Keywords: reaction-diffusion, Cayley tree, solvable, autonomous

Abstract

The most general single species autonomous reaction-diffusion model on a Cayley tree with nearest-neighbor interactions is introduced. The stationary solutions of such models, as well as their dynamics, are discussed. To study dynamics of the system, directionally-symmetric Green function for evolution equation of average number density is obtained. In some limiting cases the Green function is studied. Some examples are worked out in more detail.

1 Introduction

Most of the systems encountered in the nature are basically out of equilibrium. Non-equilibrium systems have absorbed much interest recently. Different methods have been used to study non-equilibrium systems, such as approximation methods, simulation, mean-field techniques, and analytical methods. Most analytical studies on reaction diffusion systems, however, belong to one dimensional systems.

The Cayley tree is a lattice without loops, where each site is connected to ξ neighbors, where ξ is called the coordination number. The Cayley tree with $\xi = 2$ is in fact a one dimensional chain. Cayley trees with $\xi \geq 3$ are far richer than the one dimensional chains. The no-loop property of Cayley tree results in the solvability of some models, for general coordination numbers. Reaction diffusion models on the Cayley tree have been studied in, for example, [1–10]. In [1–3] diffusion-limited aggregations, and in [3] two-particle annihilation reactions for immobile reactants have been studied. There are also some exact results for deposition processes on the Bethe lattice [6].

In [7] the most general reaction-diffusion model on a Cayley tree with nearest-neighbor interactions was introduced, which can be solved exactly through the empty-interval method. The stationary solutions as well as the dynamics of such models have been investigated there. In [8], It has been shown that there exist two exactly solvable models. For the first model, the probabilities of finding m particles on the l -th shell of the Cayley tree have been calculated. For the second model, some other probabilities have been calculated.

Recently, a nonconsensus opinion model on Bethe lattices has been studied. It is argued there that the phase diagram corresponding to such a model is different from that of regular percolation [9]. A class of cooperative sequential adsorption models on a Cayley tree with constant and variable attachment rates has been studied in [10]. Possible applications for ionic self-assembly of thin films and drug encapsulation of nanoparticles have been also studied.

Most of the studies on autonomous reaction-diffusion systems are on one-dimensional chains. Some of the results could be easily generalized for multi-dimensional square lattices. A Cayley tree, on the other hand, is an infinite-dimensional lattice, by which it is meant that the number of sites the distances of which with a fixed site are less than a grows faster than any power of a .

Here a system is studied which consists of a Cayley tree with sites being either occupied or empty. The evolution of the system is taken to consist of nearest neighbor interaction, with the further constraint that the system be autonomous, by which it is meant that the evolution of densities (one-point functions) is closed. The Green's function for the initial value problem of the densities is calculated, and studied in more detail in some limiting cases. Some special cases are also investigated more explicitly. Especially, it is seen that the large-time behavior of the system is different for the coordination number equal to 2, and the coordination number larger than 2.

The scheme of the paper is as follows. In section 2, a system of interacting particles on a Cayley tree is introduced. The reactions are nearest neighbor

interaction, and the rates are such that the evolution equation of the average densities is closed. The stationary solutions of such models are discussed. In section 3, a Green's function approach is used to study the dynamics of the system. The Green's function is calculated and used to obtain, among other things, the large time behavior of the system. Some examples are worked out in more detail. Section 4 is devoted to the concluding remarks.

2 The reactions

The Cayley tree is a lattice without loops where each site is connected to ξ neighboring sites. Two sites are called neighbors if they are connected through a link, and ξ is called the coordination number of the Cayley tree.

Part of a Cayley tree with $\xi = 3$

Assume a system of interacting particles on the Cayley tree. Each site is either empty or occupied by one particle. The time evolution of each site depends on only that site and its nearest neighbors, those which directly related to it through a link. Each site can be either occupied, denoted by $\bullet$, or vacant, denoted by $\circ$. The number operator corresponding to the site i is denoted by n_i , which is 0 (1), if the site i is vacant (occupied). The evolution of such a system is governed by a Hamiltonian H . Two neighboring sites with the joint state $(\nu \mu)$ can evolve to another joint state $(\lambda \kappa) \neq (\nu \mu)$ with the rate $H^{\lambda \kappa}_{\nu \mu}$.

