}(\mathcal{M}), \mathfrak{u}, \mathfrak{d}$, etc. We write $\mathfrak{c}$ for $2^{\aleph_{0}}$.

Here we work with variants of Matet forcing [29] that come from various constraints on the reservoir of the pure components of the conditions. The full Matet forcing preserves any $P$-point from the ground model [17, Theorem 4] and destroys any Ramsey ultrafilter, since it adds an unbounded real. The (non-complete) subforcings with pure parts from a Milliken-Taylor ultrafilter have specific preservation properties; they destroy some $P$-points and preserve others, see [17, Theorem 2.5]. We show that the reservoir Milliken-Taylor ultrafilter $\mathcal{U}$ can be extended to a new Milliken-Taylor ultrafilter after forcing. A new technical ingredient is the work with names for diagonal constructions.

We prove a preservation theorem for countable support iterations and show that there is a model of $\aleph_{1}=\mathfrak{u}<\mathfrak{d}=\mathfrak{c}=\aleph_{2}$ with at least three names of different near coherence classes of ultrafilters and a Milliken-Taylor ultrafilter of character $\mathfrak{c}$.

We fix some $k \in \omega \backslash\{0\}$. We introduce Milliken-Taylor ultrafilters that are related to Hindman's theorem for colourings of $\mathrm{Fin}_{k}$ as Milliken-Taylor ultrafilters are related to Hindman's theorem, and investigate Matet forcing with MillikenTaylor ultrafilters. We show that this generalisation gives nothing new in point of near coherence classes.

Then we change the condensation order into the Tetris condensation order $\sqsubseteq_{k}^{\mathrm{Tetr}}$ (see Def. 6.1) and introduce a variant of Matet forcing in which particular projections of pure conditions are taken from prescribed pairwise nnc Ramsey ultrafilters $\mathcal{R}_{i, x}, i=1, \ldots, k, x=\min , \max$. To get the pure decision property and hence properness, we introduce a space

$$
\begin{align*}
\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})= & \left\{\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}: \forall\left(X_{i} \in \mathcal{R}_{i, \min }, Y_{i} \in \mathcal{R}_{i, \max }\right)_{1 \leq i \leq k}\right. \\
& \left(\exists^{\left.\min -\mathrm{unb}_{s} \in \operatorname{TFU}_{k}(\bar{a})\right)}\right.  \tag{1.1}\\
& \left.(\forall i \in\{1, \ldots, k\})\left(\min _{i}(s) \in X_{i} \wedge \max _{i}(s) \in Y_{i}\right)\right\}
\end{align*}
$$

and investigate $\left(\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}}), \sqsubseteq_{k}^{\text {Tetr }}\right)$ (see Def. (6.8) and prove a new generalisation of Gowers' theorem and of Blass' theorem [7, Theorem 2.3].
Theorem6.16, Let $k \geq 1$ and let $\overline{\mathcal{R}}=\left\langle\mathcal{R}_{i, \min }, \mathcal{R}_{i, \max }: i=1, \ldots k\right\rangle$ be a sequence of pairwise non nearly coherent Ramsey ultrafilters.
(1) Any $\sqsubseteq_{k}^{\mathrm{Tetr}}$-descending $\omega$-sequence of elements of $\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ has $a \sqsubseteq_{k}^{\mathrm{Tetr}, *}{ }_{-}$ lower bound in $\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$.
(2) Let $n \in \omega \backslash\{0\}$ and $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ and let $c$ be a_colouring of $\left[\operatorname{TFU}_{k}(\bar{a})\right]_{<}^{n}$ into finitely many colours. Then there is a $\bar{b} \sqsubseteq_{k} \bar{a}, \bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ such that $\left[\operatorname{TFU}_{k}(\bar{b})\right]_{<}^{n}$ is c-monochromatic.
As a corollary we get the following theorems about existence and additional structure:

Theorem 6.33. For any pairwise nnc Ramsey ultrafilters $\mathcal{R}_{i, x}, i=1, \ldots, k, x=$ min, max under CH or MA ( $\sigma$-centred) there is a Gowers-Milliken-Taylor ultrafilter $\mathcal{U}$ such that for $i=1 \ldots, k, \min _{i}(\mathcal{U})=\mathcal{R}_{i, \min }$ and $\max _{i}(\mathcal{U})=\mathcal{R}_{i, \max }$.

Pairwise non-near-coherence and Ramseyness is necessary, however, more structure emerges in the cases $k \geq 2$ : The statement about the higher core filters $\Phi_{\geq i+1}$ is novel. For the definition of $\Phi_{\geq i+1}$ see Def. 6.34,
Theorem 6.35. For any Gowers-Milliken-Taylor ultrafilter $\mathcal{U}$ over $\operatorname{Fin}_{k}$ the following holds:
(1) For each $1 \leq i \leq k, \mathcal{R}_{i, \min }$ and $\mathcal{R}_{i, \max }$ are nnc and for $i<k, \mathcal{R}_{i, \min }$ and $\mathcal{R}_{i, \text { max }}$ are nnc $\Phi_{\geq i+1}(\mathcal{U})$.
(2) The projections $\min _{1}(\mathcal{U}), \ldots, \min _{k}(\mathcal{U}), \max _{k}(\mathcal{U}), \ldots, \max _{1}(\mathcal{U})$ are pairwise non-nearly coherent Ramsey ultrafilters over $\omega$.
(3) All cores $\Phi_{i}(\mathcal{U})$ are nearly coherent.

Now we turn to the second line of research: the number of near-coherence classes of (non-principal) ultrafilters over $\omega$, see Def. 1.1. In 11] a model with one nearcoherence class is given. Blass [5] showed that under $\mathfrak{d} \leq \mathfrak{u}$ there are $2^{\mathfrak{u}}$ nearcoherence classes. Banakh and Blass [1] showed: If the number of near-coherence classes is infinite then it is $2^{\left(2^{\omega}\right)}$.

One of our main results about one iterand is:
Theorem 3.3. Let $\mathcal{E}$ be a P-point and $\mathcal{U}$ be a Milliken-Taylor ultrafilter with $\Phi(\mathcal{U}) \not Z_{\mathrm{RB}} \mathcal{E}$. Then in the forcing extension by $\mathbb{M}(\mathcal{U})$ the Milliken-Taylor ultrafilter $\mathcal{U}$ is destroyed and can be completed to a Milliken-Taylor ultrafilter $\mathcal{U}^{\text {ext }} \supseteq \mathcal{U}$ with $\Phi\left(\mathcal{U}^{\text {ext }}\right) \not \mathbb{Z}_{\mathrm{RB}} \mathcal{E}$.

The notion of a $P$-point will be explained in this section, the core $\Phi(\mathcal{U})$ is defined in Def. 2.11, the Rudin-Blass order $\leq_{\mathrm{RB}}$ is defined in Def. 2.12, Milliken-Taylor ultrafilters are defined in Def. [2.6(6), the forcing $\mathbb{M}(\mathcal{U})$ is defined in Def. 2.14. By [17, Theorem 2.5], $\mathcal{E}$ generates a $P$-point in the extension.

Theorem 3.3 serves as a successor step in the forcing that is used in the following theorem:

Theorem 4.9. Assume CH. Then there is a countable support iteration of proper iterands $\mathbb{P}=\left\langle\mathbb{P}_{\alpha}, \mathbb{M}\left(\mathcal{U}_{\beta}\right): \beta<\omega_{2}, \alpha \leq \omega_{2}\right\rangle$ such that in the extension there at least three near-coherence classes of ultrafilters and there is a Milliken-Taylor ultrafilter of character $\mathfrak{c}$.

We generalise from the set of blocks to $\mathrm{Fin}_{k}$ for some $k \geq 1$ and show that this does hardly change the situation.

We use the new Ramsey space $\left(\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}}), \sqsubseteq_{k}^{\text {Tetr }}\right)$ to define Gowers-Matet forcing $\mathbb{G M}_{k}(\overline{\mathcal{R}})$ in a localisation $\overline{\mathcal{R}}$ to a $2 k$-sequence $\overline{\mathcal{R}}$ of non-isomorphic Ramsey ultrafilters and prove our main result:

Theorem 7.18. Assume CH and let $k \geq 1$ and fix $2 k$ pairwise nnc Ramsey ultrafilters $\overline{\mathcal{R}}_{0}=\left\langle\mathcal{R}_{i, x, 0}: i=1, \ldots, k, x=\min , \max \right\rangle \mathbb{1}^{1}$ Then there is a countable support iteration of proper iterands $\mathbb{P}=\left\langle\mathbb{P}_{\alpha}, \mathbb{G M}_{k}\left(\overline{\mathcal{R}}_{\beta}\right): \beta<\omega_{2}, \alpha \leq \omega_{2}\right\rangle$ such that in the extension there exactly $2 k+1$ near-coherence classes of ultrafilters. Namely,

[^1]one class is represented by a P-point of character $\omega_{1}$ and $2 k$ classes represented by Ramsey ultrafilters $\mathcal{R}_{i, x, \omega_{2}}, i=1, \ldots, k, x=\min$, max.

A slight variation of the model gives exactly $2 k$ near coherence classes. We thus get the full finite near-coherence spectrum.

Corollary 7.20. For any $n \in \omega$, the statement "there are exactly $n+1$ nearcoherence classes of ultrafilters" is consistent relative to ZFC.

By work of Mioduszewski our result has applications to analysis, namely the number of composants of $\beta\left(\mathbb{R}^{+}\right)-\mathbb{R}^{+}$corresponds by 33, 34] to the number of near-coherence classes of ultrafilters. Blass [5] gives applications to cofinality classes of short non standard models of arithmetic, and to the decomposition of the ideal of compact linear operators on a Hilbert space into proper subideals. His results on equivalent characterisations of indecomposability can be translated to: For $n \geq 1$, There is a decomposition of the ideal of compact operators into $n$ proper subideals such that the union of any two different of them is the whole ideal, if and only if there are exactly $n$ near-coherence classes. The correspondence is defined in [13].

In the remainder of the introduction we recall some definitions from the realm of near coherence and special ultrafilters over $\omega$. For the cardinal invariants $\mathfrak{d}$ and $\operatorname{cov}(\mathcal{M})$ we refer the reader to [10].

Let $S$ be a countable set. By a filter over $S$ we mean a non-empty subset of $\mathcal{P}(S)$ that is closed under supersets and under finite intersections and that does not contain the empty set. We call a filter over $S$ non-principal if it contains all cofinite subsets of $S$. A $\subseteq$-maximal filter is an ultrafilter.

For $B \subseteq \omega$ and $f: \omega \rightarrow \omega$, we let $f[B]=\{f(b): b \in B\}$ and $f^{-1}[B]=\{n:$ $f(n) \in B\}$. The set of all infinite subsets of $\omega$ is denoted by $[\omega]^{\omega}$. For $\mathcal{B} \subseteq \mathcal{P}(\omega)$ we let $f(\mathcal{B})=\left\{X \subseteq \omega: f^{-1}[X] \in \mathcal{B}\right\}$. 2 This double lifting is an important function from $\mathcal{P} \mathcal{P}(\omega)$ into itself. In analysis the special case of $f$ being finite-to-one (that means that the preimage of each natural number is finite) is particularly useful, see e.g., 6].

From now on all filters over $\omega$ will be non-principal filters over $\omega$, though we write only "filter" over $\omega$. If $f: \omega \rightarrow \omega$ is finite-to-one, then also $f(\mathcal{F})$ is a non-principal filter. It is the filter generated by $\{f[X]: X \in \mathcal{F}\}$.
Definition 1.1. (1) A non-empty family $\mathcal{G} \subseteq[\omega]^{\omega}$ is called a filter subbase (over $\omega)$ if any intersection of finitely many elements of $\mathcal{G}$ is infinite. We write

$$
\operatorname{fil}(\mathcal{G})=\left\{X \in[\omega]^{\omega}:(\exists n \in \omega)\left(\exists G_{0} \ldots \exists G_{n} \in \mathcal{G}\right)\left(X \supseteq G_{0} \cap \cdots \cap G_{n}\right)\right\}
$$

for the filter generated by $\mathcal{G}$. The character of a filter $\mathcal{F}$ is the smallest size of a generating subbase.
(2) Two filters $\mathcal{F}, \mathcal{G} \subseteq[\omega]^{\omega}$ are nearly coherent, if there is some finite-to-one $f: \omega \rightarrow \omega$ such that $f(\mathcal{F}) \cup f(\mathcal{G})$ generates a filter.
(3) On the set of non-principal ultrafilters near-coherence is an equivalence relation (for a proof see [5], e.g.) whose equivalence classes are called nearcoherence classes.
(4) Two subsets $\mathcal{H}_{1}, \mathcal{H}_{2}$ of $[\omega]^{\omega}$ are called $n n c$, if for any $X_{i} \in \mathcal{H}_{i}, i=1,2$ and any finite-to-one $h$ there is $Y_{i} \subseteq X_{i}, Y_{i} \in \mathcal{H}_{i}, i=1,2$ such that $h\left[Y_{1}\right] \cap h\left[Y_{2}\right]=\emptyset$.

[^2](5) $\mathcal{H} \subseteq[\omega]^{\omega}$ is called nowhere almost a filter if for any $X \in \mathcal{H}$, and any finite-toone $h$ the set $\{h[Y]: Y \in \mathcal{H} \wedge Y \subseteq X\}$ does not have the finite intersection property.

For filters, nnc is the negation of near coherence. Near coherence is witnessed by a weakly increasing surjective finite-to-one function. $f$ is weakly increasing if $x<y \rightarrow f(x) \leq f(y)$. A coideal $\mathcal{H}$ is nowhere almost a filter if and only if it is nowhere almost an ultrafilter. We will use the property for coideals.

We say " $A$ is almost a subset of $B$ " and write $A \subseteq^{*} B$ if $A \backslash B$ is finite. Similarly, the symbol $=^{*}$ denotes equality up to finitely many exceptions between elements of $[S]^{\omega}$ for a set $S$.

Let $\kappa$ be a regular uncountable cardinal. An ultrafilter $\mathcal{W}$ is called a $P_{\kappa}$-point if for every $\gamma<\kappa$, for every $A_{i} \in \mathcal{U}, i<\gamma$, there is some $A \in \mathcal{W}$ such that for any $i<\gamma, A \subseteq^{*} A_{i}$; such an $A$ is called a pseudo-intersection of $\left\{A_{i}: i<\gamma\right\}$. A $P_{\aleph_{1}}$-point is called a $P$-point.

Let $\mathbb{P}$ be a notion of forcing. We say that $\mathbb{P}$ preserves an ultrafilter $\mathcal{W}$ over $I$ if

$$
\Vdash_{\mathbb{P}} "(\forall X \subseteq I)(\exists Y \in \mathcal{W})(Y \subseteq X \vee Y \subseteq I \backslash X) "
$$

and in the contrary case we say " $\mathbb{P}$ destroys $\mathcal{W}$ ". In the first case $\left\{X \in[\omega]^{\omega} \cap \mathbf{V}[G]\right.$ : $(\exists Y \in \mathcal{W}) X \supseteq Y\}$ is an ultrafilter in $\mathbf{V}[G]$ and $\mathcal{W}$ generates an ultrafilter in $\mathbf{V}[G]$. We just say: $\mathcal{W}$ is an ultrafilter in $\mathbf{V}[G]$. If $\mathbb{P}$ is proper and preserves $\mathcal{W}$ and $\mathcal{W}$ is a $P$-point in the ground model, then $\mathcal{W}$ stays a $P$-point in the forcing extension by [11, Lemma 3.2].

An ultrafilter $\mathcal{W}$ over $\omega$ is called a $Q$-point if for every strictly increasing sequence $\left\langle n_{i}: i \in \omega\right\rangle$ of natural numbers there is $X \in \mathcal{W}$ such that for every $i, \mid X \cap$ $\left[n_{i}, n_{i+1}\right) \mid \leq 1$. Any $Q$-point from the ground model ceases to be a $Q$-point after adding an unbounded real.

An ultrafilter $\mathcal{R}$ is called selective (or Ramsey ultrafilter) if it is a $P$-point and a $Q$-point. We use the von Neumann natural numbers $n=\{0, \ldots, n-1\}$. We often use the following, equivalent (see [14, Theorem 4.9] characterisation of selectivity:
$(*)$ For any $\subseteq$-descending sequence $\left\langle A_{n}: n \in \omega\right\rangle$ of sets $A_{n} \in \mathcal{R}$ there is $A \in \mathcal{R}$ such that $A \subseteq A_{0}$ and $(\forall n \in A)\left(A \backslash(n+1) \subseteq A_{n}\right)$.

Kunen [27] contains more information on Ramsey ultrafilters. Two Ramsey ultrafilters are nnc iff they are not isomorphic 4.

In forcing, we follow the Kunen style that the stronger condition is the smaller one. This corresponds to the close relationship between the $\leq$-relation in Matet forcing and the condensation relation $\sqsubseteq$ on the second components, the so-called pure parts, of a condition in Matet forcing.

Readers who want to focus on our extension of Gowers' theorem in Theorem 6.16, that does not contain any forcing, can just read the notational part from Def. 5.1 to Def. 5.5 and then the new Ramsey-theoretic work from the beginning of Section 6 through Question 6.31

Biggest thanks go to the referee for careful reading and detecting some gaps and errors in an earlier version. I am grateful for Andreas Blass for explaining me his proof of [7, Theorem 2.1].

## 2. Matet forcing with Milliken-Taylor ultrafilters

In this section we review results of Blass, Eisworth, and Hindman and carry it a bit further. Our nomenclature follows Blass [7], Eisworth [17] and Todorčević 40].

## Definition 2.1.

(1) We let Fin denote the set of finite non-empty subsets of $\omega$.
(2) An element $a \in$ Fin is called a block.
(3) For $a, b \in$ Fin we write $a<b$ if $(\forall n \in a)(\forall m \in b)(n<m)$.
(4) We define a well-order (of type $\omega$ ) $\leq_{\text {lex,Fin }}$ on the set Fin via $a<_{\text {lex,Fin }} b$ if $\max (a)<\max (b)$ or $(\max (a)=\max (b)$ and $\min (a \triangle b) \in a), 3$
(5) A sequence $\bar{a}=\left\langle a_{n}: n \in \omega\right\rangle$ of members of Fin is called unmeshed if for all $n, a_{n}<a_{n+1}$.
(6) $\mathrm{By}(\mathrm{Fin})^{\omega}$ we denote the set of unmeshed sequences of members in Fin.
(7) Let $a, b$ be blocks. We let $a \cup b$ be undefined unless $a<b$. Otherwise, $a \cup b$ is defined as the union.
(8) A set $X \subseteq$ Fin is called min-unbounded if for any $n \in \omega$ there is some $x \in X$ with $\min (x) \geq n$.
(9) (Fin, $\cup$ ) is a partial semigroup. The associative partial binary operation $\cup$ lifts to $\gamma$ (Fin), the space of min-unbounded ultrafilters over Fin, as follows (and we write $\cup$ for the lifted operation):

$$
\mathcal{U}_{1} \cup \mathcal{U}_{2}=\left\{X \subseteq \text { Fin }:\left\{s:\{t: s \cup t \in X\} \in \mathcal{U}_{2}\right\} \in \mathcal{U}_{1}\right\}
$$

For details and history see [26, Section 4.1].
(10) If $X$ is a subset of $\operatorname{Fin}$, we write $\mathrm{FU}(X)$ for the set of all unions of finitely many members of $X$. We write $\mathrm{FU}(\bar{a})$ instead of $\mathrm{FU}\left(\left\{a_{n}: n \in \omega\right\}\right)$. We call $X$ an FU-set if there is some unmeshed $\bar{a}$ such that $X=\mathrm{FU}(\bar{a})$.
(11) For $\emptyset \neq X \subseteq$ Fin we let $\min _{<_{\text {lex }, \text { Fin }}}(X)$ be the $\leq_{\text {lex,Fin }}$-element of $X$. For $\bar{a} \in(\text { Fin })^{\omega}$ we let $\min _{\text {Fin }}(\bar{a})=\min _{<_{\text {lex }, \text { Fin }}}\left\{a_{n}: n<\omega\right\}$, which is $a_{0}$.
(12) A filter over Fin is a non-empty subset of $\mathcal{P}$ (Fin) that is closed under intersections and supersets and does not contain the empty set.
(13) For $X \subseteq$ Fin, the set $(\operatorname{FU}(X))^{\omega}$ denotes the collection of all infinite unmeshed sequences in $\operatorname{FU}(X)$. For $\bar{a} \in(\operatorname{Fin})^{\omega}$, the set $(\operatorname{FU}(\bar{a}))^{\omega}$ denotes the collection of all infinite unmeshed sequences in $\mathrm{FU}(\bar{a})$ (recall item (9)).
(14) For $Y \subseteq$ Fin and $s \in$ Fin we write $(Y$; past $s)$ for $\{u \in Y: \max (s)<\min (u)\}$. For $\bar{a} \in(\mathrm{Fin})^{\omega}$ and $s \in$ Fin we write $(\bar{a} ;$ past $s)$ for $\left\langle a_{n}: n \geq n_{0}\right\rangle$, where $n_{0}=\min \left\{n: \max (s)<\min \left(a_{n}\right)\right\}$.
Now the set of min-unbounded elements $\mathcal{P}$ (Fin) is equipped with a partial order $\sqsubseteq$ that makes it into a topological Ramsey space in the sense of 40. We will work with the (closed) subspace of sets of the form $\operatorname{FU}(\bar{a})$. ${ }^{4}$

[^3]Definition 2.2. Given $X$ and $Y \subseteq$ Fin, we say that $Y$ is a condensation of $X$ and we write $Y \sqsubseteq X$ if $Y \subseteq \mathrm{FU}(X)$. We say $Y$ is almost a condensation of $X$ and we write $Y \sqsubseteq^{*} X$ if there is an $n \in \omega$ such that $(Y ;$ past $\{n\})$ is a condensation of $X$.

The "blurred" order $\sqsubseteq^{*}$ is an $<\omega_{1}$-complete preorder.
We use the relation $\sqsubseteq$ mainly for $Y=\operatorname{range}(\bar{b})$ with $\bar{b} \in(\operatorname{Fin})^{\omega}$, $X=\operatorname{range}(\bar{a})$ for $\bar{a} \in(\text { Fin })^{\omega}$, and then we write $\bar{b} \sqsubseteq \bar{a}$ for range $(\bar{b}) \sqsubseteq \operatorname{range}(\bar{a})$, and analogously for $\sqsubseteq^{*}$.
Definition 2.3. Let $\bar{a}, \bar{b} \in(\operatorname{Fin})^{\omega}$. We say $\bar{a}$ and $\bar{b}$ are compatible, if there is a $\bar{c} \sqsubseteq \bar{a}, \bar{b}$. In the contrary case we write $\bar{a} \perp \bar{b}$.
Lemma 2.4. If $\bar{a}$ and $\bar{b}$ are compatible, there is a weakest $\bar{c} \in(\text { Fin })^{\omega}$ such that $\bar{c}=\left\langle c_{n}: n<\omega\right\rangle \sqsubseteq \bar{b}, \bar{a}$. Moreover, $\bar{c}$ is given by the following procedure. By induction on $n$ we define $c_{n}$ as follows $c_{0}=\min _{<\mathrm{lex}, \text { Fin }}(\mathrm{FU}(\bar{a}) \cap \operatorname{FU}(\bar{b})), c_{n+1}=$ $\min _{<\text {lex, Fin }}\left\{s \in \mathrm{FU}(\bar{a}) \cap \mathrm{FU}(\bar{b}): c_{n}<s\right\}$.
Proof. By definition $\bar{c} \sqsubseteq \bar{a}, \bar{b}$. To see that $\bar{c}$ is the largest witness, for a contradiction, we suppose that there is $\bar{d} \sqsubseteq \bar{a}, \bar{b}$ such that $\bar{d} \nsubseteq \bar{c}$. We take the first $n$ such that $d_{n} \neq c_{n}$.

Since $\bar{a}$ and $\bar{b}$ are unmeshed sequences, there are $i_{1}<\cdots<i_{k}$, and $j_{1}<\cdots<j_{\ell}$ such that

$$
\begin{equation*}
c_{n}=a_{i_{1}} \cup \cdots \cup a_{i_{k}}=b_{j_{1}} \cup \cdots \cup b_{j_{\ell}} \tag{2.1}
\end{equation*}
$$

and there are no common maxima of support in the sequence ( $\left.a_{i_{1}}, a_{i_{1}+1}, \ldots, a_{i_{k}-1}\right)$ and in the sequence $\left(b_{j_{1}}, b_{j_{1}+1} \ldots, b_{j_{\ell}-1}\right)$ in at any pair $\left(a_{\varrho}, b_{\sigma}\right)$ with $\varrho \in\left[j_{1}, \ldots, j_{\ell}\right)$ and $\sigma \in\left[j_{1}, \ldots, j_{l}\right)$ and there are no $i<i_{1} . j<j_{1}$, and $a_{i}, b_{j}$ past max $\left(\operatorname{supp}\left(c_{n-1}\right)\right.$ $(-1$ in the case $n=1)$ such that $\min \left(\operatorname{supp}\left(a_{i}\right)\right)=\min \left(\operatorname{supp}\left(b_{j}\right)\right)$.

First case: $\max \left(\operatorname{supp}\left(d_{n}\right)\right)>\max \left(\operatorname{supp}\left(c_{n}\right)\right)$. However, then there is a block $d_{n}^{\prime}$ with $\max \left(\operatorname{supp}\left(d_{n}^{\prime}\right)\right)=\max \left(\operatorname{supp}\left(c_{n}\right)\right)$ and there is $d^{\prime \prime}{ }_{n} \in \mathrm{FU}\left(\bar{a} ;\right.$ past $\left.c_{n-1}\right) \cap$ $\mathrm{FU}\left(\bar{b}\right.$; past $\left.c_{n}\right)$ such that $d_{n}=d_{n}^{\prime}+d_{n}^{\prime \prime}$ and $\bar{d}$ could be replaced the strictly larger upper bound

$$
\bar{d}^{\prime}=\left\langle d_{0}, \ldots, d_{n-1}, d_{n}^{\prime}, d^{\prime \prime}{ }_{n}, d_{n+1}, \ldots\right\rangle \sqsupset \bar{d}
$$

In the second and the third case, applied to $d_{n}^{\prime}$, we show that such a $\bar{d}^{\prime} \nsubseteq \bar{c}$ cannot exist and thus we get a contradiction.

Second case: $\max \left(\operatorname{supp}\left(d_{n}\right)\right)<\max \left(\operatorname{supp}\left(c_{n}\right)\right)$. Since $\bar{a}$ and $\bar{b}$ are unmeshed sequences, then $\bar{c}$ could be broken up, similar to $\bar{d}$ is the previous case. This possibility to break up contradicts the $<_{\text {lex, Fin-minimality }}$ of $c_{n}$.

Third case: $\max \left(\operatorname{supp}\left(d_{n}\right)\right)=\max \left(\operatorname{supp}\left(c_{n}\right)\right)$. First subcase $d_{n}<_{\text {lex,Fin }} c_{n}$. This contradicts the choice of $c_{n}$.

Second subcase: $d_{n}>_{\text {lex, Fin }} c_{n}$. Then $d_{n}$ uses in its sum not all the summands $a_{i_{1}}, \ldots, a_{i_{\ell}}$ that combine to $c_{n}$ and hence $d_{n}=0$, because leaving off summands on one side or on both sides of (2.1) is not possible by the choice of $c_{n}$ and since $\max \left(\operatorname{supp}\left(d_{n}\right)\right)=\max \left(\operatorname{supp}\left(c_{n}\right)\right)$. However, $d_{n}$ is a block and hence not zero. Thus also this case ends in a contradiction.

We write $\bar{c}=\bar{a} \wedge \bar{b}$.
Definition 2.5. A set non-empty subset $\mathcal{C} \subseteq(\text { Fin })^{\omega}$ is called centred, if for any finite $C \subseteq \mathcal{C}$ there is $\bar{a} \in \mathcal{C} / \bar{a} \in(\text { Fin })^{\omega}$ that is a condensation of any $\bar{c} \in C$ and if $\mathcal{C}$ is closed under finite alterations i.e., if $\bar{d} \in \mathcal{C}$ and there are $n, m \in \omega$ such that $\left\langle d_{m}: m \geq m_{0}\right\rangle=\left\langle e_{n}: n \geq n_{0}\right\rangle$ then $\bar{e} \in \mathcal{C}$.

We specialise $\mathcal{C}$ further.

## Definition 2.6.

(1) Let $\mathcal{F}$ be a filter. A basis $\mathcal{B}$ of $\mathcal{F}$ is a subset of $\mathcal{F}$ such that $(\forall F \in \mathcal{F})(\exists B \in$ $\mathcal{B})(B \subseteq F)$.
(2) A non-principal filter $\mathcal{F}$ over Fin is said to be a union filter if it has a basis of sets of the form $\mathrm{FU}(X)$ for $X \subseteq$ Fin such that the elements of $X$ are pairwise disjoint. Note $\mathrm{FU}(X)$ need not be an FU-set.
(3) A non-principal filter $\mathcal{F}$ over $F i n$ is said to be an min-unbounded filter if $(\forall n \in \omega)(\exists X \in \mathcal{F})(\forall s \in X)(\min (s)>n)$.
(4) A non-principal filter $\mathcal{F}$ over Fin is said to be an ordered-union filter if it has a basis of sets of the form $\operatorname{FU}(\bar{d})$ for $\bar{d} \in(\text { Fin })^{\omega}$.
(5) Let $\mu$ be an uncountable cardinal. A union filter is said to be $(<\mu)$-stable if, whenever it contains $\mathrm{FU}\left(X_{\alpha}\right)$ for $X_{\alpha} \subseteq \operatorname{Fin}, \alpha<\kappa$, for some $\kappa<\mu$, then it also contains some $\mathrm{FU}(Y)$ for some $Y$ such that for each $\alpha<\kappa$ there is $n_{\alpha} \in \omega$ with $\left(Y ;\right.$ past $\left.\left\{n_{\alpha}\right\}\right) \subseteq \mathrm{FU}\left(X_{\alpha}\right)$. Such an $Y$ is called a lower bound of $\left\{X_{\alpha}: \alpha<\kappa\right\}$. For " $<\omega_{1}$-stable" we say "stable".
(6) A stable ordered-union ultrafilter is also called a Milliken-Taylor ultrafilter.
(7) An ultrafilter is called idempotent if $\mathcal{U} \cup \mathcal{U}=\mathcal{U}$.

Ordered-union ultrafilters need not exist, as their existence implies the existence of $Q$-points [7] and there are models without $Q$-points [32]. Even union ultrafilters need not exist: Blass [9, Theorem 38] showed that the existence of a union ultrafilter implies the existence of at least two near-coherence classes of ultrafilters. In 11 ] Blass and Shelah show that it is consistent relative to ZFC to have exactly one near-coherence class of non-principal ultrafilters. Union ultrafilters are idempotent. Idempotent ultrafilters exist by the Ellis-Numakura Lemma [18, 35]. With the help of Hindman's theorem one shows that CH or Martin's Axiom for $\sigma$-centred posets and $<2^{\omega}$ dense sets implies that (even $<2^{\omega_{-}}$) stable Milliken-Taylor ultrafilters exist [7]. We recall Hindman's theorem:

Theorem 2.7. (Hindman, [24, Corollary 3.3]) If the set Fin is partitioned into finitely many pieces then there is a set $\bar{d} \in(\mathrm{Fin})^{\omega}$ such that $\mathrm{FU}(\bar{d})$ is included in one piece.

The theorem also holds if instead of Fin we partition some $\mathrm{FU}(\bar{c})$ for a $\bar{c} \in(\text { Fin })^{\omega}$ and search for a homogeneous sequence $\bar{d} \sqsubseteq \bar{c}$, see [7, p. 92].
Corollary 2.8. (See [7, p. 93].) Under CH or $\mathrm{MA}_{<2^{\omega}}(\sigma$-centred), for every $\bar{a} \in$ $(\text { Fin })^{\omega}$ there is a Milliken-Taylor ultrafilter $\mathcal{U}$ such that $\mathrm{FU}(\bar{a}) \in \mathcal{U}$.

