# ON THE TWO MUTUALLY INDEPENDENT FACTORS THAT DETERMINE THE CONVERGENCE OF LEAST-SQUARES PROJECTION METHOD * 

SHUKAI DU ${ }^{\dagger}$ AND NAILIN DU $\ddagger$

#### Abstract

The paper investigates the least-squares projection method for bounded linear operators, which provides a natural regularization scheme by projection for many ill-posed problems. Yet, without additional assumptions, the convergence of this approximation scheme cannot be guaranteed. We reveal that the convergence of least-squares projection method is determined by two mutually independent factors - the "kernel approximability" and the "offset angle". The kernel approximability is a necessary condition of convergence described with kernel $\mathcal{N}(T)$ and its subspaces $\mathcal{N}(T) \cap X_{n}$, and we give several equivalent characterizations for it (Theorem 1.1). The offset angle of $X_{n}$ is defined as the largest canonical angle between space $T^{*} T\left(X_{n}\right)$ and $T^{\dagger} T\left(X_{n}\right)$ (which are subspaces of $\mathcal{N}(T)^{\perp}$ ), and it geometrically reflects the rate of convergence (Theorem 1.2). The paper also presents new observations for the unconvergence examples of Seidman [10, Example 3.1] and Du [2, Example 2.10] under the notions of kernel approximability and offset angle.

Key words. least-squares projection method, offset angle, kernel approximability
AMS subject classifications. 47A52; 65J20; 15A09

1. Introduction. In this paper we investigate the least-squares projection method for bounded linear operators. As is generally known, such investigations are the bases for numerically solving operator equations of the first and the second kind (see Du [1] and [2], Groetsch-Neubauer [5], Groetsch [6], Luecke-Hickey [9], Seidman [10], SpiesTemperini [11], Engl-Hank-Neubauer [3], Kress [8], and the references cited therein).

Let $X$ and $Y$ be Hilbert spaces, and $T \in \mathcal{B}(X, Y)$, i.e., $T: X \rightarrow Y$ be a bounded linear operator. Let $T^{\dagger}$ and $T^{*}$ denote its Moore-Penrose inverse and adjoint operator, $\mathcal{D}(T), \mathcal{N}(T), \mathcal{R}(T)$, and $\mathcal{G}(T)$ denote its domain, kernel, range, and graph, respectively. If $X_{0}$ and $Y_{0}$ are closed subspaces of $X$ and $Y, P_{X_{0}}$ and $P_{Y_{0}}$ will stand for the orthogonal projections from $X$ onto $X_{0}$ and from $Y$ onto $Y_{0}$, respectively. Let $X \times Y$ be the Hilbert space with the inner product defined by

$$
\left\langle\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right)\right\rangle:=\left\langle x_{1}, x_{2}\right\rangle+\left\langle y_{1}, y_{2}\right\rangle \quad \forall\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right) \in X \times Y .
$$

Let $\left\{X_{n}\right\}$ be a sequence of finite-dimensional subspaces of $X$ with $\operatorname{dim} X=\infty$ such that

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{X_{n}}} P_{I_{X}}
$$

and set

$$
T_{n}:=T P_{X_{n}} \quad \forall n \in \mathbb{N} .
$$

We say $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$ is a LPA (least-squares projection approximation) for $T$. All of our discussions in this paper will be based on this setting. Note that, if $\left\{X_{n}\right\}$ is an increasing sequence

$$
X_{0} \subseteq X_{1} \subseteq X_{2} \subseteq \cdots \quad \text { with } \quad \overline{\bigcup_{n=0}^{\infty} X_{n}}=X
$$

[^0]then $\left\{\left(X_{n}, T_{n}\right)\right\}$ is a natural LPA for $T$.
We are interested in approximating $T^{\dagger}$ by $T_{n}^{\dagger}$ when $\operatorname{dim} \mathcal{R}(T)=\infty$, which is the least-squares projection method for $T$. So the issue of convergence of LPA $\left\{\left(X_{n}, T_{n}\right)\right\}$
\[

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{w}-\lim _{n} T_{n}^{\dagger}=T^{\dagger} \text { on } \mathcal{D}\left(T^{\dagger}\right) \quad(\text { Weak Convergence }) ~} \tag{1.1}
\end{equation*}
$$

\]

and

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}^{\dagger} T_{n}^{\dagger}=T^{\dagger} \text { on } \mathcal{D}\left(T^{\dagger}\right) \quad(\text { Strong Convergence })} \tag{1.2}
\end{equation*}
$$

naturally arise. Note that without additional assumptions it cannot be guaranteed that (1.1) or (1.2) holds, as Seidman's example [10, Example 3.1] and Du's example [2, Example 2.10] show. By Groetsch [6, Proposition 0] and Du [2, Theorem 2.6 with Table 4.1] there exists the following convergence result:

$$
(1.1) \Longleftrightarrow(1.2) \Longleftrightarrow(1.3),
$$

where

$$
\begin{equation*}
\sup _{n}\left\|T_{n}^{\dagger} T\right\|<+\infty \tag{1.3}
\end{equation*}
$$

However, as condition (1.3) lacks geometric intuition, it is still difficult for us to choose a suitable LPA such that (1.3) holds. By Du [2, Theorem 2.2], (1.3) implies that

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n \rightarrow \infty} P_{\mathcal{N}\left(T_{n}\right)}=P_{\mathcal{N}(T)}, ., ~}
$$

which is equivalent to

$$
\begin{equation*}
\mathcal{N}(T)=\left\{x \in X: \lim _{n \rightarrow \infty} \operatorname{dist}\left(x, \mathcal{N}(T) \cap X_{n}\right)=0\right\} . \tag{1.4}
\end{equation*}
$$

Hence, (1.4) is necessary in choosing a suitable LPA for $T$, namely, (1.4) is a necessary condition of (1.3). Here, we remark that (1.4) does not naturally hold (see [2, Example 2.10]), but it is more likely to be satisfied compared to (1.3) (for instance, when $T$ is injection, (1.4) always holds). However, as (1.4) is not a sufficient condition of (1.3) (see [10, Example 3.1]), we still need some complementary conditions with which (1.4) could lead to (1.3).

In this paper, we aim to find the complementary condition which together with (1.4) constitute a necessary and sufficient condition of the convergence of least-squares projection method. We hope that the complementary condition has enough geometrical meanings, so as to give us new insight about least-squares projection method. We obtain the following main results:

- Several equivalent conditions of (1.4) are given. Notice that

$$
\mathcal{N}\left(T_{n}\right)=\mathcal{N}(T) \cap X_{n}+X_{n}^{\perp},
$$

therefore, $\mathcal{N}(T) \cap X_{n}$ will be referred to as the core of $\mathcal{N}\left(T_{n}\right)$, and the condition (1.4) will be called as kernel approximability of LPA $\left\{\left(X_{n}, T_{n}\right)\right\}$.

- A new concept called "offset angle" of $X_{n}$ is introduced to describe the complementary condition, which is defined as the largest canonical angle between space $T^{*} T\left(X_{n}\right)$ and $T^{\dagger} T\left(X_{n}\right)$. In the case of $\operatorname{dim} \mathcal{N}(T)<\infty$, we show that LPA $\left\{\left(X_{n}, T_{n}\right)\right\}$ is convergent if and only if it has the kernel approximability and the supreme of all offset angles is less than perpendicular angle. Moreover, if LPA $\left\{\left(X_{n}, T_{n}\right)\right\}$ is with kernel approximability, the rate of convergence of LPA $\left\{\left(X_{n}, T_{n}\right)\right\}$ is geometrically reflected by the offset angles.
- The classical unconvergence example of Seidman is restudied under the concept of offset angle, and we show that the reason for unconvergence is actually caused by offset angle of $X_{n}$ tending towards perpendicular angle. On the other hand, the unconvergence example of Du is also restudied, which is with constant zero offset angle, and we show that the reason for unconvergence is caused by (1.4) (kernel approximability) becoming invalid.
In order to expound our main results more precisely, the following notations are needed: If $\left\{S_{n}\right\}$ is a sequence of nonempty subsets of a Banach space, define

$$
\begin{gathered}
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n} S_{n}}:=\left\{x: \text { there is a sequence }\left\{x_{n}\right\} \text { such that } S_{n} \ni x_{n} \rightarrow x\right\}, \\
\underset{n \rightarrow \infty}{ }-\widetilde{\lim _{n}} S_{n}:=\left\{x: \text { there is a sequence }\left\{x_{n}\right\} \text { such that } \bigcup_{k=n}^{\infty} S_{k} \ni x_{n} \rightharpoonup x\right\} .
\end{gathered}
$$

If $M$ and $N$ are both closed subspaces of a Hilbert space $H$, define

$$
\operatorname{gap}(M, N):=\max \{\delta(M, N), \delta(N, M)\}
$$

where

$$
\delta(M, N):=\left\{\begin{aligned}
\sup \{\operatorname{dist}(x, N): x \in M,\|x\|=1\}, & \text { if } M \neq\{0\}, \\
0, & \text { if } M=\{0\} .
\end{aligned}\right.
$$

gap $(M, N)$ is called the gap between $M$ and $N$ (see [7]). When

$$
m:=\operatorname{dim}(M) \leq \operatorname{dim}(N)<\infty,
$$

the canonical angles (or principal angles) between $M$ and $N$ can be defined, which are a sequence of $m$ angles $0 \leq \vartheta_{1} \leq \vartheta_{2} \leq \ldots \leq \vartheta_{m} \leq \frac{\pi}{2}$. By [4], the canonical angles are defined recursively by

$$
\cos \vartheta_{k}=\max _{u \in M} \max _{v \in N}\langle u, v\rangle=\left\langle u_{k}, v_{k}\right\rangle
$$

subject to

$$
\left\{\begin{array}{l}
\|u\|=\|v\|=1 \\
\left\langle u, u_{i}\right\rangle=0 \quad i=1: k-1 \\
\left\langle v, v_{i}\right\rangle=0 \quad i=1: k-1
\end{array}\right.
$$

and if $\operatorname{dim}(M)=\operatorname{dim}(N)<\infty$, the largest canonical angle $\vartheta_{m}$ satisfies

$$
\begin{equation*}
\sin \vartheta_{m}=\operatorname{gap}(M, N) . \tag{1.5}
\end{equation*}
$$

With the above notions, the main theorems of the paper are stated as below:
Theorem 1.1. Let $T \in \mathcal{B}(X, Y)$ have $L P A\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$. Then the following conditions are equivalent:
(a) Kernel Approximability: (1.4) is valid, namely,

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n} \mathcal{N}}\left(T_{n}\right)=\underset{n \rightarrow \infty}{\mathrm{w}-\lim _{n} \mathcal{N}}\left(T_{n}\right)=\mathcal{N}(T)
$$

(b) Inverse-graph Approximability:

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n \rightarrow \infty} \mathcal{G}}\left(T_{n}^{\dagger}\right)=\underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim _{\infty}} \mathcal{G}}\left(T_{n}^{\dagger}\right)=\mathcal{G}\left(T^{\dagger}\right) .
$$

(c) Bounded-weak Convergence: If a sequence $\left\{y_{n}\right\} \subseteq Y$ satisfies

$$
\sup _{n}\left\|T_{n}^{\dagger} y_{n}\right\|<+\infty \quad \text { and } \quad{\underset{n}{n \rightarrow \infty}}_{\mathrm{w}-\lim _{n} y_{n}=y, ~}^{\text {, }}
$$

then

$$
y \in \mathcal{D}\left(T^{\dagger}\right) \quad \text { and } \quad \underset{n \rightarrow \infty}{\mathrm{w}-\lim _{n} T_{n}^{\dagger} y=T^{\dagger} y . . . . .}
$$

