#### Abstract

In this paper we have proposed an almost unbiased estimator using known value of some population parameter(s). A class of estimators is defined which includes Singh and Solanki [1] and Sahai and Ray [2], Sisodia and Dwivedi [3], Singh et. al. [4], Upadhyaya and Singh [5], Singh and Tailor [6] estimators. Under simple random sampling without replacement (SRSWOR) scheme the expressions for bias and mean square error (MSE) are derived. Numerical illustrations are given in support of the present study.

Key words: Auxiliary information, bias, mean square error, unbiased estimator.

## 1. Introduction

It is well known that the precision of the estimates of the population mean or total of the study variable $y$ can be considering improved by the use of known information on an auxiliary variable x which is highly correlated with the study variable y . Consider a finite population $\mathrm{U}=\mathrm{U}_{1}, \mathrm{U}_{2}, \ldots \mathrm{U}_{\mathrm{N}}$ of N units. Let y and x stand for the variable under study and auxiliary variable respectively. Let ( $y_{i}, x_{i}$ ), $i=1,2, \ldots, n$ denote the values of the units included in a sample $s_{n}$ of size $n$ drawn by simple random sampling without replacement (SRSWOR). The auxiliary information has been used in improving the precision of the estimate of a parameter (See Sukhatme et. al. [7] and the references cited there in). Out of many methods, ratio and product methods of estimation are good illustrations in this context.

In order to have a survey estimate of the population mean $\overline{\mathrm{Y}}$ of the study character y , assuming the knowledge of the population mean $\overline{\mathrm{X}}$ of the auxiliary character x , the well-known ratio estimator is

$$
\begin{equation*}
\mathrm{t}_{\mathrm{R}}=\overline{\mathrm{y}} \frac{\overline{\mathrm{X}}}{\overline{\mathrm{x}}} \tag{1.1}
\end{equation*}
$$

Bahl and Tuteja [8] suggested an exponential ratio type estimator as -

$$
\begin{equation*}
\mathrm{t}_{\exp }=\overline{\mathrm{y}} \exp \left[\frac{\overline{\mathrm{X}}-\overline{\mathrm{x}}}{\overline{\mathrm{X}}+\overline{\mathrm{x}}}\right] \tag{1.2}
\end{equation*}
$$

Several authors have used prior value of certain population parameter(s) to find more precise estimates. Sisodiya and Dwivedi [3], Sen [9] and Upadhyaya and Singh [5] used the known coefficient of variation (CV) of the auxiliary character for estimating population mean of a study character in ratio method of estimation. The use of prior value of coefficient of kurtosis in estimating the population variance of study character y was first made by Singh et.al.[10]. Later used by Singh and Kakaran [11] in the estimation of population mean of study character. Singh and Tailor [6] proposed a modified ratio estimator by using the known value of correlation coefficient. Kadilar and Cingi [12] and Singh et. al. [13] have suggested modified ratio estimators by using different pairs of known value of population parameter(s).

In this paper under SRSWOR, we have proposed almost unbiased estimator for estimating $\bar{Y}$.

To obtain the bias and MSE, we write
$\overline{\mathrm{y}}=\overline{\mathrm{Y}}\left(1+\mathrm{e}_{0}\right), \quad \overline{\mathrm{x}}=\overline{\mathrm{X}}\left(1+\mathrm{e}_{1}\right)$,
such that
$E\left(e_{0}\right)=E\left(e_{1}\right)=0$.
$E\left(e_{0}^{2}\right)=f_{1} C_{y}^{2}, \quad E\left(e_{1}^{2}\right)=f_{1} C_{x}^{2}, \quad E\left(e_{0} e_{1}\right)=f_{1} \rho C_{y} C_{x}$

$$
\begin{aligned}
& \text { where } f_{1}=\left(\frac{1}{n}-\frac{1}{N}\right), \quad S_{y}^{2}=\frac{1}{(N-1)} \sum_{i=1}^{N}\left(y_{i}-\bar{Y}\right)^{2}, \quad S_{x}^{2}=\frac{1}{(N-1)} \sum_{i=1}^{N}\left(x_{i}-\bar{X}\right)^{2}, \\
& C_{y}=\frac{S_{y}}{Y}, C_{x}=\frac{S_{x}}{X}, \quad K_{x}=\rho_{y x}\left(\frac{C_{y}}{C_{x}}\right), \rho_{y x}=\frac{S_{y x}}{\left(S_{y} S_{x}\right.}, S_{y x}=\frac{1}{(N-1)} \sum_{i=1}^{N}\left(y_{i}-\bar{Y}\right)\left(x_{i}-\bar{X}\right)
\end{aligned}
$$