We let for $X \subseteq$ Fin, $[X]_{<}^{n}$ be the set of increasing unmeshed $n$-sequences of members of $X$. For the evaluation of our forcings, Taylor's theorem [39] is utilised:

Theorem 2.9. (Taylor 39.) Let $\mathcal{U}$ be a Milliken-Taylor ultrafilter, $n \in \omega$. Let $[\mathrm{Fin}]^{n}<$ be partitioned into finitely many sets. Then there is $A \in \mathcal{U}$ such that $[\mathrm{FU}(A)]_{<}^{n}$ is monochromatic.
Corollary 2.10. ([17, Cor. 1.3]) Existence of diagonal lower bounds in
$\left((\mathrm{Fin})^{\omega}, \sqsubseteq\right)$. Let $\mathcal{U}$ be a Milliken-Taylor ultrafilter, and let $\left\langle A_{n}: n \in \omega\right\rangle$ be a
$\sqsubseteq$-descending sequence of members of $\mathcal{U}$. Then there is a $B \in \mathcal{U}$ such $B \sqsubseteq A_{0}$ and

$$
\begin{equation*}
(\forall s \in B)\left((B ; \text { past } s) \text { is a condensation of } A_{\max (s)+1}\right) \tag{2.2}
\end{equation*}
$$

Such a $B$ is called a diagonal lower bound of $\left\langle A_{n}: n \in \omega\right\rangle$.
In Equation (2.2) we can equivalently let $s$ range over $\mathrm{FU}(B)$. If $B$ is a diagonal lower bound and $B^{\prime} \sqsubseteq B$ then $B^{\prime}$ is a diagonal lower bound as well.

Definition 2.11. Let $\mathcal{H}$ be a subset of $\mathcal{P}($ Fin $)$.
(1) The core of $\mathcal{H}$ is the set $\Phi(\mathcal{H}) \subseteq[\omega]^{\omega}$ such that

$$
X \in \Phi(\mathcal{H}) \text { iff }(\exists Y \in \mathcal{H})(\bigcup Y \subseteq X)
$$

(2) The minimum projection of $\mathcal{H}$ is the set

$$
\min (\mathcal{H})=\{\min [Y]: Y \in \mathcal{H}\}
$$

where

$$
\min [Y]=\{\min (y): y \in Y\}
$$

and analogously we define the maximum projection $\max (\mathcal{H})$.
(3) For $\bar{a} \in(\text { Fin })^{\omega}$ we write $\min [\bar{a}]=\left\{\min \left(a_{i}\right): i \in \omega\right\}$.
(4) For $\bar{a} \in(\text { Fin })^{\omega}$ we write $\operatorname{set}(\bar{a})=\bigcup\left\{a_{i}: i \in \omega\right\}$.
(5) For $\mathcal{H} \subseteq(\text { Fin })^{\omega}$ we let $\Phi(\mathcal{H})=\Phi(\{\operatorname{range}(\bar{a}): \bar{a} \in \mathcal{H}\})$ and $\min (\mathcal{H})=$ $\{\min [\bar{a}]: \bar{a} \in \mathcal{H}\}$.

Note that $\min [\bar{a}]=\min [\mathrm{FU}(\bar{a})]$ and $\bigcup\left\{a_{n}: n \in \omega\right\}=\bigcup \mathrm{FU}(\bar{a})$.
If $\mathcal{C} \subseteq(\text { Fin })^{\omega}$ is centred, then the core of $\mathcal{C}$ is a filter over $\omega$. For centred $\mathcal{C} \subseteq$ $(\text { Fin })^{\omega}$ and for filters $\mathcal{C}$ over Fin the projection $\min (\mathcal{C})$ is a filter and $\min (\mathcal{C}), \max (\mathcal{C}) \supseteq$ $\Phi(\mathcal{C})$. Blass ([7, 3.6-3.9] together with [9, Theorem 38]) showed that for a MillikenTaylor ultrafilter $\mathcal{U}, \min (\mathcal{U})$ and $\max (\mathcal{U})$ are nnc Ramsey ultrafilters.

The cores of centred systems are just filters over $\omega$. Even if $\mathcal{U}$ is an ultrafilter over Fin, for any finite-to-one $f, f(\Phi(\mathcal{U}))$ need not be an ultrafilter over $\omega$. Blass (9, Theorem 38]) showed that for union-ultrafilters $\mathcal{U}$, for any finite-to-one $f, f(\Phi(\mathcal{U}))$ is not an ultrafilter because among its supersets there two nnc ultrafilters generated by the $f$-images of the minimum projection and the maximum projection..

If $\mathcal{U}$ is a Milliken-Taylor ultrafilter, then $\Phi(\mathcal{U})$ does not have a pseudointersection (see [17, Prop. 2.3]) and also any finite-to-one image of $\Phi(\mathcal{U})$ does not have a pseudointersection by the same proof. Hence, by Talagrand 38 $\Phi(\mathcal{U})$ is not meagre. Thus the filter dichotomy principle (see, e.g., [10]) precludes the existence of a Milliken-Taylor ultrafilter.

Definition 2.12. The Rudin-Blass ordering for filters over $\omega$ is defined as follows: Let $\mathcal{F} \leq{ }_{R B} \mathcal{G}$ if there is a finite-to-one $f$ such that $f(\mathcal{F}) \subseteq f(\mathcal{G})$.

For filters $\mathcal{F}, \mathcal{G}$, the relation $\mathcal{F} \leq_{\mathrm{RB}} \mathcal{G}$ implies that $\mathcal{F}$ is nearly coherent to $\mathcal{G}$. If $\mathcal{G}$ is an ultrafilter, also the converse holds.

Now we turn to forcing:

[^4]Definition 2.13. Conditions in Matet forcing, $\mathbb{M}$, are pairs $(s, \bar{c})$ such that $s \in$ Fin and $\bar{c} \in(\mathrm{Fin})^{\omega}$ and $s<c_{0}$. The forcing order is $(t, \bar{d}) \leq(s, \bar{c})$ (recall the stronger condition is the smaller one) if $s \subseteq t$ and $t$ is the union of $s$ and finitely many of the $c_{n}$ and $\bar{d}$ is a condensation of $\bar{c}$.
Definition 2.14. For a family $\mathcal{H} \subseteq(\text { Fin })^{\omega}$, the notion of forcing $\mathbb{M}(\mathcal{H})$ consists of all pairs $(s, \bar{a})$ such that $\bar{a} \in \mathcal{H}$. The forcing order is the same as in the Matet forcing.

We write $\operatorname{set}(\bar{a})=\bigcup\left\{a_{n}: n \in \omega\right\}$.
For a centred system $\mathcal{C} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$, the set $\Phi(\mathcal{C})$ is the filter $\operatorname{fil}(\{\operatorname{set}(\bar{a}): \bar{a} \in \mathcal{C}\})$. The forcing $\mathbb{M}(\mathcal{C})$ diagonalises $\Phi(\mathcal{C})$. Let $G$ be a $\mathbb{M}(\mathcal{C})$-generic filter over $\mathbf{V}$. Then the generic real

$$
\mu:=\bigcup\{s: \exists \bar{c}:(s, \bar{c}) \in G\}
$$

is a pseudointersection of $\Phi(\mathcal{C})$.
The following property of Milliken-Taylor ultrafilters $\mathcal{U}$ will be important for our proof:

Theorem 2.15. (Eisworth [17] " $\rightarrow$ " Cor. 2.5, " $\leftarrow$ " Theorem 4, this direction works also with non- $P$ ultrafilters]) Let $\mathcal{U}$ be a Milliken-Taylor ultrafilter over Fin and let $\mathcal{W}$ be a P-point. Then $\mathcal{W} \not ¥_{R B} \Phi(\mathcal{U})$ if and only if $\mathcal{W}$ continues to generate an ultrafilter after we force with $\mathbb{M}(\mathcal{U})$.

We remark:
Proposition 2.16. Suppose that $\mathcal{U}$ is a Milliken-Taylor ultrafilter and $\mathcal{F}$ is a filter over $\omega$ and $\Phi(\mathcal{U}) \leq_{R B} \mathcal{F}$. Then $\mathbb{M}(\mathcal{U})$ forces that for any finite-to-one function from the ground model, $f(\mathcal{F})$ is not an ultrafilter.
Proof. Let $f \in \mathbf{V}$ be finite-to-one such that $f(\Phi(\mathcal{U})) \subseteq f(\mathcal{F})$. Let $G$ be $\mathbb{M}(\mathcal{U})$ generic over $\mathbf{V}$, and let $\underset{\sim}{\mu}$ be a name for the generic real $\mu$. We show:

$$
(\forall(s, \bar{a}) \in \mathbb{M}(\mathcal{U}))(\forall Y \in \mathcal{F})\left(\exists(t, \bar{b}) \leq_{\mathbb{M}(\mathcal{U})}(s, \bar{a})\right)(t, \bar{b}) \Vdash_{\mathbb{M}(\mathcal{U})} f[Y] \cap f[\underset{\sim}{\mu}] \neq \emptyset
$$

$$
(\forall(s, \bar{a}) \in \mathbb{M}(\mathcal{U}))(\forall Y \in \mathcal{F})\left(\exists(t, \bar{b}) \leq_{\mathbb{M}(\mathcal{U})}(s, \bar{a})\right)(t, \bar{b}) \Vdash_{\mathbb{M}(\mathcal{U})} f[Y] \cap(\omega \backslash f[\underset{\sim}{\mu}]) \neq \emptyset
$$

Let $(s, \bar{a})$ and $Y$ be given. Since $f[\operatorname{set}(\bar{a})] \in f(\Phi(\mathcal{U})) \subseteq f(\mathcal{F})$, we have $f[\operatorname{set}(\bar{a})] \cap$ $f[Y]$ is infinite. So there is $t \in \operatorname{FU}(\bar{a})$ such that $f[t] \cap f[Y] \neq \emptyset$. It follows that $(s \cup t, \bar{a} ;$ past $t) \Vdash_{\mathbb{M}(\mathcal{U})} f[Y] \cap f[\mu] \neq \emptyset$.

Now for the second property:
Next we define a colouring $h$ of $[\mathrm{FU}(\bar{a} ; \text { past } s)]_{<}^{2}$ by

$$
h(u<v)= \begin{cases}1 & \text { if } f[u]<f[v] \wedge \\ & (\max (f[u]), \min (f[v])) \cap f[Y] \neq \emptyset \\ 0 & \text { else }\end{cases}
$$

Since $\mathcal{U}$ is a Milliken-Taylor ultrafilter by Theorem 39 there is a monochromatic $\bar{b} \sqsubseteq(\bar{a} ;$ past $s), \bar{b} \in \mathcal{U}$. Since $f$ is finite-to-one, the colour is 1 . So we have $(s, \bar{b}) \Vdash_{\mathbb{M}(\mathcal{U})} f[Y] \cap(\omega \backslash f[\mu]) \neq \emptyset$.

Now let $\underset{\sim}{f}$ be a name for the function $n \mapsto|\mu \cap n|$. Then

$$
\mathbb{M}(\mathcal{U}) \Vdash \underset{\sim}{f} \text { is finite-to-one and } \underset{\sim}{f}[\mu]=^{*} \omega
$$

and the above proof breaks down. Information on $\underset{\sim}{g}(\mathcal{F})$ for particular filters $\mathcal{F}$ with $\Phi(\mathcal{U}) \leq_{\mathrm{RB}} \mathcal{F}$ and any name $\underset{\sim}{g}$ for a finite-to-one function is contained in Theorem 3.25
Definition 2.17. Let $\mathcal{F}$ be a filter. $\mathcal{F}^{+}=\left\{X \in[\omega]^{\omega}:(\forall Y \in \mathcal{F})(Y \cap X \neq \emptyset)\right\}$.
For a non-principal $\mathcal{F}, \mathcal{F}^{+}$coincides with $\left\{X \in[\omega]^{\omega}:(\forall Y \in \mathcal{F})\left(Y \cap X \in[\omega]^{\omega}\right)\right\}$.

## 3. Ramsey-theoretic computations in $\mathbb{M}(\mathcal{U})$-EXtensions

Now we consider the Ramsey space $\left((\operatorname{Fin})^{\omega}, \sqsubseteq\right)$ in an $\mathbb{M}(\mathcal{U})$-extension. We use the notation $\mathbf{V}^{\mathbb{P}}$ for any $\mathbf{V}[G]$, with a $\mathbb{P}$-generic filter $G$ over $\mathbf{V}$. All computations are about names and we use the forcing theorem freely and identify names often with their evaluations. The first aim is to examine $\mathcal{U}$ in the forcing extension $\mathbf{V}^{\mathbb{M}(\mathcal{U})}$. Is there an extension of the destroyed Milliken-Taylor ultrafilter $\mathcal{U}$ to a new MillikenTaylor ultrafilter? We show that under CH there are even $2^{\omega_{1}}$ possibilities with pairwise nnc cores. This will be the successor step of an iteration of iterands of type $\mathbb{M}\left(\mathcal{U}_{\alpha}\right)$. We introduce Ramsey-theoretic computations with names for elements of $(\text { Fin })^{\omega}$ in order to establish the existence of names for Milliken-Taylor ultrafilters. Although in the end, like in Cor. 2.10, min-unbounded FU-subsets of Fin are the elements of Milliken-Taylor ultrafilters, intermediate work is better carried out with sequences $\bar{a} \in(\text { Fin })^{\omega}$. We use letters $\bar{a}, \bar{b}, \bar{a} \ldots, A, B, \ldots$ for elements of (Fin) ${ }^{\omega}$, where capital letters are in particular used in work with sequences of sequences. Capital letters are also used for subsets of Fin.

Definition 3.1. (1) Let $\bar{a} \in(\operatorname{Fin})^{\omega}$ and $X \in[\omega]^{\omega}$. We let $\bar{a} \upharpoonright X=\left\langle a_{n}: n \in\right.$ $\left.\omega, a_{n} \subseteq X\right\rangle$. Note, we do not take those $a_{n}$ with $a_{n} \cap X \neq \emptyset$ that are not subsets of $X$.
(2) Let $\mathcal{U} \subseteq(F i n)^{\omega}$ and $X \in[\omega]^{\omega}$. We use the restriction symbol also for subsets of $(\mathrm{Fin})^{\omega}$ and let $\left.\mathcal{U} \upharpoonright X=\{\bar{a} \upharpoonright X: \bar{a} \in \mathcal{U}\}\right)$.

Lemma 3.2. Now let $\mu$ be a name for the Matet generic real $\bigcup\{s: \exists \bar{a}(s, \bar{a}) \in$ $G\}$.
(1) $\mathbb{M}(\mathcal{U}) \Vdash \forall \bar{a} \in \mathcal{U} \bar{a} \upharpoonright \mu \in(\operatorname{Fin})^{\omega}$.
(2) $\mathbb{M}(\mathcal{U}) \Vdash \mathcal{U} \upharpoonright \mu$ is an ordered-union filter.

Proof. (1) is an easy density argument. For (2), we use

$$
\mathbb{M}(\mathcal{U}) \Vdash(\bar{a} \wedge \bar{b}) \upharpoonright \mu=(\bar{a} \upharpoonright \mu) \wedge(\bar{b} \upharpoonright \mu) \wedge \mathrm{FU}(\bar{a} \upharpoonright \mu)=\mathrm{FU}(\bar{a}) \upharpoonright \mu
$$

Now we restate and prove
Theorem 3.3. Let $\mathcal{E}$ be a $\mathbb{P}$-point and let $\mathcal{U}$ be a Milliken-Taylor ultrafilter such that $\Phi(\mathcal{U}) \not \mathbb{Z}_{\mathrm{RK}} \mathcal{E}$. In $\mathbf{V}^{\mathbb{M}(\mathcal{U})}$ there is a Milliken-Taylor ultrafilter $\mathcal{U}^{\text {ext }} \supseteq \mathcal{U} \upharpoonright \mu$ such that $\Phi\left(\mathcal{U}^{\mathrm{ext}}\right) \not \mathbb{Z}_{R K} \mathcal{E}$.

In the remainder of this section we prove this theorem in an iterable form, Theorem 3.9.

Definition 3.4. (See [17, Def. 3.1]) A set $\mathcal{H} \subseteq(\text { Fin })^{\omega}$ is called a Matet-adequate family if the following hold:
(i) $\mathcal{H}$ is closed $\sqsubseteq^{*}$-upwards.
(ii) $\mathcal{H}$ is countably closed, i.e., any $\sqsubseteq$-descending $\omega$-sequence of members of $\mathcal{H}$ has a $\sqsubseteq^{*}$-lower bound in $\mathcal{H}$.
(iii) $\mathcal{H}$ has the Hindman property: If $\bar{a} \in \mathcal{H}$ and $\operatorname{FU}(\bar{a})$ is partitioned into two pieces then there is some $\bar{b} \sqsubseteq \bar{a}, \bar{b} \in \mathcal{H}$ such that $\mathrm{FU}(\bar{b})$ is a subset of a single piece of the partition.

Definition 3.5. Let $\left\langle\bar{a}_{n}: n<\omega\right\rangle$ be $\sqsubseteq$-descending of elements $\bar{a}_{n} \in(\text { Fin })^{\omega}$. A sequence $\bar{b} \in(\mathrm{Fin})^{\omega}$ is a diagonal lower bound of $\left\langle\bar{a}_{n}: n<\omega\right\rangle$ if

$$
\begin{equation*}
(\forall s \in \mathrm{FU}(\bar{b}))\left((\bar{b} ; \text { past } s) \sqsubseteq \bar{a}_{\max (s)+1}\right) \tag{3.1}
\end{equation*}
$$

It is equivalent to say $(\forall s \in \bar{b}))\left((\bar{b} ;\right.$ past $\left.s) \sqsubseteq \bar{a}_{\max (s)+1}\right)$ in (3.1).
The Hindman property of $\mathcal{H}$ together with the countable closure of $\mathcal{H}$ implies the existence of diagonal lower bounds of sequences in $\mathcal{H}$, see [17, Cor.1.3], which is based on the deep theorem [7, 4.2]. We give an alternative proof in Lemma 3.6

Matet-adequate families have better properties than stated in the definition; this is similar to [7, Theorem 4.2].

Lemma 3.6. Let $\mathcal{H}$ be a Matet-adequate family.
(a) Let $n \geq 1$. If $A \in \mathcal{H}$ and $[\mathrm{FU}(\bar{a})]_{<}^{n}$ is partitioned into two pieces then there is some $\bar{b} \sqsubseteq \bar{a}, \bar{b} \in \mathcal{H}$ such that $\left[\mathrm{FU}_{k}(\bar{b})\right]_{<}^{n}$ is a subset of a single piece of the partition.
(b) $\mathcal{H}$ contains for each descending sequence a diagonal lower bound.

Proof. (a) is proved in [7, Theorem 4.2]. We write an alternative proof that also serves to show that ultraness is not used. For simplicity we write the step from 1 to 2 . We let $c:\left[\mathrm{FU}_{k}(\bar{a})\right]_{<}^{2} \rightarrow r$ for some finite $r \geq 1$. We enumerate $\mathrm{FU}_{k}(\bar{a})$ as $\left\langle s_{\ell}: \ell \in \omega\right\rangle$ such that for any $\ell$, all the $s_{i}$ with $\max \left(\operatorname{supp}\left(s_{i}\right)\right)<\max \left(\operatorname{supp}\left(s_{\ell}\right)\right)$ have $i<\ell$. Let $\bar{c}_{-1}=\bar{a}$. For each $s_{\ell} \in \mathrm{FU}_{k}(\bar{a})$ by induction hypothesis we may take a $\bar{c}_{\ell} \sqsubseteq_{k}\left(\bar{c}_{\ell-1} ;\right.$ past $\left.s_{\ell}\right)$ such that

$$
\begin{aligned}
& f_{\ell}: \mathrm{FU}_{k}\left(\bar{c}_{\ell-1} ; \text { past } s_{\ell}\right) \rightarrow m \\
& \quad t \mapsto c\left(s_{\ell}, t\right)
\end{aligned}
$$

is monochromatic on $\mathrm{FU}_{k}\left(\bar{c}_{\ell}\right)$. Let $\bar{b} \sqsubseteq_{k}^{*} \bar{c}_{\ell}$ for any $\ell<\omega$. Now we take $g: \omega \rightarrow \omega$ with $g(0)=0$ and $g(\ell+1)>g(\ell)$ so large that

$$
\begin{equation*}
(\forall r \leq g(\ell))\left((\bar{b} ; \text { past }\{g(\ell+1)\}) \sqsubseteq_{k} \bar{c}_{r}\right) . \tag{3.2}
\end{equation*}
$$

Next we let for $s \in \mathrm{FU}_{k}(\bar{b})$, say $s=s_{\ell}, \underline{f}(s)=c(s, t)$ for any $t \in \mathrm{FU}_{k}\left(\bar{c}_{\ell}\right) \cap \mathrm{FU}(\bar{b})$. By the induction hypothesis there is $\bar{c} \sqsubseteq_{k} \bar{b}, \bar{c} \in \mathcal{H}$, such that $\mathrm{FU}_{k}(\bar{c})$ is monochromatic under the colouring $f$. Then we colour $s \in \mathrm{FU}_{k}(\bar{c})$ with colour $j \in 2$ if $\max (\operatorname{supp}(s))$ is in $\bigcup\{[g(2 r+j), g(2 r+j+1)): r \in \omega\}$, and take $\bar{d} \sqsubseteq_{k} \bar{c}$ such that $\mathrm{FU}_{k}(\bar{d})$ is monochromatic for the latter colouring. Finally we take $\bar{e} \sqsubseteq_{k} \bar{d}$ such that for each $r$ there is at most one $\ell$ such that $\operatorname{supp}\left(e_{\ell}\right) \cap[g(2 r+j), g(2 r+j+1)) \neq \emptyset$. The existence of such an $\bar{e} \in \mathcal{H}$ follows by [7, Theorem 3.9]. Then $\left[\mathrm{FU}_{k}(\bar{e})\right]_{<}^{2}$ is $c$-monochromatic.
(b) Let $\left\langle\bar{a}_{n}: n \in \omega\right\rangle$ be a $\sqsubseteq_{k}$-descending sequence of element of $\mathcal{H}$ and let $\bar{c} \in \mathcal{H}$ be a $\sqsubseteq_{k}^{*}$-lower bound such that $\bar{c} \sqsubseteq_{k} \bar{a}_{0}$. We colour $\left.\mathrm{FU}_{k}(\bar{c})\right]_{<}^{2}$ via

$$
c(u, v)= \begin{cases}1 & \text { if } v \in \mathrm{FU}_{k}\left(\bar{a}_{\max (\operatorname{supp}(u))+1}\right) \\ 0 & \text { else }\end{cases}
$$

Since $\bar{c}$ is a $\sqsubseteq_{k}^{*}$-lower bound of $\left\langle\bar{a}_{n}: n<\omega\right\rangle$, any $\bar{d} \sqsubseteq_{k} \bar{c}$ such that $\left[\mathrm{FU}_{k}(\bar{d})\right]_{<}^{2}$ is $c$-monochromatic has colour 1 and hence is a diagonal lower bound.

Definition 3.7. Let $\mathcal{C} \subseteq(\text { Fin })^{\omega}$ be centred. $\mathcal{C}^{+}=\left\{\bar{a} \in(\text { Fin })^{\omega}: \forall \bar{c} \in \mathcal{C}, \bar{c} \not \perp \bar{a}\right\}$
We introduce an abbreviation:
Definition 3.8. Let $\mathcal{H} \subseteq(\text { Fin })^{\omega}$ and let $\mathcal{E}$ be a $P$-point. We say $\mathcal{H}$ avoids $\mathcal{E}$ if $\{\operatorname{set}(\bar{a}): \bar{a} \in \mathcal{H}\}$ is nnc to $\mathcal{E}$. For nnc see Definition 1.1(4).

The technical core of the proof of Theorem 3.3 is:
Theorem 3.9. After forcing with $\mathbb{M}(\mathcal{U}),(\mathcal{U} \upharpoonright \mu)^{+}$is a Matet-adequate family that for any finite-to-one $h$, for any $\bar{a} \in(\mathcal{U} \upharpoonright \mu)^{+}$,

$$
\left(\exists \bar{b}^{1}, \bar{b}^{2} \sqsubseteq \bar{a}\right)\left(\bar{b}^{0} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \bar{b}^{1} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge h\left[\operatorname{set}\left(\bar{b}^{1}\right)\right] \cap h\left[\left(\operatorname{set}\left(\bar{b}^{2}\right)\right]=\emptyset\right) .\right.
$$

By the latter property, $(\mathcal{U} \upharpoonright \mu)^{+}$avoids any ultrafilter from the ground model, in particular $\mathcal{E}$. Once Theorem 3.9 is proved, a routine downwards construction along $\omega_{1}$ (see e.g., [7, Theorem 2.4]) completes the proof of Theorem 3.3: Under CH in $\mathbf{V}^{\mathbb{M}(\mathcal{U})}$ there is a Milliken-Taylor ultrafilter $\mathcal{U}^{\text {ext }} \supseteq \mathcal{U}$ that avoids $\mathcal{E}$.

Showing adequacy requires some technical work to evaluate the forcing.
Definition 3.10. $(t, \bar{b}) \leq(s, \bar{a})$ is called a pure extension of $(s, \bar{a})$ if $s=t$.
Lemma 3.11. ([17, Lemma 2.6]) $\mathbb{M}(\mathcal{U})$ has the pure decision property, that is, for any $\varphi$ in the forcing language for any $(s, \bar{a}) \in \mathbb{M}(\mathcal{U})$, there is $\bar{b} \in \mathcal{U}, \bar{b} \sqsubseteq \bar{a}$ such that $(s, \bar{b})$ decides $\varphi$.

Eisworth introduced the notion of a neat condition for a name of a subset of $\omega$. We extend the notion of neatness for our purposes. 6

Definition 3.12. (1) Let $\underset{\sim}{A}$ be a name for an infinite subset of Fin (that means, the weakest condition forces this). We say $(s, \bar{b})$ is neat for $\underset{\sim}{A}$ if

$$
\begin{aligned}
& (\forall t \in \mathrm{FU}(\bar{b}))(\forall r \in \mathrm{FU}(\bar{b} ; \text { past } t))(\forall u \subseteq \max (r)) \\
& \left(\forall r^{\prime} \in \mathrm{FU}(\bar{b} ; \text { past } r)\right)\left(\left(s \cup t \cup r^{\prime},\left(\bar{b} ; \text { past } r^{\prime}\right)\right)\right. \\
& \text { decides } \left.u \in \underset{\sim}{A} \text { and the decision does not depend on } r^{\prime}\right) .
\end{aligned}
$$

(2) Let $\underset{\sim}{h}$ be a name for a finite-to-one function such that $h(i) \leq i$. We say $(s, \bar{b})$ is neat for $\underset{\sim}{h}$ if

$$
\begin{aligned}
& (\forall t \in \mathrm{FU}(\bar{b}))(\forall r \in \mathrm{FU}(\bar{b} ; \text { past } t))(\forall i \leq \max (r)) \\
& \left(\forall r^{\prime} \in \mathrm{FU}(\bar{b} ; \text { past } r)\right)\left(\left(s \cup t \cup r^{\prime},\left(\bar{b} ; \text { past } r^{\prime}\right)\right)\right. \\
& \text { decides } \left.\underset{\sim}{h}(i) \text { and the decision does not depend on } r^{\prime}\right) .
\end{aligned}
$$

(3) Let $\underset{\sim}{c}$ be a name for a function $\underset{\sim}{c}$ : Fin $\rightarrow\{0,1\}$. We say $(s, \bar{b})$ is neat for $\underset{\sim}{c}$ if

$$
\begin{aligned}
& (\forall t \in \mathrm{FU}(\bar{b}))(\forall r \in \mathrm{FU}(\bar{b} ; \text { past } t))(\forall u \subseteq \max (r)) \\
& \left(\forall r^{\prime} \in \mathrm{FU}(\bar{b} ; \text { past } r)\right)\left(\left(s \cup t \cup r^{\prime},\left(\bar{b} ; \text { past } r^{\prime}\right)\right)\right. \\
& \text { decides } \left.\underset{\sim}{c}(u) \text { and the decision does not depend on } r^{\prime}\right) .
\end{aligned}
$$

[^5](4) Let $\left\langle\underset{\sim}{A_{j}}: j<\omega\right\rangle$ be a sequence of names for elements of (Fin) ${ }^{\omega}$. We say $(s, \bar{b})$ is neat for $\left\langle A_{j}: j<\omega\right\rangle$ if
\[

$$
\begin{aligned}
& (\forall t \in \mathrm{FU}(\bar{b}))(\forall r \in \mathrm{FU}(\bar{b} ; \text { past } t))(\forall j \leq \max (r))(\forall u \subseteq \max (r)) \\
& \left(\forall r^{\prime} \in \mathrm{FU}(\bar{b} ; \text { past } r)\right)\left(\left(s \cup t \cup r^{\prime},\left(\bar{b} ; \text { past } r^{\prime}\right)\right)\right.
\end{aligned}
$$
\]

decides $u \in \underset{\sim}{A} A_{j}$ and the decision does not depend on $\left.r^{\prime}\right)$.
Lemma 3.13. ([17, Lemma 2.7, Lemma 2.8]) $(s, \bar{a}) \in \mathbb{M}(\mathcal{U}) . \operatorname{Let}\left(\underset{\sim}{X}, \underset{\sim}{h}, \underset{\sim}{c},\left\langle{\underset{\sim}{j}}_{j}\right.\right.$ : $j<\omega\rangle$ ) given such that the weakest condition forces: $\underset{\sim}{X}$ is a min-unbounded subset of Fin, $\underset{\sim}{h}$ is a surjective weakly increasing finite-to-one function, $\underset{\sim}{c}$ is a name for a colouring, $\left\langle\underset{\sim}{A} A_{j}: j<\omega\right\rangle$ is a sequence of members of (Fin) ${ }^{\omega}$. Then there is $\bar{b} \sqsubseteq \bar{a}$ such that $(s, \tilde{b}) \in M(\mathcal{U})$ is neat for $\underset{\sim}{X}, \underset{\sim}{h}, \underset{\sim}{c},\left\langle A_{j}: j<\omega\right\rangle$.

Remark 3.14. Since the proof does not use the fact that $\mathcal{U}$ is a filter, Lemma 3.13 also holds for $\mathbb{M}(\mathcal{H})$ for any Matet-adequate family $\mathcal{H}$.

Now we prove Theorem 3.9. It is obvious that the set of positive sets $(\mathcal{U} \upharpoonright \mu)^{+}$ is upwards closed in the $\sqsubseteq^{*}$-order. Now we show that any $\sqsubseteq$-descending $\omega$-sequence has a $\sqsubseteq^{*}$-lower bound. It is not harder to directly show that there is a diagonal lower bound.

We recall that $\min _{<, \text {lex, Fin }}$ was defined in Definition 2.1(11). A $\mathbb{Q}$-name is a set of the form $\tau=\{\langle\sigma, q\rangle:\langle\sigma, q\rangle \in \tau\}$ with names $\sigma$ of lower rank. For $x \in \mathbf{V}$ we have the $\mathbb{Q}$-name $\check{x}=\{\langle\check{y}, q\rangle: y \in x, q \in \mathbb{Q}\}$. We drop the $\check{x}$-sign.

The following technique is one of the cornerstones of our forcing constructions and interesting for itself:

Lemma 3.15. (Existence of positive diagonal lower bounds) Let $\mathcal{U}$ be a MillikenTaylor ultrafilter, $\mathcal{E}$ be a P-point, $\Phi(\mathcal{U}) \not \leq_{\mathrm{RB}} \mathcal{E}$. Let $\mathbb{Q}=\mathbb{M}(\mathcal{U})$ and let $\mu$ be the name for the generic real. Let $\underset{\sim}{\bar{X}}=\langle\underset{\sim}{X} n: n \in \omega\rangle$ be a sequence of $\mathbb{Q}$-names for elements of $(\mathrm{Fin})^{\omega}$ such that

$$
\mathbb{Q} \Vdash(\forall n \in \omega)\left(\underset{\sim}{X} n \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge X_{\sim}^{n+1} \sqsubseteq{\underset{\sim}{x}}^{X_{n}}\right) .
$$

Then

$$
\begin{gather*}
\underset{\sim}{D}=\left\{\langle t,(s, \bar{a})\rangle:(s, \bar{a}) \in \mathbb{Q} \wedge(\exists k \in \omega)\left(\exists t_{0}<t_{1}<\cdots<t_{k-1} \in[\mathrm{Fin}]_{<}^{k}\right)\right. \\
\left(t_{k-1}<t_{k}=t \wedge(s, \bar{a}) \Vdash " t_{0}=\min _{<\operatorname{lex}, \text { Fin }}\left(X_{\sim} X_{0} \upharpoonright \mu\right) \wedge\right.  \tag{3.3}\\
\left.\left.\bigwedge_{i<k}\left(t_{i+1}=\min _{<\operatorname{lex}, \text { Fin }}\left(\left(X_{\sim}^{\max \left(t_{i}\right)+1} \upharpoonright \mu\right) ; \text { past } t_{i}\right)\right) "\right)\right\}
\end{gather*}
$$

fulfils

$$
\begin{equation*}
\mathbb{Q} \Vdash \underset{\sim}{D} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \underset{\sim}{D} \sqsubseteq \underset{\sim}{X} X_{0} \wedge(\forall t \in \underset{\sim}{D})\left((\underset{\sim}{D} ; \text { past } t) \sqsubseteq X_{\max }^{\max }(t)+1\right) . \tag{3.4}
\end{equation*}
$$

Proof. Let $(s, \bar{a})$ be given such that $(s, \bar{a})$ is neat for $\underset{\sim}{D}$ and for $\left\langle X_{i_{\sim}} \upharpoonright \mu: i<\omega\right\rangle$. We show that there is $(s, \bar{b}) \leq_{\mathbb{Q}}(s, \bar{a})$ that forces that $\underset{\sim}{D} \upharpoonright \mu \in(\mathcal{U} \upharpoonright \mu)^{+}$.

