

DECAY RATES FOR CUSP FUNCTIONS

TRISTRAM DE PIRO

ABSTRACT. We make some observations on the decay rates of the Fourier coefficients of cusp functions.

Definition 0.1. We let $H(0, 1)$ denote the restrictions of holomorphic functions on the open disc $D(0, 1 + \epsilon)$, for some $\epsilon > 0$, and $C^\infty(S^1)$, the set of smooth, complex-valued functions on the unit circle S^1 . For $f \in H(0, 1)$, with power series expansion $f(z) = \sum_{n \in \mathbb{Z}_{\geq 0}} a_n z^n$, we let $\bar{f}(n) = a_n$, for $n \in \mathbb{Z}_{\geq 0}$, and $f_1 = f|_{\partial D(0, 1)}$. For $g \in C^\infty(S^1)$, and $n \in \mathbb{Z}$, we let;

$$\hat{g}(n) = \frac{1}{2\pi} \int_0^{2\pi} g(\theta) e^{-in\theta} d\theta$$

denote the n 'th Fourier coefficient.

Lemma 0.2. With notation as in 0.1, if $f \in H(0, 1)$, and $n \in \mathbb{Z}_{\geq 0}$, we have $\bar{f}(n) = \hat{f}_1(n)$.

Proof. By the definition of residues for holomorphic function, Cauchy's residue theorem, see [2], and Fourier series, see [3], we have, for $n \in \mathbb{Z}_{\geq 0}$, that;

$$\begin{aligned} \bar{f}(n) &= \frac{1}{2\pi i} \int_{\partial D(0, 1)} \frac{f(z)}{z^{n+1}} dz \\ &= \frac{1}{2\pi i} \int_0^{2\pi} \frac{f(e^{i\theta})}{e^{i(n+1)\theta}} i e^{i\theta} d\theta \\ &= \frac{1}{2\pi} \int_0^{2\pi} \frac{f(e^{i\theta})}{e^{in\theta}} d\theta = \hat{f}_1(n) \end{aligned}$$

□

Remarks 0.3. By rescaling, we obtain a similar result for $0 < \delta < 1$ and $f \in H(0, 1 - \delta)$, $f_{1-\delta} \in C^\infty(S^1)$, where $f_{1-\delta}(z) = f((1 - \delta)z)$, for $|z| = 1$. Namely;

$$\bar{f}(n) = \frac{1}{(1-\delta)^n} \hat{f}_{1-\delta}(n).$$

Definition 0.4. We let $\mathcal{H}_+ = \{z \in \mathcal{C} : \text{Im}(z) > 0\}$ denote the upper half plane and $H(\mathcal{H}_+)$ denote the set of holomorphic functions on \mathcal{H}_+ . We let $\text{Cusp}(\mathcal{H}_+) \subset H(\mathcal{H}_+)$ denote holomorphic functions on \mathcal{H}_+ , satisfying the additional symmetry condition;

$$(i). \quad g(z+1) = g(z), \text{ for } z \in \mathcal{C}.$$

and the cusp condition;

$$(ii). \quad \lim_{\text{Im}(z) \rightarrow \infty} g(z) = 0 \text{ (we assume the limit is uniform in } \text{Re}(z))$$

Remarks 0.5. Observe that cusp forms, see [1], are special examples of cusp functions. The map $\Phi = \exp(2\pi iz) : \mathcal{H}_+ \rightarrow D(0, 1)$ is holomorphic, and, taking a principal branch of the logarithm $\Gamma = \frac{\log(z)}{2\pi i} : (D(0, 1) \setminus [0, 1)) \rightarrow (\mathcal{H}_+ \cap U)$, where $U = \{z \in \mathcal{H}_+ : 0 < z < 1\}$, we obtain a holomorphic function $\Gamma^*(g)$ on $(D(0, 1) \setminus [0, 1))$. The condition (i) ensures that $\Gamma^*(g)$ extends uniquely to a holomorphic function f_0 on the annulus $D(0, 1) \setminus \{0\}$, such that $\Phi^*(f_0) = g$. Using a Laurent's Theorem and the condition (ii), f_0 extends uniquely to a holomorphic function f on $D(0, 1)$ with $f(0) = 0$. Taking the power series expansion $f(z) = \sum_{n \in \mathbb{Z}_{\geq 0}} a_n z^n$ on $D(0, 1)$, we obtain a convergent expansion $g(z) = \sum_{n \in \mathbb{Z}_{\geq 0}} a_n \exp(2\pi i n z)$ on \mathcal{H}_+ . Similarly to before, for $n \in \mathbb{Z}_{\geq 0}$, we let $\bar{g}(n) = a_n$.

Lemma 0.6. If $g \in \text{Cusp}(\mathcal{H}_+)$, then, for any $m \in \mathbb{Z}_{>0}$, there exist constants $C_m \in \mathcal{R}_{\geq 0}$ and $D_m \in \mathbb{Z}_{>0}$, such that;

$$|\bar{g}(n)| \leq C_m n^{-m}, \text{ for all } n \geq D_m$$

Proof. Let f denote the holomorphic function on $D(0, 1)$, obtained in Remark 0.5. For any $0 < \delta < 1$, we have that $f \in H(0, 1 - \delta)$. By Remarks 0.3, we have that $\bar{f}(n) = \frac{1}{(1-\delta)^n} \hat{f}_{1-\delta}(n)$, (*). As $f_{1-\delta} \in C^\infty(S^1)$, by a simple extension of Corollary 2.4 in [3], we have that, for any $m \in \mathbb{Z}_{>0}$, there exist constants $C_m \in \mathcal{R}_{\geq 0}$ and $B_m \in \mathbb{Z}_{>0}$, such that;

$$|\hat{f}_{1-\delta}(n)| \leq A_m n^{-m}, \text{ for all } n \geq B_m$$

Then, by (*) and Remarks 0.5, we have;

$$|\bar{g}(n)| = |\bar{f}(n)| = \frac{1}{(1-\delta)^n} |\hat{f}_{1-\delta}(n)| \leq C_m n^{-m}, \text{ for all } n \geq B_m$$

where $C_m = A_m n^{-m}$.

□

Remarks 0.7. *This result seems to improve significantly on the result of the Ramunajan-Petersson conjecture, that, for cusp forms of weight $k \geq 2$, $|\overline{g}(n)| = O(n^{\frac{k-1}{2}+\gamma})$, $\gamma > 0$, $n \in \mathbb{Z}_{\geq 0}$. The result also easily generalises to holomorphic functions on \mathcal{H}_+ , satisfying just the symmetry condition (i), in Definition 0.4, for $n \in \mathbb{Z}$, with $|n| \geq B_m$.*