## 2. The proposed estimator

We proposed the following estimator

$$
\begin{equation*}
t_{1}=\bar{y}\left(\frac{K_{1} \bar{X}+K_{2} K_{3}}{K_{1} \bar{x}+K_{2} K_{3}}\right)^{\alpha} \tag{2.1}
\end{equation*}
$$

The Bias and MSE expressions of the estimator $t_{1}$ up to the first order of approximation are, respectively, given by

$$
\begin{equation*}
\mathrm{B}\left(\mathrm{t}_{1}\right)=\overline{\mathrm{Y}}_{1} \mathrm{C}_{\mathrm{x}}^{2}\left[\frac{\alpha(\alpha+1) \mathrm{V}_{1}^{2}}{2}-\alpha \mathrm{V}_{1} \mathrm{~K}_{\mathrm{x}}\right] \tag{2.2}
\end{equation*}
$$

$$
\begin{equation*}
\operatorname{MSE}\left(\mathrm{t}_{1}\right)=\overline{\mathrm{Y}}^{2} \mathrm{f}_{1}\left[\mathrm{C}_{\mathrm{y}}^{2}+\mathrm{C}_{\mathrm{x}}^{2}\left(\alpha^{2} \mathrm{~V}_{1}^{2}-2 \mathrm{~V}_{1} \alpha \mathrm{~K}_{\mathrm{x}}\right)\right] \tag{2.3}
\end{equation*}
$$

Following Singh and Solanki [1], we propose the following estimator

$$
\begin{equation*}
\mathrm{t}_{2}=\overline{\mathrm{y}}\left\{2-\left(\frac{\overline{\mathrm{x}}}{\overline{\mathrm{X}}}\right)^{\beta} \exp \left[\lambda\left(\frac{\left(\mathrm{K}_{4} \overline{\mathrm{X}}+\mathrm{K}_{5}\right)-\left(\mathrm{K}_{4} \overline{\mathrm{x}}+\mathrm{K}_{5}\right)}{\left(\mathrm{K}_{4} \overline{\mathrm{X}}+\mathrm{K}_{5}\right)+\left(\mathrm{K}_{4} \overline{\mathrm{x}}+\mathrm{K}_{5}\right)}\right)\right]\right\} \tag{2.4}
\end{equation*}
$$

The Bias and MSE expression's of the estimator $t_{2}$ up to the first order of approximation are, respectively, given by

$$
\begin{align*}
& \mathrm{B}\left(\mathrm{t}_{2}\right)=\overline{\mathrm{Y}} \mathrm{f}_{1} \mathrm{C}_{\mathrm{x}}^{2}\left[\frac{\lambda \mathrm{~V}_{2} \beta}{2}-\frac{\beta(\beta-1)}{2}-\frac{\lambda(\lambda+2) \mathrm{V}_{2}^{2}}{8}-\beta \mathrm{K}_{\mathrm{x}}+\frac{\lambda \mathrm{V}_{2} \mathrm{~K}_{\mathrm{x}}}{2}\right]  \tag{2.5}\\
& \operatorname{MSE}\left(\mathrm{t}_{2}\right)=\overline{\mathrm{Y}}^{2} \mathrm{f}_{1}\left[\mathrm{C}_{\mathrm{y}}^{2}+\mathrm{C}_{\mathrm{x}}^{2}\left(\beta^{2}+\frac{\lambda^{2} \mathrm{~V}_{2}^{2}}{4}-\beta \lambda \mathrm{V}_{2}\right)-2 \mathrm{~K}_{\mathrm{x}} \mathrm{C}_{\mathrm{x}}^{2}\left(\beta-\frac{\lambda \mathrm{V}_{2}}{2}\right)\right] \tag{2.6}
\end{align*}
$$