Let $k \in \omega$ and $u \in \operatorname{FU}(\bar{a})$. We say that $u$ is good for $(s, \bar{a}), \bar{t}=\left(t_{0}, \ldots, t_{k-1}\right) \in$ $[\text { Fin }]_{<}^{k}, \underset{\sim}{\bar{X}}$, if
$(s \cup u, \bar{a} ;$ past $u) \Vdash t_{0}=\min _{<\operatorname{lex}, \mathrm{Fin}}\left(X_{\sim} X_{0} \upharpoonright \mu\right) \wedge \bigwedge_{i<k-1}\left(t_{i+1}=\min _{<\operatorname{lex}, \mathrm{Fin}}\left(\left(X_{\max }^{\max }\left(t_{i}\right)+1 \upharpoonright \mu\right) ;\right.\right.$ past $\left.\left.t_{i}\right)\right)$.

Note that goodness requires $t_{i} \in$ Fin and not just names for elements of Fin. We define a colouring of $[\mathrm{FU}(\bar{a})]_{<}^{2}$ as follows

$$
F(u<v)= \begin{cases}1 \quad \begin{array}{l}
\text { if for any } \bar{t} \text { such that } \\
u \text { is good for }(s, \bar{a}), \bar{t}, \bar{X} \\
\\
\text { there is a proper end extension } \bar{t}^{\prime} \text { of } \bar{t} \\
\quad \text { such that } u \cup v \text { is good for }(s, \bar{a}), \overline{t^{\prime}}, \bar{\sim} \\
0 \\
\text { else. } \tag{3.5}
\end{array}\end{cases}
$$

By Taylor's theorem 2.9 there is $(s, \bar{b}) \leq_{\mathbb{Q}}(s, \bar{a})$ such that $F$ is monochromatic on $[\mathrm{FU}(\bar{b})]_{<}^{2}$. We argue that the monochromatic colour can only be 1: It suffices to find $u<v \in \mathrm{FU}(\bar{b})$ such that $F(u, v)=1$. Suppose that $u \in \mathrm{FU}(\bar{b})$ is good for $(s, \bar{a}), \bar{t}=\left(t_{0}, \ldots, t_{k-1}\right), \underset{\sim}{\bar{X}}$. If $k=0$, we let $X_{t_{k-1}+1}=X_{0}$. Then $(s \cup u, \bar{b}) \Vdash$ $\left(X_{\max \left(t_{k-1}\right)+1} \upharpoonright \mu\right) ;$ past $\left.t_{k-1}\right) \in(\mathcal{U} \upharpoonright \mu)^{+} . \operatorname{So}(s \cup u, \bar{b}) \Vdash \exists t \in\left(X_{\max \left(t_{t_{k-1}}\right)+1} \upharpoonright\right.$ $\mu)$; past $\left.t_{k-1}\right)$.

Now we show

$$
\begin{equation*}
(s, \bar{b}) \Vdash \underset{\sim}{D} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \underset{\sim}{D} \sqsubseteq \underset{\sim}{X} X_{0} \wedge(\forall t \in \mathrm{FU}(\underset{\sim}{D}))\left((\underset{\sim}{D} ; \text { past } t) \sqsubseteq X_{\underset{\sim}{\max }(t)+1}\right) \tag{3.6}
\end{equation*}
$$

The proof comes in four parts. First we show that $\underset{\sim}{D}$ is a min-unbounded subset of Fin. Given any $k \in \omega$, the procedure above for finding $v, t^{\prime}$ is iterated $k$ times, starting at stage $k=0$ with $u=s$. Thus we find $v_{i}$ and $t_{i}$ such that

$$
\begin{aligned}
&\left(s \cup v_{0}, \bar{b} ; \text { past } v_{0}\right) \Vdash t_{0}=\min _{<\text {lex }, \text { Fin }}\left(X_{0} \upharpoonright \mu\right), \\
&\left(s \cup v_{0} \cup v_{1}, \bar{b} ; \text { past } v_{1}\right) \Vdash t_{1}=\min _{<\text {lex }, \text { Fin }}\left(X_{\max \left(t_{0}\right)+1} \upharpoonright \mu\right), \\
& \vdots \\
&\left(s \cup v_{0} \cup \cdots \cup v_{k}, \bar{b} ; \text { past } v_{k}\right) \Vdash t_{k}=\min _{<\text {lex }, \text { Fin }}\left(X_{\max \left(t_{k-1}\right)+1} \upharpoonright \mu\right), \text { and thus } \\
&\left(s \cup v_{1} \cup \cdots \cup v_{k}, \bar{b} ; \text { past } v_{k}\right) \Vdash t_{0}<\cdots<t_{k} \in \underset{\sim}{D} .
\end{aligned}
$$

Next we show $(s, \bar{b}) \Vdash \underset{\sim}{D} \in(\mathcal{U} \upharpoonright \mu)^{+}$. Suppose for a contradiction, that $\bar{c} \in \mathcal{U}$ and $\left(s^{\prime}, \bar{b}^{\prime}\right) \leq(s, \bar{b})$ and $\left(s^{\prime}, \bar{b}^{\prime}\right) \Vdash \mathrm{FU}(\bar{c}) \cap \mathrm{FU}(\underset{\sim}{D})=\emptyset$. Then we take $\bar{d} \sqsubseteq \bar{b}^{\prime},\left(\bar{c} ;\right.$ past $\left.s^{\prime}\right)$, such that $\bar{d} \in \mathcal{U}$ and see that $\left(s^{\prime}, \bar{d}\right) \Vdash\left(\underset{\sim}{D} ;\right.$ past $\left.s^{\prime}\right) \subseteq \operatorname{FU}(\bar{c} \upharpoonright \mu)$. Contradiction.

Since $\mathbb{Q} \Vdash X_{n+1} \sqsubseteq X_{n}$, by definition of $\underset{\sim}{D},(s, \bar{b}) \Vdash \underset{\sim}{D} \subseteq X_{0}$.
For the last conjunctive clause in Equation (3.6), we work with the characterisation of diagonal lower bound that is given immediately after Def. 3.5. We suppose that $(s \cup v, \bar{b} ;$ past $v) \Vdash t<t^{\prime} \in \underset{\sim}{D}$. Then by the definition of $\underset{\sim}{D}$ $(s \cup v, \bar{b} ;$ past $v) \Vdash t^{\prime} \in \mathrm{FU}(\underset{\sim}{X} \underset{\max (t)+1}{ } \upharpoonright \mu ;$; past $t)$.

Recall $\operatorname{set}\left(\left\langle a_{n}: n<\omega\right\rangle\right)=\bigcup\left\{a_{n}: n<\omega\right\}$.
Lemma 3.16. Let $(s, \bar{a}) \Vdash_{\mathbb{M}(\mathcal{U})} \underset{\sim}{\bar{c}} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge_{\sim}^{h}$ is finite-to-one, onto and monotone. Then there are $E \in \mathcal{E}$ and $(s, \bar{b}) \leq(s, \bar{a})$ and $\bar{d}_{\sim}^{j}, j=0,1$, such that

$$
\begin{align*}
&(s, \bar{b}) \Vdash \bigwedge_{j=0,1}\left(\bar{d}^{j} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \bar{d}^{j}\right. \\
& \sqsubseteq  \tag{3.7}\\
&\underset{\sim}{c}) \wedge \\
&\left.\operatorname{set}\left({\underset{\sim}{d}}^{0}\right)\right] \cap \underset{\sim}{h}\left[\operatorname{set}\left(\bar{d}_{\sim}^{1}\right]=\emptyset \wedge \bigvee_{j=0,1}^{\bigvee} \underset{\sim}{h}[E] \cap \underset{\sim}{h}\left[\operatorname{set}\left({\underset{\sim}{d}}^{j}\right)=\emptyset .\right.\right.
\end{align*}
$$

Proof. We assume w.l.o.g. that $(s, \bar{a})$ is neat for $\bar{c}$ and $h$. Every name for a positive set $\bar{c}$ and every condition $p$ let us define names ${\underset{\sim}{d}}_{j}^{j}, j=0,1$, such that densely many $q$ below $p$ force $\underset{\sim}{h}\left[\operatorname{set}\left(\bar{d}^{0}\right)\right] \cap \underset{\sim}{h}\left[\operatorname{set}\left(\bar{d}^{1}\right)\right]=\emptyset \wedge \bigwedge_{j=0,1}\left(\bar{d}^{j} \sqsubseteq \bar{c}\right)$. Again this is proved with a colouring.

Let $k<\omega$ and $u \in \operatorname{FU}(\bar{a})$. We say that $u$ is good for $(s, \bar{a}), \bar{d}=\left(d_{0}, \ldots, d_{k-1}\right)$, $\bar{\sim}$, and $\underset{\sim}{h}$ if

$$
\begin{aligned}
(s \cup u, \bar{a} ; \text { past } u) \Vdash d_{0} & =\min _{<\operatorname{lex}, \mathrm{Fin}}(\underset{\sim}{c} \upharpoonright \mu) \wedge \\
& \bigwedge_{i<k-1}\left(d_{i+1}=\min _{<\operatorname{lex}, \mathrm{Fin}}\left\{d \in \mathrm{FU}(\underset{\sim}{\bar{c}} \upharpoonright \mu): \underset{\sim}{h}\left[d_{i}\right] \cap \underset{\sim}{h}[d]=\emptyset\right\}\right) .
\end{aligned}
$$

Again the $d_{i}$ are in the ground model, not names. This, though, is not important, since we do not use them as indices. We define a colouring of $[\mathrm{FU}(\bar{a})]_{<}^{2}$ as follows

$$
F(u<v)= \begin{cases}1 \quad \begin{array}{l}
\text { if for any } \bar{d} \text { such that } \\
u \text { is good for }(s, \bar{a}), \bar{d}, \bar{c}, \underset{\sim}{h}
\end{array}  \tag{3.8}\\
\quad \begin{array}{l}
\text { there is a proper end extension } \bar{d}^{\prime} \text { of } \bar{d} \\
\text { such that } u \cup v \text { is good for }(s, \bar{a}), \overline{d^{\prime}}, \bar{c}, h
\end{array} \\
0 \quad & \text { else. }\end{cases}
$$

By Taylor's theorem 2.9 there is $(s, \bar{b}) \leq_{\mathbb{M}(\mathcal{U})}(s, \bar{a})$ such that $F$ is monochromatic on $[\mathrm{FU}(\bar{b})]_{<}^{2}$. Since for any $k,((\underset{\sim}{c} \upharpoonright \mu)$; past $k)$ is forced to be in $(\mathcal{U} \upharpoonright \mu)^{+}$, the monochromatic colour can only be 1 . Now there are names $d_{i}$ such that

$$
\begin{align*}
(s, \bar{b}) \Vdash & \left.\vdash d_{2 k+1}: k \in \omega\right\rangle \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \\
& \left\langle d_{\sim}^{2 k}: k \in \omega\right\rangle \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \\
& \left\langle d_{\sim}^{d}: k \in \omega\right\rangle \sqsubseteq \bar{c} \wedge  \tag{3.9}\\
& \underset{\sim}{h}\left[\bigcup\left\{d_{2 k}: k \in \omega\right\}\right] \cap \underset{\sim}{h}\left[\bigcup\left\{d_{2 k+1}: k \in \omega\right\}\right]=\emptyset .
\end{align*}
$$

The first two conjunctive clauses are shown as in the proof of Equation (3.6). The last conjunctive clause follows from the new definition of goodness. We let $(s, \bar{b}) \Vdash{\underset{\sim}{d}}^{j}=\langle\underset{\sim}{d} \underset{\sim}{d+j}: k<\omega\rangle$ for $j=0,1$. Since $\mathbb{M}(\mathcal{U}) \Vdash \underset{\sim}{h}(\mathcal{E})$ is an ultrafilter, $(s, \bar{b})$ forces there are a $j=0,1$ and an $E \in \mathcal{E}$ such that $\underset{\sim}{h}[E] \cap \underset{\sim}{h}\left[\operatorname{set}\left(\bar{d}^{j}\right)\right]=\emptyset$.

The next lemma is the most important step in the proof of Theorem 3.9. Indeed, it includes again a proof that positive diagonal lower bounds exist.

Lemma 3.17. In $\mathbf{V}^{\mathbb{M}(\mathcal{U})}$, $(\mathcal{U} \upharpoonright \mu)^{+}$has the Hindman property.
For the proof of this lemma, we adapt a theorem of Eisworth.
Theorem 3.18. 17, Theorem 5] Let $\mathcal{F}$ be an ordered-union filter generated by $<\operatorname{cov}(\mathcal{B})$ sets and let $c$ be a partition of Fin into finite sets. Then there is an $\bar{a} \in \mathcal{F}^{+}$such that $\mathrm{FU}(\bar{a})$ is included in one piece of the partition.

At a crucial point in Eisworth's proof a Cohen real over an elementary submodel provides a name in a Galvin-Glazer framework. We show that also a Matet-real and even an $\mathbb{M}(\mathcal{U})$-generic real can be used. We recall the Galvin-Glazer 25] technique.

Definition 3.19. We denote by $\gamma$ (Fin) the set of min-unbounded (see Def. 2.6(3)) ultrafilters over Fin. This set is endowed with the topology generated by

$$
\{\{\mathcal{U} \in \gamma(\mathrm{Fin}): A \in \mathcal{U}\}: A \subseteq \operatorname{Fin}\} .
$$

The space $\gamma($ Fin $)$ is a compact zero-dimensional Hausdorff space. With the named topology and the semigroup operation $\cup$ from Def. 2.1(9), the semigroup $(\gamma(\operatorname{Fin}), \cup)$ is a right-topological semigroup. Details can be found in 26.
Lemma 3.20. (Ellis, [18]) Each compact subsemigroup of $(\gamma(\mathrm{Fin}), \cup)$ contains an idempotent ultrafilter.

Now we apply Ellis' lemma to $\{\mathcal{U} \in \gamma($ Fin $): \mathcal{U} \supseteq \mathcal{F}\}$ for a min-unbounded filter $\mathcal{F}$.

Lemma 3.21. ([17, Prop. 4.2]) Let $\mathcal{F}$ be a min-unbounded filter. There is an idempotent ultrafilter $\mathcal{U} \in \gamma($ Fin $)$ that extends $\mathcal{F}$.

Now we prove Lemma 3.17 Let $p$ force that $\underset{\sim}{c}$ is a partition of $\bar{b}_{0} \in(\mathcal{U} \upharpoonright \mu)^{+}$ into finitely many pieces and $\left\langle\bar{b}_{n}: n<\omega\right\rangle$ is a $\sqsubseteq$-descending sequence of elements $\bar{b}_{n} \in(\mathcal{U} \upharpoonright \mu)^{+}$. By Lemma 3.21 there is an $\mathbb{M}(\mathcal{U})$-name $\mathcal{U}_{\sim}^{i}$ such that

$$
\mathbb{M}(\mathcal{U}) \Vdash \mathcal{U}_{\sim}^{i} \supseteq \operatorname{fil}\left((\mathcal{U} \upharpoonright \mu) \cup\left\{\left\{b_{\sim, m}: m \in \omega\right\}: n \in \omega\right\}\right) \wedge \mathcal{U}_{\sim}^{i} \cup \mathcal{U}_{\sim}^{i}=\mathcal{U}_{\sim}^{i} .
$$

For $X \subseteq$ Fin and $t \in$ Fin we set

$$
X \ominus t=\{s: s \cup t \in X\}
$$

Since $\mathcal{U}_{\mathcal{U}}{ }^{i}$ is forced to be idempotent,

$$
\mathbb{M}(\mathcal{U}) \Vdash\left(\forall X \in \mathcal{U}_{\sim}^{i}\right)\left(\left\{t: X \ominus t \in \mathcal{U}_{\sim}^{i}\right\} \in \mathcal{U}_{\sim}^{i}\right) .
$$

Now we use again the Milliken-Taylor trick. We assume that $(s, \bar{a})$ is neat for $\underset{\sim}{c}$, $\left\langle b_{n}: n<\omega\right\rangle$.

Let $n \geq 1$. We call $u \in \mathrm{FU}(\bar{a})$ good for $(s, \bar{a}),\left(\underset{\sim}{X}, d_{m}: m<n\right)$ if $(s \cup$ $u, \bar{a} ;$ past $u)$ forces the following statements:
(1) ${\underset{\sim}{x}}_{0}$ is the piece of the partition $c$ of $\operatorname{FU}(\bar{b})$ that is in $\mathcal{U}^{i}$.
(2) We let $d_{-1}=\{-1\}$. For any $0 \leq m<n d_{m}$ is the $\leq_{\text {lex,Fin-least element of }}$

$$
\begin{gather*}
\left\{d \in X_{\sim} \cap \mathrm{FU}\left(\left\{a_{k}: k \in \omega\right\} \upharpoonright \mu\right) \cap \mathrm{FU}\left(\bar{b}_{\max \left(d_{m-1}\right)+1}\right):\right.  \tag{3.10}\\
\left.X_{\sim}{ }_{\sim} \ominus d \in \mathcal{U}_{\sim}^{i} \text { and } \min (d)>\max \left(d_{m_{\sim}-1}\right)\right\}
\end{gather*}
$$

(3) For any $0 \leq m<n-1, X_{\underset{\sim}{m}+1}=X_{\sim} \cap\left(X_{m} \ominus d_{m}\right)$.

Here we allow names. Only the natural numbers are meant to be pinned down. We colour $[\mathrm{FU}(\bar{a} ; \text { past } s)]_{<}^{2}$ as follows:

$$
F(u<v)= \begin{cases}1 \quad & \text { if for any }\left(X_{\sim}, d_{m}: m<n\right) \text { such that }  \tag{3.11}\\ & u \text { is good for }(s, \bar{a}),\left(X_{\sim}, d_{m}: m<n\right), \\ & \text { there is a proper end extension }\left(X_{m}, d_{m}: m<n^{\prime}\right) \\ & \text { such that } v \text { is good for }(s, \bar{a}),\left(\underset{\sim}{x}, d_{m}: m<n^{\prime}\right) \\ 0 & \text { else. }\end{cases}
$$

Then we find a monochromatic $\bar{b} \in \mathcal{U}$ with $(s, \bar{b}) \leq(s, \bar{a})$. Since $\mathcal{U}^{i}$ is idempotent and $\bar{b} \in \mathcal{U} \subseteq \mathcal{U}^{i}$, the set in (3.10) is in $\mathcal{U}^{i}$. Hence the monochromatic colour can only be 1. We let $\underset{\sim}{e}$ be a name such that $(s, \bar{b}) \Vdash(\forall n)\left\langle e_{\sim}, \ldots, e_{\sim}^{n-1}\right\rangle=\left\langle d_{\sim}, \ldots, d_{\sim}^{n-1}\right\rangle_{\sim}$.

The monochromaticity statement

$$
\mathbb{M}(\mathcal{U}) \Vdash \mathbb{F U}(\underset{\sim}{\bar{e}}) \subseteq X_{0}
$$

is proved literally as in Eisworth [17, page 460]. By item (2) in the current definition of "good", the sequence $\underset{\sim}{e}$ is a diagonal lower bound of $\left\langle\bar{b}_{n}: n<\omega\right\rangle$. Now we show that $\underset{\sim}{\bar{e}}$ is positive. For this we use the conditions on $\operatorname{FU}(\bar{a})$ in the goodness clause (2). Suppose for a contradiction that $\underset{\sim}{e}$ is not forced to be $(\mathcal{U} \upharpoonright \mu)$-positive. Hence there is $q \in \mathbb{M}(\mathcal{U}), \bar{c} \in \mathcal{U}$ such that $q$ is neat for $\underset{\sim}{e}$ and $\mu, q \leq(s, \bar{b})$, and

$$
q \Vdash_{\mathbb{M}(\mathcal{U})} \mathrm{FU}(\bar{e}) \cap \mathrm{FU}(\bar{c} \upharpoonright \mu)=\emptyset .
$$

Since $\mathcal{U}$ is a filter, we can assume $q=(t, \bar{c})$. We produce an extension $r$ of $q$ that forces the contrary.

There is a minimal $m$ such that $q$ does not determine $e_{m}$. So $q$ determines $e_{0}=d_{0}, \ldots, e_{m-1}=d_{m-1}$.

Since $[\mathrm{FU}(\bar{c} ; \text { past } t)]_{<}^{2}$ has colour 1 ,

$$
\begin{aligned}
(t, \bar{c}) \Vdash Y= & \left\{d \in \underset{\sim}{X} X_{m} \cap \mathrm{FU}\left(\left\{c_{k}: k \in \omega\right\} \upharpoonright \mu\right) \cap \mathrm{FU}\left(\bar{b}_{\max \left(d_{m-1}\right)+1}\right):\right. \\
& \left.X_{\sim} \nsupseteq d \in \mathcal{U}^{i} \text { and } \min (d)>\max \left(d_{m-1}\right)\right\} \in \mathcal{U}^{i} .
\end{aligned}
$$

Since $[\mathrm{FU}(\bar{c})]_{<}^{2}$ has colour 1 and since $q$ is neat for $\underset{\sim}{\bar{e}}$ and $\mu$, there is $r \leq q$ of the form $(t \cup u, \bar{c} ;$ past $u)$ and there is $d \in \operatorname{Fin}$

$$
r \Vdash d \in \mathrm{FU}(\underset{\sim}{\bar{e}}) \cap \mathrm{FU}(\bar{c} \upharpoonright \mu)
$$

in contradiction to the assumption on $q$.

## $\square 3.17 / 3.9] 3.3$

Henceforth we drop the tildes underneath the names.
Now we return to filters over $\omega$ and answer some instances of the question left open in the previous section: What happens to filters with $\Phi(\mathcal{U}) \leq_{\mathrm{RB}} \mathcal{F}$ ?

Mathias introduced the following notion under the name "happy family" 30, Def. 0.1.]. Louveau studied it in the special case of ultrafilters [28]. Todorcevic [40, Chapter 7] uses the name "selective coideal" for a happy family.

Definition 3.22. (See [30, Def. 0.1.], [40, Def. 7.3]) A set $\mathcal{H} \subseteq[\omega]^{\omega}$ is called a selective coideal/happy family if the following hold:
(i) $\mathcal{I}_{\mathcal{H}}:=\mathcal{P}(\omega) \backslash \mathcal{H}$ is an ideal that contains all singletons.
(ii) If $\left\langle A_{i}: i \in \omega\right\rangle$ is a $\subseteq$-descending sequence of elements $A_{i} \in \mathcal{H}$, then there is $B \in \mathcal{H}$ such that $B \subseteq A_{0}$ and $(\forall i \in B) B \backslash(i+1) \subseteq A_{i}$. We call such a $B$ a diagonal lower bound of $\left\langle A_{i}: i \in \omega\right\rangle$.
We write $\mathcal{F}_{\mathcal{H}}=\left\{\omega \backslash X: X \in \mathcal{I}_{\mathcal{H}}\right\}$ for the filter that is dual to $\mathcal{I}_{\mathcal{H}}$. Then $\mathcal{H}$ coincides with the $\mathcal{F}_{\mathcal{H}}$-positive sets, i.e.,

$$
\mathcal{H}=\mathcal{F}_{\mathcal{H}}^{+}:=\left\{X \in[\omega]^{\omega}:\left(\forall Y \in \mathcal{F}_{\mathcal{H}}\right)(X \cap Y \neq \emptyset)\right\}
$$

Lemma 3.23. Let $\mathcal{F}$ be a filter over $\omega$ and let $\mathcal{R}$ be an ultrafilter over $\omega$. $\mathcal{R} \subseteq \mathcal{F}^{+}$ iff $\mathcal{R} \supseteq \mathcal{F}$.

So the forward implication, which will be invoked many times, uses that $\mathcal{R}$ is ultra.

Remark 3.24. Let $\mathcal{H} \subseteq[\omega]^{\omega}$ and let $\mathcal{E}$ be a filter. $\mathcal{H}$ and $\mathcal{E}$ are nnc iff for any finite-to-one function $f$ and $X \in \mathcal{H}$ there are a $E \in \mathcal{E}$ and a $Y \subseteq X$, such that $Y \in \mathcal{H}$ and such that $f[E] \cap f[H]=\emptyset$.

The following theorem provides information on $\min (\mathcal{U})$ and $\max (\mathcal{U})$.
Theorem 3.25. Assume CH and that we force with $\mathbb{M}(\mathcal{U})$ for a Milliken-Taylor ultrafilter $\mathcal{U}, \mathcal{R} \in\{\min (\mathcal{U}), \max (\mathcal{U})\}$ and $\mu$ is the generic real. After forcing with $\mathbb{M}(\mathcal{U})$, the set of positive sets

$$
(\operatorname{fil}(\mathcal{R} \cup\{\mu\}))^{+}=\left\{X \in\left([\omega]^{\omega}\right)^{\mathbf{V}^{\mathbb{M}(\mathcal{U})}}:(\forall Y \in \mathcal{R})|X \cap Y \cap \mu|=\omega\right\}
$$

is a happy family that is nowhere almost a filter in $\mathbf{V}^{\mathbb{M}(\mathcal{U})}$ (and hence it is nnc to $\mathcal{E})$ and by [30, Prop. 011] is a Ramsey ultrafilter $\mathcal{R}^{\text {ext }} \supseteq \mathcal{R} \cup\{\mu\}$ that is nnc to $\mathcal{E}$,

Proof. The theorem is proved like Theorem 3.3, however, it is much easier. Lemma 3.15, giving diagonal lower bounds, and Lemma 3.16, showing the nnc-part, are adapted to names for $(\mathcal{R} \cup\{\mu\})$-positive subsets of $\omega$. There are no new ideas.

Remark 3.26. We remark that by an analogous proof to Mathias' 30, Prop. 011], under CH any happy family that is nnc to $\mathcal{E}$ contains a Ramsey ultrafilter as a subset that is nnc to $\mathcal{E}$. So we see that instead of heading for a Milliken-Taylor ultrafilter $\mathcal{U}^{\text {ext }} \supseteq \mathcal{U} \upharpoonright \mu$ that yields of course $\min \left(\mathcal{U}^{\text {ext }}\right) \supseteq \min (\mathcal{U}) \cup\{\mu\}$ and the same for the maximum projection, we could proceed into a different direction: By Theorem 3.25 we can extend the minimum and maximum projections $\min (\mathcal{U})$, $\max (\mathcal{U})$ to new Ramsey ultrafilters in $\mathbf{V}^{\mathbb{M}(\mathcal{U})}$ and not care whether these extensions are the minimum and the maximum of a Milliken-Taylor ultrafilter extending $\mathcal{U}$. This direction will be important in Section 6

## 4. A name for a Matet-adequate family at limit stages

We define by induction on $\alpha \leq \omega_{2}$ a countable support iteration $\mathbb{P}_{\alpha}=\left\langle\mathbb{P}_{\beta}, \mathbb{M}\left(\mathcal{U}_{\gamma}\right)\right.$ : $\beta \leq \alpha, \gamma<\alpha\rangle$ such that for any $\gamma<\alpha$,

$$
\begin{align*}
& \mathbb{P}_{\gamma+1}=\mathbb{P}_{\gamma} * \mathbb{M}\left(\mathcal{U}_{\gamma}\right) \text { and } \\
& \mathbb{P}_{\gamma+1} \Vdash \mu_{\gamma}=\bigcup\left\{s:(s, \bar{a}) \in G_{\mathbb{M}\left(\mathcal{U}_{\gamma}\right)}\right\} \\
& \mathbb{P}_{\gamma} \Vdash \mathcal{U}_{\gamma} \supseteq\left(\bigcup\left\{\mathcal{U}_{\delta} \upharpoonright \mu_{\delta}\right): \delta<\gamma\right)  \tag{4.1}\\
& \quad \text { is a Milliken-Taylor ultrafilter that avoids } \mathcal{E} .
\end{align*}
$$

In Theorem 3.3 we proved that there are extension of Milliken-Taylor ultrafilters in the successor steps

$$
\begin{aligned}
\mathbb{P}_{\gamma} \Vdash_{\mathbb{P}_{\gamma}} & \left(\mathbb{M}\left(\mathcal{U}_{\gamma}\right) \Vdash_{\mathbb{M}\left(\mathcal{U}_{\gamma}\right)} \mu_{\gamma}=\bigcup\left\{s:(s, \bar{a}) \in G_{\mathbb{M}\left(\mathcal{U}_{\gamma}\right)}\right\}\right. \\
& \wedge\left(\exists \mathcal{U}_{\gamma+1} \supseteq \mathcal{U}_{\gamma}\right) \\
& \left.\left(\mathcal{U}_{\gamma+1} \text { is a Milliken-Taylor ultrafilter and } \mathcal{U}_{\gamma+1} \supseteq \mathcal{U}_{\gamma} \upharpoonright \mu_{\gamma}\right)\right) .
\end{aligned}
$$

This guarantees the continuation of our construction in the successor steps, via $\mathcal{U}_{\gamma+1} \supseteq \mathcal{U}_{\gamma} \upharpoonright \mu_{\gamma}$.

Now we consider limit steps $\alpha$. If $\operatorname{cf}(\alpha)>\omega$, we can just take $\mathbb{P}_{\alpha} \vdash \mathcal{U}_{\alpha}=\bigcup_{\gamma<\alpha} \mathcal{U}_{\gamma}$ and the inductive hypotheses will be carried on, since in proper forcing every real appears at a step of at most countable cofinality, with the only exception that for $\alpha=\aleph_{2}$ the CH gets lost. So we concentrate on the hard case, $\operatorname{cf}(\alpha)=\omega$.

Theorem 4.1. Suppose that $\mathbb{P}_{\beta}, \mathcal{U}_{\beta}$ are as in Equation (4.1), $\alpha<\omega, \operatorname{cf}(\alpha)=\omega$, $\mathbb{P}_{\alpha}$ is the countable support limit of $\left\langle\mathbb{P}_{\beta}, \mathbb{M}\left(\mathcal{U}_{\beta}\right): \beta<\alpha\right\rangle$. In $\mathbf{V}^{\mathbb{P}_{\alpha}}$, the filter $\mathcal{E}$ still generates a $P$-point and the set of positive sets

$$
\left(\bigcup_{\gamma<\alpha}\left(\mathcal{U}_{\gamma} \upharpoonright \mu_{\gamma}\right)\right)^{+}
$$

forms a Matet-adequate family such that for any $\bar{a} \in(\mathcal{U} \upharpoonright \mu)^{+}$,

$$
\left(\exists \bar{b}^{1}, \bar{b}^{2} \sqsubseteq \bar{a}\right)\left(\bar{b}^{0} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \bar{b}^{1} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge h\left[\operatorname{set}\left(\bar{b}^{1}\right)\right] \cap h\left[\left(\operatorname{set}\left(\bar{b}^{2}\right)\right]=\emptyset\right) .\right.
$$

As in Theorem 3.9, the latter implies avoidance of $\mathcal{E}$. Again CH and a routine enumeration along $\omega_{1}$ gives the following.

Corollary 4.2. Suppose that $\mathbb{P}_{\beta}, \mathcal{U}_{\beta}$ are as in Equation (4.1) and $\mathbb{P}_{\alpha}$ is the countable support limit of $\left\langle\mathbb{P}_{\beta}, \mathbb{M}\left(\mathcal{U}_{\beta}\right): \beta<\alpha\right\rangle$ and that $\mathbb{C H}$ holds in $\mathbf{V}^{\mathbb{P}_{\alpha}}$. Then

$$
\begin{gathered}
\mathbb{P}_{\alpha} \Vdash \exists \mathcal{U}_{\alpha}\left(\mathcal{U}_{\alpha} \text { is a Milliken-Taylor ultrafilter that avoids } \mathcal{E}\right. \text {, and } \\
\left.\mathcal{U}_{\alpha} \supseteq \bigcup_{\gamma<\alpha}\left(\mathcal{U}_{\gamma} \upharpoonright \mu_{\gamma}\right)\right) .
\end{gathered}
$$

Now we prove Theorem 4.1] Blass and Shelah [11, Theorem 4.1] showed that in $\mathbf{V}^{\mathbb{P}_{\alpha}}$ the closure of $\mathcal{E}$ under almost supersets is a $P$-point.

