# LEBESGUE DECOMPOSITION FOR REPRESENTABLE FUNCTIONALS ON \*-ALGEBRAS

ZSIGMOND TARCSAY

ABSTRACT. We present a Lebesgue-type decomposition for a representable functional on a \*-algebra into absolutely continuous and singular parts with respect to an other. This generalizes the corresponding results of S. P. Gudder for unital Banach \*-algebras. We also prove that the corresponding absolutely continuous parts are absolutely continuous with respect to each other.

#### 1. INTRODUCTION

S. P. Gudder in [3] presented a Lebesgue-type decomposition theorem for positive functionals on a unital Banach \*-algebra  $\mathscr{A}$ . In fact, he proved that for given two positive functionals f, g there exist two positive functionals  $g_a, g_s$  such that  $g = g_a + g_s$  where  $g_a$  is absolutely continuous with respect to f and  $g_s$  is f-semi-singular. Here, the concepts of absolute continuity and semi-singularity read as follows: g is called f-absolutely continuous  $(g \ll f)$  if the properties  $f(a_n^*a_n) \to 0$  and  $g((a_n - a_m)^*(a_n - a_m)) \to 0$  imply  $g(a_n^*a_n) \to 0$ . Furthermore, g is called f-semi-singular  $(g \perp f)$  if there exists a sequence  $(a_n)_{n \in \mathbb{N}}$  such that  $f(a_n^*a_n) \to 0$ ,  $g((a_n - a_m)^*(a_n - a_m)) \to 0$  and  $g(a) = \lim_{n \to \infty} g(a_n^*a)$  for any  $a \in \mathscr{A}$ . Zs. Szűcs [11] proved that the concept of semi-singularity is symmetric in the sense that  $g \perp f$  if and only if  $f \perp g$ . Moreover,  $f \perp g$  holds if and only if h = 0 is the unique positive functional which satisfies  $h \leq f$  and  $h \leq g$ . This latter property is expressed by saying that f and g are mutually singular.

The main goal of this paper is to establish a Lebesgue decomposition theorem in a more general setting, namely, for representable positive functionals on an arbitrary (not necessarily unital) \*-algebra. Being each positive functional of a unital Banach \*-algebra representable, this will yield a proper generalization of Gudder's result. A similar generalization was considered by Szűcs [13] in developing the Lebesgue decomposition theory of so called representable forms over a complex (\*-)algebra. We will also show that the absolute continuous parts  $f_a$  and  $g_a$ , arising by decomposing f with respect to g, and g with respect to f, respectively, are absolutely continuous with respect to each other. An analogous statement was proved by T. Titkos [15] in the context of nonnegative Hermitian forms.

# 2. Preliminaries

To begin with we recall briefly the classical Gelfand–Neumark–Segal (GNS) construction which we shall use as a basic tool in our paper. The procedure presented below is slightly different from what can be find in the literature, see e.g. [2, 7],

<sup>2010</sup> Mathematics Subject Classification. Primary 46L45, 47A67, Secondary 46K10.

Key words and phrases. Representation, GNS construction, positive operators, positive functionals, representable functionals, Lebesgue decomposition, absolute continuity, singularity.

or [8]. Why we use this modified version is because we want to point out the close analogy with the Lebesgue decomposition theory of positive operators in Hilbert spaces, see [14]. To this aim we introduce first the concept of a positive operator from a vector space into its antidual, cf. [9]. Let  $\mathscr{A}$  be a (not necessarily unital) \*-algebra, and denote by  $\mathscr{A}^*$  and  $\overline{\mathscr{A}^*}$  the algebraic dual and antidual of  $\mathscr{A}$ , respectively. Here, the latter one is understood as the vector space of all mappings  $\varphi : \mathscr{A} \to \mathbb{C}$  satisfying

$$\varphi(a+b) = \varphi(a) + \varphi(b), \qquad \varphi(\lambda a) = \overline{\lambda}\varphi(a), \qquad a, b \in \mathscr{A}, \lambda \in \mathbb{C}.$$