Theorem 1.2. Let $T \in \mathcal{B}(X, Y)$ with $\operatorname{dim} \mathcal{N}(T)<\infty$ have $L P A\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$. Set

$$
\begin{equation*}
\theta_{n}:=\arcsin \operatorname{gap}\left(T^{\dagger} T\left(X_{n}\right), T^{*} T\left(X_{n}\right)\right) \quad \forall n \in \mathbb{N} \tag{1.6}
\end{equation*}
$$

which is called the offset angle of $X_{n}$ respect to $T$. Then the following propositions hold:
(a) $\left\{\theta_{n}\right\}$ is a sequence in the interval $\left[0, \frac{\pi}{2}\right)$, and there holds

$$
(1.3) \Longleftrightarrow\left\{\begin{array}{l}
(1.4), \\
\sup _{n} \theta_{n}<\frac{\pi}{2}
\end{array}\right.
$$

(b) If (1.4) is valid, then there is a $n_{*} \in \mathbb{N}$ such that, for $n \geq n_{*}$,

$$
\left\|T_{n}^{\dagger} y-T^{\dagger} y\right\| \leq \sqrt{1+\tan ^{2} \theta_{n}} \operatorname{dist}\left(T^{\dagger} y, X_{n}\right) \quad \forall y \in \mathcal{D}\left(T^{\dagger}\right)
$$

and

$$
\theta_{n}=0 \Longleftrightarrow T_{n}^{\dagger}=P_{X_{n}} T^{\dagger} \text { on } \mathcal{D}\left(T^{\dagger}\right) \Longleftrightarrow \mathcal{N}(T)+T^{*} T\left(X_{n}\right) \subseteq X_{n}
$$

REMARK 1.1. As $\operatorname{dim}\left(T^{\dagger} T\left(X_{n}\right)\right)=\operatorname{dim}\left(T^{*} T\left(X_{n}\right)\right)<\infty$, the offset angle $\theta_{n}$ of $X_{n}$ respect to $T$ is the largest canonical angle between $T^{\dagger} T\left(X_{n}\right)$ and $T^{*} T\left(X_{n}\right)$ by (1.5).

The proofs of Theorems 1.1 and 1.2 are in Section 2 and Section 3 respectively. In section 4, the two unconvergence examples of Seidman and Du will be restudied to further explain the relations among the three concepts of convergence, kernel approximability and offset angle. Our conclusions will be collected in Section 5.
2. Proof of Theorem 1.1. To prove Theorem 1.1, we need some lemmas.

Lemma 2.1. Let $H$ be a Hilbert space and $\left\{H_{n}\right\}$ a sequence of closed subspaces of $H$.
(a) There holds

$$
\left\{P_{H_{n}}\right\} \text { is strongly convergent } \Longleftrightarrow \underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} H_{n}=\underset{n \rightarrow \infty}{\mathrm{w}}-\widetilde{\lim _{n}} H_{n}
$$

and when $\left\{P_{H_{n}}\right\}$ is strongly convergent, we have

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} P_{H_{n}}=P_{M}, \quad \text { where } M:=\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} H_{n}
$$

(b) If $N$ is a closed subspace of $H$, then

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} P_{H_{n}}=P_{N} \Longleftrightarrow \underset{n \rightarrow \infty}{\mathrm{w}-\lim _{n}} P_{H_{n}}=P_{N}
$$

Proof. See [1, Lemma 2.13] and [2, Lemma 2.1]. प
Lemma 2.2. Let $T \in \mathcal{B}(X, Y)$ have $L P A\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$.
(a) There hold

$$
\left\{\begin{array}{l}
\mathcal{R}\left(T_{n}\right)=T\left(X_{n}\right) \subseteq \mathcal{R}(T), \quad \stackrel{\stackrel{s}{n} \lim _{n \rightarrow \infty} P_{\mathcal{R}\left(T_{n}\right)}=P_{\overline{\mathcal{R}(T)}},}{\mathcal{N}\left(T_{n}\right)=\left(\mathcal{N}(T) \cap X_{n}\right) \oplus X_{n}^{\perp}, \quad P_{\mathcal{N}\left(T_{n}\right)}=P_{\mathcal{N}(T) \cap X_{n}}+I-P_{X_{n}},} \tag{2.1}
\end{array}\right.
$$

and

$$
\begin{equation*}
T_{n}^{\dagger} y-T^{\dagger} y=\left(T_{n}^{\dagger} T-I\right)\left(I-P_{X_{n}}\right) T^{\dagger} y \quad \forall y \in \mathcal{D}\left(T^{\dagger}\right) \tag{2.2}
\end{equation*}
$$

(b) There hold
and

$$
(1.1) \Longleftrightarrow(1.2) \Longleftrightarrow(1.3) \Longrightarrow(1.4)
$$

(c) If (1.4) and $\operatorname{dim} \mathcal{N}(T)<\infty$ are valid, then there is a $n_{*} \in \mathbb{N}$ such that

$$
\left.\begin{array}{r}
X_{n} \supseteq \mathcal{N}(T),  \tag{2.3}\\
\mathcal{N}\left(T_{n}\right)=\mathcal{N}(T) \stackrel{\perp}{\oplus} X_{n}^{\perp}
\end{array}\right\} \quad \text { for } n \geq n_{*},
$$

Proof. (a) It is clear that

$$
\mathcal{R}\left(T_{n}\right)=T\left(X_{n}\right) \subseteq \mathcal{R}(T)
$$

and

$$
\mathcal{R}(T) \subseteq \underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n} \mathcal{R}}\left(T_{n}\right) \subseteq \underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim } \mathcal{R}}\left(T_{n}\right) \subseteq \overline{\mathcal{R}(T)}
$$

Since $\mathrm{s}-\lim _{n \rightarrow \infty} \mathcal{R}\left(T_{n}\right)$ is closed by [1, Lemma 2.7], we have

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n \rightarrow \infty} \mathcal{R}}\left(T_{n}\right)=\underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim } \mathcal{R}}\left(T_{n}\right)=\widetilde{\mathcal{R}(T)}
$$

By Lemma 2.1 that is equivalent to

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{\mathcal{R}}} P_{\mathcal{R}\left(T_{n}\right)}=P_{\overline{\mathcal{R}(T)}} \tag{2.4}
\end{equation*}
$$

It is clear that

$$
\mathcal{N}\left(T_{n}\right)=\left(\mathcal{N}(T) \cap X_{n}\right) \stackrel{\perp}{\oplus} X_{n}^{\perp}, \quad P_{\mathcal{N}\left(T_{n}\right)}=P_{\mathcal{N}(T) \cap X_{n}}+I-P_{X_{n}}
$$

and hence for all $y \in \mathcal{D}\left(T^{\dagger}\right)$

$$
\begin{aligned}
T_{n}^{\dagger} y-T^{\dagger} y & =T_{n}^{\dagger}\left(T T^{\dagger}-T P_{X_{n}} T^{\dagger}\right) y+\left(T_{n}^{\dagger} T_{n}-T^{\dagger} T\right) T^{\dagger} y \\
& =T_{n}^{\dagger} T\left(I-P_{X_{n}}\right) T^{\dagger} y+\left(P_{\mathcal{N}\left(T_{n}\right)^{\perp}}-P_{\mathcal{N}(T)^{\perp}}\right) T^{\dagger} y \\
& =T_{n}^{\dagger} T\left(I-P_{X_{n}}\right) T^{\dagger} y+\left(P_{X_{n}}-I\right) T^{\dagger} y \\
& =\left(T_{n}^{\dagger} T-I\right)\left(I-P_{X_{n}}\right) T^{\dagger} y
\end{aligned}
$$

(b) It follows from (2.1) that

Note that

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n \rightarrow}}\left(\mathcal{N}(T) \cap X_{n}\right)=\left\{x \in X: \lim _{n \rightarrow \infty} \operatorname{dist}\left(x, \mathcal{N}(T) \cap X_{n}\right)=0\right\}
$$

and

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n \rightarrow \infty}}\left(\mathcal{N}(T) \cap X_{n}\right) \subseteq \underset{n \rightarrow-\lim }{\mathrm{w}}\left(\mathcal{N}(T) \cap X_{n}\right) \subseteq \mathcal{N}(T)
$$

Then, by Lemma 2.1,

$$
\begin{aligned}
(1.4) & \Longleftrightarrow{\mathrm{s}-\lim _{n \rightarrow \infty}\left(\mathcal{N}(T) \cap X_{n}\right)=\underset{n \rightarrow \infty}{\mathrm{w}-\lim _{n}}\left(\mathcal{N}(T) \cap X_{n}\right)=\mathcal{N}(T)}{ }^{\Longleftrightarrow \operatorname{s-lim}_{n \rightarrow \infty} P_{\mathcal{N}(T) \cap X_{n}}=P_{\mathcal{N}(T)}} \\
& \Longleftrightarrow \operatorname{s-lim}_{n \rightarrow \infty} P_{\mathcal{N}\left(T_{n}\right)}=P_{\mathcal{N}(T)} .
\end{aligned}
$$

Clearly, by the uniform boundedness principle and (2.2) we have that

$$
(1.2) \Longleftrightarrow(1.1) \Longleftrightarrow(1.3)
$$

From (2.2) it follows that

$$
T_{n}^{\dagger} T_{n}-T^{\dagger} T P_{X_{n}}=\left(T_{n}^{\dagger} T-I\right)\left(I-P_{X_{n}}\right) T^{\dagger} T P_{X_{n}}
$$

so, by (2.1), there is

$$
P_{\mathcal{N}(T) \cap X_{n}}-P_{\mathcal{N}(T)} P_{X_{n}}=\left(T_{n}^{\dagger} T-I\right) P_{X_{n}^{\perp}} P_{\mathcal{N}(T)}\left(I-P_{X_{n}^{\perp}}\right)
$$

Hence, (1.3) implies that

$$
P_{\mathcal{N}(T) \cap X_{n}} \xrightarrow{\mathrm{~s}} P_{\mathcal{N}(T)}(n \rightarrow \infty), \quad \text { i.e., } \quad(1.4) \text { holds. }
$$

(c) Since (1.4) is equivalent to

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{\mathcal{N}(T) \cap X_{n}}} P P_{\mathcal{N}(T)}
$$

and since

$$
\mathcal{N}(T) \cap X_{n} \subseteq \mathcal{N}(T), \quad \operatorname{dim}\left(\mathcal{N}(T) \cap X_{n}\right) \leq \operatorname{dim} \mathcal{N}(T)<\infty
$$

there holds

$$
\lim _{n \rightarrow \infty}\left\|P_{\mathcal{N}(T) \cap X_{n}}-P_{\mathcal{N}(T)}\right\|=0
$$

Thus, there is a $n_{*} \in \mathbb{N}$ such that

$$
\left\|P_{\mathcal{N}(T) \cap X_{n}}-P_{\mathcal{N}(T)}\right\|<1 \quad \text { for } n \geq n_{*} .
$$

