Synthesis of monolayer MoS₂ is essential for fulfilling the potential of MoS₂ in catalysis, optoelectronics and valleytronics, *etc*. Herein, we report for the first time the scalable growth of high quality, domain size tunable (edge length from ~ 200 nm to 50 μm), strictly monolayer MoS₂ on commercially available Au foils, *via* a low pressure chemical vapor deposition method. The nanosized triangular MoS₂ flakes on Au foils was proved to be an excellent electrocatalyst for hydrogen evolution reaction (HER), featured by a rather low Tafel slope (61 mV/decade) and a supreme exchange current density (38.1 μA/cm²). The abundant active edge sites and the excellent electron coupling between MoS₂ and Au foils account for the extraordinary HER activity. Our work presents a sound proof that strictly monolayer MoS₂ assembled on a well selected electrode can manifest comparable or even superior HER property than that of nanoparticles or few-layer MoS₂ electrocatalyst.

The significance of two dimensional (2D) atomic layer thin materials has been fully demonstrated by a series of fascinating performances emerged in graphene.^{1,2} However, the zero band gap property of graphene impedes its applications in carbon-based nanoelectronics and optoelectronics.³ In this regard, transition metal dichalcogenides (TMDCs) with lamellar structures have subsequently drawn great interest due to its sizable band gap with indirect to direct tunability from bulk to one atomic layer,⁴⁻⁶ and plenty of intriguing performances in electrical,⁷ optical,⁸ and photovoltaic devices.⁹

Synthesizing uniform monolayer TMDC films with high crystal quality and large domain size should be the premise to fulfill the application potential of TMDC, and a variety of synthesis methods have been developed so far. Top-down micromechanical exfoliation 10 and ionic intercalation 11 were firstly employed to produce atomically thin TMDC films, the production of which was nevertheless of non-uniform thickness and versatile size distributions, thus incompatible with efficient batch fabrication. Recently, several bottom-up methods, such as transition metal sulfurization, 12 decomposition of thiomolybdates, 13 and physical vapor deposition, 14 have been explored to synthesize TMDC films on insulating substrates, but still resulting in uncontrollable film thickness ranging from monolayer to few-layer. Compared with abovementioned routes, chemical vapor deposition (CVD) technique is more simple and efficient in synthesizing monolayer TMDC films 15-20 because of its wide tunability in growth parameters and substrates.²¹ Note that, the CVD TMDC films growth on insulating substrates (SiO₂, 22 mica, 23 sapphire 24) has demonstrated their perfect application potentials in electronic and photovoltaic devices.

In particular, theoretical calculations have indicated that the free energy of hydrogen bonding to the sulfur edge of MoS₂ (a member of TMDC) is close to that of Pt,²⁵ which makes MoS₂ a potentially low-cost, high-abundance substitute of Pt in electrocatalytic hydrogen evolution reaction (HER).²⁶⁻²⁹ To this end, MoS₂-based HER electrocatalysts such as amorphous particles, 30 chemically exfoliated nanosheets, 31-33 mesopores, 34 as well as thin films 35-36 have been intensively synthesized in various routes. Although rather high HER activities have been obtained therein, the HER mechanism is still inconclusive due to the complexity of the reaction, probably mediated by a wide distribution of particle size and layers thickness, and the multiple surface texture, etc. Consequently, seeking for ideal systems, e.g. 2D monolayer MoS₂ nanoislands with tunable sizes, would be helpful in establishing a direct correlation between the catalytic activity and the microscopic structure (namely the amount of edge sites), considering that the HER activity originating from the edges of MoS₂ whilst the basal planes are catalytically inert.^{25,37} It is worthy of mentioning that ultrahigh vacuum (UHV) deposition and recognition of monolayer MoS₂ nanoislands was realized on Au(111) by scanning tunneling microscope (STM).³⁸ The as-grown sample presented a rather low Tapfel slope of ~ 55-60 mV/decade and a rather high HER activity. However, the fabrication process involved obtaining $MoS_2/Au(111)$ nevertheless instrument-dependent in was and cost-ineffective, hence retarding the large-scale production and the practical application of monolayer MoS₂.