The elements of  $\bar{\mathscr{A}^*}$  are referred to as antilinear functionals of  $\mathscr{A}$ . For  $\varphi \in \bar{\mathscr{A}^*}$  and  $a \in \mathscr{A}$  we shall use the notation

$$\langle \varphi, a \rangle := \varphi(a).$$

In the center of our attention there are those antilinear functionals which derive from a given positive functional f ( $f(a^*a) \ge 0, a \in \mathscr{A}$ ), defined by the correspondence

(2.1) 
$$\mathscr{A} \to \mathbb{C}, \quad x \mapsto f(x^*a).$$

The mapping  $(a, b) \mapsto f(b^*a)$  defines obviously a semi-inner product on  $\mathscr{A}$ , hence the Cauchy–Schwarz inequality implies

(2.2) 
$$|f(b^*a)|^2 \le f(a^*a)f(b^*b), \qquad a, b \in \mathscr{A}.$$

We associate now a *positive operator* A with the positive functional f: For fixed  $a \in \mathscr{A}$ , let Aa denote the functional (2.1). Then A is a linear operator of  $\mathscr{A}$  into  $\overline{\mathscr{A}^*}$  which is nonnegative definite in the sense that

$$\langle Aa, a \rangle = f(a^*a) \ge 0, \qquad a \in \mathscr{A}.$$

Observe immediately that A is symmetric:

$$\langle Aa, b \rangle = \overline{\langle Ab, a \rangle}, \qquad a, b \in \mathscr{A}.$$

Hereinafter we make two additional assumptions on f: suppose that

(2.3) 
$$|f(a)|^2 \le C \cdot f(a^*a), \qquad a \in \mathscr{A}$$

holds for a nonnegative constant C and furthermore that

(2.4) 
$$f(b^*a^*ab) \le \lambda_a \cdot f(b^*b), \qquad b \in \mathscr{A}$$

holds for any  $a \in \mathscr{A}$  with some  $\lambda_a \geq 0$ . We notice here that (2.4) holds automatically in Banach \*-algebras, namely by  $\lambda_a = r(a^*a)$ , where r stands for the spectral radius. As it is well known, assumptions (2.3) and (2.4) express the representability of the positive functional f. That means that there exist a Hilbert space H, a cyclic vector  $\zeta \in H$ , and a \*-representation  $\pi$  of  $\mathscr{A}$  in  $\mathscr{B}(H)$  such that

$$f(a) = (\pi(a)\zeta \,|\, \zeta), \qquad a \in \mathscr{A}.$$

Such a triple  $(H, \pi, \zeta)$  is obtained due to the well known Gelfand–Neumark–Segal (GNS) construction (see [9]): Consider the range space ran A of the linear operator A in  $\overline{\mathscr{A}^*}$ . This becomes a pre-Hilbert space endowed by the inner product

(2.5) 
$$(Aa \mid Ab)_A := f(b^*a), \qquad a \in \mathscr{A}$$

(Note that the Cauchy–Schwarz inequality (2.2) shows that  $(Aa | Aa)_A = 0$  implies Aa = 0 for  $a \in \mathscr{A}$  and hence that  $(\cdot | \cdot)_A$  defines an inner product on ran A, indeed.)

The completion  $H_A$  is then a Hilbert space in which we introduce a densely defined continuous operator  $\pi_A(x)$  for any fixed  $x \in \mathscr{A}$  by letting

(2.6) 
$$\pi_A(x)(Aa) := A(xa), \qquad a \in \mathscr{A}.$$

The continuity of  $\pi_A(x)$  is due to (2.4):

$$(A(xa) \mid A(xa))_A = f(a^*x^*xa) \le \lambda_x \cdot f(a^*a) = \lambda_x \cdot (Aa \mid Aa)_A.$$

If we continue to write  $\pi_A(x)$  for its unique norm preserving extension then it is easy to verify that  $\pi_A$  is a \*-representation of  $\mathscr{A}$  in  $\mathscr{B}(H_A)$ . The cyclic vector of  $\pi_A$ is obtained by considering the linear functional  $Aa \mapsto f(a)$  from  $H_A$  into  $\mathbb{C}$  whose continuity is guaranteed by (2.3). The Riesz representation theorem yields then a unique vector  $\zeta_A \in H_A$  satisfying