$\alpha, \lambda$ and $\beta$ are suitable chossen constants. Also $K_{1}, \mathrm{~K}_{3}, \mathrm{~K}_{4}, \mathrm{~K}_{5}$ are either real numbers or function of known parameters of the auxiliary variable x such as $\mathrm{C}_{\mathrm{x}}, \beta_{2}(\mathrm{x}), \rho_{\mathrm{yx}}$ and $\mathrm{K}_{\mathrm{x}} . \mathrm{K}_{2}$ is an integer which takes values +1 and -1 for designing the estimators and

$$
\left.\begin{array}{l}
\mathrm{V}_{1}=\frac{\mathrm{K}_{1} \overline{\mathrm{X}}}{\mathrm{~K}_{1} \overline{\mathrm{X}}+\mathrm{K}_{2} \mathrm{~K}_{3}} \\
\mathrm{~V}_{2}=\frac{\mathrm{K}_{4} \overline{\mathrm{X}}}{\mathrm{~K}_{4} \overline{\mathrm{X}}+\mathrm{K}_{5}}
\end{array}\right\}
$$

We see that the estimators $t_{1}$ and $t_{2}$ are biased estimators. In some applications bias is disadvantageous. Following these estimators we have proposed almost unbiased estimator of $\overline{\mathrm{Y}}$.

## 3. Almost unbiased estimator

Suppose $t_{0}=\bar{y} t_{1}=\bar{y}\left(\frac{K_{1} \bar{X}+K_{2} K_{3}}{\mathrm{~K}_{1} \bar{x}+\mathrm{K}_{2} \mathrm{~K}_{3}}\right)^{\alpha} \mathrm{t}_{2}=\overline{\mathrm{y}}\left\{2-\left(\frac{\bar{x}}{\overline{\mathrm{X}}}\right)^{\beta} \exp \left[\lambda\left(\frac{\left(\mathrm{K}_{4} \overline{\mathrm{X}}+\mathrm{K}_{5}\right)-\left(\mathrm{K}_{4} \overline{\mathrm{x}}+\mathrm{K}_{5}\right)}{\left(\mathrm{K}_{4} \overline{\mathrm{X}}+\mathrm{K}_{5}\right)+\left(\mathrm{K}_{4} \overline{\mathrm{x}}+\mathrm{K}_{5}\right)}\right)\right]\right\}$

Such that $t_{0}, t_{1}, t_{2} \in W$, where $W$ denotes the set of all possible estimators for estimating the population mean $\overline{\mathrm{Y}}$. By definition, the set W is a linear variety if
$\mathrm{t}_{\mathrm{p}}=\sum_{\mathrm{i}=0}^{3} \mathrm{w}_{\mathrm{i}} \mathrm{t}_{\mathrm{i}} \in \mathrm{W}$

Such that, $\sum_{i=0}^{3} w_{i}=1 \quad$ and $w_{i} \in R$
where $\mathrm{w}_{\mathrm{i}}(\mathrm{i}=0,1,2,3)$ denotes the constants used for reducing the bias in the class of estimators, H denotes the set of those estimators that can be constructed from $t_{i}(i=0,1,2,3)$ and $R$ denotes the set of real numbers.

Expressing (3.1) in terms of e's, we have

$$
t_{p}=\bar{Y}\left[1+e_{0}+w_{1}\left(\frac{\alpha(\alpha+1) V_{1}^{2} e_{1}^{2}}{2}-\alpha V_{1} e_{1}-\alpha V_{1} e_{0} e_{1}\right)\right.
$$

$$
\begin{equation*}
\left.+\mathrm{w}_{2}\left(-\beta \mathrm{e}_{1}-\frac{\beta(\beta-1) \mathrm{e}_{1}^{2}}{2}+\frac{\lambda \mathrm{V}_{2} \mathrm{e}_{1}}{2}+\frac{\lambda \mathrm{V}_{2} \beta \mathrm{e}_{1}^{2}}{2}-\frac{\lambda(\lambda+2) \mathrm{V}_{2}^{2} \mathrm{e}_{1}^{2}}{8}-\beta \mathrm{e}_{0} \mathrm{e}_{1}+\frac{\lambda \mathrm{V}_{2} \mathrm{e}_{0} \mathrm{e}_{1}}{2}\right)\right] \tag{3.3}
\end{equation*}
$$