Note that this implies that $\operatorname{rank} P_{\mathcal{N}(T) \cap X_{n}}=\operatorname{rank} P_{\mathcal{N}(T)}$ by [12, Theorem 2.3] (in fact, $P_{\mathcal{N}(T) \cap X_{n}}$ and $P_{\mathcal{N}(T)}$ are unitarily equivalent by [7, p.56, Theorem 6.32]), and therefore

$$
\operatorname{dim}\left(\mathcal{N}(T) \cap X_{n}\right)=\operatorname{dim} \mathcal{N}(T) \quad \text { for } n \geq n_{*}
$$

So, we have

$$
X_{n} \supseteq \mathcal{N}(T) \cap X_{n}=\mathcal{N}(T) \quad \text { for } n \geq n_{*},
$$

and therefore

$$
\mathcal{N}\left(T_{n}\right)=\left(\mathcal{N}(T) \cap X_{n}\right) \stackrel{\perp}{\oplus} X_{n}^{\perp}=\mathcal{N}(T) \stackrel{\perp}{\oplus} X_{n}^{\perp} \quad \text { for } n \geq n_{*}
$$

Thus, we obtain (2.3).
Lemma 2.3. Let $T \in \mathcal{B}(X, Y)$ have $L P A\left\{\left(X_{n}, T_{n}\right)\right\}$. Then

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n} \mathcal{G}}\left(T_{n}\right)=\underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim } \mathcal{G}}\left(T_{n}\right)=\mathcal{G}(T)
$$

Proof. It is clear that $\mathrm{s}-\lim _{n \rightarrow \infty} \mathcal{G}\left(T_{n}\right) \subseteq \mathrm{w}-\widetilde{\lim }_{n \rightarrow \infty} \mathcal{G}\left(T_{n}\right)$. Hence, we need only to show that

$$
\underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim _{n}} \mathcal{G}}\left(T_{n}\right) \subseteq \mathcal{G}(T) \subseteq \underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n \rightarrow \infty} \mathcal{G}}\left(T_{n}\right)
$$

Let $(x, y) \in \mathcal{G}(T)$. Then $\left(x, T_{n} x\right) \in \mathcal{G}\left(T_{n}\right)$, and $\left(x, T_{n} x\right) \rightarrow(x, y)(n \rightarrow \infty)$. Therefore, $(x, y) \in \mathrm{s}-\lim _{n \rightarrow \infty} \mathcal{G}\left(T_{n}\right)$. This gives that

$$
\mathcal{G}(T) \subseteq{\mathrm{s}-\lim _{n \rightarrow \infty} \mathcal{G}}\left(T_{n}\right)
$$

Let $(x, y) \in \mathrm{w}-\widetilde{\lim }_{n \rightarrow \infty} \mathcal{G}\left(T_{n}\right)$. Then there is a sequence $\left\{\left(x_{n}, y_{n}\right)\right\}$ such that $\cup_{k=n}^{\infty} \mathcal{G}\left(T_{k}\right) \ni$ $\left(x_{n}, y_{n}\right) \rightharpoonup(x, y)(n \rightarrow \infty)$. Thus, there is a sequence $\left\{k_{n}\right\}$ such that

$$
k_{n} \geq n, \quad x_{n} \rightharpoonup x \quad(n \rightarrow \infty), \quad T_{k_{n}} x_{n}=y_{n} \rightharpoonup y(n \rightarrow \infty)
$$

Note that for all $v \in Y$ there holds

$$
\begin{aligned}
|\langle T x-y, v\rangle| & \leq\left|\left\langle T\left(x-x_{n}\right), v\right\rangle\right|+\left|\left\langle\left(T-T_{k_{n}}\right) x_{n}, v\right\rangle\right|+\left|\left\langle y_{n}-y, v\right\rangle\right| \\
& =\left|\left\langle x-x_{n}, T^{*} v\right\rangle\right|+\left|\left\langle x_{n},\left(I-P_{X_{k_{n}}}\right) T^{*} v\right\rangle\right|+\left|\left\langle y_{n}-y, v\right\rangle\right|
\end{aligned}
$$

Thus, we have

$$
\langle T x-y, v\rangle=0 \forall v \in X, \quad \text { that is, } \quad(x, y) \in \mathcal{G}(T)
$$

This gives that

$$
\underset{n \rightarrow \infty}{\mathrm{x}-\widetilde{\lim _{\rightarrow \infty}} \mathcal{G}}\left(T_{n}\right) \subseteq \mathcal{G}(T)
$$

$\square$
Now, we can prove Theorem 1.1 as follows.
Proof. [Proof of Theorem 1.1] By statement (b) of Lemma 2.2 and Lemma 2.1, we have

$$
(1.4) \Longleftrightarrow \underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n} \mathcal{N}}\left(T_{n}\right)=\underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim _{n}} \mathcal{N}}\left(T_{n}\right)=\mathcal{N}(T)
$$

$(\mathrm{a}) \Longrightarrow(\mathrm{b})$ : Let (a) hold. Then, by Lemma 2.1, we have

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} P_{\mathcal{N}\left(T_{n}\right)^{\perp}}=P_{\mathcal{N}(T)^{\perp}} \tag{2.5}
\end{equation*}
$$

By statement (a) of Lemma 2.2,

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{\mathcal{R}}} P_{\mathcal{R}\left(T_{n}\right)^{\perp}}=P_{\mathcal{R}(T)^{\perp}} \tag{2.6}
\end{equation*}
$$

To prove (b) we need only to show that

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim _{\infty}} \mathcal{G}}\left(T_{n}^{\dagger}\right) \subseteq \mathcal{G}\left(T^{\dagger}\right) \subseteq \underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n} \mathcal{G}}\left(T_{n}^{\dagger}\right) \tag{2.7}
\end{equation*}
$$

Let $(y, x) \in \mathcal{G}\left(T^{\dagger}\right)$. Then

$$
\left(T^{\dagger} y, P_{\overline{\mathcal{R}(T)}} y\right)=\left(T^{\dagger} y, T T^{\dagger} y\right)=(x, T x) \in \mathcal{G}(T)
$$

By Lemma 2.3, s-lim $\lim _{n \rightarrow \infty} \mathcal{G}\left(T_{n}\right)=\mathcal{G}(T)$, hence there is a sequence $\left\{x_{n}\right\}$ such that

$$
x_{n} \rightarrow x \quad(n \rightarrow \infty), \quad T_{n} x_{n} \rightarrow T x \quad(n \rightarrow \infty)
$$

This with (2.5) and (2.6) implies that

$$
\left\{\begin{array}{l}
T_{n} x_{n} \rightarrow T x(n \rightarrow \infty), \\
P_{\mathcal{N}\left(T_{n}\right)^{\perp} x_{n} \rightarrow P_{\mathcal{N}(T)^{\perp}} x(n \rightarrow \infty),} P_{\mathcal{R}\left(T_{n}\right)^{\perp} y \rightarrow P_{\mathcal{R}(T)^{\perp}} y(n \rightarrow \infty),},
\end{array}\right.
$$

and therefore

$$
\left\{\begin{array}{l}
T_{n} x_{n}+P_{\mathcal{R}\left(T_{n}\right)^{\perp} y \rightarrow T x+P_{\mathcal{R}(T)^{\perp}} y=y(n \rightarrow \infty)} \\
T_{n}^{\dagger}\left(T_{n} x_{n}+P_{\mathcal{R}\left(T_{n}\right)^{\perp}} y\right) \rightarrow T^{\dagger} T x=T^{\dagger} y=x \quad(n \rightarrow \infty) .
\end{array}\right.
$$

Thus, $(y, x) \in \mathrm{s}-\lim _{n \rightarrow \infty} \mathcal{G}\left(T_{n}^{\dagger}\right)$, we get

$$
\mathcal{G}\left(T^{\dagger}\right) \subseteq \underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{\mathcal{C}} \mathcal{G}}\left(T_{n}^{\dagger}\right)
$$

Let $(y, x) \in \mathrm{w}-\widetilde{\lim }_{n \rightarrow \infty} \mathcal{G}\left(T_{n}^{\dagger}\right)$. Then there is a sequence $\left\{\left(y_{n}, x_{n}\right)\right\}$ such that

$$
\bigcup_{k=n}^{\infty} \mathcal{G}\left(T_{k}^{\dagger}\right) \ni\left(y_{n}, x_{n}\right) \rightharpoonup(y, x) \quad(n \rightarrow \infty)
$$

Hence, there is a sequence $\left\{k_{n}\right\}$ such that

$$
\begin{equation*}
k_{n} \geq n, \quad y_{n} \rightharpoonup y(n \rightarrow \infty), \quad T_{k_{n}}^{\dagger} y_{n}=x_{n} \rightharpoonup x(n \rightarrow \infty) \tag{2.8}
\end{equation*}
$$

By (2.1) in statement (a) of Lemma 2.2, we have (2.4) and $T_{k_{n}}^{\dagger} y_{n} \in \mathcal{N}\left(T_{k_{n}}\right)^{\perp} \subseteq X_{k_{n}}$. From (2.8), (2.5), by Lemma 2.1, we have

$$
\begin{gathered}
x \in \underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim _{n}} \mathcal{N}}\left(T_{n}\right)^{\perp}=\mathcal{N}(T)^{\perp}, \\
T_{k_{n}} x_{n}=T_{k_{n}} T_{k_{n}}^{\dagger} y_{n}=T T_{k_{n}}^{\dagger} y_{n} \rightharpoonup T x \quad(n \rightarrow \infty),
\end{gathered}
$$

and for any $v \in X$

$$
\begin{aligned}
\left\langle T_{k_{n}} x_{n}, v\right\rangle & =\left\langle P_{\mathcal{R}\left(T_{k_{n}}\right)} y_{n}, v\right\rangle=\left\langle y_{n}, P_{\mathcal{R}\left(T_{k_{n}}\right)} v\right\rangle \\
& =\left\langle y_{n},\left(P_{\mathcal{R}\left(T_{k_{n}}\right)}-P_{\overline{\mathcal{R}(T)}}\right) v\right\rangle+\left\langle y_{n}, P_{\overline{\mathcal{R}(T)}} v\right\rangle \\
& \rightarrow\left\langle y, P_{\overline{\mathcal{R}(T)}} v\right\rangle=\left\langle P_{\overline{\mathcal{R}(T)}} y, v\right\rangle(n \rightarrow \infty) .
\end{aligned}
$$

Thus,

$$
x \in \mathcal{N}(T)^{\perp}, T x=P_{\overline{\mathcal{R}(T)}} y, \quad \text { that is }, \quad(y, x) \in \mathcal{G}\left(T^{\dagger}\right)
$$

So, we obtain that

$$
\underset{n \rightarrow \infty}{\mathrm{~W}-\widetilde{\lim _{n}} \mathcal{G}}\left(T_{n}^{\dagger}\right) \subseteq \mathcal{G}\left(T^{\dagger}\right)
$$

Now, (2.7) is proved.
$(\mathrm{b}) \Longrightarrow(\mathrm{c}):$ Let $(\mathrm{b})$ hold. To prove $(\mathrm{c})$ let $\left\{y_{n}\right\} \subseteq Y$ satisfy

$$
\sup _{n}\left\|T_{n}^{\dagger} y_{n}\right\|<+\infty \quad \text { and } \quad \operatorname{w}_{n \rightarrow \infty}-\lim _{n} y_{n}=y
$$