(2.7) 
$$f(a) = (Aa \mid \zeta_A)_A, \qquad a \in \mathscr{A}.$$

It is again easy to verify the identity

(2.8) 
$$\pi_A(a)\zeta_A = Aa, \qquad a \in \mathscr{A},$$

whence we infer that

(2.9) 
$$f(a) = (\pi_A(a)\zeta_A | \zeta_A)_A, \qquad a \in \mathscr{A}$$

That  $\zeta_A$  is a cyclic vector of  $\pi_A$  follows from identity (2.8).

## 3. Lebesgue decomposition for representable functionals

Throughout this section we fix two representable positive functionals f and g on the \*-algebra  $\mathscr{A}$ . Let A and B stand for the positive operators associated with fand g, respectively. The GNS-triplets  $(H_A, \pi_A, \zeta_A)$  and  $(H_B, \pi_B, \zeta_B)$ , induced by f and g, respectively, are defined along the construction of the previous section. Let us recall the notions of absolute continuity and singularity regarding positive functionals (see [3] and [12]): g is called *absolutely continuous* with respect to f(shortly, g is f-absolutely continuous) if

$$f(a_n^*a_n) \to 0$$
 and  $g((a_n - a_m)^*(a_n - a_m)) \to 0$  imply  $g(a_n^*a_n) \to 0$ 

for any sequence  $(a_n)_{n \in \mathbb{N}}$  of  $\mathscr{A}$ . On the other hand, f and g are mutually singular if the properties  $h \leq f$  and  $h \leq g$  imply h = 0 for any representable positive functional h.

Our aim in the rest of this section is to establish a Lebesgue decomposition theorem for representable positive functionals. More precisely, we shall show that g splits into a sum  $g = g_a + g_s$  where both  $g_a$  and  $g_s$  are representable positive functionals with  $g_a$  f-absolutely continuous and  $g_s$  f-singular. Such a result was proved by Gudder [3] for positive functionals on a unital Banach \*-algebra and by Szűcs [13] in a more general setting, namely for representable forms over a complex algebra.

Our treatment is based on the following observation: If  $(a_n)_{n\in\mathbb{N}}$  is a sequence from  $\mathscr{A}$  such that

 $(3.1) \qquad (Aa_n \mid Aa_n)_A \to 0 \qquad \text{and} \qquad (B(a_n - a_m) \mid B(a_n - a_m))_B \to 0,$ 

then  $Ba_n \to \zeta$  for some  $\zeta \in H$ . If g is f-absolutely continuous then  $\zeta$  must be 0. We introduce therefore the following closed linear subspace of  $H_B$  (cf. also [6, 10, 14]):

$$(3.2) \qquad \mathfrak{M} := \{ \zeta \in H_B \,|\, \exists (a_n)_{n \in \mathbb{N}} \subseteq \mathscr{A}, (Aa_n \,|\, Aa_n)_A \to 0, Ba_n \to \zeta \text{ in } H_B \}.$$

In fact,  $\mathfrak{M}$  is nothing but the so called *multivalued part* of the closure of the following linear relation

$$(3.3) T := \{ (Aa, Ba) \in H_A \times H_B \mid a \in \mathscr{A} \},$$

cf. [4] and [14]. That is to say,

$$\mathfrak{M} = \operatorname{mul} \overline{T} := \{ \zeta \in H_B \mid (0, \zeta) \in \overline{T} \}.$$

Furthermore, g is f-absolutely continuous precisely if  $\mathfrak{M} = \{0\}$ , i.e., when T is (the graph of) a closable operator. We will see below that  $\mathfrak{M} = H_B$  holds if and only if g and f are mutually singular. In any other cases,  $\mathfrak{M}$  is a proper closed  $\pi_B$ -invariant subspace of  $H_B$  (see Lemma 3.1 below).