Herein, we demonstrate, for the first time, the scalable synthesis of monolayer MoS₂ on commercially available Au foils *via* a facile low-pressure CVD (LPCVD) method. Notably, the domain size of monolayer MoS₂ flakes can be tuned from nanometer to micronmeter by varying the growth temperature or the precursor substrate distance. This is beneficial for the utilization of monolayer MoS₂/Au directly in efficient HER and in constructing electronic and optoelectronic devices after a suitable sample transfer process. The domain size, crystal quality, and thickness of as-synthesized MoS₂ on Au foils were probed by various characterization techniques. Moreover, the HER performance of as-grown nanosized monolayer MoS₂ on Au foils was examined as a function of film coverage or edge density. The mechanism of the enhanced HER activity was investigated for the LPCVD grown MoS₂ on Au foils.

Figure 1a schematically illustrates the formation of MoS_2 2D flakes on Au foils, where the MoO_3 powder was partially reduced by S to form volatile suboxide species of MoO_{3-x} , and then sulfurized into MoS_2 on the downstream Au foils with the aid of Ar carrier gas, as described by the reaction:

$$S_2 + MoO_{3-x} \rightarrow MoS_2 + SO_2 \tag{1}$$

The LPCVD setup employed in this work is depicted in Fig. 1b (See Methods for further details of the growth methodology). The X-ray photoemission spectroscopy (XPS) spectra (Fig. 1c and Supplementary Fig. S1) was captured to confirm the formation of MoS_2 , as characterized by the Mo $3d_{5/2}$ (at 229.1eV) and Mo $3d_{3/2}$ (at 232.3eV) peaks associated with Mo^{4+} , as well as the S $2p_{3/2}$ (at 162.1eV) and S $2p_{1/2}$

(at 163.2eV) peaks assigned to S²-, which are all in good agreement with those previously reported for MoS₂. 15

Scanning electron microscope (SEM) (Fig. 1d-g) micrographs were then captured to show the domain size evolution of as-grown MoS_2 on Au foils. Notably, after 1 h growth at 530 °C (Fig. 1d), triangular MoS_2 flakes with a nearly uniform edge lengths of ~ 200 nm can be obtained on Au foils. Upon increasing the growth temperature to 680 °C while keeping other growth parameters identical (Fig. 1e and Supplementary Fig. S2), the edge length of triangular MoS_2 flake can be enlarging to ~ 55 μ m. Further increasing the growth temperature to ~ 750 °C leads to the decline in edge length (~ 30 μ m) of the triangular domains (Fig. 1g). Intriguingly, the 2D large domain MoS_2 flakes (formed at 680 °C) can be visible by optical microscope (OM) (Fig. 1h). It is worthy of mentioning that, with our LPCVD method, the area of as-grown MoS_2 sample is only limited by the size of Au foils, where the photograph in Fig. 1i represents a typical sample from the batch production with a 3 × 3 cm² coverage area.

Raman spectroscopy measurements were carried out to probe the layer thickness as well as the crystal quality of the as-grown MoS_2 samples on Au foils (Fig. 1j). The out-of-plane vibration of S atoms (A_{1g}) at ~ 406.9 cm⁻¹ and in-plane vibration of Mo and S atoms (E_{2g}^1) at ~ 387.0 cm⁻¹, and a frequency difference $\Delta \sim 19.9$ cm⁻¹ acquired from various samples shown in Fig. 1d-g seems in good agreement with those reported for monolayer MoS_2 ,³⁹ thus indicating monolayer MoS_2 formation on Au foils at various synthesis temperatures.

It is expected that, in the sample growth zone, the concentration of MoO_{3-x} will decrease with the increase of the distance between MoO_3 precursor and Au substrate (D_{ss}) , leading to different coverage of MoS_2 . In order to confirm this, a series of Au foils were successively placed on the downstream region of the quartz tube (Fig. 2a). It is found that with different D_{ss} (10.0 cm, 11.0 cm and 12.0 cm) (Fig. 2b-d, ~ 530 °C growth), the coverage of MoS_2 on Au foils can effectively tuned from ~ 70%, 50% to 10%, as clearly imaged by SEM with domain size variable from ~ 500 nm to ~ 200 nm. Upon increasing the growth temperature to 680 °C, MoS_2 samples with the coverage of ~ 90%, 80% and 10% can be observed with domain size tunable from 50 μ m to 20 μ m (Fig. 2e-g, ~ 680 °C growth). In this regard, though an appropriate control of D_{ss} and growth temperature, a complete monolayer MoS_2 film can be obtained directly on Au foils via a facile LPCVD method. MoS_2 grown on Au foils may serve as a perfect candidate in diverse fields such as effective photocatalysts, 40 solar energy funnels. 41 and integrated circuits. 42