Then any subsequence $\left\{T_{n_{k}}^{\dagger} y_{n_{k}}\right\}$ of $\left\{T_{n}^{\dagger} y_{n}\right\}$ has a subsequence, again denoted by $\left\{T_{n_{k}}^{\dagger} y_{n_{k}}\right\}$, converging weakly to some $u \in X$. By use of (b) we have that

$$
(y, u) \in \underset{n \rightarrow \infty}{\mathrm{w}-\widetilde{\lim _{\infty}} \mathcal{G}}\left(T_{n}^{\dagger}\right)=\mathcal{G}\left(T^{\dagger}\right)
$$

This gives that

$$
y \in \mathcal{D}\left(T^{\dagger}\right), \quad T_{n_{k}}^{\dagger} y_{n_{k}} \rightharpoonup u=T^{\dagger} y \quad(k \rightarrow \infty)
$$

So, every subsequence of $\left\{T_{n}^{\dagger} y_{n}\right\}$ has a subsequence converging weakly to $T^{\dagger} y$ and hence

$$
T_{n}^{\dagger} y_{n} \rightharpoonup T^{\dagger} y \quad(n \rightarrow \infty)
$$

Thus, we obtain (c).
$(\mathrm{c}) \Longrightarrow(\mathrm{a})$ : Let (c) hold. To prove (a), by statement (b) of Lemma 2.2 we need only to show that

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} P_{\mathcal{N}\left(T_{n}\right)}=P_{\mathcal{N}(T)} \tag{2.9}
\end{equation*}
$$

In fact, for any $x \in X$ let

$$
y_{n}:=T_{n} x \quad(n \in \mathbb{N})
$$

then

$$
y_{n} \rightarrow T x \quad(n \rightarrow \infty) \quad \text { and } \quad \sup _{n}\left\|T_{n}^{\dagger} y_{n}\right\| \leq\|x\|
$$

Due to (c), it follows that

$$
T_{n}^{\dagger} T_{n} x=T_{n}^{\dagger} y_{n} \rightharpoonup T^{\dagger} T x \quad(n \rightarrow \infty)
$$

Hence we have that

$$
\underset{n \rightarrow \infty}{\mathrm{w}-\lim _{\mathcal{N}\left(T_{n}\right)}} P P_{\mathcal{N}(T)}
$$

This is equivalent to (2.9) by Lemma 2.1.
3. Proof of Theorem 1.2. To prove Theorem 1.2, we need more lemmas besides Lemma 2.2.

Lemma 3.1. If $P, Q$ are orthogonal-projections on a Hilbert space $H$, then

$$
\|P-Q\|=\max \{\|(I-Q) P\|,\|(I-P) Q\|\} \leq 1
$$

and if $\|P-Q\|<1$, there holds

$$
\|P-Q\|=\|(I-Q) P\|=\|(I-P) Q\|
$$

Proof. Since $(I-Q) P=(P-Q) P,(I-P) Q=(Q-P) Q$, it follows that

$$
\|(I-Q) P\| \leq\|P-Q\|, \quad\|(I-P) Q\| \leq\|P-Q\|
$$

and therefore

$$
\max \{\|(I-Q) P\|,\|(I-P) Q\|\} \leq\|P-Q\|
$$

Note that for each $x \in H$ there hold

$$
\begin{aligned}
\|(P-Q) x\|^{2} & =\|(I-Q) P x\|^{2}+\|Q(I-P) x\|^{2} \\
& \leq\|(I-Q) P\|^{2}\|P x\|^{2}+\|Q(I-P)\|^{2}\|(I-P) x\|^{2} \\
& =\|(I-Q) P\|^{2}\|P x\|^{2}+\left\|(I-P)^{*} Q^{*}\right\|^{2}\|(I-P) x\|^{2} \\
& \leq(\max \{\|(I-Q) P\|,\|(I-P) Q\|\})^{2}\|x\|^{2}
\end{aligned}
$$

that is

$$
\|P-Q\| \leq \max \{\|(I-Q) P\|,\|(I-P) Q\|\}
$$

Thus we obtain

$$
\|P-Q\|=\max \{\|(I-Q) P\|,\|(I-P) Q\| \leq 1
$$

The rest follows from [7, Theorem 6.34, pp.56-58]. $\mathrm{\square}$
Lemma 3.2. Let $M, N$ be two closed subspaces of a Hilbert space $H$. Then

$$
\delta(M, N)=\left\|\left(I-P_{N}\right) P_{M}\right\|, \quad \operatorname{gap}(M, N)=\left\|P_{M}-P_{N}\right\|
$$

and

$$
\operatorname{gap}(M, N)=\delta(M, N)=\delta(N, M) \quad \text { if gap }(M, N)<1
$$

Proof. If $M=0$, it is clear that

$$
\delta(M, N)=0=\left\|\left(I-P_{N}\right) P_{M}\right\|
$$

Next, assume $M \neq\{0\}$. Then we have that

$$
\begin{aligned}
\delta(M, N) & =\sup \{\operatorname{dist}(x, N): x \in M,\|x\|=1\} \\
& =\sup \left\{\left\|\left(I-P_{N}\right) x\right\|: x \in M,\|x\|=1\right\} \\
& =\sup \left\{\left\|\left(I-P_{N}\right) P_{M} x\right\|: x \in M,\|x\|=1\right\} \\
& \leq\left\|\left(I-P_{N}\right) P_{M}\right\|,
\end{aligned}
$$

and that for $x \in H$ with $\|x\|=1$ there holds

$$
\begin{aligned}
\left\|\left(I-P_{N}\right) P_{M} x\right\| & =\operatorname{dist}\left(P_{M} x, N\right) \\
& \leq \delta(M, N)\left\|P_{M} x\right\| \leq \delta(M, N),
\end{aligned}
$$

that is,

$$
\left\|\left(I-P_{N}\right) P_{M}\right\| \leq \delta(M, N) .
$$

Thus, we obtain

$$
\delta(M, N)=\left\|\left(I-P_{N}\right) P_{M}\right\| .
$$

This with Lemma 3.1 gives that

$$
\operatorname{gap}(M, N)=\left\|P_{M}-P_{N}\right\|,
$$

and

$$
\operatorname{gap}(M, N)=\delta(M, N)=\delta(N, M) \quad \text { if } \operatorname{gap}(M, N)<1 .
$$

$\square$
Lemma 3.3. Let $S$ be an oblique-projection on a Hilbert space $H \quad\left(S^{2}=S \in\right.$ $\mathcal{B}(H)$ ). Then

$$
\left\|P_{\mathcal{R}(S)}-P_{\mathcal{R}\left(S^{*}\right)}\right\|=\left\|P_{\mathcal{R}(S)} P_{\mathcal{N}(S)}\right\|=\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|,
$$

and

$$
\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|=\left\{\begin{array}{rr}
\sqrt{1-\|S\|^{-2}}, & \text { as } S \neq 0 \\
0, & \text { as } S=0
\end{array}\right.
$$

Proof. Let $x \in H$. Since $\mathcal{N}(S)=\mathcal{R}(I-S)$, we have

$$
\begin{aligned}
\|x\|^{2} & =\left\|S x+P_{\mathcal{N}(S)}(I-S) x\right\|^{2} \\
& =\left\|P_{\mathcal{N}(S)} x\right\|^{2}+\left\|\left(I-P_{\mathcal{N}(S)}\right) S x\right\|^{2} \\
& =\left\|P_{\mathcal{N}(S)} x\right\|^{2}+\|S x\|^{2}-\left\|P_{\mathcal{N}(S)} S x\right\|^{2} \\
& =\left\|P_{\mathcal{N}(S)} x\right\|^{2}+\|S x\|^{2}-\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)} S x\right\|^{2} \\
& \geqslant\left\|P_{\mathcal{N}(S)} x\right\|^{2}+\|S x\|^{2}\left(1-\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|^{2}\right),
\end{aligned}
$$

and therefore

$$
\left\|\left(I-P_{\mathcal{N}(S)}\right) x\right\|^{2}=\|x\|^{2}-\left\|P_{\mathcal{N}(S)} x\right\|^{2} \geq\left(1-\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|^{2}\right)\|S x\|^{2} .
$$

This implies

$$
\left\|I-P_{\mathcal{N}(S)}\right\|^{2} \geq\left(1-\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|^{2}\right)\|S\|^{2} .
$$

So, if $S \neq 0$, there holds

$$
1=\left\|I-P_{\mathcal{N}(S)}\right\|^{2} \geq\|S\|^{2}\left(1-\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|^{2}\right),
$$

namely

$$
\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\| \geq \sqrt{1-\|S\|^{-2}}
$$

To prove the reverse inequality, observe that for each $x \in H$ we have

$$
\begin{aligned}
\left\|P_{\mathcal{R}(S)} x\right\|^{2} & =\left\|S P_{\mathcal{R}(S)} x-S P_{\mathcal{N}(S)} P_{\mathcal{R}(S)} x\right\|^{2} \\
& \leq\|S\|^{2}\left\|P_{\mathcal{R}(S)} x-P_{\mathcal{N}(S)} P_{\mathcal{R}(S)} x\right\|^{2} \\
& =\|S\|^{2}\left(\left\|P_{\mathcal{R}(S)} x\right\|^{2}-\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)} x\right\|^{2}\right) .
\end{aligned}
$$

Hence, if $S \neq 0$, we have

$$
\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)} x\right\|^{2} \leq\left(1-\|S\|^{-2}\right)\left\|P_{\mathcal{R}(S)} x\right\|^{2} \leq\left(1-\|S\|^{-2}\right)\|x\|^{2}
$$

namely

$$
\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\| \leq \sqrt{1-\|S\|^{-2}}
$$

Thus, if $S \neq 0$, there holds

$$
\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|=\sqrt{1-\|S\|^{-2}}<1
$$

Now, if $S \neq 0$, by Lemma 3.1, we get

$$
\begin{aligned}
\left\|P_{\mathcal{R}(S)}-P_{\mathcal{R}\left(S^{*}\right)}\right\| & =\max \left\{\left\|\left(I-P_{\mathcal{R}\left(S^{*}\right)}\right) P_{\mathcal{R}(S)}\right\|,\left\|\left(I-P_{\mathcal{R}(S)}\right) P_{\mathcal{R}\left(S^{*}\right)}\right\|\right\} \\
& =\max \left\{\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|,\left\|P_{\mathcal{N}\left(S^{*}\right)} P_{\mathcal{R}\left(S^{*}\right)}\right\|\right\} \\
& =\sqrt{1-\|S\|^{-2}}=\sqrt{1-\left\|S^{*}\right\|^{-2}}<1
\end{aligned}
$$

and therefore

$$
\left\|P_{\mathcal{R}(S)}-P_{\mathcal{R}\left(S^{*}\right)}\right\|=\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|=\left\|P_{\mathcal{N}\left(S^{*}\right)} P_{\mathcal{R}\left(S^{*}\right)}\right\|
$$

Note that

$$
\left\|P_{\mathcal{R}(S)} P_{\mathcal{N}(S)}\right\|=\left\|\left(P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right)^{*}\right\|=\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|
$$

So, it follows that

$$
\begin{gathered}
\left\|P_{\mathcal{R}(S)}-P_{\mathcal{R}\left(S^{*}\right)}\right\|=\left\|P_{\mathcal{R}(S)} P_{\mathcal{N}(S)}\right\|=\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|, \quad \text { and } \\
\left\|P_{\mathcal{N}(S)} P_{\mathcal{R}(S)}\right\|=\left\{\begin{array}{r}
\sqrt{1-\|S\|^{-2}}, \\
0, \\
0 \text { as } S \neq 0 \\
0,
\end{array}\right. \\
\text { as } S=0
\end{gathered}
$$