Let P stand for the orthogonal projection of  $H_B$  onto  $\mathfrak{M}$ , and introduce the functionals  $g_a$  and  $g_s$  as follows

(3.4) 
$$g_a(a) := (\pi_B(a)(I-P)\zeta_B | (I-P)\zeta_B)_B, \qquad g_s(a) := (\pi_B(a)P\zeta_B | P\zeta_B)_B,$$

for  $a \in \mathscr{A}$ . Our main purpose is to prove that both  $g_a$  and  $g_s$  are representable positive functionals such that  $g = g_a + g_s$  where  $g_a$  is *f*-absolutely continuous and  $g_s$  is singular with respect to *f*. Moreover,  $g_a$  is maximal in the sense that  $h \leq g_a$ holds for each *f*-absolutely continuous representable functional *h* satisfying  $h \leq g$ .

**Lemma 3.1.** Let  $\mathscr{A}$  be \*-algebra and let f, g be representable functionals of  $\mathscr{A}$ . Then  $\mathfrak{M}$  and  $\mathfrak{M}^{\perp}$  are both  $\pi_B$ -invariant subspaces of  $H_B$ , and the following identities hold:

(a) 
$$\pi_B(a)P\zeta_B = P\pi_B(a)\zeta_B = P(Ba), a \in \mathscr{A},$$
  
(b)  $\pi_B(a)(I-P)\zeta_B = (I-P)\pi_B(a)\zeta_B = (I-P)(Ba), a \in \mathscr{A}.$ 

*Proof.* In order to prove the  $\pi_B$ -invariancy of  $\mathfrak{M}$  fix  $a \in \mathscr{A}$  and  $\zeta \in \mathfrak{M}$ , and consider a sequence  $(a_n)_{n \in \mathbb{N}}$  from  $\mathscr{A}$  satisfying

$$(Aa_n | Aa_n)_A \to 0$$
 and  $Ba_n \to \zeta$  in  $H_B$ .

Then we have

$$A(aa_n) = \pi_A(a)(Aa_n) \to 0$$
 and  $B(aa_n) = \pi_B(a)(Ba_n) \to \pi_B(a)\zeta$  in  $H_B$ ,

so that  $\pi(a)\zeta \in \mathfrak{M}$ , indeed. Consequently,  $\pi_B(a)\langle \mathfrak{M} \rangle \subseteq \mathfrak{M}$  for all  $a \in \mathscr{A}$ , as claimed. That  $\mathfrak{M}^{\perp}$  is also  $\pi_B$ -invariant follows immediately from the fact that  $\pi_B$  is a \*representation. We are going to prove now (a): for  $a \in \mathscr{A}$  we have  $\pi_B(a)\zeta_B = Ba$ by (2.8) so it suffices to show the first equality of (a). So fix  $\zeta \in \mathfrak{M}$ ; by the  $\pi_B$ invariancy of  $\mathfrak{M}$  we have that

$$(P\pi_B(a)\zeta_B - \pi_B(a)P\zeta_B \mid \zeta)_B = (\pi_B(a)\zeta_B - \pi_B(a)P\zeta_B \mid \zeta)_B$$
$$= (\pi_B(a)(I - P)\zeta_B \mid \zeta)_B = 0,$$

as  $\pi_B(a)(I-P)\zeta_B \in \mathfrak{M}^{\perp}$  which yields (a). Assertion (b) is obtained easily from (a).

As an immediate consequence we have the following

**Corollary 3.2.** Both of the positive functionals  $g_a$  and  $g_s$  are representable and their sum satisfies

$$(3.5) g = g_a + g_s.$$

More precisely,  $\pi_{B,a} := \pi_B(\cdot)(I-P)$  and  $\pi_{B,s} := \pi_B(\cdot)P$  are both \*-representations of  $\mathscr{A}$  in the Hilbert spaces  $\mathfrak{M}^{\perp}$  and  $\mathfrak{M}$ , respectively, with cyclic vectors  $(I-P)\zeta_B$ and  $P\zeta_B$ , respectively, which satisfy

(3.6) 
$$g_a(a) = (\pi_{B,a}(a)(I-P)\zeta_B | (I-P)\zeta_B)_B, \qquad g_s(a) = (\pi_{B,s}(a)P\zeta_B | P\zeta_B)_B,$$
  
for  $a \in \mathscr{A}$ .