For the new part, by induction we define an increasing sequence $\bar{R}=\left\langle R_{\gamma}: \gamma<\right.$ $\alpha\rangle$ of relations $R_{\gamma}$ in $\mathbf{V}^{\mathbb{P}_{\gamma}}$ such that a property called

$$
\begin{equation*}
\text { " } \mathbb{P}_{\gamma} \text { is } R_{\gamma} \text {-preserving" } \tag{4.2}
\end{equation*}
$$

is a notion we want to carry from $\gamma<\alpha, \operatorname{cf}(\gamma)<\omega_{1}$, to $\alpha$ in addition to the property (4.1) and properness in the inductive choice of the iteration.

Now we define the relation $R_{\alpha}$ for which we want to preserve statements of the form $(\forall f)(\exists \bar{g})\left(f R_{\alpha} \bar{g}\right)$. The relation $R_{\alpha}$ will be a Borel relation on the Baire space in $\mathbf{V}^{\mathbb{P}_{\alpha}}$ that contain complex parameters from the ground model, e.g. Milliken-Taylor ultrafilters and names for Milliken-Taylor ultrafilters.

Definition 4.3. By induction on $\alpha \leq \omega_{2}$ we define the following relations.
(1) We say that a $\mathbb{P}_{\alpha}$-name $\bar{a}$ for an element of $(\text { Fin })^{\omega}$ is $\alpha$-positive if $1 \Vdash_{\mathbb{P}_{\alpha}} \bar{a} \in$ $\left(\bigcup\left\{\mathcal{U}_{\gamma} \upharpoonright \mu_{\gamma}: \gamma<\alpha\right\}\right)^{+}$.
(2) Assume that $\left\langle\mathcal{U}_{\gamma}: \gamma<\alpha\right\rangle$ is an ascending sequence of Milliken-Taylor ultrafilters $\mathcal{U}_{\gamma} \in \mathbf{V}^{\mathbb{P}_{\gamma}}$, such that $\mathbb{P}_{\gamma} \Vdash \Phi\left(\mathcal{U}_{\gamma}\right) \not Z_{\mathrm{RB}} \mathcal{E}$ and $\forall \gamma<\delta<\alpha$, $\mathbb{P}_{\delta} \Vdash \mathcal{U}_{\gamma} \upharpoonright \mu_{\gamma} \subseteq \mathcal{U}_{\delta}$. We say $f R_{\alpha} \bar{g}$ if the following holds in $\mathbf{V}^{\mathbb{P}_{\alpha}}$ :
(a) $f=(\bar{A}, h, c)$,
(b) $\bar{A}=\left\langle A_{\ell}: \ell \in \omega\right\rangle$ is a $\sqsubseteq$-descending sequence of $\alpha$-positive sequences $A_{\ell} \in(\mathrm{Fin})^{\omega}$,
(c) $h$ is finite-to-one,
(d) $c$ is a partition of $\mathrm{FU}\left(A_{0}\right)$.
(e) For $j=0,1$ we let $\bar{g}^{j}:=\left\langle g_{2 n+j}: n \in \omega\right\rangle$. Then
(i) For $j=0,1, \bar{g}^{j}$ is an $\alpha$-positive diagonal lower bound of $\bar{A}$.
(ii) For $j=0,1, \mathrm{FU}\left(\bar{g}^{j}\right)$ is in one piece of the partition $c$.
(iii) $h\left[\operatorname{set}\left(\bar{g}^{0}\right)\right] \cap h\left[\operatorname{set}\left(\bar{g}^{1}\right)\right]=\emptyset$.

So $R_{\alpha}$ is a $\mathbb{P}_{\alpha}$-name for a relation.

Definition 4.4. We say $\mathbb{P}_{\alpha}$ is $R_{\alpha}$-preserving if $\mathbb{P}_{\alpha}$ is proper and

$$
\mathbb{P}_{\alpha} \Vdash \forall f \in \operatorname{dom}\left(R_{\alpha}\right) \exists \bar{g}\left(f R_{\alpha} \bar{g}\right) .
$$

There are two main differences to the known "Case A" of iteration theorem 37, Ch XVIII], [21]: For our $R_{\alpha}$, it is not the case that for countably many tasks $f_{n}$, $n \in \omega$ there is one answer $\bar{g}, E$ such that $\forall n f R_{\alpha, n}(\bar{g}, E)$ where $R_{\alpha, n}$ is $R_{\alpha}$ up to mistakes before $n$. There are $\sqsubseteq^{*}$-incompatible positive elements $\bar{g}$. Secondly, not only the quests $f$ but also the answers $\bar{g}$ are now from the forcing extension. This differs from the traditional applications in the preservation of cardinal invariants, see e.g. [2]. We do not write tildes below the $R_{\alpha}$ 's.

Lemma 4.5. Assume $\mathrm{CH}, \alpha<\omega_{2}, \operatorname{cf}(\alpha)<\omega_{1}$. If $\mathbb{P}_{\alpha}$ is $R_{\alpha}$-preserving then

$$
\begin{aligned}
\mathbb{P}_{\alpha} \Vdash & \left(\bigcup\left\{\mathcal{U}_{\beta} \upharpoonright \mu_{\beta}: \beta<\alpha\right\}\right)^{+} \text {is a Matet-adequate family such that } \\
& \left(\forall \bar{a} \in(\mathcal{U} \upharpoonright \mu)^{+}\right)\left(\exists \bar{b}^{1}, \bar{b}^{2} \sqsubseteq \bar{a}\right) \\
& \left(\bar{b}^{0} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \bar{b}^{1} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge h\left[\operatorname{set}\left(\bar{b}^{1}\right)\right] \cap h\left[\left(\operatorname{set}\left(\bar{b}^{2}\right)\right]=\emptyset\right) .\right.
\end{aligned}
$$

Proof. This follows from Definition 4.4.
Now we carry the preservation property upwards by induction.
Lemma 4.6. Assume $\mathrm{CH}, \alpha<\omega_{2}$, and $\operatorname{cf}(\alpha)=\omega$. Let $\mathbb{P}_{\alpha}$ be the countable support limit of $\mathbb{P}_{\beta}, \beta<\alpha$. If for $\beta<\alpha$ such that $\operatorname{cf}(\beta)<\omega_{1}, \mathbb{P}_{\beta}$ is $R_{\beta}$-preserving and for any $\beta<\alpha$ Equation (4.1) holds then $\mathbb{P}_{\alpha}$ is $R_{\alpha}$-preserving.

This lemma will proved with Lemma 4.8. For definiteness, we can take $\chi=$ $\left(2^{\left|\mathbb{P}_{\alpha}\right|}\right)^{+}$. Under CH , for $\alpha<\omega_{2},\left|\mathbb{P}_{\alpha}\right| \leq \aleph_{1}$ by [36, page 96]. So $\chi=\left(2^{\aleph_{1}}\right)^{+}$is sufficiently large. The following lemma on the translation to countable elementary submodels is well-known, see [37, Theorem 2.11 and Ch. XVIII].

Lemma 4.7. The following are equivalent.
(1) $\mathbb{P}_{\alpha}$ is $R_{\alpha}$-preserving.
(2) For all $M \prec H(\chi)$ such that $\mathbb{P}_{\alpha},\left\langle\mathcal{U}_{\beta}: \beta<\alpha\right\rangle, \mathcal{E} \in M$ for all $\mathbb{P}_{\alpha}$-names $f \in M$ for all $p \in \mathbb{P}_{\alpha} \cap M$, if $p \Vdash f \in \operatorname{dom}\left(R_{\alpha}\right)$ then there is an $\left(M, \mathbb{P}_{\alpha}\right)$-generic $q \geq p$ and there is a $\mathbb{P}_{\alpha}$-name $\bar{g} \in M$ such that $q \Vdash f R_{\alpha} \bar{g}$.

The property of Lemma 4.7(2) is carried on by induction in the following slightly stronger technical form that is suitable for induction.

Lemma 4.8. The induction lemma. Suppose $\mathrm{CH}, \xi<\zeta \leq \aleph_{2}$, and $\operatorname{cf}(\zeta)<\omega_{1}$. Let $M \prec H(\chi), \zeta \in M, \mathbb{P}_{\zeta} \in M, p \in \mathbb{P}_{\zeta} \cap M$ and $q_{0} \leq p \upharpoonright \xi$ be $\left(M, \mathbb{P}_{\xi}\right)$-generic. Let $f \in M$ be a $\mathbb{P}_{\zeta}$-name such that

$$
p \Vdash_{\mathbb{P}_{\zeta}} f=\left(\left\langle A_{n}: n \in \omega\right\rangle, c, h\right) \in \operatorname{dom}\left(R_{\zeta}\right) .
$$

Then there is some $\left(M, \mathbb{P}_{\zeta}\right)$-generic condition $q \leq p \upharpoonright[\xi, \eta) \cup q_{0}$ such that $q \Vdash$ $(\exists \bar{g})\left(f R_{\zeta} \bar{g}\right)$.

Proof. Moreover we get $\operatorname{dom}\left(q_{0}\right) \backslash \xi \subseteq \zeta \cap M$. We go by induction on $\zeta$. For $\zeta=0$ there is nothing to prove, for $\zeta$ successor a proof is included in the proof of Theorem 3.3, namely in Lemmata 3.15, 3.16, 3.17, So let $\zeta$ be a limit. We fix a strictly increasing sequence $\left\langle\zeta_{\ell}: \ell<\omega\right\rangle$ with $\zeta_{0}=\xi, \zeta_{\ell} \in M$, and $\sup \zeta_{\ell}=\zeta$. We
also fix an enumeration $\left\langle D_{n}: n<\omega\right\rangle$ of the dense subsets of $\mathbb{P}_{\zeta}$ that are elements of $M$. We let $\mathcal{U}^{i}$ be a $\mathbb{P}_{\zeta}$-name in $M$ such that

$$
\begin{align*}
& \mathbb{P}_{\zeta} \Vdash \mathcal{U}^{i} \text { is idempotent and } \\
& \qquad \mathcal{U}^{i} \supseteq \operatorname{fil}\left(\bigcup\left\{\left(\mathcal{U}_{\gamma} \upharpoonright \mu_{\gamma}\right): \gamma<\zeta\right\} \cup\left\{A_{n}: n \in \omega\right\}\right) . \tag{4.3}
\end{align*}
$$

By 3.21 such a name $\mathcal{U}^{i}$ exists. We choose by induction on $n, q_{n} \in \mathbb{P}_{\zeta_{n}}$, a $\mathbb{P}_{\zeta_{n}}$-name for a $\mathbb{P}_{\zeta_{n}, \zeta}$-name $d_{n}$ for an element of $F i n$, a $\mathbb{P}_{\zeta_{n}}$ name for a $\mathbb{P}_{\zeta_{n}, \zeta}$-name $X_{n}$ for an element of $\mathcal{U}^{i}$, and a $\mathbb{P}_{\zeta_{n}}$-name of a $p_{n} \in \mathbb{P}_{\zeta_{n}, \zeta}$ with the following properties:
(a) $q_{n} \in \mathbb{P}_{\zeta_{n}}, \operatorname{dom}\left(q_{n}\right) \backslash \xi \subseteq M \cap \zeta_{n}, q_{n+1} \upharpoonright \zeta_{n}=q_{n}$,
(b) $q_{n}$ is $\left(M, \mathbb{P}_{\zeta_{n}}\right)$-generic,
(c) $q_{n+1} \Vdash_{\mathbb{P}_{\zeta_{n}}} p_{n+1} \in D_{n} \cap M \cap G$,
(d) $p_{0} \upharpoonright \zeta_{0} \geq q_{0}$ in $\mathbb{P}_{\zeta_{0}}$,
(e) $q_{n+1} \Vdash_{\mathbb{P}_{\zeta_{n+1}}} p_{n+1} \upharpoonright\left[\zeta_{n}, \zeta_{n+1}\right) \leq p_{n} \upharpoonright\left[\zeta_{n}, \zeta_{n+1}\right)\left(\right.$ in $\left.\mathbb{P}_{\zeta_{n}, \zeta_{n+1}}\right)$,
(f) $q_{1}, p_{1}, X_{0}, d_{0}, X_{1}$ is such that
$q_{1} \Vdash_{\mathbb{P}_{\zeta_{1}}}\left(p_{1} \Vdash_{\mathbb{P}_{\zeta_{1}, \zeta}}\left(X_{0}\right.\right.$ is the piece of the partition $c \upharpoonright \operatorname{FU}\left(A_{0}\right)$ that lies in $\mathcal{U}^{i}$

$$
\begin{aligned}
& \wedge d_{0}=\min _{\text {lex }, \text { Fin }}\left\{d \in X_{0} \cap \mathrm{FU}\left(A_{0}\right): X_{0} \ominus d \in \mathcal{U}^{i}\right\} \\
& \left.\left.\wedge X_{1}=X_{0} \cap\left(X_{0} \ominus d_{0}\right)\right)\right)
\end{aligned}
$$

Moreover $q_{1} \Vdash p_{1} \Vdash d_{0} \in M, q_{1} \Vdash p_{1} \in M \cap G \cap D_{0}$.
(g) $q_{n+1}, p_{n+1}, d_{n}, X_{n+1}$ is such that

$$
\begin{aligned}
q_{n+1} \Vdash_{\mathbb{P}_{\zeta_{n+1}}} & \left(p_{n+1} \in M \cap G \cap D_{n} \wedge\right. \\
& p_{n+1} \Vdash_{\mathbb{P}_{\zeta_{n+1}, \zeta}}\left(d_{n}=\min _{\text {lex }, \text { Fin }}\left\{d \in X_{n} \cap \mathrm{FU}\left(A_{n}\right): X_{n} \ominus d \in \mathcal{U}^{i}\right. \text { and }\right. \\
& \left.\min (d)>\max \left(d_{n-1}\right) \wedge h\left[d_{n-1}\right] \cap h[d]=\emptyset\right\} \\
& \left.\left.\wedge X_{n+1}=X_{n} \cap\left(X_{n} \ominus d_{n}\right)\right)\right) .
\end{aligned}
$$

Since the name $d_{n+1}$ is defined from elements in $M, q_{n+1} \Vdash_{\mathbb{P}_{\zeta_{n+1}}} p_{n+1} \Vdash_{\mathbb{P}_{\zeta_{n+1}, \zeta}}$ $d_{n+1} \in M$.
Since $M \prec H(\chi)$, such a sequence exists by the induction hypothesis and the maximum principle.

In the end we let $\bar{g}$ such that

$$
q_{n} \Vdash_{\mathbb{P}_{\zeta_{n}}} p_{n} \Vdash_{\mathbb{P}_{\zeta_{n}, \zeta}} \bar{g} \upharpoonright n=\left\langle d_{i}: i<n\right\rangle
$$

and $q=\bigcup_{n<\omega} q_{n}$ and we let $\bar{g}^{j}$ be a name such that $q \Vdash \bar{g}^{j}=\left\langle g_{2 n+j}: n<\omega\right\rangle$.
Now it is easy to see that $q, \bar{g}^{j}$ are as desired, i.e., $q \leq p$ is $\left(M, \mathbb{P}_{\zeta}\right)$ generic and

$$
\begin{equation*}
q \Vdash f R_{\alpha} \bar{g} \tag{4.4}
\end{equation*}
$$

Let $G$ be $\mathbb{P}_{\alpha}$-generic over $V$ with $q \in G$. Since $M[G] \prec H(\chi)[G]$ (again, see 37, Theorem 2.11]) there are also names $\bar{g} \in M$ as in Equation (4.4).
4.84 .1

Putting Theorem 3.3 and Theorem 4.1 together yields the following.

Theorem 4.9. Let $\mathcal{E}$ be a P-point and assume CH . Then there is a countable support iteration of proper iterands $\mathbb{P}=\left\langle\mathbb{P}_{\alpha}, \mathbb{M}\left(\mathcal{U}_{\beta}\right): \beta<\omega_{2}, \alpha \leq \omega_{2}\right\rangle$ such that in the extension $\mathcal{E}$ is a $P$-point, there at least three near-coherence classes of ultrafilters and there is a Milliken-Taylor ultrafilter of character $\mathfrak{d}=\mathfrak{c}=\aleph_{2}$.

We note that Fernández-Bréton [19] recently built a model in which, like in ours, $\operatorname{cov}(\mathcal{M})=\aleph_{1}<\mathfrak{d}=\aleph_{2}$ with a Milliken-Taylor ultrafilter.

## 5. Generalisation to $\mathrm{Fin}_{k}$

In this section we generalise the results of Sections 2, 3 and 4 from Fin to Fin $k$ for $k \geq 1$. We introduce Milliken-Taylor ultrafilters over $\operatorname{Fin}_{k}$ and Matet forcing for $\mathrm{Fin}_{k}$.

Definition 5.1. Let $k \in \omega \backslash\{0\}$ unless stated otherwise.
(1) For $p: \omega \rightarrow k+1$ we let $\operatorname{supp}(p)=\{n \in \omega: p(n) \neq 0\}$.

$$
\operatorname{Fin}_{k}=\{p: \omega \rightarrow k+1: \operatorname{supp}(p) \text { is finite } \wedge k \in \operatorname{range}(p)\}
$$

(2) For $a, b \in \operatorname{Fin}_{k}$, we let $a<b$ denote $\operatorname{supp}(a)<\operatorname{supp}(b)$, i.e., $(\forall m \in \operatorname{supp}(a))$ $(\forall n \in \operatorname{supp}(b))(m<n)$, see Def. 2.1(3). A finite or infinite sequence $\left\langle a_{i}\right.$ : $i<m \leq \omega\rangle$ of elements of $\mathrm{Fin}_{k}$ is in block-position if for any $i<j<m$, $a_{i}<a_{j}$. The set $\left(\operatorname{Fin}_{k}\right)^{\omega}$ is the set of $\omega$-sequences in block-position, also called block sequences. For $n \geq 1$, the set $\left[\mathrm{Fin}_{k}\right]_{<}^{n}$ is the set of $n$-sequences in block-position over $\operatorname{Fin}_{k}$.
(3) We define a well-order (of type $\omega$ ) $\leq_{\operatorname{lex}^{2}, \text { Fin }_{k}}$ on the set $\operatorname{Fin}_{k}$ via $a<_{\operatorname{lex}, \text { Fin }_{k}} b$ if $\max (\operatorname{supp}(a))<\max (\operatorname{supp}(b))$ or $(\max (\operatorname{supp}(a))=\max (\operatorname{supp}(b))$ and there is an $m$ such that $a \upharpoonright m=b \upharpoonright m$ and $a(m)>b(m)$. For a non-empty set $X \subseteq \operatorname{Fin}_{k}$ we let $\min _{<_{\text {lex, } \operatorname{Fin}_{k}}}(X)$ be the $\leq_{\text {lex, } \text { Fin }_{k}}$-least element of $X$, in parallel to Definition [2.1(11).
(4) For $k \geq 1, a, b \in \operatorname{Fin}_{[1, k]}$, we define the partial semigroup operation + as follows: If $\operatorname{supp}(a)<\operatorname{supp}(b)$, then $a+b \in \operatorname{Fin}_{k}$ is defined. We let $(a+b)(n)=$ $a(n)+b(n)$. Otherwise $a+b$ is undefined. Thus $a+b=a \upharpoonright \operatorname{supp}(a) \cup b \upharpoonright$ $\operatorname{supp}(b) \cup 0 \upharpoonright(\omega \backslash(\operatorname{supp}(a) \cup \operatorname{supp}(b)))$.
(5) Let $B$ be a min-unbounded subset of $\operatorname{Fin}_{k}$, i.e., for any $n, B \cap\left\{s \in \operatorname{Fin}_{k}\right.$ : $\{n\}<s\} \neq \emptyset$. We let

$$
\begin{aligned}
\mathrm{FU}_{k}(B)= & \left\{b_{n_{0}}+\cdots+b_{n_{\ell}}:\right. \\
& \left.\ell \in \omega, b_{n_{i}} \in B, b_{n_{0}}<\cdots<b_{n_{\ell}}\right\}
\end{aligned}
$$

be the partial subsemigroup of $\mathrm{Fin}_{k}$ generated by $B$. We call $B$ an $\mathrm{FU}_{k}$-set if there is a sequence $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ such that $B=\mathrm{FU}_{k}(\bar{a})$.
(6) The set $\gamma\left(\operatorname{Fin}_{k}\right)$ is the set of ultrafilters over $\operatorname{Fin}_{k}$ that contain all sets of the form $\left\{p \in \operatorname{Fin}_{k}:\{n\}<p\right\}, n \in \omega$.
(7) We lift + to $\left(\bigcup_{k \geq 1} \gamma\left(\operatorname{Fin}_{k}\right)\right)^{2}$ (so also mixed pairs are allowed) via

$$
\mathcal{U}+\mathcal{V}=\left\{X \subseteq \operatorname{Fin}_{k}:\{s:\{t: s+t \in X\} \in \mathcal{V}\} \in \mathcal{U}\right\}
$$

(8) For $A \subseteq \operatorname{Fin}_{k}, s \in \operatorname{Fin}_{k}$ and $n \in \omega$ we let $(A ;$ past $s)=\{a \in A$ : $\max (\operatorname{supp}(s))<\min (\operatorname{supp}(a))\}$. For $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}, s \in \operatorname{Fin}_{k}$ and $n \in \omega$ we let $(\bar{a} ;$ past $s)=\left\langle a_{m}: m \geq m_{0}\right\rangle$, where $m_{0}$ is the minimal $m$ such that $\max (\operatorname{supp}(s))<\min \left(\operatorname{supp}\left(a_{m}\right)\right)$.
(9) For min-unbounded sets $A, B \subseteq \operatorname{Fin}_{k}$ we let $B \sqsubseteq_{k} A$ if $B \subseteq \mathrm{FU}_{k}(A)$. We say $B$ is a $k$-condensation of $A$. We let $B \sqsubseteq_{k}^{*} A$ if there is an $n \in \omega$ such that $(B ;$ past $\{n\}) \subseteq \mathrm{FU}_{k}(A)$. For $\bar{a}, \bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ we let $\bar{b} \sqsubseteq_{k} \bar{a}$ if $\bar{b}=\left\langle b_{n}: n<\omega\right\rangle$ and $\left\{b_{n}: n<\bar{\omega}\right\} \subseteq \mathrm{FU}_{k}\left(\left\{a_{n}: n<\omega\right\}\right)$, and $\bar{b} \sqsubseteq^{*} \bar{a}$ has the obvious meaning.

So $\left(\operatorname{Fin}_{1},+\right) \cong(\operatorname{Fin}, \cup)$ via $p \mapsto \operatorname{supp}(p)$, and $\left(\left(\operatorname{Fin}_{1}\right)^{\omega}, \sqsubseteq_{1}\right) \cong\left((\operatorname{Fin})^{\omega}, \sqsubseteq\right)$ via $\left\langle a_{n}: m \in \omega\right\rangle \mapsto\left\langle\operatorname{supp}\left(a_{n}\right): n<\omega\right\rangle$. For checking whether there is a minunbounded $C \sqsubseteq_{k} A, B$, a piecewise construction recursively along $\omega$ with the aid of $<_{\text {lex, } \mathrm{Fin}_{k}}$ as in the proof of Lemma 3.15 yields $\sqsubseteq$-weakest (i.e., largest) common lower bounds. Since this is not entirely obvious in the Fin ${ }_{k}$-setting, we state it explicitly.

Lemma 5.2. Assume that $\bar{a}, \bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ and that there is a $\bar{c} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ such that $\bar{c} \sqsubseteq_{k} \bar{a}, \bar{b}$. Then there is $a \sqsubseteq_{k}$-largest witness $\bar{c}=\left\langle c_{n}: n<\omega\right\rangle$ to this, that can be found in the following recursive way:

$$
\begin{aligned}
c_{0} & =\min _{<\operatorname{lex}, \mathrm{Fin}_{k}}\left(\mathrm{FU}_{k}(\bar{a}) \cap \mathrm{FU}_{k}(\bar{b})\right), \\
c_{n+1} & =\min _{<{\operatorname{lex}, \mathrm{Fin}_{k}}\left(\mathrm{FU}_{k}\left(\bar{a} ; \text { past } c_{n}\right) \cap \mathrm{FU}_{k}\left(\bar{b} ; \text { past } c_{n}\right)\right) .} .
\end{aligned}
$$

The proof is like Lemma 2.4.
We write $\bar{c}=\bar{a} \wedge \bar{b}$ for the largest $\bar{c} \sqsubseteq_{k}, \bar{a}, \bar{b}$.
Hindman's theorem is generalised to $\left(\operatorname{Fin}_{k}\right)^{\omega}$ :
Theorem 5.3. (Hindman [24, Cor. 3.3]) Let $k \geq 1$ and $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$. For every finite colouring of $\mathrm{FU}_{k}(\bar{a})$ there is a infinite block sequence $\bar{b} \sqsubseteq_{k} \bar{a}$ such that the elements of $\mathrm{FU}_{k}(\bar{b})$ are monochromatic.
Definition 5.4. A set $\mathcal{H} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$ is called a adequate family if the following hold:
(i) $\mathcal{H}$ is closed $\sqsubseteq_{k}^{*}$-upwards.
(ii) $\mathcal{H}$ is stable, i.e., any $\sqsubseteq_{k}$-descending $\omega$-sequence of members of $\mathcal{H}$ has a $\sqsubseteq^{*}$ lower bound in $\mathcal{H}$.
(iii) $\mathcal{H}$ has the Hindman property: If $\bar{a} \in \mathcal{H}$ and $\mathrm{FU}_{k}(\bar{a})$ is partitioned into finitely many pieces then there is some $\bar{b} \sqsubseteq_{k} \bar{a}, \bar{b} \in \mathcal{H}$ such that $\mathrm{FU}_{k}(\bar{b})$ is a subset of a single piece of the partition.

Again Lemma 3.6 applies.
Definition 5.5. (1) For $\bar{a}, \bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ we write $\bar{a} \not \perp \bar{b}$ and say that $\bar{a}, \bar{b}$ are compatible, if there is $\bar{c} \sqsubseteq_{k} \bar{a}, \bar{b}$.
(2) A set $\mathcal{C} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$ is called centred, if for any finite $C \subseteq \mathcal{C}$ there is $\bar{a} \in \mathcal{C}$ that is a generalised condensation of any $\bar{c} \in C$ and if $\mathcal{C}$ is closed under finite alterations i.e., if $\bar{d} \in \mathcal{C}$ and $\bar{d}={ }^{*} \bar{e}$ then $\bar{e} \in \mathcal{C}$.
(3) A non-principal filter $\mathcal{F}$ on $\mathrm{Fin}_{k}$ is said to be an ordered-union filter if it has a basis of sets of the form $\mathrm{FU}_{k}(\bar{d})$ for $\bar{d} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$.
(4) For a $\sqsubseteq_{k}$-descending $\omega$-sequence of members of $\left(\operatorname{Fin}_{k}\right)^{\omega}\left\langle\bar{a}_{n}: n \in \omega\right\rangle$ and $\bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ we say: $\bar{b}$ is a diagonal lower bound if $\bar{b} \sqsubseteq \bar{a}_{0}$ and

$$
\left(\forall s \in \mathrm{FU}_{k}(\bar{b})\right)(\bar{b} ; \text { past } s) \sqsubseteq_{k} \bar{a}_{\max (\operatorname{supp}(s))+1} .
$$

(5) Let $\mu$ be an uncountable cardinal. An ordered-union filter is said to be $(<\mu)$ stable if, whenever it contains $\mathrm{FU}_{k}\left(\bar{b}_{\alpha}\right)$ for $\bar{a}_{\alpha} \in(\mathrm{Fin})^{\omega}, \alpha<\kappa$, for some $\kappa<\mu$, then it also contains some $\mathrm{FU}_{k}(\bar{b})$ for some $\bar{b}$ such that for each $\alpha$ there is $n_{\alpha}$ with $\left(\bar{b}\right.$; past $\left.\left\{n_{\alpha}\right\}\right) \sqsubseteq_{k} \bar{b}_{\alpha}$ ) for $\alpha<\kappa$. Such an $\bar{b}$ is called a lower bound of $\left\{\bar{b}_{\alpha}: \alpha<\kappa\right\}$. For " $<\omega_{1}$-stable" we say "stable".
(6) A stable ordered-union ultrafilter over $\mathrm{Fin}_{k}$ is called a Milliken-Taylor ultrafilter (over $\mathrm{Fin}_{k}$ ).
(7) An ultrafilter is called idempotent if $\mathcal{U}+\mathcal{U}=\mathcal{U}$.

In particular, any Milliken-Taylor ultrafilter is Matet-adequate and Lemma 3.6 holds.

Definition 5.6. Let $k \geq 1$. Conditions Matet forcing (over $\mathrm{Fin}_{k}$ ), $\mathbb{M}_{k}$, are pairs $(s, \bar{c})$ such that $s \in \operatorname{Fin}_{k}$ and $\bar{c} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ and $\operatorname{supp}(s)<\operatorname{supp}\left(c_{0}\right)$. The forcing order is $(t, \bar{d}) \leq_{k}(s, \bar{c})$ (recall the stronger condition is the smaller one) if the following holds:
(a) $s=t$ or there are $n, i_{0}<\cdots<i_{n} \in \omega$, and $j_{r} \in\{0, \ldots, k-1\}$ for $r \leq n$ with at least one $j_{r}=0$ such that $t$ is a sum in the sense of Def. 5.1(5) of the form

$$
t=s+c_{i_{0}}+\cdots+c_{i_{n}}
$$

(b) $\bar{d} \sqsubseteq_{k} \bar{c}$ (see Def. $\left.5.1(9)\right)$.

In the case of $s=t$ we call $(t, \bar{b})$ a pure extension of $(s, \bar{a})=p . s$ is called the trunk of $p$ and $\bar{a}$ is called the pure part of $p$.

Since the trunk and the pure part are in block position and since the pure parts are block-sequences, $s \upharpoonright \operatorname{supp}(s)=t \upharpoonright \operatorname{supp}(s)$ is equivalent to $s \upharpoonright(\max (\operatorname{supp}(s))+$ $1)=t \upharpoonright(\max (\operatorname{supp}(s))+1)$.

Definition 5.7. Given a Matet-adequate family $\mathcal{H} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$, the notion of forcing $\mathbb{M}_{k}(\mathcal{H})$ consists of all pairs $(s, \bar{a})$ such that $\bar{a} \in \mathcal{H}$. The forcing order is the same as in the Matet forcing.
Definition 5.8. Let $\mathcal{H}$ be a subset of $\mathscr{P}\left(\operatorname{Fin}_{k}\right), X \subseteq \operatorname{Fin}_{k}, s \in \operatorname{Fin}_{k}$.
(1) For $1 \leq i \leq k$ we let $\operatorname{set}_{i}(s)=s^{-1}[\{i\}]$, $_{\operatorname{set}_{i}}[X]=\bigcup\left\{\operatorname{set}_{i}(s): s \in X\right\}$. $\operatorname{set}[X]=\bigcup\{\operatorname{supp}(s): s \in X\}$.
(2) For $1 \leq i \leq k$ we let $\min _{i}(s)=\min \left(s^{-1}[\{i\}]\right), \min _{i}[X]=\left\{\min _{i}(s): s \in X\right\}$. We have the analogous notions for max.
(3) The core of $\mathcal{H}$ is the set $\Phi(\mathcal{H}) \subseteq[\omega]^{\omega}$ such that

$$
X \in \Phi(\mathcal{H}) \operatorname{iff}(\exists Y \in \mathcal{H})(\operatorname{set}[Y] \subseteq X)
$$

(4) For $j=1, \ldots, k$, the core of $\mathcal{H}$ at colour $j$ is the set $\Phi_{j}(\mathcal{H}) \subseteq[\omega]^{\omega}$ such that

$$
X \in \Phi_{j}(\mathcal{H}) \text { iff }(\exists Y \in \mathcal{H})\left(\operatorname{set}_{j}[Y] \subseteq X\right)
$$

(5) The minimum projection of $\mathcal{H}$ at colour $j$ is the set

$$
\min _{j}(\mathcal{H})=\left\{\min _{i}[Y]: Y \in \mathcal{H}\right\}
$$

and analogously we define $\max _{j}(\mathcal{H})$, the maximum projection at colour $j$.
(6) Let $\mathcal{E}$ be an ultrafilter over $\omega$. We say $\mathcal{H}$ avoids $\mathcal{E}$ if $\Phi(\mathcal{H})$ is nnc to $\mathcal{E}$.
(7) The $\mathbb{M}_{k}(\mathcal{H})$-generic function from $\omega$ to $k+1$ is

$$
\mu=\bigcup\{s \upharpoonright(\max (\operatorname{supp}(s))+1):(\exists \bar{a})((s, \bar{a}) \in G)\} .
$$

A name for $\mu$ is

$$
\underset{\sim}{\mu}=\bigcup\left\{\left\langle(s \upharpoonright(\max (\operatorname{supp}(s))+1),(s, \bar{a})\rangle:(s, \bar{a}) \in \mathbb{M}_{k}(\mathcal{H})\right\} .\right.
$$

Usually we do not write the tildes.
(8) In addition we define the generic $i$-fibres for $i=1, \ldots, k$ by letting

$$
\mu_{i}:=\mu^{-1}[\{i\}]
$$

Again we have $\left\{\min \left(y^{-1}[\{i\}]\right): y \in \mathrm{FU}_{k}(\bar{a})\right\}=\left\{\min \left(a_{n}^{-1}[\{i\}]\right): n \in \omega\right\}$ and $\bigcup\left\{b^{-1}[\{i\}]: b \in \mathrm{FU}(\bar{a})\right\}=\bigcup\left\{a_{n}^{-1}[\{i\}]: n \in \omega\right\}$. Sometimes we identify each $\mathrm{FU}_{k}$-set $\mathrm{FU}_{k}(\bar{a})$ with its generating $\bar{a} \in\left(\mathrm{Fin}_{k}\right)^{\omega}$. Especially in the forcing notion $\mathbb{M}(\mathcal{H})$ we think of $\mathcal{H}$ as a subset of $\left(\operatorname{Fin}_{k}\right)^{\omega}$ even when we insert an Milliken-Taylor ultrafilter $\mathcal{U}$ for $\mathcal{H}$.