$\square$
Lemma 3.4. Let $T \in \mathcal{B}(X, Y)$ have LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}},\left\{Q_{n}\right\}_{n \in \mathbb{N}}$ be defined as

$$
\begin{equation*}
Q_{n}:=T^{\dagger} P_{T\left(X_{n}\right)} T \quad \forall n \in \mathbb{N} \tag{3.1}
\end{equation*}
$$

Then $\left\{Q_{n}\right\}$ is a sequence of oblique-projections in $\mathcal{B}(X)\left(Q_{n}^{2}=Q_{n} \in \mathcal{B}(X)\right)$ which satisfies:

$$
\begin{equation*}
\mathcal{N}\left(Q_{n}\right)=\left[T^{*} T\left(X_{n}\right)\right]^{\perp}, \quad \mathcal{R}\left(Q_{n}\right)=T^{\dagger} T\left(X_{n}\right), \tag{3.2}
\end{equation*}
$$

and

Proof. Since $T^{\dagger}$ is a closed operator and $T\left(X_{n}\right) \subseteq \mathcal{D}\left(T^{\dagger}\right)(\forall n)$, due to the closed graph theorem and $T\left(X_{n}\right)$ being closed in $Y$, we see that each $\left.T^{\dagger}\right|_{T\left(X_{n}\right)}$ is a bound linear operator. Hence, $Q_{n}:=T^{\dagger} P_{T\left(X_{n}\right)} T \in \mathcal{B}(X)$, and

$$
Q_{n}^{2}=T^{\dagger} P_{T\left(X_{n}\right)} P_{\overline{\mathcal{R}}(T)} P_{T\left(X_{n}\right)} T=Q_{n} .
$$

It is clear that

$$
\mathcal{N}\left(Q_{n}\right)=\mathcal{N}\left(P_{T\left(X_{n}\right)} T\right)=\mathcal{R}\left(T^{*} P_{T\left(X_{n}\right)}\right)^{\perp}=\left[T^{*} T\left(X_{n}\right)\right]^{\perp}
$$

and

$$
\mathcal{R}\left(Q_{n}\right)=T^{\dagger} T\left(X_{n}\right)=P_{\mathcal{N}(T)^{\perp}}\left(X_{n}\right)=P_{\overline{\mathcal{R}\left(T^{*}\right)}}\left(X_{n}\right)
$$

Thus, we have (3.2) and

$$
P_{\mathcal{N}\left(Q_{n}\right)}=I-P_{T^{*} T\left(X_{n}\right)}, \quad P_{\mathcal{R}\left(Q_{n}\right)}=P_{P_{\overline{\mathcal{R}}\left(T^{* *}\right)}\left(X_{n}\right)} .
$$

Note that (2.4) holds by statement (a) of Lemma 2.2. Since $T^{*} T, P_{\overline{\mathcal{R}}\left(T^{*}\right)} \in \mathcal{B}(X)$, by replacing $T$ with $T^{*} T$ or $P_{\overline{\mathcal{R}}\left(T^{*}\right)}$ in (2.4), it follows that

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{\rightarrow \infty}} P_{T^{*} T\left(X_{n}\right)}=P_{\overline{\mathcal{R}\left(T^{*} T\right)}}=P_{\mathcal{N}(T)^{\perp}}
$$

and

$$
{\underset{n}{\mathrm{~s}}-\lim _{\rightarrow \infty} P_{P_{\overline{\mathcal{R}\left(T^{*}\right)}}}\left(X_{n}\right)}=P_{\overline{\mathcal{R}\left(T^{*}\right)}}=P_{\mathcal{N}(T)^{+}}
$$

Thus, (3.3) holds.
Lemma 3.5. Let $T \in \mathcal{B}(X, Y)$ have LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}},\left\{Q_{n}\right\}_{n \in \mathbb{N}}$ be defined as (3.1). Then, for all $n \in \mathbb{N}$,

$$
\begin{gathered}
1 \leq\left\|I-Q_{n}\right\|<+\infty, \\
\left\|P_{T^{*} T\left(X_{n}\right)}-P_{T^{\dagger} T\left(X_{n}\right)}\right\|=\sqrt{1-\left\|I-Q_{n}\right\|^{-2}} \in[0,1) .
\end{gathered}
$$

Proof. Since $\operatorname{dim} \mathcal{R}\left(Q_{n}\right)<\operatorname{dim} X(=\infty)$, then $I-Q_{n} \neq 0$, and therefore

$$
1 \leq\left\|I-Q_{n}\right\|<+\infty \quad(\forall n \in \mathbb{N}) .
$$

By Lemma 3.3, we have

$$
\begin{aligned}
\left\|P_{\mathcal{R}\left(I-Q_{n}\right)}-P_{\mathcal{R}\left(I-Q_{n}^{*}\right)}\right\| & =\left\|P_{\mathcal{R}\left(I-Q_{n}\right)} P_{\mathcal{N}\left(I-Q_{n}\right)}\right\| \\
& =\left\|P_{\mathcal{N}\left(I-Q_{n}\right)} P_{\mathcal{R}\left(I-Q_{n}\right)}\right\| \\
& =\sqrt{1-\left\|I-Q_{n}\right\|^{-2}} \in[0,1) .
\end{aligned}
$$

Note that, by Lemma 3.4,

$$
\mathcal{N}\left(Q_{n}\right)=\left[T^{*} T\left(X_{n}\right)\right]^{\perp}, \quad \mathcal{R}\left(Q_{n}\right)=T^{\dagger} T\left(X_{n}\right)
$$

Hence, there holds

$$
\begin{aligned}
\left\|P_{T^{*} T\left(X_{n}\right)}-P_{T^{\dagger} T\left(X_{n}\right)}\right\| & =\left\|P_{\mathcal{N}\left(Q_{n}\right)}-P_{\mathcal{R}\left(Q_{n}\right)^{\perp}}\right\| \\
& =\left\|P_{\mathcal{R}\left(I-Q_{n}\right)}-P_{\mathcal{R}\left(I-Q_{n}^{*}\right)}\right\| \\
& =\sqrt{1-\left\|I-Q_{n}\right\|^{-2}} \in[0,1) .
\end{aligned}
$$

Now, we can present the proof of Theorem 1.2.
Proof. [Proof of Theorem 1.2] By (1.6) we see that

$$
\sin \theta_{n}=\operatorname{gap}\left(T^{\dagger} T\left(X_{n}\right), T^{*} T\left(X_{n}\right)\right), \quad n \in \mathbb{N}
$$

This, by Lemma 3.2 and Lemma 3.5, gives that

$$
\begin{equation*}
\sin \theta_{n}=\left\|P_{T^{\dagger} T\left(X_{n}\right)}-P_{T^{*} T\left(X_{n}\right)}\right\|=\sqrt{1-\left\|I-Q_{n}\right\|^{-2}} \in[0,1), \quad n \in \mathbb{N} \tag{3.4}
\end{equation*}
$$

(a) It is clear from (3.4) that $\left\{\theta_{n}\right\}$ is a sequence in the interval $\left[0, \frac{\pi}{2}\right)$, and

$$
\begin{equation*}
\left\|I-Q_{n}\right\|=\frac{1}{\cos \theta_{n}}=\sqrt{1+\tan ^{2} \theta_{n}} \in[1,+\infty), \quad n \in \mathbb{N} \tag{3.5}
\end{equation*}
$$

Note that

$$
P_{\mathcal{N}(T)^{\perp}} T_{n}^{\dagger} T=T^{\dagger} T T_{n}^{\dagger} T=T^{\dagger} T_{n} T_{n}^{\dagger} T=T^{\dagger} P_{\mathcal{R}\left(T_{n}\right)} T=Q_{n}
$$

and therefore

$$
\begin{equation*}
Q_{n}=P_{\mathcal{N}(T)^{\perp}} T_{n}^{\dagger} T \quad \forall n \in \mathbb{N} . \tag{3.6}
\end{equation*}
$$

Assume that (1.3) is valid, this with (3.6) implies that

$$
\begin{equation*}
\sup _{n}\left\|Q_{n}\right\|<+\infty, \quad \sup _{n}\left\|I-Q_{n}\right\|<+\infty \tag{3.7}
\end{equation*}
$$

Hence, from (3.7) and (3.5) we obtain

$$
\sup _{n} \theta_{n}<\frac{\pi}{2}
$$

In addition, by the assertion (b) of Lemma 2.2, we also have

$$
(1.3) \Longrightarrow(1.4)
$$

Thus, there holds

$$
(1.3) \Longrightarrow\left\{\begin{array}{l}
(1.4) \\
\sup _{n} \theta_{n}<\frac{\pi}{2}
\end{array}\right.
$$

Inversely, suppose (1.4) and $\sup _{n} \theta_{n}<\frac{\pi}{2}$ hold. Then (3.7) holds by (3.5). Due to the assertion (c) of Lemma 2.2, it follows from (1.4) with $\operatorname{dim} \mathcal{N}(T)<\infty$ that there is a $n_{*} \in \mathbb{N}$ such that (2.3) holds and hence

$$
\begin{equation*}
\mathcal{R}\left(T_{n}^{\dagger}\right)=\mathcal{N}\left(T_{n}\right)^{\perp}=\mathcal{N}(T)^{\perp} \cap X_{n} \text { for } n \geq n_{*} \tag{3.8}
\end{equation*}
$$

From (3.6) and (3.8) we have

$$
\begin{equation*}
T_{n}^{\dagger} T=Q_{n}+P_{\mathcal{N}(T)} T_{n}^{\dagger} T=Q_{n} \quad \text { for } n \geq n_{*} . \tag{3.9}
\end{equation*}
$$

Hence, (1.3) follows from (3.9) and (3.7).
(b) Let (1.4) (with $\operatorname{dim} \mathcal{N}(T)<\infty)$ hold. Then (2.2), (2.3), (3.5), and (3.9) hold by Lemmas $2.2,3.2$, and 3.5. Hence, there is a $n_{*} \in \mathbb{N}$ such that

$$
\begin{equation*}
T_{n}^{\dagger}-T^{\dagger}=\left(Q_{n}-I\right) P_{X_{n}^{\perp}} T^{\dagger} \quad \text { on } \mathcal{D}\left(T^{\dagger}\right), \quad \text { for } n \geq n_{*} \tag{3.10}
\end{equation*}
$$

and

$$
\left.\begin{array}{c}
X_{n}=\mathcal{N}(T) \oplus\left(X_{n} \cap \mathcal{N}(T)^{\perp}\right),  \tag{3.11}\\
P_{X_{n}}=P_{\mathcal{N}(T)}+P_{X_{n} \cap \mathcal{N}(T)^{\perp}},
\end{array}\right\} \quad \text { for } n \geq n_{*}
$$

From (3.10) and (3.5) it is clear that, for $n \geq n_{*}$,

$$
\begin{equation*}
\left\|T_{n}^{\dagger} y-T^{\dagger} y\right\| \leq \sqrt{1+\tan ^{2} \theta_{n}} \operatorname{dist}\left(T^{\dagger} y, X_{n}\right), \quad y \in \mathcal{D}\left(T^{\dagger}\right) \tag{3.12}
\end{equation*}
$$