The LPCVD monolayer MoS_2 on Au foils was considered to be a more achievable system for exploring the electrocatalytic HER activity than that of $MoS_2/Au(111)$ prepared under UHV conditions.³⁸ A series of 530 $\mathbb C$ grown MoS_2 samples with coverage from 10% to 80% (obtained in the same growth batch by only adjusting D_{ss}) was selected to serves as electrocatalysts. The representative SEM images of the samples are shown in Fig. 3a-c. It is worth noting that the individual MoS_2 flake

usually present a triangular shape with very sharp boundaries. The average edge length of these MoS_2 flakes increases with the growing coverage, displaying distinctly statistical values of 0.20 \pm 0.04, 0.43 \pm 0.03, and 0.49 \pm 0.05 μ m corresponding to 10%, 40%, and 80% flake coverage, respectively.

The HER activities of as-grown MoS₂ on Au foils with different flake coverage are reflected in the polarization curves in Fig. 3d, where the Au foil serves as the reference. Notably, MoS₂ sample with \sim 80% flake coverage exhibits the lowest overpotential (η) of -0.1 V νs . reversible hydrogen electrode (RHE), suggesting a superior HER activity, and a significant enhancement of H₂ evolution ($J = 10 \text{ mA/cm}^2$) for the same sample occurs at a voltage as low as -0.198 V (Fig. 3d). However, the MoS₂ samples produced from the identical growth batch with coverage from 60%, 40%, 20%, to 10% exhibit increasing overpotential of -0.141 V, -0.161 V, -0.177 V, and -0.229 V, respectively. The trend depicted in Fig. 3e reveals that the HER activity attenuates with the decrease of MoS₂ flake coverage.

The overall Tafel slopes were measured to be variable from 61 to 74 mV/decade (Fig. 3f). The lowest Tafel slope (61 mV/decade) is achieved from the sample with 80% coverage, which is comparable with that of the UHV deposited MoS₂/Au(111) of 55-60 mV/decade,³⁸ whilst much lower than that of CVD grown few-layer MoS₂ on glassy carbon (GC) electrodes (140-145 mV/decade).³⁵ It is known that Tafel slope is an inherent property of the catalyst which is determined by the rate-limiting step of the HER. Three possible principle steps have been proposed for the HER in acidic medium.⁴³ The first is a primary discharge step (Volmer reaction, equation (2)):

$$H_3O^+ + e^- \rightarrow H_{ads} + H_2O$$
 (2)

Which is followed by either the electrochemical desorption step (Heyrovsky reaction, equation (3)) or recombination step (Tafel reaction, equation (4)):

$$H_{ads} + H_3O^+ + e^- \rightarrow H_2 + H_2O$$
 (3)

$$H_{ads} + H_{ads} \rightarrow H_2 \tag{4}$$

Under a specific set of conditions, once the Volmer reaction accounts for the rate-limiting step, a Tafel slope of ~ 120 mV/decade should result. In addition, Tafel slope of 30 and 40 mV/decade is associated with the Heyrovsky or Tafel reaction acting as the rate-limiting step, respectively. However, to date the HER mechanism for MoS_2 has still not been unraveled due to the complexity of the reaction. The Tafel slope of 61 mV/decade obtained in this work is close to that of MoS_2 nanoislands prepared in UHV^{38} and defect-rich MoS_2 nanoplates synthesized by chemical routes, 28 suggesting the similar surface chemistry of as-grown monolayer MoS_2 on Au foils.

The HER process of MoS_2 as-grown on Au foils is schematically shown in Fig. 4a, based on theoretical²⁵ and experimental results²⁹ that the HER activity relates closely to the edge sites of MoS_2 flakes and the basal surfaces are catalytically inert. The edge structure of near triangular MoS_2 flakes should be of Mo-terminated edge, which is reactive for HER.⁴⁴ By applying extrapolation method to the Tafel plots, exchange current density (j_0), another parameter for the HER rate, can be deduced for all the samples mentioned above (Fig. 4b), where the sample with 80% coverage exhibits a remarkable j_0 of 38.1 μ A/cm², by far the highest value amongst those reported for

MoS₂ catalyst, which is almost 120 times larger than the value for bulk MoS₂ (0.32 μ A/cm²).³³