Subtracting $\overline{\mathrm{Y}}$ from both sides of equation (3.3) and then taking expectation of both sides, we get the bias of the estimator $t_{p}$ up to the first order of approximation, as

$$
\begin{array}{r}
\mathrm{B}\left(\mathrm{t}_{\mathrm{p}}\right)=\overline{\mathrm{Y}} f_{1} \mathrm{w}_{1} \mathrm{C}_{\mathrm{x}}^{2}\left(\frac{\alpha(\alpha+1) \mathrm{V}_{1}^{2}}{2}-\alpha \mathrm{V}_{1} \mathrm{~K}_{\mathrm{x}}\right)+\overline{\mathrm{Y}} \mathrm{f}_{1} \mathrm{w}_{2} \mathrm{C}_{\mathrm{x}}^{2}\left(\frac{\lambda \mathrm{~V}_{2} \beta}{2}-\frac{\beta(\beta-1)}{2}-\frac{\lambda(\lambda+2) \mathrm{V}_{2}^{2}}{8}\right. \\
\left.-\beta \mathrm{K}_{\mathrm{x}}+\frac{\lambda \mathrm{V}_{2} \mathrm{~K}_{\mathrm{x}}}{2}\right) \tag{3.4}
\end{array}
$$

From (3.3), we have
$\left(t_{p}-\bar{Y}\right)=\overline{\mathrm{Y}}\left[\mathrm{e}_{0}-\mathrm{w}_{1} \alpha \mathrm{~V}_{1} \mathrm{e}_{1}-\mathrm{w}_{2}\left(\beta \mathrm{e}_{1}+\frac{\lambda \mathrm{V}_{2} \mathrm{e}_{1}}{2}\right)\right]$
Squaring both sides of (3.5) and then taking expectation, we get the MSE of the estimator $t_{p}$ up to the first order of approximation, as

$$
\begin{equation*}
\operatorname{MSE}\left(\mathrm{t}_{\mathrm{p}}\right)=\overline{\mathrm{Y}}^{2} \mathrm{f}_{1}\left[\mathrm{C}_{\mathrm{y}}^{2}+\mathrm{C}_{\mathrm{x}}^{2}\left(\mathrm{Q}^{2}-2 \mathrm{QK}_{\mathrm{x}}\right)\right] \tag{3.6}
\end{equation*}
$$

Which is minimum when
$\mathrm{Q}=\mathrm{K}_{\mathrm{x}}$
Where $\mathrm{Q}=\mathrm{w}_{1} \alpha \mathrm{~V}_{1}+\mathrm{w}_{2}\left(\beta-\frac{\lambda \mathrm{V}_{2}}{2}\right)$

Putting the value of $\mathrm{Q}=\mathrm{K}_{\mathrm{x}}$ in (3.6) we have optimum value of estimator as $\mathrm{t}_{\mathrm{p}}$ (optimum).

Thus the minimum MSE of $t_{p}$ is given by

$$
\begin{equation*}
\min \cdot \operatorname{MSE}\left(\mathrm{t}_{\mathrm{p}}\right)=\overline{\mathrm{Y}}^{2} \mathrm{f}_{1} \mathrm{C}_{\mathrm{y}}^{2}\left(1-\rho_{\mathrm{yx}}^{2}\right) \tag{3.9}
\end{equation*}
$$

Which is same as that of traditional linear regression estimator.
from (3.2) and (3.8), we have only two equations in three unknowns. It is not possible to find the unique values for $\mathrm{w}_{\mathrm{i}}{ }^{\prime} \mathrm{s}, 1=0,1,2$. In order to get unique values of $\mathrm{w}_{\mathrm{i}}$ 's, we shall impose the linear restriction
$\sum_{i=0}^{2} w_{i} B\left(t_{i}\right)=0$
where $\mathrm{B}\left(\mathrm{t}_{\mathrm{i}}\right)$ denotes the bias in the $\mathrm{i}^{\text {th }}$ estimator.