Next, we need only to show that, for $n \geq n_{*}$,

$$
\begin{equation*}
\theta_{n}=0 \Longleftrightarrow T_{n}^{\dagger}=P_{X_{n}} T^{\dagger} \text { on } \mathcal{D}\left(T^{\dagger}\right) \Longleftrightarrow \mathcal{N}(T)+T^{*} T\left(X_{n}\right) \subseteq X_{n} \tag{3.13}
\end{equation*}
$$

If $\theta_{n}=0\left(n \geq n_{*}\right)$, then from (3.12) and $\mathcal{R}\left(T_{n}^{\dagger}\right)=\mathcal{N}\left(T_{n}\right)^{\perp} \subseteq X_{n}$ it is clear that

$$
T_{n}^{\dagger}=P_{X_{n}} T^{\dagger} \text { on } \mathcal{D}\left(T^{\dagger}\right), \quad n \geq n_{*}
$$

If the above equality is valid, it follows from (3.9) and (3.11) that

$$
Q_{n}=T_{n}^{\dagger} T=P_{X_{n}} P_{\mathcal{N}(T)^{\perp}}=P_{X_{n} \cap \mathcal{N}(T)^{\perp}}, \quad n \geq n_{*}
$$

and therefore $Q_{n}$ is an orthogonal-projection. By use of (3.2) (of Lemma 3.4), there hold

$$
\begin{aligned}
T^{*} T\left(X_{n}\right) & =\mathcal{N}\left(Q_{n}\right)^{\perp}=\mathcal{R}\left(Q_{n}\right)=T^{\dagger} T\left(X_{n}\right) \\
& \subseteq T^{-1} T\left(X_{n}\right)=X_{n}+\mathcal{N}(T)=X_{n}, \quad n \geq n_{*}
\end{aligned}
$$

this gives

$$
T^{*} T\left(X_{n}\right)+\mathcal{N}(T) \subseteq X_{n}, \quad n \geq n_{*}
$$

If the above inclusions hold, then

$$
T^{*} T\left(X_{n}\right) \subseteq T^{\dagger} T\left(X_{n}\right), \quad n \geq n_{*}
$$

and therefore

$$
T^{\dagger} T\left(X_{n}\right)=T^{*} T\left(X_{n}\right), \quad n \geq n_{*} .
$$

This gives that

$$
\sin \theta_{n}=\operatorname{gap}\left(T^{\dagger} T\left(X_{n}\right), T^{*} T\left(X_{n}\right)\right)=0, \quad n \geq n_{*}
$$

that is, $\theta_{n}=0\left(n \geq n_{*}\right)$. Now, (3.13) is proved.
REMARK 3.1. From the proof of Theorem 1.2, we obtain that, even if $\operatorname{dim} \mathcal{N}(T)=$ $\infty$,

$$
(1.3) \Longrightarrow\left\{\begin{array}{l}
(1.4) \\
\sup _{n} \theta_{n}<\frac{\pi}{2}
\end{array}\right.
$$

4. Examples and Remarks. In this section, the two unconvergence examples of Seidman and Du will be restudied under the concepts of offset angle and kernel approximability. This can further explain the relations among the three concepts of strong convergence, offset angle and kernel approximability, and also leads to some remarks on Theorems 1.1 and 1.2.

Example 4.1 (Seidman's Example [10, Example 3.1]). Let

$$
X:=l^{2}, \quad X_{n}:=\operatorname{span}\left\{\mathbf{e}^{1}, \mathbf{e}^{2}, \ldots, \mathbf{e}^{n}\right\}
$$

where

$$
\mathbf{e}^{k}=(0, \ldots, 0, \underset{\substack{\uparrow \\ k \mathrm{th}}}{1}, 0, \ldots) \quad \forall k \in \mathbb{N},
$$

and $T: X \rightarrow X$ be given in the form

$$
T \mathbf{x}:=\sum_{k=1}^{\infty}\left(\alpha_{k} \xi_{k}+\beta_{k} \xi_{1}\right) \mathbf{e}^{k} \quad \forall \mathbf{x}=\sum_{k=1}^{\infty} \xi_{k} \mathbf{e}^{k} \in X
$$

with

$$
\alpha_{j}:=\left\{\begin{array}{ll}
j^{-1}, & j \text { odd }, \\
j^{-3}, & j \text { even },
\end{array} \quad \beta_{j}:=\left\{\begin{aligned}
0, & j=1 \\
j^{-1}, & j>1
\end{aligned}\right.\right.
$$

This defines a compact, injective linear operator $T$ with dense range, its $L P A\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$ has kernel approximability ((1.4) holds), and the offset angle sequence $\left\{\theta_{n}\right\}$ satisfies

$$
\begin{equation*}
0<\theta_{n}=\arcsin \operatorname{gap}\left(X_{n}, T^{*} T\left(X_{n}\right)\right)<\frac{\pi}{2}(\forall n) \tag{4.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\sup _{n} \theta_{n}=\frac{\pi}{2} \tag{4.2}
\end{equation*}
$$

REMARK 4.1. For the LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$ of Seidman's example, the weak/strong convergence or the condition (1.3) do not hold. The reason for such a unconvergence is caused by the offset angle $\theta_{n}$ tending towards perpendicular angle as (4.2)
shows. Note: LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$ has kernel-approximability since $\mathcal{N}(T)=\{0\}$, and therefore has inverse-graph approximability and bounded-weak convergence by Theorem 1.1.

Proof. It is easy to see that

$$
T^{*} \mathbf{y}=\sum_{k=1}^{\infty} \eta_{k}\left(\overline{\alpha_{k}} \mathbf{e}^{k}+\overline{\beta_{k}} \mathbf{e}^{1}\right) \quad \forall \mathbf{y}=\sum_{k=1}^{\infty} \eta_{k} \mathbf{e}^{k} \in X,
$$

and

$$
T^{*} T \mathbf{x}=\sum_{k=1}^{\infty}\left(\alpha_{k} \xi_{k}+\beta_{k} \xi_{1}\right)\left(\overline{\alpha_{k}} \mathbf{e}^{k}+\overline{\beta_{k}} \mathbf{e}^{1}\right) \quad \forall \mathbf{x}=\sum_{k=1}^{\infty} \xi_{k} \mathbf{e}^{k} \in X
$$

It is clear that

$$
\mathcal{N}(T)=\{0\} \subseteq X_{n}(\forall n), \quad T^{\dagger}=T^{-1}: \mathcal{R}(T) \subseteq X \rightarrow X
$$

$$
\frac{\pi^{2}}{6} \mathbf{e}^{1}+\sum_{k=2}^{\infty} \alpha_{k} \beta_{k} \mathbf{e}^{k}=T^{*} T \mathbf{e}^{1} \in T^{*} T\left(X_{n}\right) \backslash X_{n}(\forall n)
$$

This implies (1.4) and (4.1). Next, we will show (4.2) holds.
We rewrite $T^{*} T \mathbf{x}$ for $\mathbf{x}=\mathbf{x}_{n}:=\sum_{k=1}^{n} \xi_{k} \mathbf{e}^{k} \in X_{n}\left(\xi_{k}:=0 \forall k \geq n+1\right)$,

$$
\begin{aligned}
T^{*} T \mathbf{x}_{n}= & {\left[\sum_{k=2}^{\infty}\left(\alpha_{k} \xi_{k}+\beta_{k} \xi_{1}\right) \beta_{k}+\alpha_{1}^{2} \xi_{1}\right] \mathbf{e}^{1} } \\
& +\sum_{k=2}^{n}\left(\alpha_{k} \xi_{k}+\beta_{k} \xi_{1}\right) \alpha_{k} \mathbf{e}^{k}+\sum_{k=n+1}^{\infty} \alpha_{k} \beta_{k} \xi_{1} \mathbf{e}^{k}
\end{aligned}
$$

then we have

$$
\begin{aligned}
P_{X_{n}}\left(T^{*} T \mathbf{x}_{n}\right)= & {\left[\sum_{k=2}^{\infty}\left(\alpha_{k} \xi_{k}+\beta_{k} \xi_{1}\right) \beta_{k}+\alpha_{1}^{2} \xi_{1}\right] \mathbf{e}^{1} } \\
& +\sum_{k=2}^{n}\left(\alpha_{k} \xi_{k}+\beta_{k} \xi_{1}\right) \alpha_{k} \mathbf{e}^{k}
\end{aligned}
$$

and

$$
P_{X_{n}^{\perp}}\left(T^{*} T \mathbf{x}_{n}\right)=\sum_{k=n+1}^{\infty} \alpha_{k} \beta_{k} \xi_{1} \mathbf{e}^{k}
$$

Now we take $\mathbf{x}_{n}$ that satisfies

$$
\xi_{1}=1, \xi_{k}=-\frac{\beta_{k} \xi_{1}}{\alpha_{k}}, \quad k=2, \ldots, n-1
$$

and let $\lambda:=\alpha_{n} \xi_{n}+\beta_{n} \xi_{1}$ be undetermined, we have

$$
\begin{aligned}
T^{*} T \mathbf{x}_{n} & =\left[\lambda \beta_{n}+\alpha_{1}^{2}+\sum_{k=n+1}^{\infty} \beta_{k}^{2}\right] \mathbf{e}^{1}+\lambda \alpha_{n} \mathbf{e}^{n}+\sum_{k=n+1}^{\infty} \alpha_{k} \beta_{k} \mathbf{e}^{k} \\
& =\left(\lambda \beta_{n}+c_{n}^{2}\right) \mathbf{e}^{1}+\lambda \alpha_{n} \mathbf{e}^{n}+\sum_{k=n+1}^{\infty} \alpha_{k} \beta_{k} \mathbf{e}^{k}
\end{aligned}
$$

where

$$
c_{n}=\alpha_{1}^{2}+\sum_{k=n+1}^{\infty} \beta_{k}^{2} \leq \sum_{k=1}^{\infty} \frac{1}{k^{2}}=\frac{\pi^{2}}{6}
$$

Take $\lambda=\frac{-c_{n} \beta_{n}}{\alpha_{n}^{2}+\beta_{n}^{2}}$, then

$$
\left\{\begin{array}{l}
\left\|T^{*} T \mathbf{x}_{n}\right\|^{2}=\frac{c_{n}^{2} \alpha_{n}^{2}}{\alpha_{n}^{2}+\beta_{n}^{2}}+\sum_{k=n+1}^{\infty}\left(\alpha_{k} \beta_{k}\right)^{2} \leq \frac{\frac{\pi^{4}}{36} \alpha_{n}^{2}}{\alpha_{n}^{2}+\beta_{n}^{2}}+\sum_{k=n+1}^{\infty}\left(\alpha_{k} \beta_{k}\right)^{2}, \\
\left\|P_{X_{n}^{\perp}}\left(T^{*} T \mathbf{x}_{n}\right)\right\|^{2}=\sum_{k=n+1}^{\infty}\left(\alpha_{k} \beta_{k}\right)^{2}
\end{array}\right.
$$

Note that, for $n$ even,

$$
\frac{\frac{\pi^{4}}{36} \alpha_{n}^{2}}{\alpha_{n}^{2}+\beta_{n}^{2}}=\frac{O\left(n^{-6}\right)}{O\left(n^{-6}\right)+O\left(n^{-2}\right)}=O\left(n^{-4}\right), \quad \sum_{k=n+1}^{\infty}\left(\alpha_{k} \beta_{k}\right)^{2}=O\left(n^{-3}\right)
$$