Statistical relations of j_0 as a function of coverage and edge length per area of MoS₂ flakes on Au foils are presented in Fig. 4c,d and Supplementary Table S1. Intriguingly, a 10% coverage LPCVD sample exhibits an exchange current density (j_0) of 1.51 μ A/cm², much larger than that of UHV deposited MoS₂/Au(111) (0.31 μ A/cm²) at the same coverage.³⁸ Moreover, j_0 is correlated linearly with the edge length per area of MoS₂, suggesting a linear increase of HER activity with the growing number of the edge sites. In brief, monolayer MoS₂ flakes directly grown on Au foils can act as a perfect electrocatalyst for HER, with the unique traits of a wide MoS₂ coverage tunability and a perfect MoS₂-electrode contact.

The electrochemical impedance spectroscopy (EIS) was also recorded to investigate the electrode kinetics under HER operating conditions, where the Nyquist plots (Fig. 4e) present a remarkable decrease of the charge-transfer resistance (R_{CT}) from 1296 Ω for the 10% coverage to 25 Ω for the \sim 80% coverage sample. It is noted that the R_{CT} for the 80% coverage sample is rather low as compared with related systems, and even much lower than that of the free MoS₂ particles ($R_{CT} \sim 10 \text{K}\Omega$)), 30,33 accounting for the remarkable augmentation of j_0 in the current system. The unblocked transfer of electron between MoS₂ and Au, as deduced by the obvious fluorescence quenching effect from PL spectra (as will be discussed in the next part) should also be an important factor in lending to the extraordinary HER activity of MoS₂/Au hybrid catalyst. Another important criterion for a good electrocatalyst lies in its high

durability. Figure 4f shows the polarization curve of a 40% coverage sample, where negligible differences can be noticed between the initial and after 1000 cyclic voltammetry (CV) cycling states, indicative of the excellent electrocatalytic durability of LPCVD grown MoS₂ on Au foils.

This study has demonstrated that the as-grown monolayer MoS_2 flakes on Au foils synthesized at 530 °C is an excellent system for examining the HER performances of MoS_2 . The high edge density as well as a strong electron coupling between MoS_2 and Au foil would contribute jointly to the advanced HER activity. Note that, the polarization curves and corresponding Tafel plots of the samples synthesized at elevated growth temperatures (610 °C, 680 °C, and 750 °C) usually present retarded HER activities (Supplementary Fig. S3), probably due to the gradual reduction of the density of the active sites located at the edge of MoS_2 (Supplementary Fig. S4 and Table S2).

In addition to the universally existing near-triangular shapes, the MoS₂ synthesized at higher temperature (> 610 °C) usually manifest more complicated shapes, e.g., stars or butterfly-like shapes (Supplementary Fig. S5). Raman mapping was employed to probe the thickness uniformity and the crystal quality of monolayer MoS₂ flakes synthesized at higher growth temperature, with the flakes initially identified by SEM and OM images (Fig. 5a-f). Both butterfly-like individual flake and nearly complete MoS₂ film show quite homogeneous contrasts in the mapping micrographs (Fig. 5c,f), indicating a rather high thickness uniformity of the as-grown MoS₂ samples. This fact

was further confirmed by single point Raman spectra randomly collected on a 20 μ m \times 20 μ m mapping area (Fig. 5g), which display almost no shift of the typical vibrations modes (A_{1g} , E_{2g}^1) among different locations, consistent with that of the published results for monolayer MoS_2 .⁴⁵ Moreover, the photoluminescence (PL) spectra of the as-grown MoS_2 sample was also obtained to show almost no feature at the wavelength range from 500 to 800 nm, probably due to a fluorescence quenching effect of Au foil substrates. More SEM, OM and Raman mapping images of different shapes of MoS_2 domain on Au foils are shown in Supplementary Fig. S6,7.

Transference of as-grown LPCVD MoS₂ samples onto arbitrary substrates like SiO₂/Si is highly demanded for revealing the intrinsic electronic property and for engineering its applications in addition to HER. Herein, a chemical wet etching method is utilized to transfer the as-grown sample. Figure 5h-j displays the OM view, Raman mapping image, and PL mapping image of MoS₂ samples transferred onto SiO₂/Si, respectively, where the nearly intact morphologies before and after transfer suggest a successful transfer of the sample on Au foils. Note that, other effective transfer method involved with a recyclable use of Au foils is still highly needed.