We are now in position to state and prove the main result of the paper, the Lebesgue decomposition theorem of representable functionals:

**Theorem 3.3.** Let  $\mathscr{A}$  be \*-algebra, f, g representable functionals on  $\mathscr{A}$ . Then

$$g = g_a + g_s$$

is according to the Lebesgue decomposition, that is to say, both  $g_a$  and  $g_s$  are representable functionals such that  $g_a$  is absolutely continuous with respect to f and that  $g_s$  and f are mutually singular. Furthermore,  $g_a$  is maximal in the following sense:  $h \leq g$  and  $h \ll f$  imply  $h \leq g_a$  for any representable positive functional h.

*Proof.* We start by proving that  $g_a$  is f-absolutely continuous. Consider therefore a sequence  $(a_n)_{n \in \mathbb{N}}$  such that

$$f(a_n^*a_n) \to 0$$
, and  $g_a((a_n - a_m)^*(a_n - a_m)) \to 0$ .

Then, by Lemma 3.1 we have

$$(Aa_n | Aa_n)_A \to 0, \qquad ((I-P)(B(a_n - a_m)) | (I-P)(B(a_n - a_m)))_B \to 0.$$

Nevertheless, the operator  $H_A \supseteq \operatorname{ran} A \to H_B$ ,  $Ax \mapsto (I-P)(Bx)$  coincides with the so called regular part  $T_{\operatorname{reg}}$  (see [4, (4.1)]) of the linear relation T of (3.3) hence it is closable in virtue of [4, Theorem 4.1]. Consequently,

$$g_a(a_n^*a_n) = ((I-P)(Ba_n) | (I-P)(Ba_n))_B \to 0,$$

which proves the absolute continuity part of the statement.

In the next step we prove the extremal property of  $g_a$ . Consider a representable functional h on  $\mathscr{A}$  such that  $h \leq g$  and that h is f-absolutely continuous. Then we have by representability

$$|h(a)|^2 \le C \cdot h(a^*a) \le C \cdot g(a^*a) = C \cdot (Ba \mid Ba)_{\scriptscriptstyle B}, \qquad a \in \mathscr{A},$$

hence the linear functional  $Ba \mapsto h(a)$  is continuous on ran B of  $H_B$ . The Riesz representation theorem yields therefore a (unique) representing vector  $\zeta_h \in H_B$ that fulfills

(3.7) 
$$h(a) = (Ba \mid \zeta_h)_B, \qquad a \in \mathscr{A}.$$

We state that  $\zeta_h \in \mathfrak{M}^{\perp}$ . Fix therefore  $\zeta \in \mathfrak{M}$  and consider a sequence  $(a_n)_{n \in \mathbb{N}}$  from  $\mathscr{A}$  such that

$$(Aa_n | Aa_n)_A \to 0$$
 and  $Ba_n \to \zeta$  in  $H_B$ 

In particular,  $(Ba_n)_{n\in\mathbb{N}}$  is Cauchy in  $H_B$ , therefore  $h((a_n - a_m)^*(a_n - a_m)) \to 0$ holds by  $h \leq g$  and thus  $h(a_n^*a_n) \to 0$  as h is f-absolutely continuous. That implies that

$$|(\zeta \mid \zeta_h)_{\scriptscriptstyle B}|^2 = \lim_{n \to \infty} |(Ba_n \mid \zeta_h)_{\scriptscriptstyle B}|^2 = \lim_{n \to \infty} |h(a_n)|^2 \le C \cdot \lim_{n \to \infty} h(a_n^*a_n) \to 0,$$

which yields the desired identity. Fix now  $a \in \mathscr{A}$ ; by Lemma 3.1 and according to identity  $(I - P)\zeta_h = \zeta_h$  we conclude that

$$h(a^*a) = (B(a^*a) | \zeta_h)_B = ((I - P)(Ba) | \pi_B(a)\zeta_h)_B$$
  
$$\leq ||(I - P)(Ba)||_B ||\pi_B(a)\zeta_h||_B = \sqrt{g_a(a^*a)} ||\pi_B(a)\zeta_h||_B,$$

thus  $h \leq g_a$  will be obtained once we prove that

(3.8) 
$$(\pi_B(a)\zeta_h | \pi_B(a)\zeta_h)_B \le h(a^*a), \qquad a \in \mathscr{A}.$$