According to the definition of $\delta\left(T^{*} T\left(X_{n}\right), X_{n}\right)$, we have

$$
\delta\left(T^{*} T\left(X_{n}\right), X_{n}\right)=\sup _{\mathbf{x} \in X_{n}} \frac{\left\|P_{X_{n}^{\perp}}\left(T^{*} T \mathbf{x}\right)\right\|}{\left\|T^{*} T \mathbf{x}\right\|}
$$

So for $n$ even, we obtain that

$$
\begin{aligned}
{\left[\operatorname{gap}\left(X_{n}, T^{*} T\left(X_{n}\right)\right)\right]^{2} } & =\left[\delta\left(T^{*} T X_{n}, X_{n}\right)\right]^{2} \quad(\text { by Lemma 3.2) } \\
& \geq \frac{1}{1+O\left(n^{-1}\right)}
\end{aligned}
$$

This gives (4.2).
EXAMPLE 4.2 (Best-LPA). Let $K: X \rightarrow Y$ be a compact linear operator, $\left\{\left(\sigma_{n} ; v_{n}, u_{n}\right)\right\}_{n=0}^{\infty}$ be the singular system for $K$. Then the $\left\{\sigma_{n}^{2}\right\}$ are the nonzero eigenvalues of the self-adjoint operator $K^{*} K$ (and also of $K K^{*}$ ), written down in decreasing order with multiplicity, $\sigma_{n}>0$, the $\left\{v_{n}\right\}_{n=0}^{\infty}$ is a corresponding complete orthonormal system of eigenvectors of $K^{*} K$ (which spans $\overline{\mathcal{R}\left(K^{*}\right)}=\overline{\mathcal{R}\left(K^{*} K\right)}$ ), and the $\left\{u_{n}\right\}_{n=0}^{\infty}$ is defined by vectors

$$
u_{n}:=\frac{K v_{n}}{\left\|K v_{n}\right\|} \quad(n=0,1, \cdots)
$$

The $\left\{u_{n}\right\}_{n=0}^{\infty}$ is a complete orthonormal system of eigenvectors of $K K^{*}$ and span $\overline{\mathcal{R}(K)}=\overline{\mathcal{R}\left(K K^{*}\right)}$, and the following formulae hold:

$$
K v_{n}=\sigma_{n} u_{n}, \quad K^{*} u_{n}=\sigma_{n} v_{n}
$$

Now, if $\operatorname{dim} \mathcal{N}(K)<\infty$, and if $\left\{m_{n}\right\} \subseteq \mathbb{N}$ is an increasing sequence with $\lim _{n \rightarrow \infty} m_{n}=$ $\infty$, take

$$
X_{n}:=\mathcal{N}(K)+\operatorname{span}\left\{v_{1}, v_{2}, \cdots, v_{m_{n}}\right\} \quad \forall n \in \mathbb{N} .
$$

Then

$$
\mathcal{N}(K)+K^{*} K\left(X_{n}\right)=\mathcal{N}(K)+\operatorname{span}\left\{\sigma_{1}^{2} v_{1}, \sigma_{2}^{2} v_{2}, \cdots, \sigma_{m_{n}}^{2} v_{m_{n}},\right\} \subseteq X_{n}
$$

In this case, we have the best LPA $\left\{\left(X_{n}, K_{n}\right)\right\}_{n \in \mathbb{N}}$ for $K$ :

$$
\mathcal{N}(K) \cap X_{n}=\mathcal{N}(K), \quad \theta_{n}:=\operatorname{arcsingap}\left(K^{\dagger} K\left(X_{n}\right), K^{*} K\left(X_{n}\right)\right)=0(\forall n),
$$

and

$$
K_{n}^{\dagger}=P_{X_{n}} K^{\dagger} \text { on } \mathcal{D}\left(K^{\dagger}\right) .
$$

Example 4.3 (Du's Example [2, Example 2.10]). Let

$$
X:=l^{2}, \quad X_{n}:=\operatorname{span}\left\{\mathbf{e}^{1}, \mathbf{e}^{2}, \ldots, \mathbf{e}^{n}\right\},
$$

and $T: X \rightarrow X$ defined as follows:

$$
T x:=x-\langle x, \mathbf{e}\rangle \mathbf{e} \quad(x \in X)
$$

where $\langle\cdot, \cdot\rangle$ is the inner product on $X$ and

$$
\mathbf{e}:=\frac{\sqrt{3}}{2} \mathbf{e}^{1}+\frac{\sqrt{3}}{2^{2}} \mathbf{e}^{2}+\cdots+\frac{\sqrt{3}}{2^{k}} \mathbf{e}^{k}+\cdots .
$$

This operator satisfies

$$
T=T^{2}=T^{*}=T^{\dagger} \quad \text { and } \quad \mathcal{N}(T)=\operatorname{span}\{\mathbf{e}\} ;
$$

that is, $T$ is the orthogonal projection of $X$ onto $\mathbf{e}^{\perp}$. For its LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$, where

$$
T_{n}:=T P_{X_{n}}, \quad P_{n}:=P_{X_{n}}, \quad n \in \mathbb{N},
$$

we have the following facts:
(a) The offset angle $\theta_{n}$ satisfies

$$
\theta_{n}:=\arcsin \operatorname{gap}\left(T^{\dagger} T\left(X_{n}\right), T^{*} T\left(X_{n}\right)\right)=0(\forall n) .
$$

(b) The kernel approximability is invalid since

$$
\mathcal{N}(T) \cap X_{n}=\{0\} \neq \mathcal{N}(T) \quad(\forall n) .
$$

(c) $T_{n}^{\dagger} y=P_{n} y-4^{n}\left\langle\left(I-P_{n}\right) y, e\right\rangle P_{n} e(\forall y \in X)$, and for any fixed $y \in X$,

$$
\left\{\begin{array}{l}
\sup _{n}\left\|T_{n}^{\dagger} y\right\|<\infty \Longleftrightarrow \sup _{n} 4^{n}\left|\left\langle\left(I-P_{n}\right) y, e\right\rangle\right|<\infty, \\
{\underset{n}{n \rightarrow \infty}}_{\mathrm{w}-\lim _{n}^{\dagger} y=T^{\dagger} y \Longleftrightarrow \lim _{n \rightarrow \infty} 4^{n}\left\langle\left(I-P_{n}\right) y, e\right\rangle=\langle y, e\rangle}
\end{array}\right.
$$

taking

$$
y:=\left(\frac{\sqrt{3}}{4}, \frac{3 \sqrt{3}}{4^{2}}, \ldots, \frac{\left(2^{n}-1\right) \sqrt{3}}{4^{n}}, \ldots\right),
$$

there hold

$$
\sup _{n}\left\|T_{n}^{\dagger} y\right\|<\infty \quad \text { and } \quad \underset{n \rightarrow \infty}{\mathrm{w}-\lim _{n}} T_{n}^{\dagger} y \neq T^{\dagger} y .
$$

That indicates that the bounded-weak convergence is invalid.
(d) For any fixed $y \in \mathcal{D}\left(T^{\dagger}\right)=X$,

$$
\underset{n \rightarrow \infty}{\mathrm{w}-\lim } T_{n}^{\dagger} y=T^{\dagger} y \Longleftrightarrow \underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} T_{n}^{\dagger} y=T^{\dagger} y \Longleftrightarrow \varlimsup_{n \rightarrow \infty}\left\|T_{n}^{\dagger} y\right\| \leq\left\|T^{\dagger} y\right\|
$$

REMARK 4.2. For the LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$ of $D u$ 's example, the weak/strong convergence or the condition (1.3) do not hold. The reason for unconvergence is caused by the fact that kernel approximability is invalid.

Proof. (a) Since $T^{\dagger}=T=T^{*}$, it is clear that $\theta_{n}=0(\forall n)$.
(b) See [2, Proposition A.1].
(c) See [2, Propositions A. 2 and A.3].
(d) For any fixed $y \in X$, if $\mathrm{w}-\lim _{n \rightarrow \infty} T_{n}^{\dagger} y=T^{\dagger} y$, by (c) and $T^{\dagger}=T$,

$$
\lim _{n \rightarrow \infty} 4^{n}\left\langle\left(I-P_{n}\right) y, e\right\rangle=\langle y, e\rangle
$$

and therefore

$$
\begin{aligned}
\left\|T_{n}^{\dagger} y-T^{\dagger} y\right\| & =\left\|P_{n} y-4^{n}\left\langle\left(I-P_{n}\right) y, \mathbf{e}\right\rangle P_{n} \mathbf{e}-y+\langle y, \mathbf{e}\rangle \mathbf{e}\right\| \\
& \leq\left\|P_{n} y-y\right\|+\left|4^{n}\left\langle\left(I-P_{n}\right) y, \mathbf{e}\right\rangle-\langle y, \mathbf{e}\rangle\right|+|\langle y, \mathbf{e}\rangle|\left\|P_{n} \mathbf{e}-\mathbf{e}\right\| \\
& \rightarrow 0 \quad(n \rightarrow \infty)
\end{aligned}
$$

that is, $\mathrm{s}-\lim _{n \rightarrow \infty} T_{n}^{\dagger} y=T^{\dagger} y$.
If s-lim$n \rightarrow \infty=T_{n}^{\dagger} y=T^{\dagger} y$ holds, then $\varlimsup_{n \rightarrow \infty}\left\|T_{n}^{\dagger} y\right\| \leq\left\|T^{\dagger} y\right\|$.
If $y \in \mathcal{D}\left(T^{\dagger}\right)$ and $\varlimsup_{n \rightarrow \infty}\left\|T_{n}^{\dagger} y\right\| \leq\left\|T^{\dagger} y\right\|$, then any subsequence $\left\{T_{n_{k}}^{\dagger} y\right\}$ of $\left\{T_{n}^{\dagger} y\right\}$ has a subsequence, again denoted by $\left\{T_{n_{k}}^{\dagger} y\right\}$, converging weakly to some $u \in$ $X$, and

$$
\begin{equation*}
\|u\| \leq \underset{k \rightarrow \infty}{\lim }\left\|T_{n_{k}}^{\dagger} y\right\| \leq \varlimsup_{k \rightarrow \infty}\left\|T_{n_{k}}^{\dagger} y\right\| \leq \varlimsup_{n \rightarrow \infty}\left\|T_{n}^{\dagger} y\right\| \leq\left\|T^{\dagger} y\right\| \tag{4.3}
\end{equation*}
$$

Since $T$ is bounded and
we have that, for all $v \in X$,

$$
\begin{aligned}
\left\langle T\left(u-T^{\dagger} y\right), v\right\rangle & =\left\langle T u-T T_{n_{k}}^{\dagger} y, v\right\rangle+\left\langle T T_{n_{k}}^{\dagger} y-T T^{\dagger} y, v\right\rangle \\
& =\left\langle u-T_{n_{k}}^{\dagger} y, T^{*} v\right\rangle+\left\langle T_{n_{k}} T_{n_{k}}^{\dagger} y-T T^{\dagger} y, v\right\rangle \\
& =\left\langle u-T_{n_{k}}^{\dagger} y, T^{*} v\right\rangle+\left\langle P_{\mathcal{R}\left(T_{n_{k}}\right)} y-P_{\overline{\mathcal{R}(T)}} y, v\right\rangle \\
& \rightarrow 0 \quad(k \rightarrow \infty)
\end{aligned}
$$

and hence

$$
u \in T^{\dagger} y+\mathcal{N}(T), \quad\|u\|^{2}=\left\|T^{\dagger} y\right\|^{2}+\left\|u-T^{\dagger} y\right\|^{2}
$$