Equations (3.2), (3.8) and (3.10) can be written in the matrix form as
$\left[\begin{array}{ccc}1 & 1 & 1 \\ 0 & \alpha \mathrm{~V}_{1} & \beta-\frac{\lambda \mathrm{V}_{2}}{2} \\ 0 & \mathrm{~B}\left(\mathrm{t}_{1}\right) & \mathrm{B}\left(\mathrm{t}_{2}\right)\end{array}\right]\left[\begin{array}{l}\mathrm{w}_{0} \\ \mathrm{w}_{1} \\ \mathrm{w}_{2}\end{array}\right]=\left[\begin{array}{c}1 \\ \mathrm{k}_{\mathrm{x}} \\ 0\end{array}\right]$

Using (3.11), we get the unique values of $\mathrm{w}_{\mathrm{i}}$ 's, $1=0,1,2$ as
$\mathrm{w}_{0}=\frac{\alpha \mathrm{V}_{1}\left[\alpha \mathrm{~V}_{1} \mathrm{~A}_{2}-\mathrm{A}_{1} \mathrm{X}_{1}\right]-\mathrm{X}_{1} \mathrm{~K}_{\mathrm{x}} \mathrm{A}_{1}-\mathrm{X}_{2} \alpha \mathrm{~V}_{1}\left[\alpha \mathrm{~V}_{1} \mathrm{~A}_{2}-\mathrm{A}_{1} \mathrm{X}_{1}\right]-\alpha \mathrm{V}_{1} \mathrm{~K}_{\mathrm{x}} \mathrm{A}_{1}}{\alpha \mathrm{~V}_{1}\left[\alpha \mathrm{~V}_{1} \mathrm{~A}_{2}-\mathrm{A}_{1} \mathrm{X}_{1}\right]}$
$\mathrm{w}_{1}=\frac{\mathrm{X}_{1} \mathrm{~K}_{\mathrm{x}} \mathrm{A}_{1}}{\alpha \mathrm{~V}_{1}\left[\alpha \mathrm{~V}_{1} \mathrm{~A}_{2}-\mathrm{A}_{1} \mathrm{X}_{1}\right]}+\mathrm{X}_{2}$
$w_{2}=\frac{K_{x} A_{1}}{\left[\alpha V_{1} A_{2}-A_{1} X_{1}\right]}$
where,

$$
\left.\begin{array}{l}
\mathrm{A}_{1}=\frac{\alpha(\alpha+1) \mathrm{V}_{1}^{2}}{2}-\alpha \mathrm{V}_{1} \mathrm{~K}_{\mathrm{x}} \\
\mathrm{~A}_{2}=\frac{\lambda \mathrm{V}_{2} \beta}{2}-\frac{\beta(\beta-1)}{2}-\frac{\lambda(\lambda+2) \mathrm{V}_{2}^{2}}{8}-\beta \mathrm{K}_{\mathrm{x}}+\frac{\lambda \mathrm{V}_{2} \mathrm{~K}_{\mathrm{x}}}{2} \\
\mathrm{X}_{1}=\mathrm{A}_{1}\left[\beta-\frac{\lambda \mathrm{V}_{2}}{2}\right] \\
\mathrm{X}_{2}=\frac{\mathrm{K}_{\mathrm{x}}}{\alpha \mathrm{~V}_{1}}
\end{array}\right\}
$$

Use of these $W_{i}{ }^{\prime} \mathrm{s}, 1=0,1,2$ remove the bias up to terms of order $o\left(\mathrm{n}^{-1}\right)$ at (3.1).

## 4. Empirical study

For empirical study we use the data sets earlier used by Kadilar and Cingi [12] (population 1) and Khosnevisan et. al. [14] (population 2) to verify the theoretical results.

## Data statistics:

| Population | N | n | $\overline{\mathrm{Y}}$ | $\overline{\mathrm{X}}$ | $\mathrm{C}_{\mathrm{y}}$ | $\mathrm{C}_{\mathrm{x}}$ | $\rho_{\mathrm{yx}}$ | $\beta_{2}(\mathrm{x})$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Population 1 | 106 | 20 | 2212.59 | 27421.7 | 5.22 | 2.10 | 0.86 | 34.57 |
| Population 2 | 20 | 8 | 19.55 | 18.8 | 0.355 | 0.394 | -0.92 | 3.06 |

Table 4.1: Values of $\mathrm{w}_{\mathrm{i}}$

| $\mathbf{w}_{\mathbf{i}}$ | Population 1 | Population 2 |
| :---: | :---: | :---: |
| $\mathrm{w}_{0}$ | 2.104965 | 3.692323 |
| $\mathrm{w}_{1}$ | -6.48599 | 1.379436 |
| $\mathrm{w}_{2}$ | 5.381022 | -4.07176 |

The percent relative efficiencies (PRE) of various estimators of $\bar{Y}$ are computed and presented in Table 4.2 below.