It is proposed that, on the as-grown sample, a strong interface interaction exists between MoS_2 and Au foils, enabling a suppression of the atom vibration (related to E_{2g}^1 mode) due to a higher force constant. Consequently, the E_{2g}^1 modes are supposed to soften (red-shift). After sample transfer, Raman spectra (Fig. 5k) presents a frequency difference of $\Delta \sim 18.6$ cm⁻¹ between E_{2g}^1 and A_{1g} modes ($\Delta \sim 19.9$ cm⁻¹ before transfer). The E_{2g}^1 mode of the transferred MoS_2 is found to be blue-shifted

by $\sim 1.3~{\rm cm}^{-1}$ whereas the A_{1g} mode remains nearly unchanged, which can be explained from a released interface interaction. Moreover, it is worth mentioning that a striking PL peak appears at $\sim 667~{\rm nm}$ (A excitonic emission) on transferred sample, along with a tiny shoulder peak at $\sim 610~{\rm nm}$ (B excitonic emission) (Fig. 51), which could be addressed by the disappearance of the fluorescence quenching effect exerted by the Au substrate, namely the n-doping effect by Au.

In summary, we have demonstrated for the first time the scalable synthesis of monolayer MoS_2 on commercially available Au foils via a facile LPCVD route. The directly grown triangular MoS_2 flakes synthesized at a low growth temperature was convinced to be a perfect electrocatalyst for HER. A rather low Tafel slope (61 mV/decade) and so far the most high exchange current density of $\sim 38.1~\mu\text{A/cm}^2$ were achieved. We propose that, in addition to the abundant active edge sites of monolayer MoS_2 triangles, the excellent electron coupling between MoS_2 and Au foils should account for the extraordinary HER activity. Our work not only paves a new way for the controllable growth of high quality, uniform monolayer MoS_2 by introducing Au foil as substrates, but also offers special insight into MoS_2 -based HER and the potential usage of monolayer MoS_2 in various application sectors.

Methods

MoS₂ growth and transfer. The growth of monolayer MoS₂ on Au foils was performed inside a multi-temperature-zone tubular furnace (Lindberg/Blue M)

equipped with a 1-inch-diameter quartz tube. Sulfur powder, placed outside the hot zone, was mildly sublimated at $\sim 102\,^{\circ}$ C with heating belts, and carried by Ar gas (50 standard cubic centimeter per minute (sccm)), to the downstream growth zone. MoO₃ powders (Alfa Aesar, purity 99.9%) and Au foils (Alfa Aesar, purity 99.985%, thickness $\sim 25\,\mu\text{m}$) were successively placed on the downstream region of the quartz tube. The MoO₃ powders were heated from room temperature to $\sim 530\,^{\circ}$ C within 30 minutes along with a heating rate of $\sim 17\,^{\circ}$ C/min.

The pressure for growth MoS_2 on Au foils was set at 30 Pa, and the growth time was set at 60 minutes under growth temperatures of 530 °C, 610 °C, 680 °C and 750 °C, respectively. To transfer the as-grown MoS_2 films, the MoS_2 /Au sample was firstly spin coated with polymethylmethacrylate (PMMA) and then baked at 170 °C for 10 minutes. The sample was then soaked in Au etchant for the removal of Au. Finally, the PMMA-supported MoS_2 was rinsed with deionized (DI) water and fished by an oxidized silicon wafer, then rinsed with acetone for removing the PMMA.

Characterizations of MoS_2 films. The prepared MoS_2 flakes were systematically characterized using optical microscopy (Olympus DX51), Raman spectroscopy (Horiba, LabRAM HR-800), SEM (Hitachi S-4800, acceleration voltage of 2 kV), XPS (Kratos, Axis Ultra, Mg K_{α} as the excitation source), PL (Horiba, LabRAM HR-800, excitation light of 514 nm in wavelength).

Electrochemical Measurements. All of the electrochemical measurements were performed in a three-electrode system on an electrochemical workstation (CHI660D), using MoS₂ flakes on Au foils as the working electrode, a Pt foil as a counter

electrode, and a saturated calomel reference electrode (SCE). All of the potentials were calibrated by a reversible hydrogen electrode (RHE). Linear sweep voltammetry with a scan rate of 5 mV/s, from +0.30 V to -0.35 V vs. RHE was conducted in 0.5 M H₂SO₄ (sparged with pure N₂, purity 99.999%). The Nyquist plots were obtained with frequencies ranging from 100 kHz to 0.1 Hz at an overpotential of 10 mV. The impedance data were fitted to a simplified Randles circuit to extract the series and charge-transfer resistances.