By using the density of ran B in  $H_B$  it follows that

$$\begin{aligned} (\pi_B(a)\zeta_h \,|\, \pi_B(a)\zeta_h)_B &= \sup\{ |(Bx \,|\, \pi_B(a)\zeta_h)_B|^2 \,|\, x \in \mathscr{A}, (Bx \,|\, Bx)_B \le 1 \} \\ &= \sup\{ |(B(a^*x) \,|\, \zeta_h)_B|^2 \,|\, x \in \mathscr{A}, g(x^*x) \le 1 \} \\ &= \sup\{ |h(a^*x)|^2 \,|\, x \in \mathscr{A}, g(x^*x) \le 1 \} \\ &\leq \sup\{ h(a^*a)h(x^*x) \,|\, x \in \mathscr{A}, g(x^*x) \le 1 \} \\ &\leq h(a^*a), \end{aligned}$$

as it is claimed.

There is nothing left but to prove that  $g_s$  and f are singular with respect to each other. Fix therefore a representable functional h of  $\mathscr{A}$  such that  $h \leq f$  and  $h \leq g_s$ . Then clearly  $h \leq g$  and h is f-absolutely continuous. By the previous step, there exists  $\zeta_h \in \mathfrak{M}^{\perp}$  such that (3.7) holds. By density of ran B we may choose  $(a_n)_{n \in \mathbb{N}}$ from  $\mathscr{A}$  such that  $Ba_n \to \zeta_h$  in  $H_B$ . Then we find that

$$\begin{aligned} |(\zeta_h | \zeta_h)_B|^2 &= \lim_{n \to \infty} |(Ba_n | \zeta_h)_B|^2 = \lim_{n \to \infty} |h(a_n)|^2 \le C \cdot \limsup_{n \to \infty} h(a_n^*a_n) \\ &\le C \cdot \limsup_{n \to \infty} g_s(a_n^*a_n) = C \cdot \limsup_{n \to \infty} (P(Ba_n) | P(Ba_n))_B \\ &= C \cdot (P\zeta_h | P\zeta_h)_B = 0, \end{aligned}$$

hence h = 0. The proof is therefore complete.

## 4. MUTUALLY ABSOLUTE CONTINUITY OF THE ABSOLUTE CONTINUOUS PARTS

Let f,g be representable positive functionals on the \*-algebra  $\mathscr A$  and consider the Lebesgue decompositions

$$f = f_a + f_s, \qquad g = g_a + g_s,$$

where  $f_a, f_s$  and  $g_a, g_s$  are obtained along the procedure presented in the previous section. In accordance with Theorem 3.3,  $f_a \ll g$  and  $g_a \ll f$ . Our purpose in this section is to show that the absolute continuous parts  $f_a$  and  $g_a$  are mutually absolute continuous, that is that  $f_a \ll g_a$  and  $g_a \ll f_a$  hold true. The heart of the matter is in the following lemma which may be of interest on its own right.

**Lemma 4.1.** Let T be a linear relation between two Hilbert spaces H and K. Let  $\overline{T}$  stand for the closure of T and let P, Q be the orthogonal projections onto ker  $\overline{T}$  and mul  $\overline{T}$ , respectively. Then

$$S_0 := \{ ((I - P)h, (I - Q)k) \,|\, (h, k) \in T \}$$

is (the graph of) a closable linear operator whose closure  $\overline{S_0}$  is one-to-one.