Table 4.2: PRE of different estimators of $\bar{Y}$ with respect to $\bar{y}$

| Choice of scalars |  |  |  |  |  |  |  |  |  |  |  |  |

## 5. Proposed estimators in two phase sampling

When $\bar{X}$ is unknown, it is sometimes estimated from a preliminary large sample of size $n^{\prime}$ on which only the characteristic $x$ is measured (for details see Singh et. al. (2007)). Then a second phase sample of size $\mathrm{n}\left(\mathrm{n}<\mathrm{n}^{\prime}\right)$ is drawn on which both y and x characteristics are measured. Let $\bar{x}=$ $\frac{1}{n^{\prime}} \sum_{i=1}^{n^{\prime}} x_{i}$ denote the sample mean of x based on first phase sample of size $\mathrm{n}^{\prime}, \bar{y}=\frac{1}{n} \sum_{i=1}^{n} y_{i}$ and $\bar{x}=\frac{1}{n} \sum_{i=1}^{n} x_{i}$, be the sample means of y and x respectively based on second phase of size n .

In two-phase sampling the estimator $\mathrm{t}_{\mathrm{p}}$ will take the following form

$$
\begin{equation*}
\mathrm{t}_{\mathrm{pd}}=\sum_{\mathrm{i}=0}^{3} \mathrm{~h}_{\mathrm{i}} \mathrm{t}_{\mathrm{id}} \in \mathrm{H} \tag{5.1}
\end{equation*}
$$

Such that, $\sum_{\mathrm{i}=0}^{3} \mathrm{~h}_{\mathrm{i}}=1$ and $\mathrm{h}_{\mathrm{i}} \in \mathrm{R}$

Where,

$$
t_{0 d}=\bar{y}, t_{1 d}=\bar{y}\left(\frac{K_{1} \overline{x^{\prime}}+K_{2} K_{3}}{K_{1} \bar{x}+K_{2} K_{3}}\right)^{m}, t_{2 d}=\bar{y}\left\{2-\left(\frac{\bar{x}}{\overline{x^{\prime}}}\right)^{q} \exp \left[\gamma\left(\frac{\left(K_{4} \overline{x^{\prime}}+K_{5}\right)-\left(K_{4} \bar{x}+K_{5}\right)}{\left(K_{4} \overline{x^{\prime}}+K_{5}\right)+\left(K_{4} \bar{x}+K_{5}\right)}\right)\right]\right\}
$$

The Bias and MSE expression's of the estimator $t_{1 d}$ and $t_{2 d}$ up to the first order of approximation are, respectively, given by

$$
\begin{align*}
& B\left(t_{1 d}\right)=\bar{Y}\left[\frac{m(m-1) R_{1}^{2} f_{2} C_{x}^{2}}{2}+\frac{m(m+1) R_{1}^{2} f_{1} C_{x}^{2}}{2}-m^{2} R_{1}^{2} f_{2} C_{x}^{2}+m R_{1} f_{3} K_{x} C_{x}^{2}\right]  \tag{5.3}\\
& \operatorname{MSE}\left(t_{1 d}\right)=\bar{Y}^{2}\left[f_{1} C_{y}^{2}+m^{2} R_{1}^{2} f_{3} C_{x}^{2}-2 m R_{1} K_{x} f_{3} C_{x}^{2}\right]  \tag{5.4}\\
& B\left(t_{2 d}\right)=\bar{Y}\left[-\frac{q(q-1) f_{1} C_{x}^{2}}{2}+\frac{q(q+1) f_{2} C_{x}^{2}}{2}+q_{2} K_{x} C_{x}^{2}+q^{2} f_{2} C_{x}^{2}+f_{3} \gamma R_{2} K_{x} C_{x}^{2}+f_{3} \gamma R_{2} q C_{x}^{2}\right]  \tag{5.5}\\
& \operatorname{MSE}\left(t_{2 d}\right)=\bar{Y}^{2}\left[f_{1} C_{y}^{2}+L_{1}^{2} f_{3} C_{x}^{2}\right] \tag{5.6}
\end{align*}
$$