Acknowledgements: This work was financially supported by National Natural Science Foundation of China (Grants Nos.51222201, 51290272, 21073003, 21201012, 51121091, 51072004, 51201069) and the Ministry of Science and Technology of China (Grants Nos.2011CB921903, 2012CB921404, 2012CB933404, 2013CB932603, 2011CB933003), the Keygrant Project of Chinese Ministry of Education (Grants No. 313026) and the Program for New Century Excellent Talents in University (Grants No. NCET-10-0437).

Author Contributions: Y. F. Z. conceived and supervised the project. J. P. S. and D.L. M. developed and performed the synthesis experiments. J. P. S., D. L. M., Y. Z., Q.

Q. J., T. G. and J. Y. S., carried out SEM, OM, Raman, XPS and PL measurements. G. F. H. and X. Y. L. performed electrochemical measurements. J. P. S. and Y. F. Z. wrote the paper and all authors discussed and revised the final manuscript.

Additional Information: Supplementary information is available in the online version of the paper. Reprints and permissions information is available online at http://www.nature.com/reprints. Correspondence and requests for materials should be addressed to Y. F. Z.

Competing Financial Interests: The authors declare no competing financial interests.

Figure Legends

Figure 1 | LPCVD synthesis of monolayer MoS₂ on Au foils. a, Schematic view of the surface growth of MoS₂ on Au foils. b, Experimental setup of the LPCVD system. c, X-ray photoemission spectroscopy (XPS) spectra of as-grown MoS₂ on Au foils. d-g, Scanning electron microscopy (SEM) images of MoS₂ grown under distinct growth temperatures displaying different domain sizes, respectively. h, Optical microscope (OM) image of as-grown MoS₂ on Au foils. i, Photograph of the batch production of MoS₂ on Au foils. j, Raman spectra of MoS₂ flakes shown in d-g indicating the monolayer nature of the flakes.

Figure 2 | SEM images of monolayer MoS₂ grown on Au foils with different precursor substrate distances (D_{ss}) and different temperature. a. A schematic illustration of various MoS₂ samples with different coverage on Au foils (A–C) according to the distance (D_{ss}). b-d, SEM images of monolayer MoS₂ samples with coverage of ~ 70%, 50% and 10% synthesized at the same condition (at 530 °C) but with different D_{ss} of 10.0 cm, 11.0 cm and 12.0 cm, respectively. e-g, Similar MoS₂ samples grown at 680 °C with the coverage of 90%, 80% and 10%, respectively.

Figure 3 | HER activity of nanosized as-grown MoS₂ on Au foils. a-c, SEM images of monolayer MoS₂ flakes with different coverage (10%, 40% and 80%) the distribution of the domain sizes for each coverage is shown in the corresponding histogram (statistics based on SEM images including at least 100 flakes). d-f,

Coverage-dependent polarization curves, overpotential and corresponding Tafel plots of MoS_2/Au foils samples.

Figure 4 | Analysis of MoS₂-based HER activities. a, Schematic view illustrating the edges of monolayer MoS_2 functioning as the active catalytic sites for HER. b, Calculated exchange current density of different samples by applying an extrapolation method to the Tafel plots. c, d, Statistical relation of exchange current density with coverage and edge length of MoS_2 . e, Nyquist plots of different samples. f, Durability test for the MoS_2/Au hybrid catalyst.

Figure 5 | Raman and photoluminescence (PL) mapping of monolayer MoS₂ flakes prior to (on Au foils) and after transfer onto standard SiO₂/Si substrates (300 nm thick). a-f, SEM, OM and Raman mapping images of a butterfly-like shape flake and a near complete film on Au foils with the Raman signal integrated from 350 to 450 cm⁻¹. g, Single point Raman spectra randomly collected from f. h-j, OM, Raman and PL mapping images of as-transferred MoS₂ on SiO₂/Si. k, l, Comparison of Raman and PL (PL intensity normalized by Raman A_{1g} phonon peak at ~ 406.9 cm⁻¹) spectra between the as-grown and as-transferred MoS₂ samples.