Remark 5.9. In the case of a centred adequate family $\mathcal{C} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$, a density argument shows for any $j=1, \ldots, k$,

$$
\mathbb{M}_{k}(\mathcal{C}) \Vdash \mu_{j} \in[\omega]^{\omega} \wedge\left(\forall X \in \Phi_{j}(\mathcal{C})\right)\left(\mu_{j} \subseteq^{*} X\right)
$$

The proof of the following theorem is carried out as in the original. It makes frequent use of the good properties from Lemma 3.6 .
Theorem 5.10. (Generalisation of [17, " $\leftarrow$ " Theorem 4, " $\rightarrow$ " Cor. 2.5, this direction works also with non- $P$ ultrafilters]) Let $\mathcal{U}$ be a Milliken-Taylor ultrafilter over $\mathrm{Fin}_{k}$ and let $\mathcal{W}$ be a P-point. $\mathcal{W} \not ¥_{R B} \Phi(\mathcal{U})$ iff $\mathcal{W}$ continues to generate an ultrafilter after we force with $\mathbb{M}_{k}(\mathcal{U})$.

Now here is the Fin ${ }_{k}$-analogon to Theorem 3.3
Theorem 5.11. Let $\mathcal{E}$ be a P-point and let $\mathcal{U}$ be a Milliken-Taylor ultrafilter over $\operatorname{Fin}_{k}$ such that $\Phi(\mathcal{U}) \not Z_{R K} \mathcal{E}$. In $\mathbf{V}^{\mathbb{M}_{k}(\mathcal{U})}$ there is a Milliken-Taylor ultrafilter $\mathcal{U}^{\text {ext }} \supseteq \mathcal{U} \upharpoonright \mu$ with $\Phi\left(\mathcal{U}^{\text {ext }}\right) \not Z_{R K} \mathcal{E}$.

We introduce some notions that allow us to adapt the proof of Theorem 3.3 to a proof of Theorem 5.11.

Definition 5.12. Let $\mathcal{C} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$ be centred. $\mathcal{C}^{+}=\left\{\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}: \forall \bar{c} \in \mathcal{C}, \bar{c} \not \perp \bar{a}\right\}$
Definition 5.13. Let $f: \omega \rightarrow(k+1)$ and let $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ and let $\mathcal{U} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$.
(1) We let $\bar{a} \upharpoonright f=\left\langle a_{n}: a_{n}=f \upharpoonright \operatorname{supp}\left(a_{n}\right), n \in \omega\right\rangle$.
(2) We let $\mathcal{U} \upharpoonright f=\{\bar{a} \upharpoonright f: \bar{a} \in \mathcal{U}\}$.

Density arguments show:
Lemma 5.14. Let $\mathcal{U}$ be a Milliken-Taylor ultrafilter over $\mathrm{Fin}_{k}$ and let $\mu$ be the generic function, see Def. 5.8(7). Then

$$
\begin{gathered}
1 \Vdash_{\mathbb{M}_{k}(\mathcal{U})} \mu: \omega \rightarrow(k+1) . \\
1 \Vdash_{\mathbb{M}_{k}(\mathcal{U})}(\forall \bar{a} \in \mathcal{U}) \bar{a} \upharpoonright \mu \in\left(\operatorname{Fin}_{k}\right)^{\omega} .
\end{gathered}
$$

Also Theorem 3.9 is generalised, and the following now is proved literally as there.

Theorem 5.15. After forcing with $\mathbb{M}_{k}(\mathcal{U}),(\mathcal{U} \upharpoonright \mu)^{+}$is a Matet-adequate family for any finite-to-one $h$, for any $\bar{a} \in(\mathcal{U} \upharpoonright \mu)^{+}$,

$$
\left(\exists \bar{b}^{1}, \bar{b}^{2} \sqsubseteq \bar{a}\right)\left(\bar{b}^{0} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge \bar{b}^{1} \in(\mathcal{U} \upharpoonright \mu)^{+} \wedge h\left[\operatorname{set}\left(\bar{b}^{1}\right)\right] \cap h\left[\left(\operatorname{set}\left(\bar{b}^{2}\right)\right]=\emptyset\right) .\right.
$$

Thus Theorem 5.11 is proved. There is no problem in generalising the iteration theory from Section 4 and hence we arrive at the following result:

Theorem 5.16. Assume CH and let $k \geq 1$. Then there is a countable support iteration of proper iterands $\mathbb{P}=\left\langle\mathbb{P}_{\alpha}, \mathbb{M}_{k}\left(\mathcal{U}_{\beta}\right): \beta<\omega_{2}, \alpha \leq \omega_{2}\right\rangle$ such that in the extension $\mathcal{E}$ is a P-point and there is a Milliken-Taylor ultrafilter over $\mathrm{Fin}_{k}$ of character $\mathfrak{c}=\aleph_{2}=\mathfrak{d}$.

The rest of the section is not used in the main theorem.
Now we are concerned with the number of near-coherence classes among the ultrafilters that contain $\Phi(\mathcal{U})$ as a subset.

The following generalises [9, Theorem 38] and adds a new aspect:
Theorem 5.17. For any union-ultrafilter $\mathcal{U}$ over $\operatorname{Fin}_{k}$, all the ultrafilters among the projections

$$
\min _{i}(\mathcal{U}), i=1,2 \ldots, k
$$

are nearly coherent to $\min _{k}(\mathcal{U})$ and that class is different from the class of $\max _{k}(\mathcal{U})$, which is the class of any of the ultrafilters among

$$
\max _{j}(\mathcal{U}), j=1, \ldots, k
$$

Proof. We let $M \subseteq\{1, \ldots k-1\}$ be maximal such that for any $m \in M$ the set of $X \in \mathcal{U}$ such that $\operatorname{set}_{m}[X]$ is infinite is $\subseteq$-dense in $\mathcal{U}$. Then exactly for $m \in$ $M \cup\{k\}, \max _{m}(\mathcal{U})$ and $\min _{m}(\mathcal{U})$ are ultrafilters. Recall, ultrafilter means nonprincipal ultrafilter. by [7, Proposition 3.9].

In [9, Section 6] Blass proves that the minimum and the maximum class are different.

Theorem 5.18. Let $\mathcal{U}$ be a Milliken-Taylor ultrafilter over $\operatorname{Fin}_{k}$. Let $M$ be as above. The cores $\Phi_{j}(\mathcal{U}), j \in M \cup\{k\}$, are all nearly coherent.
Proof. Let $A=\mathrm{FU}_{k}(\bar{a}) \in \mathcal{U}$. We define $I_{0}=\left[0, \max \left(\operatorname{supp}\left(a_{0}\right)\right)\right)$,
$I_{n+1}=\left[\max \left(\operatorname{supp}\left(a_{n}\right)\right), \max \left(\operatorname{supp}\left(a_{n+1}\right)\right)\right)$. Then we take a finite-to-one function $h_{\bar{a}}$ that is constant on $I_{n}$ for $n \in \omega$. Then for any $i, j \in M$,

$$
(\forall n \in \omega)\left(h_{\bar{a}}\left[\operatorname{set}_{i}\left(a_{n}\right)\right] \cap h_{\bar{a}}\left[\operatorname{set}_{j}\left(a_{n}\right)\right] \neq \emptyset\right)
$$

Since $\mathcal{U}$ is centred, for any $\operatorname{FU}(\bar{b}), \operatorname{FU}(\bar{c}) \in \mathcal{U}$ there is $\bar{d} \sqsubseteq_{k} \bar{a}, \bar{b}, \bar{c}, \operatorname{FU}(\bar{d}) \in \mathcal{U}$. Hence we have for $\bar{d}=\left\langle d_{\ell}: \ell<\omega\right\rangle$ for any $\ell \in \omega$ that there are natural numbers $n, m, r \geq 1$ and natural numbers $i_{1}<\cdots<i_{n}, j_{1}<\cdots<j_{m}, k_{1}<\cdots<k_{r}$, such that

$$
d_{\ell}=a_{i_{1}}+\cdots+a_{i_{n}}=b_{j_{1}}+\cdots+b_{j_{m}}=c_{k_{1}}+\cdots+c_{k_{r}} .
$$

Then

$$
h_{\bar{a}}\left[\operatorname{set}_{i}\left(d_{\ell}\right)\right] \cap h_{\bar{a}}\left[\operatorname{set}_{j}\left(d_{\ell}\right)\right] \text { has size at least } \max (n, m, r) .
$$

Hence

$$
h_{\bar{a}}\left[\bigcup\left\{\operatorname{set}_{i}\left(d_{\ell}\right): \ell \in \omega\right\}\right] \cap h_{\bar{a}}\left[\bigcup\left\{\operatorname{set}_{j}\left(d_{\ell}\right): \ell \in \omega\right\}\right] \text { is infinite. }
$$

Thus also the superset

$$
h_{\bar{a}}\left[\bigcup\left\{\operatorname{set}_{i}\left(b_{\ell}\right): \ell \in \omega\right\}\right] \cap h_{\bar{a}}\left[\bigcup\left\{\operatorname{set}_{j}\left(c_{\ell}\right): \ell \in \omega\right\}\right] \text { is infinite. }
$$

Remark 5.19. Theorem5.18 can also be proved with the help of Theorem5.10 and the following folklore result.
Proposition 5.20. Any forcing that diagonalises two ncc filters adds a dominating real.

Proof. Let $\mathcal{F}$ and $\mathcal{F}^{\prime} \in \mathbf{V}$ be nnc filters and let $x, y \in \mathbf{V}[G]$ be such that $(\forall F \in$ $\mathcal{F})\left(x \subseteq^{*} F\right),\left(\forall F^{\prime} \in \mathcal{F}^{\prime}\right)\left(y \subseteq^{*} F^{\prime}\right)$. Then by the next lemma,

$$
n \mapsto \max \{\min (x \backslash(n+1)), \min (y \backslash(n+1))\}
$$

is a dominating function.
Lemma 5.21. (Proof of [6, Theorem 3.2]) Let $\mathcal{V}$, $\mathcal{W}$ be non-principal filters over $\omega$. $\mathcal{V}$ is nearly coherent to $\mathcal{W}$ iff

$$
\{\max (\operatorname{next}(\cdot, X), \operatorname{next}(\cdot, Y)): X \in \mathcal{V}, Y \in \mathcal{W}\}
$$

is not $a \leq^{*}$-dominating family.
We give a proof for the direction we use: Assume that $\mathcal{V}$ and $\mathcal{W}$ are not nearly coherent. Let $h \in{ }_{\tilde{h}}{ }^{\omega} \omega$ be given, w.l.o.g. we assume that $h$ is strictly increasing and $h(0)>0$. We let $\tilde{h}$ be the iterate of $h: \tilde{h}(0)=0, \tilde{h}(n+1)=h(\tilde{h}(n))$. We let $f_{e}(n)=i$ for $n \in[\tilde{h}(2 i), \tilde{h}(2 i+2))$ and we let $\tilde{h}(-1)=0$ and $f_{o}(n)=i$ for $n \in[\tilde{h}(2 i-1), \tilde{h}(2 i+$ $1)$ ). Then there are $V_{e}, V_{o} \in \mathcal{V}$ and $W_{e}, W_{0} \in \mathcal{W}$ such that $f_{e}\left[V_{e}\right] \cap f_{e}\left[W_{e}\right]=\emptyset$ and $f_{o}\left[V_{o}\right] \cap f_{o}\left[W_{o}\right]=\emptyset$. Since $\mathcal{V}$ and $\mathcal{W}$ are filters, we can assume $V_{e}=V_{o}$ and $W_{e}=W_{o}$. Then for any $n \in \omega$ we have $\max \left(\operatorname{next}\left(n, V_{e}\right)\right.$, $\left.\operatorname{next}\left(n, W_{e}\right)\right) \geq h(n)$.

Now we finish the alternative proof of Theorem 5.18: $\mathbb{M}_{k}(\mathcal{U})$ preserves $\mathcal{E}$ according to Theorem 5.10 and hence does not add a dominating real. However $\mathbb{M}_{k}(\mathcal{U})$ diagonalises $\Phi_{j}(\mathcal{U})$ for $j=1, \ldots, k$ by Remark 5.9. By Proposition 5.20 all the $\Phi_{j}(\mathcal{U}), j=1, \ldots, k$, are nearly coherent.

## 6. A Ramsey subspace of the space of $\mathrm{Fin}_{k}$-SEQUENCes

Now we change from the Hindman $\mathrm{Fin}_{k}$ space to the Gowers Fin $k$ space, i.e., we incorporate the Tetris operation and use the resulting generalised type of condensation as partial order. Then we localise the space $\left(\left(\operatorname{Fin}_{k}\right)^{\omega}, \sqsubseteq_{k}^{\mathrm{Tetr}}\right)$ by choosing $2 k$ pairwise nnc Ramsey ultrafilters $\mathcal{R}_{i, \min }, \mathcal{R}_{i, \max }, i=1, \ldots, k$, that will serve as representatives of names of near-coherence classes and get a subspace $\left(\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}}), \sqsubseteq_{k}^{\mathrm{Tetr}}\right)$, see Def. 6.8. We show that this space has good Ramsey theoretic properties, as in Theorem 6.15, and we introduce Gowers-Milliken-Taylor ultrafilters.

We tell more about our plans: In Section 7 we define a variant of Matet forcing with a non-centred reservoir that is given by the sequences $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$. The resulting forcings are in contrast to the partial order $\mathbb{M}_{k}(\mathcal{U})$ with a Milliken-Taylor ultrafilter $\mathcal{U}$ (or to $\mathbb{G M}_{k}(\mathcal{U})$ with a Gowers-Milliken-Taylor ultrafilter $\mathcal{U}$ ) not $\sigma$ centred. Nevertheless they still fulfil Axiom A and hence are proper.

In order to prove that the new forcings are proper, we insert this section whose main result, Theorem 6.16, is a common strengthening of Gowers' theorem and of Blass' theorem [7, Theorem 2.2].
Definition 6.1. Let $k \in \omega \backslash\{0\}$ unless stated otherwise.
(1) For any $j \geq 2$ we define on $\operatorname{Fin}_{j}$ the Tetris operation: $T_{j}: \operatorname{Fin}_{j} \rightarrow \operatorname{Fin}_{j-1}$ by $T_{j}(p)(n)=\max \{p(n)-1,0\}$ and let $T=\bigcup\left\{T_{j}: 2 \leq j \leq k\right\}$.

For $\bar{a} \in\left(\operatorname{Fin}_{j}\right)^{\omega}$, we write $T[\bar{a}]$ for $\left\langle T\left(a_{n}\right): n<\omega\right\rangle$. For $X \subseteq \operatorname{Fin}_{j}$, we write $T[X]$ for $\{T(x): x \in X\}$.
(2) Let $B$ be a min-unbounded subset of $\operatorname{Fin}_{k}$. We let

$$
\begin{aligned}
\operatorname{TFU}_{k}(B)= & \left\{T^{\left(j_{0}\right)}\left(b_{n_{0}}\right)+\cdots+T^{\left(j_{\ell}\right)}\left(b_{n_{\ell}}\right):\right. \\
& \ell \in \omega, b_{n_{i}} \in B \\
& \left.b_{n_{0}}<\cdots<b_{n_{\ell}}, j_{i} \in k,(\exists i \leq \ell)\left(j_{i}=0\right)\right\}
\end{aligned}
$$

be the partial subsemigroup of $\operatorname{Fin}_{k}$ generated by $B$. Here $T^{(0)}$ is the identity, $T^{(1)}=T, T^{(j+1)}=T \circ T^{(j)}$.
(3) For $\bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ we let $\operatorname{TFU}_{k}(\bar{b})=\operatorname{TFU}_{k}\left(\left\{b_{n}: n \in \omega\right\}\right)$. We call $B$ a $\operatorname{TFU}_{k}$ set if $B=\operatorname{TFU}_{k}(\bar{b})$ for some $\bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$.
(4) For $j \geq 2$, we define $\mathrm{T}: \gamma\left(\mathrm{Fin}_{j}\right) \rightarrow \gamma\left(\mathrm{Fin}_{j-1}\right)$ via

$$
\mathrm{T}(\mathcal{U})=\left\{X \subseteq \operatorname{Fin}_{j-1}:\{s: T(s) \in X\} \in \mathcal{U}\right\}
$$

(5) For min-unbounded sets $A, B \subseteq \operatorname{Fin}_{k}$ we let $B \sqsubseteq_{k}^{\mathrm{Tetr}} A$ if $B \subseteq \operatorname{TFU}_{k}(A)$. Note that here $k$ is not allowed to drop. We say $B$ is a $k$-Tetris-condensation of $A$. We write $B \sqsubseteq_{k}^{\mathrm{Tetr}, *} A$ if there is an $n \in \omega$ such that ( $B$; past $\left.n\right) \subseteq \operatorname{TFU}_{k}(A)$.
(6) We introduce the Tetris condensation order $\sqsubseteq_{k}^{\mathrm{Tetr}}$ on sequences. For $\bar{a}, \bar{b} \in$ $\left(\operatorname{Fin}_{k}\right)^{\omega}$ we let $\bar{b} \sqsubseteq_{k}^{\text {Tetr }} \bar{a}$ if $\bar{b}=\left\langle b_{n}: n<\omega\right\rangle$ and $\left\{b_{n}: n<\omega\right\} \subseteq \operatorname{TFU}_{k}\left(\left\{a_{n}\right.\right.$ : $n<\omega\}$ ), and $\bar{b} \sqsubseteq_{k}^{\mathrm{Tetr}, *} \bar{a}$ has the obvious meaning.

From the following lemma we will use only the part of the statement that the described procedure produces a lower bound.

Lemma 6.2. Assume that $\bar{a}, \bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ and that there is a $\bar{c} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ such that $\bar{c} \sqsubseteq_{k}^{\mathrm{Tetr}} \bar{a}, \bar{b}$. Then there is $a \sqsubseteq_{k}^{\mathrm{Tetr}}$-largest witness $\bar{c}$ to this, that can be gotten in the following recursive way:

$$
\begin{aligned}
c_{0} & =\min _{<{\operatorname{lex}, \operatorname{Fin}_{k}}\left(\operatorname{TFU}_{k}(\bar{a}) \cap \operatorname{TFU}_{k}(\bar{b})\right),}^{c_{n+1}}
\end{aligned}=\min _{<{\operatorname{lex}, \mathrm{Fin}_{k}}\left(\operatorname{TFU}_{k}\left(\bar{a} ; \text { past } c_{n}\right) \cap \operatorname{TFU}_{k}\left(\bar{b} ; \text { past } c_{n}\right)\right) .} .
$$

The proof that $\bar{c}$ is the largest lower bound requires additional analysis in the second subcase of the third case in the proof of Proposition [2.4. due to the Tetris operation. We skip it.

An important and deep property of the space $\left(\left(\operatorname{Fin}_{k}\right)^{\omega}, \sqsubseteq_{k}^{\mathrm{Tetr}}\right)$ is the following:
Theorem 6.3. (Gowers, see e.g. [22], [40, Theorem 2.22]) Let $k \geq 1$ and $\bar{a} \in$ $\left(\operatorname{Fin}_{k}\right)^{\omega}$. For every finite colouring of $\operatorname{TFU}_{k}(\bar{a})$ there is a infinite block sequence $\bar{b} \sqsubseteq_{k}^{\text {Tetr }} \bar{a}$ such that the elements of $\mathrm{TFU}_{k}(\bar{b})$ are monochromatic.

The following proposition gives a first picture:
Proposition 6.4. For each $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ there is a $\bar{b} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}$ such that for each $s \in \operatorname{TFU}_{k}(\bar{b})$ we have

$$
\begin{equation*}
\min _{1}(s)<\min _{2}(s)<\cdots<\min _{k}(s)<\max _{k}(s)<\max _{k-1}(s)<\cdots<\max _{1}(s) \tag{6.1}
\end{equation*}
$$

HEIKE MILDENBERGER

Proof. For $s \in \operatorname{TFU}_{k}(\bar{a})$ we let $c(s)=1$ if $s$ fulfils (6.1) and $c(s)=0$ otherwise. By Gowers' Theorem there is $\bar{b} \sqsubseteq_{k}^{\text {Tetr }} \bar{a}$, such that $\operatorname{TFU}_{k}(\bar{b})$ is monochromatic for $c$. We show that the colour can only be 1 . We take $s_{i} \in \operatorname{TFU}_{k}(\bar{b}), s_{1}<s_{2}<\cdots<s_{2 k-1}$. Then

$$
\begin{align*}
s= & T^{(k-1)}\left(s_{1}\right)+T^{(k-2)}\left(s_{2}\right)+\cdots+T\left(s_{k-1}\right)+s_{k}  \tag{6.2}\\
& +T\left(s_{k+1}\right)+\cdots+T^{(k-1)}\left(s_{2 k-1}\right) \in \operatorname{TFU}_{k}(\bar{b})
\end{align*}
$$

fulfils $c(s)=1$.

## Definition 6.5.

(1) A non-principal filter $\mathcal{F}$ over $\mathrm{Fin}_{k}$ is said to be an Tetris-ordered-union filter if it has a basis of sets of the form $\operatorname{TFU}_{k}(\bar{d})$ for $\bar{d} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$.
(2) For a $\sqsubseteq_{k}^{\mathrm{Tetr}}$-descending $\omega$-sequence of members of $\left(\operatorname{Fin}_{k}\right)^{\omega}\left\langle\bar{a}_{n}: n \in \omega\right\rangle$ and $\bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ we say: $\bar{b}$ is a diagonal lower bound if $\bar{b} \sqsubseteq_{k}^{\text {Tetr }} \bar{a}_{0}$ and

$$
\left(\forall s \in \operatorname{TFU}_{k}(\bar{b})\right)(\bar{b} ; \text { past } s) \sqsubseteq_{k}^{\mathrm{Tetr}} \bar{a}_{\max (\operatorname{supp}(s))+1}
$$

(3) Let $\mu$ be an uncountable cardinal. A Tetris-ordered-union filter is said to be $(<\mu)$-stable if, whenever it contains $\operatorname{TFU}_{k}\left(\bar{b}_{\alpha}\right)$ for $\bar{b}_{\alpha} \in\left(\operatorname{Fin}_{k}\right)^{\omega}, \alpha<\kappa$, for some $\kappa<\mu$, then it also contains some $\operatorname{TFU}_{k}(\bar{b})$ for some $\bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ such that for each $\alpha$ there is $n_{\alpha}$ with $\left(\bar{b}\right.$; past $\left.\left\{n_{\alpha}\right\}\right) \sqsubseteq_{k}^{\text {Tetr }} \bar{b}_{\alpha}$ for $\alpha<\kappa$. Such an $\bar{b}$ is called a lower bound of $\left\{\bar{b}_{\alpha}: \alpha<\kappa\right\}$. For " $<\omega_{1}$-stable" we say "stable".
(4) A stable Tetris-ordered-union ultrafilter is called a Gowers-Milliken-Taylor ultrafilter.

Definition 6.6. A set $\mathcal{H} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$ is called a Gowers-adequate family if the following hold:
(i) $\mathcal{H}$ is closed $\sqsubseteq_{k}^{\mathrm{Tetr}, *}$-upwards.
(ii) $\mathcal{H}$ is stable, i.e., any $\sqsubseteq_{k}^{\mathrm{Tetr}}$-descending $\omega$-sequence of members of $\mathcal{H}$ has a $\sqsubseteq_{k}^{\mathrm{Tetr}, *}$-lower bound in $\mathcal{H}$.
(iii) $\mathcal{H}$ has the Gowers property: If $\bar{a} \in \mathcal{H}$ and $\operatorname{TFU}_{k}(\bar{a})$ is partitioned into finitely many pieces then there is some $\bar{b} \sqsubseteq_{k}^{\text {Tetr }} \bar{a}, \bar{b} \in \mathcal{H}$, such that $\operatorname{TFU}_{k}(\bar{b})$ is a subset of a single piece of the partition.

In particular, any Gowers-Milliken-Taylor ultrafilter is Gowers-adequate. Gowersadequate families have better properties than stated in the definition; the analogue to Lemma 3.6 hold for them.

Definition 6.7. In the general case of $i \in\{1, \ldots, k\}, x \in\{\min , \max \}$, we let the variable $x$ range over $\{\min , \max \}$, and we also write $x_{i}(a)$ for $\min _{i}(a), \max _{i}(a)$. We call $i \in\{1, \ldots, k\}$ sometimes a coordinate, a value or a level.

We introduce a new space, called $\left(\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}}), \sqsubseteq_{k}^{\text {Tetr }}\right)$, the one advertised in the Equation (1.1) in the introduction.

Definition 6.8. Let $k \geq 1$ and let

$$
\overline{\mathcal{R}}=\left\langle\mathcal{R}_{i, x}: i=1, \ldots, k, x=\min , \max \right\rangle
$$

be a $\{1, \ldots, k\} \times\{\min , \max \}$-sequence of pairwise nnc Ramsey ultrafilters. We define

$$
\begin{align*}
\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})= & \left\{\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}: \forall\left(X_{i} \in \mathcal{R}_{i, \min }, Y_{i} \in \mathcal{R}_{i, \max }\right)_{1 \leq i \leq k}\right. \\
& \left.\left(\exists^{\min -\mathrm{unb}} s \in \operatorname{TFU}_{k}(\bar{a})\right) \bigwedge_{1 \leq i \leq k}\left(\min _{i}(s) \in X_{i} \wedge \max _{i}(s) \in Y_{i}\right)\right\} \tag{6.3}
\end{align*}
$$

Here we write $\left(\exists^{\min -\mathrm{unb}} s\right)$ as a abbreviation for "the set of witnesses $s$ in minunbounded".

Remark 6.9. We remark that Equation(6.3) is equivalent to

$$
\begin{aligned}
\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})= & \left\{\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}: \forall\left(X_{i} \in \mathcal{R}_{i, \min }, Y_{i} \in \mathcal{R}_{i, \max }\right)_{1 \leq i \leq k}\right. \\
& \left.\left(\exists \bar{b} \sqsubseteq_{k}^{\operatorname{Tetr}} \bar{a}\right)(\forall n) \bigwedge_{1 \leq i \leq k}\left(\min _{i}\left(b_{n}\right) \in X_{i} \wedge \max _{i}\left(b_{n}\right) \in Y_{i}\right)\right\} .
\end{aligned}
$$

However, it speaks about the $b_{n}$ and not about the elements of $\operatorname{TFU}_{k}(\bar{b})$.
First we recall [7, Lemma 1.1]:
Lemma 6.10. Let $\mathcal{R}_{1, \min }, \mathcal{R}_{1, \max }$ be nnc Ramsey ultrafilters, $X_{1} \in \mathcal{R}_{1, \min }, Y_{1} \in$ $\mathcal{R}_{1, \max }$ and let $\left(B_{n}\right)_{n}$ be a descending sequence of elements of $\mathcal{R}_{1, \min },\left(D_{n}\right)_{n}$ be a descending sequence of elements of $\mathcal{R}_{1, \max }$. Then there are $X_{1}^{1} \subseteq X_{1}, Y_{1}^{1} \subseteq Y_{1}$, $X_{1}^{1} \in \mathcal{R}_{1, \text { min }}, Y_{1}^{1} \in \mathcal{R}_{1, \text { max }}$ such that
(1) $\left(\forall x \in X_{1}^{1}\right)\left(\forall y \in Y_{1}^{1}\right)\left(y<x \rightarrow x \in B_{y}\right)$.
(2) $\left(\forall y \in Y_{1}^{1}\right)\left(\forall x \in X_{1}^{1}\right)\left(x<y \rightarrow y \in D_{x}\right)$.
(3) In the increasing enumeration of $X_{1}^{1} \cup Y_{1}^{1}$ the elements of $X_{1}^{1}$ and $Y_{1}^{1}$ alternate.

Lemma 6.11. There are $\sqsubseteq_{k}^{*}$-incompatible elements in $\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$.
Proof. For notational simplicity we assume that $k=1$ and the Ramsey ultrafilters are $\mathcal{R}_{\text {min }} \mathcal{R}_{\text {max }}$. For transferring the situation to the general case, just replace the value 1 by $k$ and work only with the top ultrafilters $\mathcal{R}_{k, \text { min }}, \mathcal{R}_{k, \text { max }}$. Lemma 6.10 applied to $X_{1}=Y_{1}=\omega, A_{n}=B_{n}=[2 n, \omega)$ yields sets $X \in \mathcal{R}_{\min }$ and $Y \in \mathcal{R}_{\max }$ such that in the increasing enumeration $\left\langle x_{n}: n<\omega\right\rangle$ of $X \cup Y$ the even numbers just give $X$ and the odd number just give $Y$ and that the $x_{n}$ have distance at least 2. Then we take a natural number, call $\ell_{n}$, such that $x_{2 n}<\ell_{n}<x_{2 n+1}$. Then

$$
\begin{aligned}
& \bar{a}=\left\langle\left\{x_{2 n}, x_{2 n+1}\right\}: n \in \omega\right\rangle \\
& \bar{b}=\left\langle\left\{x_{2 n}, \ell_{n}, x_{2 n+1}\right\}: n \in \omega\right\rangle
\end{aligned}
$$

have

$$
\begin{equation*}
X=\left\{\min _{1}\left(a_{n}\right): n \in \omega\right\} \wedge Y=\left\{\max _{1}\left(a_{n}\right): n \in \omega\right\} \tag{6.5}
\end{equation*}
$$

and hence $\bar{a} \in\left(\operatorname{Fin}_{1}\right)\left(\mathcal{R}_{\text {min }}, \mathcal{R}_{\max }\right)$, and the same holds for $\bar{b}$. Obviously, the conditions $\bar{a}, \bar{b} \in\left(\operatorname{Fin}_{1}\right)^{\omega}(\overline{\mathcal{R}})$ are $\sqsubseteq_{1}^{\text {Tetr }}$-incompatible.

By the way, our only possibility to verify that some sequence is in $\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ is to construct one that has ultrafilter projections as in Equation (6.5).

By applying e.g. the trick in [7, Cor. 2.3] one sees that also below every condition there are incompatible conditions.

Lemma 6.12. For any ultrafilter $\mathcal{U}$ over $\operatorname{Fin}_{k}$, the projections $\min _{k}(\mathcal{U}), \max _{k}(\mathcal{U})$ generate (by adding supersets) ultrafilters, and for $1 \leq i<k$, either each of the projections $\min _{i}(\mathcal{U}), \max _{i}(\mathcal{U})$ generates a filter or each of them contains the empty set.

Proof. They are filters: $\min _{i}(\mathcal{U})=\left\{\min _{i}[X]: X \in \mathcal{U}\right\}$. Since $\mathcal{U}$ is a filter, the projection $\min _{i}(\mathcal{U})$ is closed under finite intersections. For $i<k$ it is possible that there is an $X \in \mathcal{U}$ such that $\min _{i}[X]=\max _{i}[X]=\emptyset$. By definition of $\mathrm{Fin}_{k}$, the top coordinate $\min _{k}(\mathcal{U})$ does not contain the empty set. The family $\min _{k}(\mathcal{U})$ generates an ultrafilter: Let $A \subseteq \omega$. Then $\operatorname{Fin}_{k}=\left\{a \in \operatorname{Fin}_{k}: \min _{k}(a) \in A\right\} \cup\left\{a \in \operatorname{Fin}_{k}\right.$ : $\left.\min _{k}(a) \notin A\right\}$ is a partition of $\operatorname{Fin}_{k}$, and one part lies in $\mathcal{U}$. The same holds for the maximum projection.