This with (4.3) implies that

$$
\underset{k \rightarrow \infty}{\mathrm{w}-\lim } T_{n_{k}}^{\dagger} y=u=T^{\dagger} y \quad \text { with } \quad \lim _{k \rightarrow \infty}\left\|T_{n_{k}}^{\dagger} y\right\|=\left\|T^{\dagger} y\right\|
$$

that is,

$$
\underset{k \rightarrow \infty}{\mathrm{~s}-\lim _{n}} T_{n_{k}}^{\dagger} y=T^{\dagger} y
$$

Thus, every subsequence of $\left\{T_{n}^{\dagger} y\right\}$ has a subsequence converging weakly to $T^{\dagger} y$ and hence

Note that the proof of this paragraph applies to a general LPA! $\square$
REMARK 4.3. From the above proof we actually obtain a more general result compared with the one obtained by Luecke and Hickey [9, Theorem 11], who give the result in the situation of $L P A\left\{\left(X_{n}, T_{n}\right)\right\}$ with an increasing sequence:

$$
X_{0} \subseteq X_{1} \subseteq X_{2} \subseteq \cdots \quad \text { with } \overline{\bigcup_{n=0}^{\infty} X_{n}}=X
$$

The extended version is as below:
Proposition 4.1. Let $T \in \mathcal{B}(X, Y)$ have $L P A\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$. For a fixed $y \in \mathcal{D}\left(T^{\dagger}\right)$ there holds

$$
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} T_{n}^{\dagger} y=T^{\dagger} y \Longleftrightarrow \varlimsup_{n \rightarrow \infty}\left\|T_{n}^{\dagger} y\right\| \leq\left\|T^{\dagger} y\right\|
$$

REMARK 4.4. It should be noted that the following proposition is false.
Proposition 4.2. Let $T \in \mathcal{B}(X, Y)$ have $L P A\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$. For a fixed $y \in \mathcal{D}\left(T^{\dagger}\right)$,

$$
\begin{equation*}
\mathrm{w}_{n \rightarrow \infty}-\lim _{n} T_{n}^{\dagger} y=T^{\dagger} y \Longleftrightarrow \sup _{n}\left\|T_{n}^{\dagger} y\right\|<+\infty \tag{False}
\end{equation*}
$$

5. Conclusions. In this paper, we propose two concepts - the offset angle and the kernel approximability of LPA, and show their roles in the convergence of leastsquares projection method. These concepts come from the wish to understand two counter-examples (due to Seidman [10] and Du [2]) which respectively represent two important cases in which least-squares projection method fails to converge. Let us reformulate the concepts of the offset angles, the kernel approximability, and the strong/weak convergence of least-squares projection method:

- Offset Angle:

$$
\theta_{n}:=\arcsin \operatorname{gap}\left(T^{\dagger} T\left(X_{n}\right), T^{*} T\left(X_{n}\right)\right) \quad \forall n \in \mathbb{N}
$$

- Kernel Approximability:

$$
\mathcal{N}(T)=\left\{x \in X: \lim _{n \rightarrow \infty} \operatorname{dist}\left(x, \mathcal{N}(T) \cap X_{n}\right)=0\right\} .
$$

$$
\lim _{n \rightarrow \infty} T_{n}^{\dagger} y=T^{\dagger} y \quad \forall y \in \mathcal{D}\left(T^{\dagger}\right)
$$

- Weak Convergence $\left(\underset{n \rightarrow \infty}{\mathrm{w}-\lim } T_{n}^{\dagger}=T^{\dagger}\right.$ on $\mathcal{D}\left(T^{\dagger}\right)$ ):

$$
\underset{n \rightarrow \infty}{\mathrm{w}-\lim _{n}^{\dagger} T_{n}^{\dagger} y=T^{\dagger} y \quad \forall y \in \mathcal{D}\left(T^{\dagger}\right) . ~ . ~}
$$

To understand the relevance among the four concepts, we make a table to show the true and false status of these concepts in the several examples we have mentioned ( T for true, F for false).

| Examples | $\sup _{n} \theta_{n}<\frac{\pi}{2}$ | Kernel Approximability | Strong/weak Convergence |
| :---: | :---: | :---: | :---: |
| Seidman's | F | T | F |
| Du's | T | F | F |
| Best-LPA | T | T | T |

From this table we can see that the conditions "kernel approximability" and " $\sup _{n} \theta_{n}<\frac{\pi}{2}$ " are two mutually independent important factors of a convergent LPA $\left\{\left(X_{n}, T_{n}\right)\right\}$. In fact, both of them are necessary if we want the convergence of LPA $\left\{\left(X_{n}, T_{n}\right)\right\}$, for we have that (see Remak 3.1)

$$
\text { weak convergence } \Longleftrightarrow \text { strong convergence } \Longrightarrow\left\{\begin{array}{l}
\text { kernel approximability, } \\
\sup _{n} \theta_{n}<\frac{\pi}{2} .
\end{array}\right.
$$

We hope the three are equivalent, if so, the problem of strong/weak convergence of least-squares projection method could be divided into two subproblems, namely, the kernel approximability problem and the offset angle problem.

In this paper, the main result (Theorem 1.2) we get is: $\operatorname{If} \operatorname{dim} \mathcal{N}(T)<\infty$, then
$\left.\begin{array}{l}\text { kernel approximability } \\ \sup _{n} \theta_{n}<\frac{\pi}{2}\end{array}\right\} \Longleftrightarrow$ strong convergence $\Longleftrightarrow$ weak convergence,
and when the kernel approximability is valid, for $n$ large enough,

$$
\left\|T_{n}^{\dagger} y-T^{\dagger} y\right\| \leq \sqrt{1+\tan ^{2} \theta_{n}} \text { dist }\left(T^{\dagger} y, X_{n}\right) \quad \forall y \in \mathcal{D}\left(T^{\dagger}\right) .
$$

Now, we consider the three special cases of " $\mathcal{N}(T)=\{0\}$ ", " $\mathcal{R}(T)=\overline{\mathcal{R}(T) ", ~ a n d ~}$ " $\mathcal{N}(T)=\{0\} \& \mathcal{R}(T)=\overline{\mathcal{R}(T)} "$, then there hold the following interesting corollaries:

- If $\mathcal{N}(T)=\{0\}$, then, for any LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$ for $T$,

$$
\sup _{n} \theta_{n}<\frac{\pi}{2} \Longleftrightarrow \text { strong convergence }
$$

and for all $n \in \mathbb{N}$,

$$
\left\|T_{n}^{\dagger} y-T^{\dagger} y\right\| \leq \sqrt{1+\tan ^{2} \theta_{n}} \operatorname{dist}\left(T^{\dagger} y, X_{n}\right) \quad \forall y \in \mathcal{D}\left(T^{\dagger}\right) .
$$

- If $\operatorname{dim} \mathcal{N}(T)<\infty$ and $\mathcal{R}(T)$ is closed, then, for any LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$ for $T$,

$$
\left\{\begin{array}{l}
\text { kernel approximability } \Longleftrightarrow \text { strong convergence, } \\
\sup _{n} \theta_{n}<\frac{\pi}{2},
\end{array}\right.
$$

and when the kernel approximability holds, for $n$ large enough,

$$
\left\|T_{n}^{\dagger} y-T^{\dagger} y\right\| \leq \sqrt{1+\tan ^{2} \theta_{n}} \text { dist }\left(T^{\dagger} y, X_{n}\right) \quad \forall y \in Y .
$$

- If $\mathcal{N}(T)=\{0\}$ and $\mathcal{R}(T)$ is closed, then for any LPA $\left\{\left(X_{n}, T_{n}\right)\right\}_{n \in \mathbb{N}}$ for $T$,

$$
\sup _{n} \theta_{n}<\frac{\pi}{2},
$$

and for all $n \in \mathbb{N}$,

$$
\left\|T_{n}^{\dagger} y-T^{\dagger} y\right\| \leq \sqrt{1+\tan ^{2} \theta_{n}} \text { dist }\left(T^{\dagger} y, X_{n}\right) \quad \forall y \in Y .
$$

Here, we remark that: If there are positive constants $\alpha$ and $\beta$ such that $T \in \mathcal{B}(X)$ satisfies

$$
\left.\begin{array}{l}
|\langle T u, u\rangle| \geq \alpha\|u\|^{2}, \\
|\langle T u, v\rangle| \leq \beta\|u\|\|v\|
\end{array}\right\} \text { for all } u, v \in X,
$$

then $T$ has a bounded inverse $T^{-1} \in \mathcal{B}(X)$ by Lax-Milgram theorem (see [8, Theorem 13.26]), and

$$
\sup _{n} \sqrt{1+\tan ^{2} \theta_{n}} \leq\|T\|\left\|T^{-1}\right\| \leq \frac{\beta}{\alpha} .
$$

The significance of Theorem 1.2 is partially revealed by its corollaries. The theorem shows us the clue to choose convergent LPA: First, we need $X_{n}(n \in \mathbb{N})$ to guarantee the kernel approximability, which restricts the class of choices for $X_{n}$. Then, we choose specific $X_{n}(n \in \mathbb{N})$ such that their offset angles $\theta_{n}$ are as small as possible, because the small angles can not only guarantee the convergence but also give us faster rate of convergence.

The kernel approximability of LPA is often easy to be satisfied because it is a much weaker condition compared to the condition (1.3) (For instance, in the case of $T$ being an injection, it is always true). Theorem 1.1 presents several equivalent conditions of kernel approximability, which are:

$$
\begin{aligned}
\text { kernel approximability } & \Longleftrightarrow \mathrm{s}-\lim _{n \rightarrow \infty} P_{\mathcal{N}\left(T_{n}\right)}=P_{\mathcal{N}(T)} \\
& \Longleftrightarrow \mathrm{s}-\lim _{n \rightarrow \infty} P_{\mathcal{G}\left(T_{n}^{\dagger}\right)}=P_{\mathcal{G}\left(T^{\dagger}\right)} \\
& \Longleftrightarrow \text { bounded-weak convergence. }
\end{aligned}
$$

These equivalent characterizations of kernel approximability could help us better understand it. From these equivalent characterizations, we can see that the kernel approximability is a weaker version of convergence (that is also the reason why we name one of its equivalent characterizations as bounded-weak convergence).

The interesting points about offset angle and kernel approximability are the geometrical revelations they show. To be more specific, the offset angle $\theta_{n}$ is just the largest canonical angle between $T^{*} T\left(X_{n}\right)$ and $T^{\dagger} T\left(X_{n}\right)$, which are subspaces of $\mathcal{N}(T)^{\perp}$; the kernel approximability is defined by the sequence $\left\{\mathcal{N}(T) \cap X_{n}\right\}$, in which each element $\mathcal{N}(T) \cap X_{n}$ is a subspace of $\mathcal{N}(T)$. Thus the angle between $T^{*} T\left(X_{n}\right)$ and $T^{\dagger} T\left(X_{n}\right)$ in $\mathcal{N}(T)^{\perp}$, and the kernel approximability determined by the spaces $\mathcal{N}(T) \cap X_{n}$ in $\mathcal{N}(T)$, together geometrically depict the convergence of least-squares projection method.