where,

$$
\left.\begin{array}{l}
\mathrm{R}_{1}=\frac{\mathrm{K}_{1} \overline{\mathrm{X}}}{\mathrm{~K}_{1} \overline{\mathrm{X}}+\mathrm{K}_{2} \mathrm{~K}_{3}} \\
\mathrm{R}_{2}=\frac{\mathrm{K}_{4} \overline{\mathrm{X}}}{2\left[\mathrm{~K}_{4} \overline{\mathrm{X}}+\mathrm{K}_{5}\right]} \\
\mathrm{L}_{1}=\mathrm{q}-\gamma \mathrm{A}_{2} \tag{5.7}
\end{array}\right\}
$$

Expressing (5.1) in terms of e's, we have

$$
\mathrm{t}_{\mathrm{pd}}=\overline{\mathrm{Y}}\left[1+\mathrm{e}_{0}+\mathrm{w}_{1}\left(\frac{\mathrm{~m}(\mathrm{~m}+1) \mathrm{R}_{1}^{2} \mathrm{e}_{1}^{2}}{2}-m \mathrm{R}_{1} \mathrm{e}_{1}-\mathrm{mR}_{1} \mathrm{e}_{0} \mathrm{e}_{1}+\mathrm{mR}_{1} \mathrm{e}_{0} \mathrm{e}_{1}+\frac{\mathrm{m}(\mathrm{~m}-1) \mathrm{R}_{1}^{2} \mathrm{e}_{1}^{\prime 2}}{2}+m R_{1} \mathrm{e}_{0} \mathrm{e}^{\prime}{ }_{1}\right)\right.
$$

$\left.+w_{2}\left(-q e_{1}-\frac{q(q-1) e_{1}^{2}}{2}+q e^{\prime}{ }_{1}+q^{2} e_{1} e^{\prime}{ }_{1}-\frac{q(q+1) e_{1}^{\prime 2}}{2}-\gamma R_{2}\left(e_{1}^{\prime}-e_{1}\right)+\gamma R_{2}\left(e_{0} e_{1}-e_{0} e^{\prime}{ }_{1}\right)-q e_{0} e_{1}\right)\right]$

Subtracting $\overline{\mathrm{Y}}$ from both sides of equation (5.8) and then taking expectation of both sides, we get the bias of the estimator $\mathrm{t}_{\mathrm{pd}}$ up to the first order of approximation, as
$\mathrm{B}\left(\mathrm{t}_{\mathrm{pd}}\right)=\overline{\mathrm{Y}}\left[\mathrm{B}\left(\mathrm{t}_{1 \mathrm{~d}}\right)+\mathrm{B}\left(\mathrm{t}_{2 \mathrm{~d}}\right)\right]$
Also,
$\left(\mathrm{t}_{\mathrm{pd}}-\overline{\mathrm{Y}}\right)=\overline{\mathrm{Y}}\left[\mathrm{e}_{0}+\mathrm{w}_{1}\left[\mathrm{mR}_{1} \mathrm{e}_{1}^{\prime}-\mathrm{mR}_{1} \mathrm{e}_{1}\right]+\mathrm{w}_{2}\left(-\mathrm{qe}_{1}+\mathrm{qe}_{1}-\gamma \mathrm{R}_{2} \mathrm{e}_{1}+\gamma \mathrm{R}_{2} \mathrm{e}_{1}\right)\right]$

Squaring both sides of (5.10) and then taking expectation, we get the MSE of the estimator $t_{p d}$ up to the first order of approximation, as

$$
\begin{equation*}
\operatorname{MSE}\left(\mathrm{t}_{\mathrm{pd}}\right)=\overline{\mathrm{Y}}^{2} \mathrm{f}_{1} \mathrm{C}_{\mathrm{y}}^{2}+\mathrm{L}_{2}^{2} \mathrm{f}_{3} \mathrm{C}_{\mathrm{x}}^{2}-2 \mathrm{~L}_{2} \mathrm{f}_{3} \mathrm{~K}_{\mathrm{x}} \mathrm{C}_{\mathrm{x}}^{2} \tag{5.11}
\end{equation*}
$$

Which is minimum when

$$
\begin{equation*}
\mathrm{L}_{2}=\mathrm{K}_{\mathrm{x}} \tag{5.12}
\end{equation*}
$$

Where $L_{2}=h_{1} \mathrm{mR}_{1}+h_{2}\left(q-\gamma R_{2}\right)$

Putting the value of $L_{2}=K_{x}$ in (5.11), we have optimum value of estimator as $t_{p d}$ (optimum).