Definition 6.13. For an ultrafilter $\mathcal{U} \in \gamma\left(\operatorname{Fin}_{k}\right)$ we say
$\mathcal{U}$ projects to $\overline{\mathcal{R}}$, if

$$
(\forall i \in\{1, \ldots, k\})\left(\min _{i}(\mathcal{U})=\mathcal{R}_{i, \min } \wedge \max _{i}(\mathcal{U})=\mathcal{R}_{i, \max }\right)
$$

Definition 6.14. Let $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega} \cdot \operatorname{set}(\bar{a})=\bigcup\left\{\operatorname{supp}\left(a_{n}\right): n<\omega\right\}$.
In the following Theorem 6.15, the case of $k=1$ is due to Blass' 7, Theorem 2.2], and the unlocalised case of $k \geq 1$ is proved in Gowers' theorem 40, 2.22]. In a sense the result can be seen as an instance of the programme outlined by Todorcevic in 40, Remark 7.27]. The author is thankful to Andreas Blass for his careful explanation of his proof of [7. Theorem 2.1].

Theorem 6.15. Assume CH. For any $k, \overline{\mathcal{R}}$ as in Def. 6.8 the following hold:
(1) Let $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ and let $c$ be a colouring of $\operatorname{TFU}_{k}(\bar{a})$ into finitely many colours. Then there is a $\bar{b} \sqsubseteq_{k}^{\text {Tetr }} \bar{a}$, such that $\bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ and $\operatorname{TFU}_{k}(\bar{b})$ is c-monochromatic.
(2) Let $\bar{a}_{n} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}}), n \in \omega$, be $\sqsubseteq_{k}^{\text {Tetr }}$-decending. Then there is $a \sqsubseteq_{k}^{\mathrm{Tetr}, *}$-lower bound in $\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$.
(3) If $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ and $\mathcal{R}_{0, \min }, \mathcal{R}_{0, \text { max }}$ are two additional nnc ultrafilters, that are nnc to each of the $\mathcal{R}_{i, x}, i=1, \ldots, k, x=\min , \max$, then there is a Gowers-Milliken-Taylor ultrafilter $\mathcal{U}_{k}$ over $\operatorname{Fin}_{k}$ such that $\operatorname{TFU}_{k}(\bar{a}) \in \mathcal{U}_{k}$ and for $i=1, \ldots, k, \min _{i}(\mathcal{U})=\mathcal{R}_{i, \min }, \max _{i}(\mathcal{U})=\mathcal{R}_{i, \max }$ and $\Phi\left(\mathcal{U}_{k}\right)$ is nnc $\mathcal{R}_{0, x}$, $x=\min , \max$.

Since parts (1) and (2) are absolute, we get:
Theorem 6.16. Let $k \geq 1$ and let $\overline{\mathcal{R}}=\left\langle\mathcal{R}_{i, \min }, \mathcal{R}_{i, \max }: i=1, \ldots k\right\rangle$ be a sequence of pairwise non nearly coherent Ramsey ultrafilters.
(1) Any $\sqsubseteq_{k}^{\mathrm{Tetr}}$-descending $\omega$-sequence of elements of $\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ has $a \sqsubseteq_{k}^{\mathrm{Tetr}, *}$ _ lower bound in $\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$.
(2) Let $n \in \omega \backslash\{0\}$ and $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ and let $c$ be a colouring of $\left[\operatorname{TFU}_{k}(\bar{a})\right]_{<}^{n}$ into finitely many colours. Then there is a $\bar{b} \sqsubseteq_{k} \bar{a}, \bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ such that $\left[\operatorname{TFU}_{k}(\bar{b})\right]_{<}^{n}$ is c-monochromatic.
We prove Theorem 6.15
Proof. We prove (1), (2) and (3) simultaneously by induction on $k$. The case of $k=1$ is given by Blass and will be repeated below for $k=1$.

It suffices to prove (1) of the theorem for a partition of $\mathrm{Fin}_{k}$ instead of $\mathrm{TFU}_{k}(\bar{a})$ since $T^{j_{0}}\left(a_{n_{0}}\right)+\cdots+T^{j_{r}}\left(a_{n_{r}}\right) \in \operatorname{TFU}_{k}(\bar{a})$ corresponds to $\left(n_{0}, k-j_{0}\right), \ldots,\left(n_{r}, k-\right.$ $\left.j_{r}\right) \in \operatorname{Fin}_{k}$.

We collect some technical facts separately, before we prove Theorem 6.15,
First we give a general pattern for proving the existence of a particular ultrafilter over $\mathrm{Fin}_{i}$ via compactness.

Lemma 6.17. Let $\mathcal{R}_{\min }, \mathcal{R}_{\max }$ be two nnc Ramsey ultrafilters. Let $\bar{a} \in\left(\operatorname{Fin}_{1}\right)^{\omega}\left(\mathcal{R}_{\min }, \mathcal{R}_{\max }\right)$. The compact Hausdorff space

$$
\left\{\mathcal{U} \in \gamma\left(\operatorname{Fin}_{1}\right): \min (\mathcal{U})=\mathcal{R}_{\min } \wedge \max (\mathcal{U})=\mathcal{R}_{\max } \wedge \mathrm{TFU}_{1}(\bar{a}) \in \mathcal{U}\right\}
$$

is not empty.
Proof. Since min and max are continuous function, the space is compact. We show that there is an ultrafilter $\mathcal{U}$ over $\mathrm{Fin}_{1}$ in the named space. For this it suffices to show that for any $X \in \mathcal{R}_{\text {min }}$ and any $Y \in \mathcal{R}_{\text {max }}$

$$
\text { There are min-unboundedly many } s \in \operatorname{TFU}_{1}(\bar{a})
$$

such that $\min _{1}(s) \in X$ and $\max _{1}(s) \in Y$.
We argue why this suffices: Then the open and closed set
$C(X, Y)=\left\{\mathcal{U} \in \gamma\left(\operatorname{Fin}_{1}\right):(\exists A \in \mathcal{U})(A\right.$ is a min-unb. set of witnesses to $\left.R(X, Y))\right\}$ is not empty.

Since $\mathcal{R}_{i, x}$ are ultrafilters, the intersection of finitely many sets of the form $C(X, Y)$ is again a set of the $C\left(X^{\prime}, Y^{\prime}\right)$ with $X^{\prime}$ being the intersection of the finitely many $X^{\prime}$ 's and $Y^{\prime}$ being the intersection of the finitely many $Y$ 's.

Thus any finite intersection of sets of the form $C(X, Y)$ is not empty, and by compactness of $\gamma\left(\operatorname{Fin}_{i}\right)$, there is an ultrafilter

$$
\mathcal{U} \in \bigcap\left\{C(X, Y): X \in \mathcal{R}_{k, \min }, Y \in \mathcal{R}_{k, \max }\right\} \subseteq \gamma\left(\operatorname{Fin}_{i}\right)
$$

which means

$$
\min _{i}(\mathcal{U})=\mathcal{R}_{k, \min } \wedge \max _{1}(\mathcal{U})=\mathcal{R}_{k, \max } .
$$

To fulfil requirement $R(X, Y)$ : We verify that for any $n \in \omega$ there is a block $s \in\left(\operatorname{TFU}_{1}(\bar{a}) ;\right.$ past $\left.\{n\}\right)$ such that $\min _{1}(s) \in X$ and $\max _{1}(s) \in Y$. Why? Since $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$, and $X \in \mathcal{R}_{\text {min }}$ and $Y \in \mathcal{R}_{\text {max }}$ there are min-unboundedly many $s \in \operatorname{TFU}_{1}(\bar{a})$ such that $\min _{1}(s) \in X \wedge \max _{1}(s) \in Y$.

Starting from now, we just write the requirements and show how to fulfil them. For proving statement (1) at $k$ on the bases of (1) and (3) at $k-1$, we rework and extend the proof of Gowers' original theorem as given by Todorcevic 40, pp. 35-36].

Lemma 6.18. Let $\mathcal{R}_{i, x}, i=1, \ldots, k, x=\min$, max be pairwise nnc Ramsey ultrafilters. For any $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ the following are equivalent:
(1) $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$.
(2) There is an ultrafilter $\mathcal{U} \in \gamma\left(\operatorname{Fin}_{k}\right)$ such that

$$
\operatorname{TFU}_{k}(\bar{a}) \in \mathcal{U} \wedge(\forall i \in\{1, \ldots k\})\left(\min _{i}(\mathcal{U})=\mathcal{R}_{i, \min } \wedge \max _{i}(\mathcal{U})=\mathcal{R}_{i, \max }\right)
$$

Proof. (1) implies (2): By the compactness method as explained in the previous lemma it suffices to show that for any $\left(X_{i} \in \mathcal{R}_{i, \text { min }} Y_{i} \in \mathcal{R}_{i, \max }\right)$

$$
\begin{equation*}
\left(\exists^{\min -\mathrm{unb}} s \in \operatorname{TFU}_{k}(\bar{a})\right)(\forall i \in\{1, \ldots, k\})\left(\min _{i}(s) \in X_{i} \wedge \max _{i}(s) \in Y_{i}\right) \tag{6.6}
\end{equation*}
$$

However, this is guaranteed by $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\mathcal{R})$.
(2) implies (1). Let $\mathcal{U}$ be as in (2). Given sets $X_{i} \in \mathcal{R}_{i, \min }, Y_{i} \in \mathcal{R}_{i, \max }$, $i=1, \ldots, k$, there is a set $S \in \mathcal{U}$ such that

$$
S \subseteq \operatorname{TFU}_{k}(\bar{a}) \wedge(\forall i \in\{1, \ldots, k\})\left(\min _{i}[S] \subseteq X_{i} \wedge \max _{i}[S] \subseteq Y_{i}\right)
$$

Since $S \in \mathcal{U}, S$ is min-unbounded. Any $s \in S$ fulfils $\min _{i}(s) \in X_{i} \wedge \max _{i}(s) \in$ $Y_{i}$.

We name the set of ultrafilters with given projections:
Definition 6.19. For $1 \leq i \leq k$ and a sequence $\left\langle\mathcal{R}_{j, x}: 1 \leq j \leq i, x \in\{\min , \max \}\right\rangle$ or pairwise nnc Ramsey ultrafilters we let

$$
\begin{align*}
& \gamma^{\operatorname{good}}\left(\operatorname{Fin}_{i}, \overline{\mathcal{R}}\right)=\left\{\mathcal{U} \in \gamma\left(\operatorname{Fin}_{i}\right):(\forall j \in\{1, \ldots, i\})\right. \\
& \left.\left(\min _{j}(\mathcal{U})=\mathcal{R}_{j, \text { min }} \wedge \max _{j}(\mathcal{U})=\mathcal{R}_{j, \text { max }}\right)\right\} \tag{6.7}
\end{align*}
$$

Cave: Sometimes we use ultrafilter sequences that carry shifted indices.
Lemma 6.20. For any $i, \overline{\mathcal{R}}$ as above, the space $\gamma^{\text {good }}\left(\operatorname{Fin}_{i}, \overline{\mathcal{R}}\right)$ is closed under + .
Proof. This is proved in [7, page 99, second but last paragraph].
In Lemma 6.22 we shall look at "mixed additions." First we state some simple observations.

## Lemma 6.21.

(1) For any $X \subseteq \operatorname{Fin}_{i}$, for any $1 \leq j<j^{\prime} \leq i$ we have

$$
\min _{j}[X] \cap \min _{j^{\prime}}[X]=\emptyset
$$

since for each $s \in \operatorname{Fin}_{i}, \min _{j}(s) \neq \min _{j^{\prime}}(s)$.
(2) Given $t \in \operatorname{Fin}_{j}$, there is a particular (in $<_{\operatorname{Fin}_{j+1}, \text { lex }}$ largest) $s \in \operatorname{Fin}_{j+1}$ with $T(s)=t$ : We let $\operatorname{supp}(t)=\operatorname{supp}(s)$ and $t(n)=s(n)+1$ for $n \in \operatorname{supp}(s)$. We write for this $t$ now $s^{\sharp}$.
(3) We can lift the sharp operation by letting $X^{\sharp}:=\left\{s^{\sharp}: s \in X\right\}$. Given $\mathcal{U} \in$ $\gamma\left(\operatorname{Fin}_{j}\right)$, there is a particular ultrafilter $\mathcal{V} \in \gamma\left(\operatorname{Fin}_{j+1}\right)$ with $\mathrm{T}(\mathcal{V})=\mathcal{U}$, namely

$$
\mathcal{V}=\left\{X^{\sharp}: X \in \mathcal{U}\right\} .
$$

We write $\mathcal{V}=\operatorname{lift}(\mathcal{U})$. Then $\min _{j^{\prime}+1}(\mathcal{V})=\min _{j^{\prime}}(\mathcal{U})$ for $j^{\prime}=1, \ldots, j$, and $\min _{1}(\mathcal{V})=\{\emptyset\}$ and analogously for max.

Now we prove a technical lemma about the sums of good ultrafilters. Prima facie the ultrafilters do not fit, e.g., $\min _{k}(\mathcal{X})=\mathcal{R}_{k, \min }$ and $\min _{k-1}(\mathcal{V})=\mathcal{R}_{k, \min }$. However, this mixed sum is defined on purpose.

Lemma 6.22. Let $\overline{\mathcal{R}}=\left\langle\mathcal{R}_{i, x}: 1 \leq i \leq k, x=\min , \max \right\rangle$. Let $\mathcal{X} \in \gamma^{\operatorname{good}}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right)$ and $\mathcal{V} \in \gamma^{\text {good }}\left(\operatorname{Fin}_{k-1},\left\langle\mathcal{R}_{2, x}, \ldots, \mathcal{R}_{k, x}, x=\min , \max \right\rangle\right)$. Then $\mathcal{W}=\mathcal{X}+\mathcal{V} \in \gamma^{\text {good }}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right)$.

Proof. We have $\mathcal{W} \in \gamma\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right)$ iff for $v=1, \ldots, k, x=\min$, max, for any $X \in \mathcal{W}$,

$$
\begin{equation*}
\left\{x_{v}(s): s \in X\right\} \in \mathcal{R}_{v, x} \tag{6.8}
\end{equation*}
$$

We fix some $X \in \mathcal{W}$. Then $\{s:\{t: s+t \in X\} \in \mathcal{V}\} \in \mathcal{X}$. For any $s \in \operatorname{Fin}_{k}$, $t \in \operatorname{Fin}_{k-1}$, such that $s<t$ and $s+t \in X$, and for any $v=1, \ldots, k, x=\min$, max,
$x_{v}(s+t)$ is either $x_{v}(s)$ or $x_{v}(t)$. Either the set of $(s, t)$ on which $x_{v}$ is the first is in

$$
\mathcal{X} \times \mathcal{V}=\left\{Z \subseteq \operatorname{Fin}_{k} \times \operatorname{Fin}_{k-1}:\{s:\{t:(s, t) \in Z\} \in \mathcal{V}\} \in \mathcal{X}\right\}
$$

or its complement is in $\mathcal{X} \times \mathcal{V}$.
We start with the high values of $v$ : For the values $v=k$, we have for any $s \in \operatorname{Fin}_{k}, t \in \operatorname{Fin}_{k-1},(s+t)^{-1}[\{v\}]=s^{-1}[\{v\}]$ and hence its minimum and/or maximum is from $x_{v}(s)$. Thus for $X \in \mathcal{X}+\mathcal{V}, x=\min$, max we have

$$
\begin{equation*}
\left\{x_{v}(s+t): s+t \in X\right\} \in \mathcal{R}_{v, x} \tag{6.9}
\end{equation*}
$$

as requested in Equation (6.8).
Now we proceed by downwards induction on $v$.
The next value is $v=k-1$ and $x=\min$ or $x=\max$. For $s \in \operatorname{Fin}_{k}, t \in \operatorname{Fin}_{k-1}$, $s<t, s+t \in X$, we have $x_{v}(s+t)=x_{v}(s)$ or $x_{v}(s+t)=x_{v}(t)$, and there is a set $Z \in \mathcal{X} \times \mathcal{V}$ such that for any $(s, t) \in Z$ the decision is the same. We claim that this decision can only be for the $s$-parts and hence $\left\{x_{v}(s+t): s+t \in X\right\}=\left\{x_{v}(s)\right.$ : $s+t \in X\} \in \mathcal{R}_{k-1, x}$. This is seen as follows: Since any $s+t \in X$ is an element of $\mathrm{Fin}_{k}$, we have

$$
\begin{equation*}
\left\{x_{v+1}(s+t): s+t \in X\right\} \cap\left\{x_{v}(s+t): s+t \in X\right\}=\emptyset \tag{6.10}
\end{equation*}
$$

For $X \in \mathcal{X}+\mathcal{V}$, the left-hand set on the left-hand side of Equation (6.10), i.e., the set $\left\{x_{k}(s+t): s+t \in X\right\}$, is already in the ultrafilter $\mathcal{R}_{k, x}$, by the analysis of the coordinate $k$ in Equation 6.9. Hence by Equation (6.10),

$$
\left\{x_{k-1}(s+t): s+t \in X\right\} \notin \mathcal{R}_{k, x}
$$

and so $Z \in \mathcal{X} \times \mathcal{V}$ did not decide for the $t$-part. Since there must be a decision on $Z$ as to whether $x_{k-1}(s+t)=x_{k-1}(s)$ or $x_{k-1}(s+t)=x_{k-1}(t)$, we have $x_{k-1}(s+t)=x_{k-1}(s)$ for $s \in Z$ and hence

$$
\left\{x_{k-1}(s+t): s+t \in X\right\} \in \mathcal{R}_{k-1, x}
$$

In the next step we verify Equation (6.8) for $v=k-2$ with the same technique, shifted by -1 in the $v$-component, and proceed by downwards induction down to $v=1$.

Lemma 6.23. (See [40, Lemma 2.23]) Let $k \geq 2$. Let $2 \leq j \leq k$. Then $\mathrm{T}: \gamma\left(\mathrm{Fin}_{j}\right) \rightarrow \gamma\left(\mathrm{Fin}_{j-1}\right)$ is a continuous onto + -homomorphism.

So we use freely $T(\mathcal{U}+\mathcal{V})=T(\mathcal{U})+T(\mathcal{V})$.
The following is a strengthening of 40, Lemma 2.24]. It is stated in more generality than we need for the proof of statement (1) at $k$ so that we can use it also for the proof of statement (3) at $k$.

Lemma 6.24. Let $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$. Let $\mathcal{U}_{k-1}$ be a Gowers-Milliken-Taylor ultrafilter over $\operatorname{Fin}_{k-1}$, such that $\operatorname{TFU}_{k-1}(T[\bar{a}]) \in \mathcal{U}_{k-1}$ and $\min _{i}\left(\mathcal{U}_{k-1}\right)=\mathcal{R}_{1+i, \min }$, $i=1, \ldots, k-1$, and same for max and such that $\mathcal{R}_{1, \min }, \mathcal{R}_{1, \max }$ are Ramsey ultrafilters that are nnc $\Phi\left(\mathcal{U}_{k-1}\right)$. In addition we let $\mathcal{S}_{1}, \mathcal{S}_{2}$ be two ultrafilters that are nnc $\Phi\left(\mathcal{U}_{k-1}\right)$ and nnc to $\mathcal{R}_{1, \min }, \mathcal{R}_{1, \max }$ Let $h$ be a finite-to-one function. The

[^6]set
\[

$$
\begin{align*}
S_{k}:= & \left\{\mathcal{X} \in \gamma^{\operatorname{good}}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right): \mathrm{T}(\mathcal{X})=\mathcal{U}_{k-1} \wedge\right. \\
& \bigwedge_{n} \mathrm{TFU}_{k}(\bar{a}) \in \mathcal{X} \wedge  \tag{6.11}\\
& \left.\bigwedge_{j=1,2}\left(\exists E_{j} \in \mathcal{S}_{j}\right)(\exists X \in \mathcal{X})\left(h[\operatorname{set}(X)] \cap h\left[E_{j}\right]=\emptyset\right)\right\}
\end{align*}
$$
\]

is a closed non-empty subset of $\gamma\left(\operatorname{Fin}_{k}\right)$.
Proof. In case $k=1$, just let $\mathcal{U}_{0}$ be the principal ultrafilter $\{f\}$ with $f(n)=0$ for any $n$, and we leave out $B$ from the requirements below. Let $\mathcal{U}_{k-1}$ be given by the induction hypothesis, be as in (2) at $k-1$ for $\mathcal{R}_{1+i, x}, i=1, \ldots k-1, x=\min$, max, such that $\mathcal{R}_{1, x}$ is nnc $\Phi\left(\mathcal{U}_{k-1}\right)$ and such that $\operatorname{TFU}_{k-1}(T[\bar{a}]) \in \mathcal{U}_{k-1}$. Let $h$ be a finite-to-one function.

Let $B \in \mathcal{U}_{k-1}$, let for $1 \leq i \leq k$ sets $X_{i} \in \mathcal{R}_{i, \min }, Y_{i} \in \mathcal{R}_{i, \max }$ be given. The requirement
$R\left(X_{1}, \ldots, X_{k}, Y_{k}, \ldots, Y_{1}, B, h\right)$ says

$$
\begin{aligned}
& \left(\exists^{\min -\mathrm{unb}} s\right)\left(s_{n} \in \operatorname{TFU}_{k}\left(\bar{a}_{n}\right)\right)(\forall i=1, \ldots, k) \\
& \left(\min _{i}(s) \in X_{i} \wedge \max _{i}(s) \in Y_{i} \wedge T(s) \in B \wedge\right. \\
& \left.\bigwedge_{j=1,2}\left(\exists E_{j} \in \mathcal{S}_{j}\right)\left(h[\operatorname{set}(s)] \cap h\left[E_{i}\right]\right)=\emptyset\right) .
\end{aligned}
$$

Again the requirements are closed under finite conjunctions 8 hence it suffices that any single requirement can be fulfilled.

We take $\bar{b} \in \mathcal{U}_{k-1} \cap B$ such that $(\forall n)(\forall i=1, \ldots, k-1)\left(\min _{i}\left(b_{n}\right) \in X_{i+1} \wedge\right.$ $\left.\max _{i}\left(b_{n}\right) \in Y_{i+1}\right)$. Then look at where the sets $X_{1}, Y_{1}$ lie outside set $(\bar{b})$. We take $X_{1}^{1} \subseteq X_{1}, X_{1}^{1} \in \mathcal{R}_{1, \text { min }}$ and $Y_{1}^{1} \subseteq Y_{1}, Y_{1}^{1} \in \mathcal{R}_{1, \text { max }}$ and $\bar{c} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}, \bar{c} \in \mathcal{U}_{k-1}$ such that $X_{1}^{1}, Y_{1}^{1}$, $\operatorname{set}(\bar{c})$ are pairwise disjoint. We can do this since $\mathcal{R}_{i, x}$ nnc $\Phi(\mathcal{U})$. Let $r_{0} \in \omega$ be given. We take $x_{0} \in X_{1}^{1}, x_{0}>r_{0}, r(0) \geq r_{0}$ such that $x_{0}<\operatorname{supp}\left(c_{r(0)}\right)$ and we take $y_{0} \in Y_{1}^{1}$ that lies past $c_{r(0)}$ and let $r_{1}=y$ and such that

$$
\left(\exists d=d_{r(0)} \in \operatorname{TFU}_{k}(\bar{a})\left(\min _{1}(d)=x_{0} \wedge T(d)=c_{r(0)}\right) \wedge \max _{1}(d)=y_{0}\right)
$$

Such at $d$ exists since $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$. We choose the next triple $\left(x_{1}, c_{r(1)}, y_{1}\right)$ with $r_{1}$ in the place of $r_{0}$, and so on. Since $\mathcal{S}_{1}, \mathcal{S}_{2}$ are ultrafilters, $\mathcal{S}_{1} \cap \mathcal{S}_{2}$ is not meager and hence contains a set $E_{1}=E_{2}$ such that $h\left[E_{1}\right]$ that is disjoint from infinitely many of the sets $h\left[\left(r_{m}, r_{m+1}\right]\right], m \in \omega$. We choose such an $m$. Then $s=d_{r(m)}$ fulfils the requirement. Thus we showed that $S_{k}$ is not empty.

Remark 6.25. The version with the starting set $\operatorname{TFU}_{k}(\bar{a})$ and the extra ultrafilters $\mathcal{S}_{1}, \mathcal{S}_{2}$ will be used for the proof of (3) at $k$. For (1) at $k$, we can drop the $\mathcal{S}_{j}$ and replace $\mathrm{TFU}_{k}(\bar{a})$ by the full $\mathrm{Fin}_{k}$.

Now we are ready to resume the thread of Todorcevic's proof of 40, Lemma 2.24].

[^7]Definition 6.26. For $\mathcal{U}, \mathcal{V} \in \bigcup_{j=1}^{k} \gamma\left(\operatorname{Fin}_{j}\right)$, we let $\mathcal{V} \leq \mathcal{U}$ if $\mathcal{U}+\mathcal{V}=\mathcal{V}+\mathcal{U}=\mathcal{V}=$ $\mathcal{V}+\mathcal{V}$. So $\mathcal{V}$ is idempotent and $\mathcal{V}$ is stronger and richer than $\mathcal{U}$.

The relation $\leq$ is a preorder on $\bigcup_{j=1}^{k} \gamma\left(\operatorname{Fin}_{j}\right)$.
Lemma 6.27. Let $\mathcal{U}_{k-1}$ be as in Lemma 6.24. There is an idempotent ultrafilter $\mathcal{U}^{\text {idem }} \in \gamma^{\text {good }}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right)$ such that $\mathcal{U}^{\text {idem }} \leq \mathcal{U}_{k-1}$ and $\mathrm{T}\left(\mathcal{U}^{\text {idem }}\right)=\mathcal{U}_{k-1}$.

Proof. We let $S_{k}=\left\{\mathcal{X} \in \gamma^{\text {good }}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right): \mathrm{T}(\mathcal{X})=\mathcal{U}_{k-1}\right\}$. By Lemma 6.24 $S_{k} \neq \emptyset$. By Lemma 6.22 the set $\left\{\mathcal{X}+\mathcal{U}_{k-1}: \mathcal{X} \in S_{k}\right\}$ is a subset of $\gamma^{\text {good }}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right)$. The set $\left\{\mathcal{X}+\mathcal{U}_{k-1}: \mathcal{X} \in S_{k}\right\}$ is a non-empty closed subsemigroup, since the sum $\mathcal{V}+\mathcal{U}_{k-1}+\mathcal{W}+\mathcal{U}_{k-1}$ belongs to $S_{k}+\mathcal{U}_{k-1}$. This is seen as follows: We have

$$
\mathrm{T}\left(\mathcal{V}+\mathcal{U}_{k-1}+\mathcal{W}\right)=\mathcal{U}_{k-1}+\mathrm{T} \mathcal{U}_{k-1}+\mathcal{U}_{k-1}=\mathcal{U}_{k-1}
$$

where the latter equation holds by induction hypothesis. Then we pick an idempotent ultrafilter $\mathcal{W} \in S_{k}+\mathcal{U}_{k-1}$, say $\mathcal{W}=\mathcal{V}+\mathcal{U}_{k-1}$ with $\mathcal{V} \in S_{k}$. Let $\mathcal{U}^{\text {idem }}=$ $\mathcal{U}_{k-1}+\mathcal{V}+\mathcal{U}_{k-1}$. Then $\mathrm{T} \mathcal{U}^{\text {idem }}=\mathcal{U}_{k-1}$ and $\mathcal{U}^{\text {idem }}=\mathcal{U}_{k-1}+\mathcal{W}$, being a sum of idempotent ultrafilters, is idempotent.

Moreover $\mathcal{U}^{\text {idem }}+\mathcal{U}_{k-1}=\mathcal{U}_{k-1}+\mathcal{U}^{\text {idem }}=\mathcal{U}^{\text {idem }}$, so $\mathcal{U}^{\text {idem }} \leq \mathcal{U}_{k-1}$. By Lemma 6.22 (and a relative thereof for additions from the righthand-side) we have $\mathcal{U}^{\text {idem }} \in$ $\gamma^{\text {good }}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right)$.

Here is the penultimate step of the proof of statement (1) of Theorem 6.15. We pick an idempotent ultrafilter $\mathcal{U}^{\text {idem }}$ as in the previous lemma. Let $P$ be a piece of the given partition of $\operatorname{Fin}_{k}$ such that $P \in \mathcal{U}^{\text {idem }}$. Now by induction on $n$ we build a tree $\operatorname{Tr}$ of finite increasing sequences $x_{0}, x_{1}, \ldots, x_{n}$ of elements of $\operatorname{Fin}_{k}$ and branching sets $A_{0} \supseteq A_{1, x_{0}} \supseteq \cdots \supseteq A_{n, x_{0}, \ldots x_{n-1}} \in \mathcal{U}_{k}$ with the following properties for any $n \in \omega$,
(a) $A_{0}=P$.
(b) $x_{n} \in A_{n, x_{0}, x_{1}, \ldots, x_{n-1}}$ and $T^{(k-\ell)}\left[A_{n, x_{0}, \ldots, x_{n-1}}\right]=A_{n, x_{0}, \ldots, x_{n-1}}^{\ell}$ for $1 \leq \ell \leq k$. So $A_{n, x_{0}, \ldots, x_{n-1}}=A_{n, x_{0}, \ldots, x_{n-1}}^{k}$.
(c) $\left(\mathcal{U}^{\text {idem }} x\right)\left(T^{(k-i)}\left(x_{n}\right)+T^{(k-j)}(x) \in A_{n, x_{0}, \ldots, x_{n-1}}^{\max \{i, j\}}\right)$ for $1 \leq i, j \leq k$.
(d) The tree $\operatorname{Tr}$ has branching sets in $\mathcal{U}^{\text {idem }}$, i.e. given $\left(x_{0}, \ldots, x_{n}\right) \in \operatorname{Tr}$ for any $n$, the set of immediate tree successors of $\left(x_{0}, \ldots, x_{n}\right)$ fulfils:

$$
\begin{align*}
& \left\{x_{n+1}: x_{n+1} \text { could serve in the tree } T r\right. \\
& \left.\quad \text { as a prolongation of }\left(x_{0}, \ldots, x_{n}\right)\right\}=A_{n+1, x_{0}, \ldots, x_{n}} \in \mathcal{U}^{\text {idem }} \tag{6.12}
\end{align*}
$$

As shown in the proof of [40, Theorem 2.22], any branch $\bar{x}$ of the tree $\operatorname{Tr}$ has $\operatorname{TFU}_{k}(\bar{x}) \subseteq P$. We show that there is a branch $\bar{c}$ of $\operatorname{Tr}$ such that $\bar{c} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$. We let $\tilde{A}_{0}=A_{0}$ and or $n \in \omega$ we let

$$
\begin{align*}
\tilde{A}_{n+1}= & \bigcap\left\{A_{m+1, x_{0}, \ldots, x_{m}}: m \leq n,\left(x_{0}, \ldots, x_{m}\right) \in T r\right.  \tag{6.13}\\
& \left.\max \left(\operatorname{supp}\left(x_{m}\right)\right)<n+1\right\}
\end{align*}
$$

Then $\tilde{A}_{n} \in \mathcal{U}^{\text {idem }}$, and they are $\subseteq$-descending.
Now we come to the last step.

Final Claim
There is a branch $\bar{c}$ through the Grigorieff tree $\operatorname{Tr}$ such that $\bar{c} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}}) .9$
Proof. We recall another lemma.
Lemma 6.28. If $\mathcal{U}_{k-1}$ is a Gowers-Milliken-Taylor ultrafilter over $\operatorname{Fin}_{k-1}$ with projections and

$$
(\forall i \in\{1, \ldots, k-1\})\left(\dot{x}_{i}\left(\mathcal{U}_{k-1}\right)=\mathcal{R}_{i+1, x}\right)
$$

and $\mathcal{R}_{1, \min }, \mathcal{R}_{1, \max }$ are given and both are nnc to $\Phi\left(\mathcal{U}_{k-1}\right)$ and $\mathcal{V} \in S_{k}+\mathcal{U}_{k-1}$, $\mathcal{V} \leq \mathcal{U}_{k-1}$, then $\left(\min _{1}, \mathrm{~T}, \max _{1}\right)(\mathcal{V})=\mathcal{R}_{1, \min } \times \mathcal{U}_{k-1} \times \mathcal{R}_{1, \max }$.

Proof. No other order is possible. Since $\mathcal{V}=\mathcal{V}+\mathcal{U}_{k-1}=\mathcal{U}_{k-1}+\mathcal{V}$, we have $X \in \mathcal{V}$ iff $\left.\{s: t: s+t \in X\} \in \mathcal{U}_{k-1}\right\} \in \mathcal{V}$ and $X \in \mathcal{V}$ iff $\left.\{s: t: s+t \in X\} \in \mathcal{V}\right\} \in$ $\mathcal{U}_{k-1}$. However, since $\mathcal{U}_{k-1}$ is a Gowers-Milliken-Taylor ultrafilter, by Lemma 6.4 the high values of $s \in X \in \mathcal{U}_{k-1}$ are always in the middle. So only the order $\mathcal{R}_{1, \text { min }} \times \mathcal{U}_{k-1} \times \mathcal{R}_{1, \text { max }}$ in the triple projection is possible.