*Proof.* We shall show that

$$S := \{ ((I-P)h, (I-Q)k) \mid (h,k) \in \overline{T} \}$$

is an invertible closed operator. As  $S_0 \subseteq S$ , this contains our original assertion. Consider first the so called regular part  $(\overline{T})_{reg}$  of  $\overline{T}$ , which is defined by

$$(\overline{T})_{\operatorname{reg}} := \{ (h, (I-Q)k) \,|\, (h,k) \in \overline{T} \},\$$

cf. [4]. Let us denote it by R for the sake of brevity. We claim first that R is a closed linear operator such that  $R \subseteq \overline{T}$ . The proof of this statement can be found in [4], we include here a short proof however, for the sake of the reader. It is seen easily that  $\{0\} \times \operatorname{mul} \overline{T} \subseteq \overline{T}$ , and that  $\overline{T} - (\{0\} \times \operatorname{mul} \overline{T}) = R$ . Consequently,  $R \subseteq \overline{T}$  and, as  $\{0\} \times \operatorname{mul} \overline{T}$  and R are orthogonal to each other, we infer that  $R = \overline{T} \ominus (\{0\} \times \operatorname{mul} \overline{T})$ , hence R is closed. To see that R is an operator assume that  $(0, (I-Q)k) \in R$  where  $(0, k) \in \overline{T}$ . This implies that  $k \in \operatorname{mul} \overline{T}$  whence (I - Q)k = 0, that is, R is an operator. Observe furthermore that ker  $R = \ker \overline{T}$ : indeed, by the definition of R it is clear that ker  $\overline{T} \subseteq \ker R$ , and the converse inclusion is due to  $R \subseteq \overline{T}$ .

Consider now the relation  $(R^{-1})_{\text{reg}}$ . Then  $(R^{-1})_{\text{reg}}$  is a closed linear operator due to the above reasoning, such that  $(R^{-1})_{\text{reg}} \subseteq R^{-1}$ . At the same time,

$$\operatorname{mul} R^{-1} = \ker R = \ker \overline{T},$$

whence

$$(R^{-1})_{\text{reg}} = \{ (k', (I-P)h') \mid (h', k') \in R \}$$
  
=  $\{ ((I-Q)k, (I-P)h) \mid (h,k) \in \overline{T} \} = S^{-1}.$ 

We conclude therefore that  $S^{-1}$  is a closed operator, such that  $S^{-1} \subseteq R^{-1}$ , or equivalently,  $S \subseteq R$ . Hence S is an operator as well.

**Theorem 4.2.** Let f and g be representable positive functionals on the \*-algebra  $\mathscr{A}$ . Denote by  $f_a$  and  $g_a$  the g-absolutely continuous and the f-absolutely continuous parts of f and g, respectively. Then  $f_a$  and  $g_a$  are absolutely continuous with respect to each other:  $f_a \ll g_a$  and  $g_a \ll f_a$ .

*Proof.* Consider the linear relation T of (3.3) and let P, Q be the orthogonal projections onto ker  $\overline{T}$  and mul $\overline{T}$ , respectively. By Theorem 3.3, the corresponding absolute continuous parts satisfy

$$f_a(a^*a) = \|(I-P)Aa\|_A^2, \qquad g_a(a^*a) = \|(I-Q)Ba\|_B^2, \qquad a \in \mathscr{A}.$$

According to Lemma 4.1, the relation

$$S := \{ ((I - P)Aa, (I - Q)Ba) \mid a \in \mathscr{A} \}$$

is (the graph of) a closable operator. Hence, if

$$f_a(a_n^*a_n) = ||(I-P)Aa_n||_A^2 \to 0,$$

and

$$g_a((a_n - a_m)^*(a_n - a_m)) = ||(I - Q)B(a_n - a_m)||_B^2 \to 0$$

hold for some  $(a_n)_{n \in \mathbb{N}}$  then

$$g_a(a_n^*a_n) = ||(I-Q)Ba_n||_B^2 \to 0,$$

whence we deduce that  $g_a$  is  $f_a$ -absolutely continuous. That  $f_a$  is  $g_a$ -absolutely continuous follows from the fact that S is one-to-one with closable inverse, according again to Lemma 4.1.