Thus the minimum MSE of $t_{p d}$ is given by

$$
\begin{equation*}
\min \cdot \operatorname{MSE}\left(\mathrm{t}_{\mathrm{pd}}\right)=\overline{\mathrm{Y}}^{2} \mathrm{C}_{\mathrm{y}}^{2}\left(\mathrm{f}_{1}-\mathrm{f}_{3} \rho_{\mathrm{yx}}^{2}\right) \tag{5.14}
\end{equation*}
$$

Which is same as that of traditional linear regression estimator.
from (5.2) and (5.13), we have only two equations in three unknowns. It is not possible to find the unique values for $h_{i}$ 's, $1=0,1,2$. In order to get unique values of $h_{i}$ 's, we shall impose the linear restriction
$\sum_{i=0}^{2} h_{i} B\left(t_{i}\right)=0$
where, $\mathrm{B}\left(\mathrm{t}_{\mathrm{i}}\right)$ denotes the bias in the $\mathrm{i}^{\text {th }}$ estimator.

Equations (5.2), (5.13) and (5.15) can be written in the matrix form as

$$
\left[\begin{array}{ccc}
1 & 1 & 1  \tag{5.16}\\
0 & \mathrm{mR}_{1} & \mathrm{q}-\gamma \mathrm{R}_{2} \\
0 & \mathrm{~B}\left(\mathrm{t}_{1 \mathrm{~d}}\right) & \mathrm{B}\left(\mathrm{t}_{2 \mathrm{~d}}\right)
\end{array}\right]\left[\begin{array}{l}
\mathrm{h}_{0} \\
\mathrm{~h}_{1} \\
\mathrm{~h}_{2}
\end{array}\right]=\left[\begin{array}{c}
1 \\
\mathrm{~K}_{\mathrm{x}} \\
0
\end{array}\right]
$$

Using (5.16), we get the unique values of $h_{i}{ }^{\prime} \mathrm{s}, \mathrm{i}=0,1,2$ as

$$
\left.\begin{array}{l}
h_{0}=1-h_{1}-h_{2} \\
h_{1}=\frac{k_{x}}{m_{1}}-\frac{N_{1} K_{x}\left(q-\gamma R_{2}\right)}{N_{1} q-m R_{1} N_{2}-N_{1} \gamma R_{2}} \\
h_{2}=\frac{K_{x} N_{1}}{\left[N_{1} q-m R_{1} N_{2}-N_{1} \gamma R_{2}\right]}
\end{array}\right\}
$$

Where,

$$
\begin{aligned}
& N_{1}=\frac{m(m-1) R_{1}^{2} f_{2} C_{x}^{2}}{2}+\frac{m(m+1) R_{1}^{2} f_{1} C_{x}^{2}}{2}-m^{2} R_{1}^{2} f_{2} C_{x}^{2}+m R_{1} f_{3} K_{x} C_{x}^{2} \\
& \left.N_{2}=\left[-\frac{q(q-1) f_{1} C_{x}^{2}}{2}+\frac{q(q+1) f_{2} C_{x}^{2}}{2}+\mathrm{qf}_{2} K_{x} C_{x}^{2}+q^{2} f_{2} C_{x}^{2}+f_{3} \gamma R_{2} K_{x} C_{x}^{2}+f_{3} \gamma R_{2} q C_{x}^{2}\right]\right\}
\end{aligned}
$$

Use of these $h_{i}$ 's, $\mathrm{i}=0,1,2$ remove the bias up to terms of order o $\left(\mathrm{n}^{-1}\right)$ at (5.1).

## Conclusion

In this paper, we have proposed an unbiased estimator $\mathrm{t}_{\mathrm{p}}$. Expressions for bias and MSE's of the proposed estimators are derived up to first degree of approximation From theoretical discussion and empirical study we conclude that the proposed estimators $\mathrm{t}_{\mathrm{p}}$ under optimum conditions perform better than other estimators considered in the article. Double sampling version of the suggested class is also discussed along with its properties.

## Appendix A. Some members of the proposed family of estimators -