Now we return to the proof of the final claim. From $\tilde{A}_{n}, n \in \omega$, as given in Equation (6.13) we define three families of sets:

$$
\begin{align*}
& B_{n}:=\left\{\min _{1}(s): s \in \tilde{A}_{n}\right\} \\
& C_{n}:=\left\{T(s): s \in \tilde{A}_{n} \wedge \min _{1}(s) \in B_{n}\right\}  \tag{6.14}\\
& D_{n}:=\left\{\max _{1}(s): s \in \tilde{A}_{n} \wedge \min _{1}(s) \in B_{n} \wedge T(s) \in C_{n}\right\}
\end{align*}
$$

Since $\tilde{A}_{n} \in \mathcal{U}^{\text {idem }} \in \gamma^{\text {good }}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right)$, we have $B_{n} \in \mathcal{R}_{1, \text { min }}, C_{n} \in \mathcal{U}_{k-1}, D_{n} \in$ $\mathcal{R}_{1, \text { max }}$.

We prove a relative of Blass' Lemma 6.10 for triples:
Lemma 6.29. Fix $k \geq 1$. If $k=1$, then there is no Gowers-Milliken-Taylor ultrafilter $\mathcal{U}_{k-1}$, we replace $\mathcal{U}_{k-1}$ by the filter $\{0\}$, where 0 is a "block" with empty support. Suppose we are given
(1) A Gowers-Milliken-Taylor ultrafilter $\mathcal{U}$ over $\operatorname{Fin}_{k-1}$ with projections $\mathcal{R}_{i+1, x}$ : $1 \leq i \leq k-1\rangle$.
(2) $\mathcal{R}_{1, x}$, Ramsey and nnc $\Phi\left(\mathcal{U}_{k-1}\right), x=\min$, max, and elements $X_{1} \in \mathcal{R}_{1, x}$ and $Y_{1} \in \mathcal{R}_{1, \text { max }}$,
(3) a descending sequence $\tilde{A}_{n}$ as in Equation (6.13) of subsets of an idempotent ultrafilter $\mathcal{U}^{\text {idem }} \leq \mathcal{U}_{k-1}, \mathrm{~T}\left(\mathcal{U}^{\text {idem }}\right)=\mathcal{U}_{k-1}$ and $\mathcal{U}^{\text {idem }} \in \gamma^{\text {good }}\left(\operatorname{Fin}_{k}, \overline{\mathcal{R}}\right)$ contains $P$.
(4) $B_{n}, C_{n}, D_{n}$ are defined from $\left\langle\tilde{A}_{n}: n<\omega\right\rangle$ as in Equation (6.14).

Then there is some $\operatorname{TFU}_{k}(\bar{b}) \in \mathcal{U}_{k-1}$ and there is $X \in \mathcal{R}_{1, \min }, Y \in \mathcal{R}_{1, \max }$ with the following properties
(a) the blocks of $X$, range $(\bar{b})$ and $Y$ lie as follows

$$
x_{0}<b_{0}<y_{0}<x_{1}<b_{1}<y_{1}<\ldots
$$

[^8](b) the following three conditions on diagonal lower bounds hold
\[

$$
\begin{array}{cc}
(\forall n) & \left(x_{n} \in B_{y_{n-1}}\right), \\
(\forall n) & \left(b_{n} \in C_{x_{n}}\right), \\
(\forall n) & \left(y_{n} \in D_{\max \left(\operatorname{supp}\left(b_{n}\right)\right)}\right) .
\end{array}
$$
\]

Proof. First step:
We take on each of the three parts diagonal lower bounds. We take $X_{0.5} \in \mathcal{R}_{1, \text { min }}$ such that

$$
\forall x, y \in X_{0.5}\left(y<x \rightarrow x \in B_{y}\right)
$$

We take $Y_{0.5} \in \mathcal{R}_{1, \text { max }}$ such that

$$
\forall x, y \in Y_{0.5}\left(y<x \rightarrow x \in D_{y}\right)
$$

We take $\bar{b}_{0.5} \in \mathcal{U}_{k-1}$ such that

$$
\forall n<m\left(b_{0.5, m} \in C_{\max \left(\operatorname{supp}\left(b_{n}^{1}\right)\right)}\right)
$$

Then we take $X_{1} \subseteq X_{0.5}, Y_{1} \subseteq Y_{0.5}, \bar{b}_{1} \sqsubseteq_{k}^{\mathrm{Tetr}} \bar{b}_{0.5}, X_{1} \in \mathcal{R}_{1, \min }, Y_{1} \in \mathcal{R}_{1, \max }$, $\bar{b}_{1} \in \mathcal{U}_{k-1}$ such that $X_{1}, X_{2}$ and $\operatorname{set}\left(\bar{b}_{1}\right)$ are pairwise disjoint. Since $\mathcal{R}_{1, \text { min }}$ and $\mathcal{R}_{1, \text { max }}$ are nnc and both are nnc to $\Phi\left(\mathcal{U}_{k-1}\right)$, there are such strengthenings. The diagonal conditions hold also for $X_{1}, \bar{b}_{1}, Y_{1}$.

Second step:
We start working towards the triple alternation pattern in clause (a). We take $X_{2} \subseteq X_{1}, X_{2} \in \mathcal{R}_{1, \min }, \bar{b}_{1.5} \in \mathcal{U}_{k-1}, \bar{b}_{1.5} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}_{1}, Y_{1.5} \in \mathcal{R}_{1, \max }, Y_{1.5} \subseteq Y_{1}$, such that

$$
\begin{equation*}
\left(\forall x<x^{\prime} \in X_{2}\right)(\exists n)\left(\exists y \in Y_{1.5}\right)\left(x<\operatorname{supp}\left(b_{1.5, n}\right)<y<x^{\prime}\right) \tag{6.15}
\end{equation*}
$$

Since $\mathcal{R}_{1, \text { min }}$ is a $Q$-point and nnc $\Phi\left(\mathcal{U}_{k-1}\right)$ and nnc to $\mathcal{R}_{1, \text { min }}$, we find such a sparse set $X_{2}$ and $Y_{1.5}$ and $\bar{b}_{1.5}$.

We take $\bar{b}_{2} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}_{1.5}, \bar{b}_{2} \in \mathcal{U}_{k-1}$, such that

$$
\begin{equation*}
(\forall n<m)\left(\exists x \in X_{2}\right)\left(\exists y \in Y_{1.5}\right)\left(\operatorname{supp}\left(b_{2, n}\right)<y<x<\operatorname{supp}\left(b_{2, m}\right)\right. \tag{6.16}
\end{equation*}
$$

Such a $\bar{b}_{2}$ can be found via the Taylor-colouring law of $\left[\operatorname{TFU}_{k-1}\left(\bar{b}_{1.5}\right)\right]_{<}^{2}$ that sends $s<t$ to 1 if there are the desired elements of $X_{2}$ and of $Y_{1.5}$ between $s$ and $t$ and to 0 otherwise. We find $\bar{b}_{2} \sqsubseteq_{k}^{\mathrm{Tetr}} \bar{b}_{1.5}, \operatorname{TFU}{ }_{k-1}\left(\bar{b}_{2}\right) \in \mathcal{U}_{k-1}$ such that the monochromatic colour is 1 .

We take $Y_{2} \subseteq Y_{1.5}, Y_{2} \in \mathcal{R}_{1, \text { max }}$, such that

$$
\left(\forall y<y^{\prime} \in Y_{2}\right)(\exists n)\left(\exists x \in X_{2}\right)\left(y<x<\operatorname{supp}\left(b_{2, n}\right)<y^{\prime}\right)
$$

## Third step:

We fill up a tiny bit: If between two adjacent blocks of $\bar{b}_{2}$ there is only an element of $X_{2}$ but no larger element of $Y_{2}$, we add such a point from $Y_{1.5}$ to $Y_{2}$ and thus get, when doing this for all situations a set $Y_{3}$ such that $Y_{2} \subseteq Y_{3} \subseteq Y_{1.5}$. By Equation (6.16) there are such elements of $Y_{1.5}$ such that the alternating pattern is established.

If between two adjacent points of $X_{2}$ there is only an element of $\underline{Y}_{1.5}$ but no element of $Y_{2}$ or if there is only an element of $\bar{b}_{1.5}$ but no element of $\bar{b}_{2}$, we add, if applicable, such a point from $Y_{1}$ to $Y_{3}$ and thus get, when doing this for all situations a set $Y_{4}$ such that $Y_{3} \subseteq Y_{4} \subseteq Y_{1.5}$, and we add, if applicable, such a block from range $\left(\bar{b}_{1.5}\right)$ to $\bar{b}_{2}$ and thus get, when doing this for all situations a set
$\bar{b}_{3}$ such that $\bar{b}_{2} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}_{3} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}_{1.5}, \bar{b}_{2} \in \mathcal{U}_{k-1}$. By Equation (6.15) such a filling up is possible.

We let $X_{4}=X_{2}, \bar{b}_{4}=\bar{b}_{3}$. Thus we have an alternating chain of enumerating $X_{4} \cup \operatorname{range}\left(\bar{b}_{4}\right) \cup Y_{4}$ as $x_{0}<b_{0}<y_{0}<x_{1}<\ldots$.

Fourth step:
We "attack the possible exceptions" to the diagonalisation requirements in clause (b).

Exceptions for $x$ : Suppose that in the common increasing enumeration of $X_{4} \cup$ range $\left(\bar{b}_{4}\right) \cup Y_{4}$ there is an element $x \in X_{4}$ such that for no $x^{\prime} \in X_{1.5}, y<x^{\prime}<$ $x<b_{4, k}$. We map the last $\bar{b}_{4}$-block before $x$ to $x$ by a finite-to-one function that sends the whole interval $\left[\min \left(b_{4, n}\right), x\right]$ to $\min \left(b_{4, n}\right)$. We do this for all such $x$. We define $f$ arbitrarily on the other points so that it will be a finite-to-one function. Then we use that $\mathcal{R}_{1, \min }, \mathcal{R}_{1, \text { max }}$ nnc $\Phi\left(\mathcal{U}_{k-1}\right)$ and take $\bar{b}_{5} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}_{4}, \bar{b}_{5} \in \mathcal{U}_{k-1}$ and $X_{5} \subseteq X_{4}, X_{5} \in \mathcal{R}_{1, \min }$ and $Y_{5} \subseteq Y_{4}, Y_{4} \in \mathcal{R}_{1, \max }$ such that $h\left[Y_{5}\right] \cap h\left[\operatorname{set}\left(\bar{b}_{5}\right)\right]=\emptyset$, $h\left[X_{5}\right] \cap h\left[\operatorname{set}\left(\bar{b}_{5}\right)\right]=\emptyset$. Then for the common enumeration of $X_{5}, \bar{b}_{5}$ and $Y_{5}$ we have: Any $x \in X_{5}$ that is preceded by an element of $Y_{5}$ or one of $\bar{b}_{5}$ is shielded by an $x^{\prime} \in X_{1}$ from them and hence fulfils the condition that corresponds to the first equation in (b) for $X_{5}, \bar{b}_{5}, Y_{5}$. However clause (a) is already ruined.

Exceptions for $b_{5, k}$ : Suppose that in the common increasing enumeration of $X_{5} \cup$ range $\left(\bar{b}_{5}\right) \cup Y_{5}$ there is an element $b_{5, k} \in \operatorname{range}\left(\bar{b}_{5}\right)$ such that for no $b^{\prime} \in \bar{b}_{1}$ we have for the largest $x \in X_{5}$ preceding $b_{5, k}, y<x<b^{\prime}<b_{5, k}$. (There might be more $x$ 's in the pattern, since in the first manipulation of the foruth step we may have destroyed the alternating pattern. It is only important to do the procedure with a smaller $y$.) We take a finite-to-one function that sends the whole interval $\left[y, \max \left(b_{5}, k\right)\right]$ to $\min \left(b_{k, k-1}\right)$. We do this for all such $b_{5, k}$. We define $f$ arbitrarily on the other points so that it will be a finite-to-one function. Then we use that $\mathcal{R}_{1, \min }$, $\mathcal{R}_{1, \text { max }}$ nnc $\Phi\left(\mathcal{U}_{k-1}\right)$ and take $\bar{b}_{6} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}_{6}, \bar{b}_{6} \in \mathcal{U}_{k-1}$ and $X_{6} \subseteq X_{5}, X_{6} \in \mathcal{R}_{1, \text { min }}$ and $Y_{6} \subseteq Y_{5}, Y_{6} \in \mathcal{R}_{1, \max }$ such that $h\left[Y_{6}\right] \cap h\left[\operatorname{set}\left(\bar{b}_{6}\right)\right]=\emptyset, h\left[X_{6}\right] \cap h\left[\operatorname{set}\left(\bar{b}_{6}\right)\right]=\emptyset$.

Exceptions for $y$ : Suppose that in the common increasing enumeration of $X_{6} \cup$ range $\left(\bar{b}_{6}\right) \cup Y_{6}$ there is an element $y \in Y_{6}$ such for no $y^{\prime} \in Y_{1}$ we have that for the latest block $b_{6, n}$ before $y$ the constellation $x<b_{6, n}<y^{\prime}<y<x^{\prime}, x, x^{\prime} \in X_{6}$. Again the remark in parantheses applies. We map the last interval $[x, y]$ before $y$ to $x$ by a finite-to-one function. We do this for all such $y$. We define $f$ arbitrarily on the other points so that it will be a finite-to-one function. Since $\mathcal{R}_{1, \min }, \mathcal{R}_{1, \max }$ are nnc $\Phi\left(\mathcal{U}_{k-1}\right)$ there are $\bar{b}_{7} \sqsubseteq_{k}^{\text {Tetr }} \bar{b}_{6}, \bar{b}_{7} \in \mathcal{U}_{k-1}$ and $X_{7} \subseteq X_{6}, X_{7} \in \mathcal{R}_{1, \text { min }}$ and $Y_{7} \subseteq Y_{6}, Y_{7} \in \mathcal{R}_{1, \max }$ such that $h\left[Y_{7}\right] \cap h\left[\operatorname{set}\left(\bar{b}_{7}\right)\right]=\emptyset, h\left[X_{7}\right] \cap h\left[\operatorname{set}\left(\bar{b}_{7}\right)\right]=\emptyset$.

By the thinning out in the fourth step we ensured that $X_{7}, Y_{7}, \bar{b}_{7}$ respect clause (b) in the following form:

$$
\begin{align*}
& \left(\forall x \in X_{7}\right)\left(\forall y \in Y_{7}\right)\left(y<x \rightarrow x \in B_{y}\right) \\
& \left(\forall b \in \operatorname{range}\left(\bar{b}_{7}\right)\right)\left(\forall x \in X_{7}\right)\left(x<\operatorname{supp}(b) \rightarrow b \in C_{x}\right)  \tag{6.17}\\
& \left(\forall y \in Y_{7}\right)\left(\forall b \in \operatorname{range}\left(\bar{b}_{7}\right)\right)\left(\operatorname{supp}(b)<y \rightarrow y \in D_{\max (\operatorname{supp}(b))}\right) .
\end{align*}
$$

However, clause (a) is ruined. Note that the diagonal laws from Equation 6.17 are preserved under further thinning out.

Fifth step:
We restore the triple alternation pattern again. We repeat the steps two and three, and thus get $X_{8} \subseteq X_{7}, Y_{8} \subseteq Y_{7}, \bar{b}_{8} \sqsubseteq_{k}^{\mathrm{Tetr}} \bar{b}_{7}$ that respect (a) and (b).

We conclude the proof of part (1) of Theorem 6.15 Let $X, \bar{b}, Y$ be as in Lemma 6.29. By Equation (6.14), for each $n$, there is

$$
c_{n} \in \tilde{A}_{\max \left(\operatorname{supp}\left(c_{n-1}\right)\right)} \text { s.t. }\left(\min _{1}\left(c_{n}\right)=x_{n} \wedge T\left(c_{n}\right)=b_{n} \wedge \max _{1}\left(c_{n}\right)=y_{n}\right)
$$

By the definition of the $\tilde{A}_{n}$ we have $\mathrm{TFU}_{k}(\bar{c}) \subseteq P$. Since

$$
\begin{aligned}
& \bar{b} \in \mathcal{U}_{k-1} \in \gamma^{\operatorname{good}}\left(\operatorname{Fin}_{k-1},\left\langle\mathcal{R}_{1+i, x}: 1 \leq i \leq k-1, x=\min , \max \right\rangle\right) \\
& \left\{\min _{1}\left(c_{n}\right): n<\omega\right\}=X \in \mathcal{R}_{1, \min }, \\
& \left\{\max _{1}\left(c_{n}\right): n<\omega\right\}=Y \in \mathcal{R}_{1, \max }, \text { and } \\
& \Phi\left(\mathcal{U}_{k-1}\right) \text { is nnc } \mathcal{R}_{1, \min }, \mathcal{R}_{1, \max },
\end{aligned}
$$

we have $\bar{c} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$. So $\bar{c}$ is branch of the Grigorieff tree with the desired properties. Thus Theorem 6.15 part (1) is proved.

We prove part (2). Again we encounter the phenomenon (as in the proof of the Hindman colouring in the $\mathbb{M}(\mathcal{U})$-extension in Lemma 3.17) that we almost proved the existence of diagonal lower bounds already during the proof of the colouring theorem.

## Lemma 6.30.

$$
\begin{align*}
& a \sqsubseteq_{k}^{\mathrm{Tetr}} \text {-descending sequence } \bar{a}_{n}, n \in \omega, \bar{a}_{n} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}}) \text {, }  \tag{1}\\
& B_{n}:=\left\{\min _{1}(s): s \in \operatorname{TFU}\left(\bar{a}_{n}\right)\right\}  \tag{2}\\
& C_{n}:=\left\{T(s): s \in \operatorname{TFU}\left(\bar{a}_{n}\right) \wedge \min _{1}(s) \in B_{n}\right\}  \tag{6.18}\\
& D_{n}:=\left\{\max _{1}(s): s \in \operatorname{TFU}\left(\bar{a}_{n}\right) \wedge \min _{1}(s) \in B_{n} \wedge T(s) \in C_{n}\right\}
\end{align*}
$$

Then there is some $\bar{b} \sqsubseteq_{k}^{\text {Tetr,* }} T\left(\bar{a}_{n}\right), \bar{b} \in\left(\operatorname{Fin}_{k-1}\right)^{\omega}\left(\left\langle\mathcal{R}_{1+i, x}: 1 \leq i \leq k-1, x=\right.\right.$ $\min , \max \rangle)$ and there is $X \in \mathcal{R}_{1, \min }, Y \in \mathcal{R}_{1, \max }$ with the following properties the blocks of $\bar{b}$ and $X$ and $Y$ lie as follows

$$
x_{0}<b_{0}<y_{0}<x_{1}<b_{1}<y_{1}<\ldots
$$

and the following three conditions on diagonal lower bounds hold

$$
\begin{equation*}
(\forall n)\left(x_{n} \in B_{y_{n-1}} \wedge b_{n} \in C_{x_{n}} \wedge y_{n} \in D_{\max \left(\operatorname{supp}\left(b_{n}\right)\right)}\right) \tag{6.19}
\end{equation*}
$$

Proof. This is proved as in Lemma6.29. In the first step, we take separate diagonal lower bounds, call them as there. For the middle part $\bar{b}_{1} \in\left(\operatorname{Fin}_{k}\right)^{\omega}\left(\left\langle\mathcal{R}_{1+i, x}: 1 \leq\right.\right.$ $i \leq k-1, x=\min , \max \rangle$ ) we choose by (3) at $k-1$ a Gowers-Milliken-Taylor ultrafilter $\mathcal{U}_{k-1} \in \gamma^{\text {good }}\left(\operatorname{Fin}_{k-1}\left\langle\mathcal{R}_{1+i, x}: 1 \leq i \leq k-1, x=\min , \max \right\rangle\right)$ such that $\Phi\left(\mathcal{U}_{k-1}\right)$ is nnc $\mathcal{R}_{1, x}$ and such that $\operatorname{TFU}_{k-1}\left(\bar{b}_{1}\right) \in \mathcal{U}_{k-1}$. Then we can go on as in the proof of Lemma 6.29.

Equation 6.19 yields a diagonal bound $\bar{c} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ of $\bar{a}_{n}, n \in \omega$. This finishes the proof of statement (2) at $k$.

Now we turn to (3) at $k$ :
Let $\mathcal{S}_{1}$ and $\mathcal{S}_{2}$ be two new ultrafilters, nnc to any of the $\left\langle\mathcal{R}_{i, x}: i=1, \ldots, k, x=\right.$ $\min , \max \rangle$. Using CH , we enumerate via $\left\langle X_{\alpha}, h_{\alpha}: \alpha<\omega_{1}\right\rangle$ any subset $X_{\alpha}$ of Fin ${ }_{k}$ and any finite-to-one function $h_{\alpha}$ such that each pair appears cofinally often in the enumeration. By induction on $\alpha<\omega_{1}$ we choose $\bar{a}_{\alpha} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ such that
(1) $\bar{a}_{\alpha+1}$ decides $X_{\alpha}$ and
(2) for $i=1,2, \exists E_{i} \in \mathcal{S}_{i}, h_{\alpha}\left[\operatorname{set}\left(\bar{a}_{\alpha+1}\right)\right] \cap h_{\alpha}\left[E_{i}\right]=\emptyset$.
(3) $(\forall \beta<\alpha)\left(\bar{a}_{\beta} \sqsubseteq_{k}^{\text {Tetr,* }} \bar{a}_{\alpha}\right)$.

Then we let $\mathcal{U}$ be generated by $\left\{\operatorname{TFU}_{k}\left(\bar{a}_{\alpha}: \alpha<\omega_{1}\right\}\right.$.
Given $\bar{a}_{\beta}, \beta<\alpha$, we first take a $\sqsubseteq_{k}^{\text {Tetr, }}$ - lower bound $\bar{a}_{\alpha}$ of them as guaranteed by (2) at $k$. We let $h=h_{\alpha}$ By induction hypothesis there is a Gowers-MillikenTaylor ultrafilter $\mathcal{U}_{k-1}$ avoiding $\mathcal{S}_{i}$ and containing $\mathrm{TFU}_{k-1}\left(T\left[\bar{c}_{\alpha}\right]\right)$. In step 0 , just drop all clauses about $\bar{a}_{\alpha}$. Then we build $S_{k}$ in Lemma 6.24 (this time in the form with the $\mathcal{R}_{1, x}$ and the $\mathcal{S}_{j}$ and the starting set $\operatorname{TFU}_{k}(\bar{a})$, note that this lemma uses only (3) at $k-1$ ), i.e., the requirement pertains to $h_{\alpha}$, and $\operatorname{TFU}_{k}(\bar{a})$ such that for any $X \in \mathcal{X} \in S_{k},\left(\exists E_{i} \in \mathcal{S}_{i}\right)_{i=1,2}\left(h[\operatorname{set}[X]] \cap h\left[E_{i}\right]=\emptyset\right)$ and $\operatorname{TFU}_{k}\left(\bar{a}_{\alpha}\right) \in \mathcal{U}^{\text {idem }}$. We use, that $h$-avoiding $\mathcal{S}_{i}$ is preserved by + to find an idempotent ultrafilter $\mathcal{U}^{\text {idem }} \leq \mathcal{U}_{k-1}, \mathcal{U}^{\text {idem }} \in S_{k}+\mathcal{U}_{k-1}$ such that $\operatorname{TFU}_{k}\left(\bar{a}_{\alpha}\right) \in \mathcal{U}^{\text {idem }}$ and $\mathcal{U}^{\text {idem }} h$ avoids $\mathcal{S}_{j}$. Then we take $Y_{\alpha}$ to be $X_{\alpha}$, if $X_{\alpha} \in \mathcal{U}^{\text {idem }}$ or $Y=\operatorname{Fin}_{k} \backslash X_{\alpha}$ otherwise. Now we build all the Grigorieff tree with $\tilde{A}_{n} \in \mathcal{U}^{\text {idem }}$ and $\tilde{A}_{n} \subseteq \operatorname{TFU}_{k}\left(\bar{a}_{\alpha}\right)$. A branch of it is taken as $\bar{a}_{\alpha+1}$. Then $\operatorname{TFU}_{k}\left(\bar{a}_{\alpha+1}\right) \subseteq Y_{\alpha}$.

Thus we finish the proof of part (3) at $k$ of Theorem 6.15
Question 6.31. We do not know a proof in the Baumgartner 3 style. The analogous question for Gowers' $\operatorname{Fin}_{k}$ theorem is asked in 40.

Now we show that under CH or under MA or after forcing with the pure part of $\mathbb{G M}(\overline{\mathcal{R}})$ there is a Gowers-Milliken-Taylor ultrafilter.

Corollary 6.32. Let $k, \overline{\mathcal{R}}$ be as in Def. 6.8. The family $\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ is Gowersadequate.
Corollary 6.33. Let $k, \overline{\mathcal{R}}$ be as in Def. 6.8. Under CH or under MA( $\sigma$-centred) there is an Gowers-Milliken-Taylor ultrafilter.
Proof. We perform a $\sqsubseteq_{k}^{\text {Tetr,* }}$-downward construction of length $\mathfrak{c}$ with lower bound in the limit steps that are either given by CH or provided by $\mathrm{MA}(\sigma$-centred). In the successor we use Theorem 6.15 to decide whether the next subset of Fin $_{k}$ is in or out with the aid of Theorem 6.15,
Definition 6.34. Let $k \geq 2$ and let $1 \leq i<k$. Let $\mathcal{U}$ be an ultrafilter over $\operatorname{Fin}_{k}$. We let

$$
\Phi_{\geq i+1}(\mathcal{U})=\left\{\left\{s^{-1}[\{i+1, \ldots, k\}]: s \in X\right\}: X \in \mathcal{U}\right\}
$$

and call $\Phi_{\geq i+1}(\mathcal{U})$ the core strictly above $i$.
The following generalises [9, Theorem 38] and shows that in any Gowers-MillikenTaylor ultrafilter over $\mathrm{Fin}_{k}$ the $2 k$ pairwise nnc Ramsey projections can be found. The additional information on the higher cores can be seen as a justification of the inductive procedure in the proof 6.15.

Theorem 6.35. For any Gowers-Milliken-Taylor ultrafilter $\mathcal{U}$ over $\operatorname{Fin}_{k}$ the following holds:
(1) For each $1 \leq i \leq k, \mathcal{R}_{i, \min }$ and $\mathcal{R}_{i, \max }$ are nnc and for $i<k, \mathcal{R}_{i, \min }$ and $\mathcal{R}_{i, \max }$ are nnc $\Phi_{\geq i+1}(\mathcal{U})$.
(2) The projections $\min _{1}(\mathcal{U}), \ldots, \min _{k}(\mathcal{U}), \max _{k}(\mathcal{U}), \ldots, \max _{1}(\mathcal{U})$ are pairwise non-nearly coherent Ramsey ultrafilters over $\omega$.
(3) All cores $\Phi_{i}(\mathcal{U})$ are nearly coherent.

Proof. In [7, Proposition 3.9] it is shown that all minima and all maxima are Ramsey ultrafilters. It remains to show that they are pairwise non-nearly coherent.

We prove (1). In the first step we consider the case of $\min _{j}(\mathcal{U}), \max _{j}(\mathcal{U})$. Almost verbatim as in [9, Section 6] it is shown that for any $j \in\{1, \ldots, k\}$, the two Ramsey ultrafilters $\min _{j}(\mathcal{U})$ and $\max _{j}(\mathcal{U})$ are not nearly coherent. The reasoning uses only the closure of $\mathrm{TFU}_{k}(\bar{b})$ under + from Def. $5.1(7)$ and does not refer to the Tetris function.

We show that for any $1 \leq i<\leq k, \min _{i}(\mathcal{U})$ and $\Phi_{\geq i+1}(\mathcal{U})$ are not nearly coherent. The crucial step is the Tetris step that does not exist for the Hindman space. For a contradiction, we assume that $f$ is finite-to-one and $f\left(\min _{i}(\mathcal{U})\right) \supseteq f\left(\Phi_{\geq i+1}(\mathcal{U})\right)$. W.l.o.g. we assume that $f$ is non-decreasing and surjective. We let $I_{n}=\bar{f}^{-1}[\{n\}]$. We colour $\operatorname{Fin}_{k}$ as follows. Let $c(s)=0$ if the $k$ such that $\min \left(s^{-1}[\{i\}]\right) \in I_{k}$ is equal to the $k^{\prime}$ such that $s^{-1}[\{i+1, \ldots k\}]$ meets $I_{k^{\prime}}$; and 1 otherwise. We choose a $c$-monochromatic $\operatorname{TFU}_{k}(\bar{a}) \in \mathcal{U}$. We show that the colour is 1 . For any $r<t$, $r, t \in \operatorname{range}(\bar{a})$ whose supports do not meet the same $I$-interval we have for any $j \geq i+1$ that $j \notin \operatorname{range}\left(T^{(k-i)}(r)\right)$ but $i \in \operatorname{range}\left(T^{(k-i)}(r)\right)$ and hence

$$
c\left(T^{(k-i)}(r)+t\right)=1
$$

However, by the assumed near coherence there are infinitely many $n$ such that

$$
I_{n} \cap\left\{\min \left(a_{m}^{-1}[\{i\}]\right): m \in \omega\right\} \cap\left(\bigcup\left\{a_{\ell}^{-1}[\{i+1, \ldots, k\}]: \ell \in \omega\right\}\right) \neq \emptyset
$$

We take $n, m, \ell$ such that

$$
\min \left(a_{m}^{-1}[\{i\}]\right) \in I_{n}, a_{\ell}^{-1}[\{j\}] \cap I_{n} \neq \emptyset
$$

Then in case $m<\ell$ we have $c\left(a_{m}+a_{\ell}\right)=0$ and in case $m=\ell$ we have $c\left(a_{m}\right)=0$. Contradiction.

Similarly one shows the statement about $\mathcal{R}_{i, \max }$.
(2): Statement (1) implies (2), since for $j>i, \min _{j}(\mathcal{U}), \max _{j}(\mathcal{U}) \supseteq \Phi_{\geq i+1}(\mathcal{U})$.
(3) Now we consider the cores. We let $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ such that $\operatorname{TFU}_{k}(\bar{a}) \in \mathcal{U}$. Then there is some finite-to-one $h$ such that

$$
(\forall n)\left(h\left[a_{n}^{-1}[\{1\}]\right]=\cdots=h\left[a_{n}^{-1}[\{k\}]\right]\right) .
$$

Any set in $\mathcal{U}$ is of the form $\operatorname{TFU}_{k}(\bar{b})$ for some $\bar{b}$ compatible with $\bar{a}$, we can assume $\bar{b} \sqsubseteq_{k}^{\mathrm{Tetr}} \bar{a}$. Then by the definition of the condensation order, in each block of $\bar{b}$ there must be one block of $\bar{a}$ that does not drop by the Tetris function. Hence

$$
(\forall n)(\forall i=1, \ldots, k)\left(h \left[b_{n}^{-1}[\{i\}] \cap h\left[b_{n}^{-1}[\{j\}] \neq \emptyset\right) .\right.\right.
$$

Thus $\Phi_{i}(\mathcal{U})$ and $\Phi_{j}(\mathcal{U})$ are nearly coherent non-meagre filters.

## 7. Localised Gowers-Matet Forcing

Now we harvest a fruit from the Ramsey theoretic work: a new family of forcing orders that allows us to arrange the number of near-coherence classes. Since we use generalised condensations by including the Tetris operation, we call the new forcing Gowers-Matet forcing.

Definition 7.1. Let $k \geq 1$. Conditions in Gowers-Matet forcing, $\mathbb{G M}_{k}$, are pairs $(s, \bar{a})$ such that $s \in \operatorname{Fin}_{k}$ and $\bar{a} \in\left(\operatorname{Fin}_{k}\right)^{\omega}$ and $\operatorname{supp}(s)<\operatorname{supp}\left(a_{0}\right)$. Let $p=(s, \bar{a}) \in$ $\mathbb{G M}_{k}$. The component $s$ is called the trunk of $p$ and the component $\bar{a}$ is called the pure part of $p$.

The forcing order is $(t, \bar{b}) \leq_{k}(s, \bar{a})$ (recall the stronger condition is the smaller one) if the following holds:
(a) $s=t$ or there are $n, i_{0}<\cdots<i_{n} \in \omega$, and $j_{r} \in\{0, \ldots, k-1\}$ for $r \leq n$ with at least one $j_{r}=0$ such that $t$ is a sum of the form

$$
t=s+T^{\left(j_{0}\right)}\left(a_{i_{0}}\right)+\cdots+T^{\left(j_{n}\right)}\left(a_{i_{n}}\right)
$$

(b) $\bar{b} \sqsubseteq_{k}^{\mathrm{Tetr}} \bar{a}$ (see Def. $\left.6.1(6)\right)$.

In the case of $s=t$ we call $(t, \bar{b})$ a pure extension of $(s, \bar{a})=p$.
Definition 7.2. Given a Gowers-Matet-adequate family $\mathcal{H} \subseteq\left(\operatorname{Fin}_{k}\right)^{\omega}$, the notion of forcing $\mathbb{G M}_{k}(\mathcal{H})$ consists of all pairs $(s, \bar{a})$ such that $\bar{a} \in \mathcal{H}$. The forcing order is the same as in the Gowers-Matet forcing.

Definition 7.3. For $\mathcal{H}=\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$ from the previous section we let $\mathbb{G M}_{k}(\overline{\mathcal{R}})=$ $\mathbb{G M}_{k}(\mathcal{H})$.

Thanks to Theorem 6.15 we have:
Lemma 7.4. $\mathbb{G M}_{k}(\overline{\mathcal{R}})$ has the pure decision property, i.e., for any $\varphi \in \mathcal{L}(\in)$, $(s, \bar{a}) \in \mathbb{G M}_{k}(\overline{\mathcal{R}})$ there is $(s, \bar{b}) \leq_{0}(s, \bar{a})$ such that $((s, \bar{b}) \Vdash \varphi \vee(s, \bar{b}) \Vdash \neg \varphi)$.

Lemma 7.5. The forcing poset $\left.\left(\mathbb{G M}_{k}(\overline{\mathcal{R}}), \leq,\left(\leq_{n}\right)_{n<\omega}\right)\right)$ fulfils Axiom $A$ and hence is proper.

Proof. A derivation of Axiom A for the relations $\left(\leq_{n}\right)_{n}$ from the pure decision property for tree forcings can be found, e.g., in [2, Section 7.1]. Properness alone can also be proved as in [11, 2.3, 2.4, 2.5]. The latter proof uses the existence of lower bounds, i.e., statement (2) of Theorem 6.15, but not the pure decision property.

Definition 7.6. Let $\mathcal{H}$ be a subset of $\left(\operatorname{Fin}_{k}\right)^{\omega}$.
(1) The $\mathbb{G M}_{k}(\mathcal{H})$-generic function from $\omega$ to $k+1$ is

$$
\mu=\bigcup\{s \upharpoonright(\max (\operatorname{supp}(s))+1):(\exists \bar{a})((s, \bar{a}) \in G)\} .
$$

(2) Again the generic $i$-fibres for $i=1, \ldots, k$ are written as

$$
\mu_{i}:=\mu^{-1}[\{i\}] .
$$

(3) Any Gowers-Milliken-Taylor ultrafilter $\mathcal{U}$ avoids $\mathcal{E}$ iff $\Phi(\mathcal{U}) \not \chi_{\mathrm{RB}} \mathcal{E}$.

Now we investigate the number of near-coherence classes in models our our new forcing.

Definition 7.7. Let $X \in[\omega]^{\omega}$. We let $f_{X}(n)=|X \cap n|$.
We start with a density argument for evaluating our forcings.

Theorem 7.8. Assume CH. Let $\overline{\mathcal{R}}$ be as in Def. 6.8. Let $h: \omega \rightarrow \omega$ be a finite-to-one function. Let $\mathcal{E}$ and $\mathcal{W}$ be ultrafilters over $\omega$ such that $\mathcal{W}, \mathcal{E} \not ¥_{R B} \mathcal{R}_{i, x}$ for $i=1, \ldots, k, x=\min , \max$. Then

$$
\mathbb{G M}_{k}(\overline{\mathcal{R}}) \Vdash_{\mathbb{G M}_{k}(\overline{\mathcal{R}})} f_{\operatorname{supp}(\mu)}(\mathcal{W})=f_{\operatorname{supp}(\mu)}(\mathcal{E})
$$

Proof. Suppose for some $E \in \mathcal{E}, W \in \mathcal{W}$, some $(s, \bar{a}) \in \mathbb{G M}_{k}(\overline{\mathcal{R}})$, $(s, \bar{a}) \Vdash$ $f_{\operatorname{supp}(\mu)}[W] \cap f_{\operatorname{supp}(\mu)}[E] \cap[n, \omega)=\emptyset$. By Theorem 6.15(3), there is a Gowers-Milliken-Taylor ultrafilter $\mathcal{U}_{k}$ such that $\operatorname{TFU}_{k}(\bar{a}) \in \mathcal{U}$ and such that $\Phi\left(\mathcal{U}_{k}\right)$ avoids $\mathcal{E}, \mathcal{W}$.

So there is a $\bar{b} \sqsubseteq_{k}^{\mathrm{Tetr}} \bar{a}$ such that $\operatorname{TFU}(\bar{b}) \in \mathcal{U}_{k}$ and such that there are infinitely many elements of $E$ outside $\operatorname{set}(\bar{b})$ and infinitely many elements of $W$ outside $\operatorname{set}(\bar{b})$. Since $\operatorname{TFU}_{k}(\bar{b}) \in \mathcal{U}_{k}$, Lemma 6.18 implies that $\bar{b} \in\left(\operatorname{Fin}_{k}\right)^{\omega}(\overline{\mathcal{R}})$. We take some $e \in(E \backslash \operatorname{set}(\bar{b}))$ such that $e>\max \{n, \max (\operatorname{supp}(s))\}$. and some $w \in W \backslash \operatorname{set}(\bar{b})$ such that $w>\max \{n, \max (\operatorname{supp}(s))\}$. Then we can lengthen $s$ by taking $t>s$ such that
$\min (\operatorname{supp}(t))>w, e$ and $(s+t, \bar{b}) \leq_{\mathbb{G M}_{k}(\overline{\mathcal{R}})}(s, \bar{a})$. Then $(s+t, \bar{b}) \Vdash f_{\operatorname{supp}(\mu)}(e)=$ $f_{\text {supp }(\mu)}(w)$. Contradiction.

Theorem 7.9. (Adaption of [17, Theorem 4]) Let $k \geq 1$ and $\overline{\mathcal{R}}$ be as above and assume that $\mathcal{E}$ is a P-point with $\mathcal{E} \not ¥_{R B} \mathcal{R}_{i, \min }, \mathcal{R}_{j, \max }$ for any $i \in\{1, \ldots, k\}$. Then $\mathcal{E}$ continues to generate an ultrafilter after we force with $\mathbb{G M}_{k}(\overline{\mathcal{R}})$.

Proof. By Theorem 6.15(2) the conditions $(s, \bar{a})$ such that there is a Gowers-Milliken-Taylor ultrafilter $\Phi\left(\mathcal{U}_{k}\right)$ is nnc to $\mathcal{E}$ (which means $\Phi\left(\mathcal{U}_{k}\right) \not \mathbb{Z}_{r m R B} \mathcal{E}$ ) and such that $\bar{a} \in \mathcal{U}_{k}$ are dense in $\mathbb{G M}_{k}\left(\overline{\mathcal{R}}\right.$. Since $\mathbb{G M}_{k}(\overline{\mathcal{R}})$ has the pure decision property we can carry out the proof literally as in [17, Lemma 2.3 - Lemma 2.10].

Now we are concerned with the second iterand. The following follows from an easy density argument.
Lemma 7.10. For any $i \in\{1, \ldots, k\}, x=\min$, $\max$, we have

$$
\mathbb{G M}_{k}(\overline{\mathcal{R}}) \Vdash \mathcal{R}_{i, x} \cup\left\{\mu_{i}\right\} \text { is a filter subbase. }
$$

Now we come to the $k$-dimensional version of Theorem 3.25. It is crucial that the Ramsey ultrafilter $\mathcal{R}_{i, x}$ is not diagonalised. Otherwise we would add a dominating real. For each $1 \leq i \leq k$ the two Ramsey ultrafilters $\mathcal{R}_{\min , i}$ and $\mathcal{R}_{\max , i}$ are destroyed by the $i$-fiber $\mu_{i}$.
Theorem 7.11. Let $k, \overline{\mathcal{R}}$ be as in Def. 6.8.

$$
\begin{align*}
\mathbb{G M}_{k}(\overline{\mathcal{R}}) \Vdash & (\forall i \in\{1, \ldots, k\}, x \in\{\min , \max \}) \\
& \left(\operatorname{fil}\left(\left(\mathcal{R}_{i, x} \cup\left\{\mu_{i}\right\}\right)\right)^{+}\right. \text {is a happy family }  \tag{7.1}\\
& \text { that is nowhere almost a filter }) .
\end{align*}
$$

and hence by Mathias' [30, Prop. 011] combined with [5, proof of Theorem 14],
$\begin{aligned} \mathbb{G M}_{k}(\overline{\mathcal{R}}) \Vdash & \Vdash\left(\exists\left\langle\mathcal{R}_{i, x}^{\text {ext }}: i=1, \ldots, k, x=\min , \max \right\rangle\right)\left((\forall(i, x))\left(\mathcal{R}_{i, x}^{\text {ext }} \supseteq\left(\mathcal{R}_{i, x} \cup\left\{\mu_{i}\right\}\right) \wedge\right.\right. \\ & \left.\mathcal{R}_{i, x}^{\text {ext }} \text { is a Ramsey ultrafilter that is nnc to } \mathcal{E}\right) \\ & \text { and the extensions are pairwise nnc }) .\end{aligned}$

Proof. Theorem 6.16 allows us to transfer the proof of Theorem 3.25 to $\mathbb{G M}_{k}(\overline{\mathcal{R}})$.

We rework Section 4 the iteration theory for limit steps, for iterands of the form $\mathbb{G M}_{k}(\overline{\mathcal{R}})$. We fix $k$ and $\overline{\mathcal{R}}=\overline{\mathcal{R}}_{0}$ as in Def. 6.8. We define by induction on $\alpha \leq \omega_{2}$ a countable support iteration (in the sense of [37, Def. III, 3.1]) $\mathbb{P}_{\alpha}=\left\langle\mathbb{P}_{\beta}, \mathbb{G M}\left(\overline{\mathcal{R}}_{\sim}\right)\right.$ : $\beta \leq \alpha, \gamma<\alpha\rangle$ such that for any $\beta<\alpha$,

$$
\begin{equation*}
\mathbb{P}_{\beta} \Vdash(\forall(i, x))\left(\mathcal{R}_{i, x, \beta} \supseteq \bigcup\left\{\mathcal{R}_{i, x, \gamma} \cup\left\{\mu_{\gamma, i}\right\}: \gamma<\beta\right\}\right. \tag{7.2}
\end{equation*}
$$

$\wedge \mathcal{R}_{i, x, \beta}$ is a Ramsey ultrafilter that is nnc to $\mathcal{E}$ )
and the $\mathcal{R}_{i, x, \beta}, i=1, \ldots, k, x=\min$, max, are pairwise nnc.
We use for names the same letters as for the corresponding evaluated names.
Here $\mathbb{P}_{\beta+1}$ forces that $\mu_{\beta}$ is the $\mathbb{G M}_{k}\left(\overline{\mathcal{R}}_{\beta}\right)$-generic real, and $\mu_{\beta, i}$ denotes its $i$ fibre according to Definition 5.8(8). In Theorem 7.11 we proved that there are extensions in the successor steps. This guarantees the existence of $\overline{\mathcal{R}}_{\beta+1}$ with the desired properties.

Now we consider limit steps $\alpha$. If $\operatorname{cf}(\alpha)>\omega$, we can just take $\mathbb{P}_{\alpha} \Vdash \mathcal{R}_{i, x, \alpha}=$ $\bigcup_{\gamma<\alpha} \mathcal{R}_{i, x, \gamma}$ and the inductive hypotheses will be carried on, since in proper forcing every real appears at a step of at most countable cofinality, with the only exception that for $\alpha=\aleph_{2}$ the CH gets lost. So we concentrate on the hard case, $\operatorname{cf}(\alpha)=\omega$.

$$
\begin{align*}
\mathbb{P}_{\alpha} \Vdash\left(\exists \overline{\mathcal{R}}_{\alpha}\right) & \left(\bigwedge_{i, x} \mathcal{R}_{i, x, \alpha} \supseteq \bigcup\left\{\mathcal{R}_{i, x, \beta} \cup\left\{\mu_{\beta, i}\right\}\right): \beta<\alpha\right\} \\
& \text { and the } \mathcal{R}_{i, x, \alpha}, i=1, \ldots, k, x=\min , \text { max, are pairwise nnc }  \tag{7.3}\\
& \text { Ramsey ultrafilters that are nnc to } \mathcal{E}),
\end{align*}
$$

will follow from the CH , a routine enumeration according to [30, Prop. 011] and [5, proof of Theorem 14] the following theorem:

Theorem 7.12. Suppose $\mathrm{CH}, \alpha<\omega_{2}, \operatorname{cf}(\alpha)=\omega$, and that $\mathbb{P}_{\beta}, \overline{\mathcal{R}}_{\beta}$ are as in Equation (7.2) and $\mathbb{P}_{\alpha}$ is the countable support limit of $\left\langle\mathbb{P}_{\beta}, \mathbb{G M}_{k}\left(\overline{\mathcal{R}}_{\beta}\right): \beta<\alpha\right\rangle$. In $\mathbf{V}^{\mathbb{P}_{\alpha}}$, for any $i, x$, the set of positive sets

$$
\left(\bigcup_{\gamma<\alpha}\left(\mathcal{R}_{i, x, \gamma} \cup\left\{\mu_{\gamma, i}\right\}\right)\right)^{+}
$$

forms a happy family that is nowhere almost a filter.
As in the proofs of Theorem4.1 we introduce an increasing sequence $\left\langle R_{\gamma}\left(\overline{\mathcal{R}}_{<\gamma}\right)\right.$ : $\gamma<\alpha\rangle$ of relations $R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)$ in $\mathbf{V}^{\mathbb{P}_{\alpha}}$ such that a property called

$$
\begin{equation*}
\text { " } \mathbb{P}_{\alpha} \text { is } R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right) \text {-preserving" } \tag{7.4}
\end{equation*}
$$

is carried in addition to the property (7.2) and properness in the inductive choice of the iteration.

We define a relation $R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)$ and are concerned with statements of the form $(\forall f)(\exists g)\left(f R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right) g\right)$ for a Borel relation $R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)$ on the Baire space in $\mathbf{V}^{\mathbb{P}_{\alpha}}$. Here the argument $\overline{\mathcal{R}}_{<\alpha}$ indicates the invoked parameters from the ground model: Ramsey ultrafilters in the stage 0 and names for Ramsey ultrafilters in any later stage.

We do not write tildes below the $R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)$ 's, although these relations are names.

Definition 7.13. By induction on $\alpha \leq \omega_{2}$ we define the following relations.
(1) Let $\mathbb{P}_{\alpha}=\left\langle\mathbb{P}_{\beta}, \mathbb{G M}_{k}\left(\overline{\mathcal{R}}_{\gamma}\right): \beta \leq \alpha, \gamma<\alpha\right\rangle$ be defined with (7.2). Let $i \in$ $\{1, \ldots, k\}, x \in\{\min , \max \}$. We say that a $\mathbb{P}_{\alpha}$-name $g$ for an element of $[\omega]^{\omega}$ is $\alpha-(i, x)$-positive if $1 \Vdash_{\mathbb{P}_{\alpha}} g \in\left(\bigcup\left\{\operatorname{fil}\left(\mathcal{R}_{i, x, \gamma} \cup\left\{\mu_{\gamma, i}\right\}\right): \gamma<\alpha\right\}\right)^{+}$.
(2) Let $\mathbb{P}_{\alpha}=\left\langle\mathbb{P}_{\beta}, \mathbb{G M}_{k}\left(\overline{\mathcal{R}}_{\gamma}\right): \beta \leq \alpha, \gamma<\alpha\right\rangle$ be defined with (7.2). We say $f R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right) g$ if the following holds in $\mathbf{V}^{\mathbb{P}_{\alpha}}$ :
(a) $f=(\bar{A}, h,(i, x))$,
(b) $\bar{A}=\left\langle A_{\ell}: \ell \in \omega\right\rangle$ is a $\subseteq$-descending sequence of $\alpha$ - $(i, x)$-positive members of $[\omega]^{\omega}$,
(c) $h$ is finite-to-one,
(d) for $j=0,1$ there are $g^{j} \in[\omega]^{\omega}$, with the following properties:
(i) $g=g^{0} \cup g^{1}$,
(ii) $g^{j}$ is an $\alpha-(i, x)$-positive diagonal lower bound of $\bar{A}$ and
(iii) $h\left[g^{0}\right] \cap h\left[g^{1}\right]=\emptyset$.

Definition 7.14. We say $\mathbb{P}_{\alpha}$ is $R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)$-preserving if $\mathbb{P}_{\alpha}$ is proper and

$$
\mathbb{P}_{\alpha} \Vdash\left(\forall f \in \operatorname{dom}\left(R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)\right)\right)(\exists g)\left(f R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right) g\right) .
$$

Lemma 7.15. We assume $\mathrm{CH}, \alpha<\omega_{2}$ and $\operatorname{cf}(\alpha)=\omega$. If $\mathbb{P}_{\alpha}=\left\langle\mathbb{P}_{\beta}, \mathbb{G M}_{k}\left(\overline{\mathcal{R}}_{\gamma}\right)\right.$ : $\beta \leq \alpha, \gamma<\alpha\rangle$ is $R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)$ preserving then

$$
\mathbb{P}_{\alpha} \Vdash\left(\bigcup\left\{\operatorname{fil}\left(\mathcal{R}_{i, x, \beta} \cup\left\{\mu_{i, \beta}\right\}\right): \beta<\alpha\right\}\right)^{+}
$$

is a happy family that is nowhere almost a filter).
Proof. This follows from Definition 7.14 .
As mentioned a routine enumeration gives:
Corollary 7.16. If $\mathbb{P}_{\alpha} \Vdash \mathrm{CH}$ and $\mathbb{P}_{\alpha}$ is $R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)$-preserving then Equation (7.3) holds.

We carry the preservation property upwards by induction.
Lemma 7.17. Assume $\mathrm{CH}, \alpha<\omega_{2}, \operatorname{cf}(\alpha)=\omega$. Let $\mathbb{P}_{\alpha}$ be the countable support limit of $\mathbb{P}_{\beta}, \beta<\alpha$. If for $\beta<\alpha$ such that $\operatorname{cf}(\beta)<\omega_{1}, \mathbb{P}_{\beta}$ is $R_{\beta}\left(\overline{\mathcal{R}}_{<\beta}\right)$-preserving and for any $\beta<\alpha$, (7.2) holds then $\mathbb{P}_{\alpha}$ is $R_{\alpha}\left(\overline{\mathcal{R}}_{<\alpha}\right)$ preserving.
Proof. As in Lemma 4.6
This finishes the proof of Theorem 7.12,
Finally we answer Banakh's and Blass' question on the finite part near-coherence spectrum:

Theorem 7.18. Assume CH and let $k \geq 1$. Then there is a countable support iteration of proper iterands $\mathbb{P}=\left\langle\mathbb{P}_{\alpha}, \mathbb{G M}_{k}\left(\overline{\mathcal{R}_{\beta}}\right): \beta<\omega_{2}, \alpha \leq \omega_{2}\right\rangle$ such that in the extension there exactly $2 k+1$ near-coherence classes of ultrafilters. Namely, one class is represented by a P-point of character $\omega_{1}$ and $2 k$ classes represented by the names Ramsey ultrafilters $\mathcal{R}_{i, x, \omega_{2}}, i=1, \ldots, k, x=\min , \max$.
Proof. We start with a ground model $\mathbf{V}$ that fulfils CH . By CH there are a $P$-point $\mathcal{E}$ and a $\{1, \ldots, k\} \times\{\min , \max \}$-sequence of Ramsey ultrafilters $\overline{\mathcal{R}}_{0}$, such that any two
of them are nnc. A countable support iteration $\left\langle\mathbb{P}_{\beta}, \mathbb{G M}_{k}\left(\overline{\mathcal{R}}_{\gamma}\right)\right.$ : $\left.\beta \leq \omega_{2}, \gamma<\omega_{2}\right\rangle$ of proper forcings with (7.2) at any stage $\beta$ forces: There are at least the nearcoherence classes of $\mathcal{E}, \mathcal{R}_{i, x, \omega_{2}}, i=1, \ldots, k, x=\min$, max.

Why are there no other near-coherence classes in $\mathbf{V}^{\mathbb{P}_{\omega_{2}}}$ ? For a contradiction, we suppose that $\mathcal{W}$ is a non-principal ultrafilter in $\mathbf{V}[G]$ for some $\mathbb{P}_{\omega_{2}}$-generic filter $G$ and $\mathcal{W}$ is nnc to any $\mathcal{R}_{i, x \omega_{2}}, i=1, \ldots, k, x=\min$, max and nnc to $\mathcal{E}$. Then by [11, Lemma 5.10] there are a $p \in \mathbb{P}_{\omega_{2}} \cap G$, say $p \in \mathbb{P}_{\alpha_{0}}$ for an $\alpha_{0} \in \omega_{2}$ (by 11, Lemma 5.6]), and an $\omega_{1}$-club $C \subseteq\left[\alpha_{0}, \omega_{2}\right)$ such that for each $\alpha \in C \cup\left\{\omega_{2}\right\}, \mathcal{W} \cap \mathbf{V}\left[G \cap \mathbb{P}_{\alpha}\right]$ has a $\mathbb{P}_{\alpha}$-name (for which we again write $\mathcal{W} \cap \mathbf{V}\left[G \cap \mathbb{P}_{\alpha}\right]$ ) and

$$
p \Vdash_{\mathbb{P}_{\alpha}} \mathcal{W} \cap \mathbf{V}\left[G \cap \mathbb{P}_{\alpha}\right] \text { is an ultrafilter that is nnc to } \mathcal{R}_{i, x, \alpha} \text { and nnc to } \mathcal{E} \text {. }
$$

We fix $\alpha=\min (C)$.
By Theorem 7.8 and Theorem 7.9 we have for any $\alpha \in C$,

$$
p \vdash_{\mathbb{P}_{\alpha+1}} f_{\operatorname{supp}\left(\mu_{\alpha}\right)}\left(\mathcal{W} \cap \mathbf{V}\left[G \cap \mathbb{P}_{\alpha}\right]\right)=f_{\operatorname{supp}\left(\mu_{\alpha}\right)}(\mathcal{E}) \wedge \mathcal{E} \text { generates an ultrafilter. }
$$

Since

$$
p \Vdash_{\mathbb{P}_{\omega_{2}}} \mathcal{W} \text { is a filter and } \mathcal{W} \supseteq \mathcal{W} \cap \mathbf{V}\left[G \cap \mathbb{P}_{\alpha}\right]
$$

we have $p \Vdash_{\mathbb{P}_{\omega_{2}}} f_{\operatorname{supp}\left(\mu_{\alpha}\right)}(\mathcal{W})=f_{\operatorname{supp}\left(\mu_{\alpha}\right)}(\mathcal{E})$.

Theorem 7.19. Under CH there is an iteration $\left\langle\mathbb{P}_{\beta}, \mathbb{Q}_{\alpha}: \beta \leq \omega_{2}, \alpha<\omega_{2}\right\rangle$ that forces exactly $2 k$ near-coherence classes.
Proof. We fix a $\diamond\left(S_{\aleph_{1}}^{\aleph_{2}}\right)$-sequence $\left\langle D_{\alpha}: \alpha \in S_{\aleph_{1}}^{\aleph_{2}}\right\rangle$ in the ground model or add one by a preliminary forcing that preserves $C H$. At iterand $\mathbb{Q}_{\alpha}=\mathbb{G M}_{k}\left(\left\langle\mathcal{R}_{i, x, \alpha}\right.\right.$ : $i=1, \ldots, k, x=\min , \max \rangle), \operatorname{cf}(\alpha)=\omega_{1}$, we work with only one top ultrafilter $\mathcal{R}_{k, \min , \alpha}$ that extends the ultrafilters $\mathcal{R}_{k, \min , \beta}, \beta<\alpha$. The other top ultrafilter $\mathcal{R}_{k \text {,max, } \alpha}$ is varied according to a $\diamond\left(S_{\aleph_{1}}^{\aleph_{2}}\right)$ sequence, namely to be some Ramsey ultrafilter that is (forced to be) nnc to $D_{\alpha}$ that is handed down by the diamond, if the diamond hands down a name of an ultrafilter $D_{\alpha}$ that is forced to be nnc to $\mathcal{E}$ and nnc to any of the $\mathcal{R}_{i, x, \alpha}, i=1, \ldots, k-1, x=\min , \max$ or $(i, x)=(k, \min ) 10$ According to Theorem 7.8 in stage $\mathbf{V}^{\mathbb{P}_{\alpha+1}}$ we have that $D_{\alpha}$ is nearly coherent to $\mathcal{E}$. If $\mathcal{W} \in \mathbf{V}^{\mathbb{P} \omega_{2}}$ extends $D_{\alpha}$, then in the final model $\mathcal{W}$ is nearly coherent to $\mathcal{E}$ via $f_{\mu_{\alpha}}$. At stages $\alpha$ of uncountable cofinality and below conditions where the diamond does not hand down an ultrafilter that is nnc to $\mathcal{E}$ and nnc to any of the $\mathcal{R}_{i, x, \alpha}, i=1, \ldots, k-1, x=\min , \max$ or $(i, x)=(k, \min )$, or at stages of countable cofinality or successor stages we choose for $\mathcal{R}_{k, \max , \alpha}$ any Ramsey ultrafilter that is nnc to any of the $\mathcal{R}_{i, x, \alpha}, i=1, \ldots, k-1, x=\min , \max$ or $(i, x)=(k, \min )$ and nnc to $\mathcal{E}$. Since for any $\mathcal{P}_{\omega_{2}}$-name $\tau$ for an ultrafilter, there are stationarily many $\alpha \in S_{\aleph_{1}}^{\aleph_{2}}$ such that $\tau \cap \mathbf{V}^{\mathbb{P}_{\alpha}}=D_{\alpha}$, any ultrafilter $\mathcal{W}$ in $\mathbb{P}_{\omega_{2}}$ extension is nearly coherent to $\mathcal{E}$ or nearly coherent to some of the $\mathcal{R}_{i, x, \omega_{2}}, i=1, \ldots, k-1$, $x=\min , \max$ or $(i, x)=(k, \min )$.

Corollary 7.20. For any $n \in \omega$, the statement "there are exactly $n+1$ nearcoherence classes of ultrafilters" is consistent relative to ZFC.

[^9]For $n=1$ we can take the Matet model without any localisation [8] or the Miller model [12] or the Blass-Shelah model [11].

The following two propositions give more information on the decompositions of the iterands.

Proposition 7.21. Fix $k, \overline{\mathcal{R}}$ as Definition 6.8. We let $\mathbb{Q}_{\text {pure }}=\left(\operatorname{Fin}_{k}^{\omega}(\overline{\mathcal{R}}), \sqsubseteq_{k}^{\mathrm{Tetr}, *}\right)$ and we let $\underset{\sim}{\mathcal{U}}=\left\{\langle\bar{a}, \bar{a}\rangle: \bar{a} \in \mathbb{Q}_{\text {pure }}\right\}$. Then the following holds:
(1) $\mathbb{Q}_{\text {pure }}$ is $\omega$-closed.
(2) $\mathbb{G M}_{k}(\overline{\mathcal{R}})$ is densely embedded into $\mathbb{Q}_{\text {pure }} * \mathbb{G M}_{k}(\mathcal{U})$.
(3) $\mathbb{Q}_{\text {pure }}$ forces that $\mathcal{U}$ is a Gowers-Milliken-Taylor ultrafilter with $\min _{i}(\mathcal{U})=$ $\mathcal{R}_{i, \min }$ and $\max _{i}(\underset{\sim}{\mathcal{U}})=\mathcal{R}_{i, \max }$ for $i=1, \ldots, k$.
(4) $\mathbb{Q}_{\text {pure }}$ forces that $\Phi(\underset{\sim}{\mathcal{U}})$ ( $\Phi$ is defined in Def. 5.8(3)) is nnc to any filter from the ground model that is nnc $\mathcal{R}_{i, x} . i=1, \ldots, k, x=\min , \max$.

Proof. (1) The forcing order $\mathbb{Q}_{\text {pure }}$ is $\omega$-closed by (2) of Theorem 6.15.
(2) We map $(s, \bar{a}) \in \mathbb{G M}_{k}(\overline{\mathcal{R}})$ to $(\bar{a},(s, \bar{a}))$. This is a dense embedding. Details can be found in [17, Proposition 3.2].
(3) By Theorem 6.15 and density arguments, the first forcing, $\mathbb{Q}_{\text {pure }}$, forces that is generic filter is an Gowers-Milliken-Taylor ultrafilter. Since $\mathbb{Q}_{\text {pure }}$ does not add reals, only colourings and descending $\omega$-sequences from the ground model have to be considered.

Statement (4) follows from Theorem 7.8, applied to $\mathbb{Q}_{\text {pure }}$.

Remark 7.22. We sketch an alternative way to force at least $2 k+1$ nameable near-cohernce classes: Force with an iteration of iterands $\mathbb{G M}_{k}\left(\mathcal{U}_{\alpha}\right), \mathcal{U}_{\alpha}$ a Gowers-Milliken-Taylor ultrafilter in $\mathbf{V}^{\mathbb{P}_{\alpha}}$ without localisation to $\overline{\mathcal{R}}$. In the successor steps one needs to prove the analogon to Theorem 3.9 about completing the destroyed Gowers-Milliken-Taylor ultrafilter $\mathcal{U}_{\alpha}$, in a non-localised form. So here for the existence of $\mathcal{U}_{\alpha+1} \supseteq \mathcal{U}_{\alpha}$ we need Gower's theorem in a computation about names. We expect that this can be done similarly to the proofs in Section 3. However, there is no way to prevent that more nnc Ramsey ultrafilters than the projections are created in the iteration, since the iteration could just be the Fin ${ }_{k}$-shadow of an iteration with Gowers-Milliken-Taylor ultrafilters over Fin ${ }_{k+1}$.

    Key words and phrases. Iterated proper forcing, combinatorics with block-sequences, $P$-point, Milliken-Taylor ultrafilters, near coherence of ultrafilters, selective coideals, preservation theorems, Gowers' Fin $k$ theorem.

[^1]:    ${ }^{1}$ The last index in the ultrafilters indicates the iteration stage $\mathbf{V}^{\mathbb{P}_{\alpha}}$. The ultrafilters grow, i.e., $\mathcal{R}_{i, x, \alpha}=\mathcal{R}_{i, x, \beta} \cap \mathbf{V}^{\mathbb{P}_{\alpha}}$ for $\alpha<\beta \leq \omega_{2}$.

[^2]:    ${ }^{2}$ If $f$ is surjective, then $f(\mathcal{B})$ can be written as $\{f[X]: X \in \mathcal{B}\}$. In any case, $f(\mathcal{B})$ is contained in the set of supersets of members of the latter set.

[^3]:    ${ }^{3}$ Note that this is not the usual lexicographic well-order; e.g., $\{0,1\} \ll_{\text {lex, Fin }}\{1\}$. The aim of this well-order is to define the $\sqsubseteq$-largest common lower bound of two $\sqsubseteq$-compatible elements of (Fin) ${ }^{\omega}$ by induction on the blocks. The relation $\sqsubseteq$ is defined in Def. 2.2
    ${ }^{4}$ Differences in behaviour of union ultrafilters that contain only min-unbounded sets, and ordered-union ultrafilters that have a bases of unmeshed sets, are not yet known. Any known proof of Hindman's theorem results in an unmeshed sequence.

[^4]:    ${ }^{5}$ Also the definition $f(\mathcal{F}) \subseteq \mathcal{G}$ is used in the literature. If $\mathcal{G}$ is a $P$-point both definitions are closely related.

[^5]:    ${ }^{6}$ It can be used for names of subsets of $H(\omega)$ and names for any $\omega$-hierarchy of hereditary finite sets whose union is a subset $H(\omega)$. We define neatness by tailoring initial segments towards computations with diagonal lower bounds.

[^6]:    7 The Gowers-Milliken-Taylor ultrafilter $\mathcal{U}_{k-1}$ is given by the by the induction hypothesis, (2) at $k-1$ with shifted indices in the ultrafilters.

[^7]:    ${ }^{8}$ Note that $h$ is fixed. In order to look at all $h$ simultaneously, it is best to work with two finite-to-one functions $h_{1}, h_{2}$. For any finitely many finite-to-one functions $h^{j}$, $j<J$, there are two finite-to-one functions $h_{1}, h_{2}$ such that for any $n \in \omega$, for any $j<J,\left(h^{j}\right)^{-1}[\{n\}] \subseteq h_{1}^{-1}[\{n\}]$ or $\subseteq h_{2}^{-1}[\{n\}]$. Such a compactness argument is not used here.

[^8]:    ${ }^{9}$ We remark that in the case of ideals (or coideals) over $\omega$, Grigorieff [23, Section 1] worked with similar trees.

[^9]:    ${ }^{10}$ Details about book-keeping functions that are defined from diamond sequences can for example be found in 31 Section 2].