A system is called autonomous when the evolution of the average density, $\langle n_i \rangle$, is closed, by which it is meant that the evolution of $\langle n_i \rangle$ is expressible in terms of only $\langle n_j \rangle$'s. The criterion for autonomy has been obtained in [11]. The argument is that corresponding to the site i , the time derivative of $\langle n_i \rangle$ is a summation of terms corresponding to the links which contain i :

$$\frac{d}{dt} \langle n_i \rangle = \sum_{j \in N_1(i)} \left(\frac{d}{dt} \langle n_i \rangle \right)_j, \quad (1)$$

where $\mathbf{N}_a(i)$ is the set of sites the distance of them from the site i is a , and

$$\begin{aligned} \left(\frac{d}{dt} \langle n_i \rangle \right)_j = & + (H^{10}_{00} + H^{11}_{00}) \langle (1 - n_i)(1 - n_j) \rangle \\ & + (H^{10}_{01} + H^{11}_{01}) \langle (1 - n_i) n_j \rangle \\ & - (H^{00}_{10} + H^{01}_{10}) \langle n_i (1 - n_j) \rangle \\ & - (H^{00}_{11} + H^{01}_{11}) \langle n_i n_j \rangle. \end{aligned} \quad (2)$$

The condition for autonomy is that the coefficient of $\langle n_i n_j \rangle$ in the right-hand side vanishes. Assuming that the interactions in each link are symmetric:

$$H^{\lambda\kappa}_{\nu\mu} = H^{\kappa\lambda}_{\mu\nu}, \quad (3)$$

one arrives at the following criterion for the autonomy:

$$H^{00}_{11} + H^{11}_{01} + H^{01}_{11} = H^{11}_{00} + H^{00}_{10} + H^{10}_{00}. \quad (4)$$

From now on, it is assumed that the interactions in each link are symmetric, and the autonomy criterion holds. Defining

$$\rho_i := \langle n_i \rangle, \quad (5)$$

the evolution for ρ would be

$$\dot{\rho}_i = \alpha \xi + \sum_{j \in \mathbf{N}_1(i)} (\beta \rho_j - \gamma \rho_i), \quad (6)$$

where ξ is the number of neighbors to each site, and

$$\begin{aligned} \alpha &:= H^{11}_{00} + H^{10}_{00}, \\ \beta &:= H^{01}_{10} + H^{11}_{10} - (H^{11}_{00} + H^{10}_{00}), \\ \gamma &:= H^{01}_{10} + H^{00}_{01} + (H^{11}_{00} + H^{10}_{00}). \end{aligned} \quad (7)$$

The requirement that the rates be nonnegative, and the criterion (4) for the autonomy, lead to the following constraints

$$\begin{aligned} \alpha &\geq 0, \\ \beta &\geq -\alpha, \\ \gamma &\geq \alpha, \\ \gamma &\geq \alpha + \beta. \end{aligned} \quad (8)$$

Equation (6) which describes the evolution of the density, is clearly translational invariant. The initial condition, however, is not necessarily so. So in general the density does depend on the site. At large times, system approaches to its stationary state, which is a state with uniform density. The stationary solution to the above evolution is ρ^{st} is

$$\rho^{\text{st}} = \frac{\alpha}{\gamma - \beta}. \quad (9)$$

Defining the dynamic solution ρ^{dy} through

$$\rho =: \rho^{\text{st}} + \rho^{\text{dy}}, \quad (10)$$

one arrives at

$$\dot{\rho}_i^{\text{dy}} = \sum_{j \in \mathbf{N}_1(i)} (\beta \rho_j^{\text{dy}} - \gamma \rho_i^{\text{dy}}), \quad (11)$$

$$=: \mathbf{h}_i^j \rho_j^{\text{dy}}. \quad (12)$$

If the initial conditions are directionally-symmetric, by which it is meant that ρ_i depends on only the distance of i from some center, then the density remains directionally-symmetric. In such a situation, one defines another density ρ through

$$\rho_a := \rho_i, \quad i \in \mathbf{N}_a(0). \quad (13)$$

The evolution of this would be

$$\begin{aligned} \dot{\rho}_0 &= \alpha \xi - \gamma \xi \rho_0 + \beta \xi \rho_1, \\ \dot{\rho}_a &= \alpha \xi + \beta \rho_{a-1} - \gamma \xi \rho_0 + \beta (\xi - 1) \rho_{a+1}, \quad a > 0. \end{aligned} \quad (14)$$

The case ($a = 0$) can be included in the general case, if one defines

$$\rho_{-1} := \rho_1. \quad (15)$$

Again, for the difference of ρ and its stationary value, one has

$$\begin{aligned} \dot{\rho}_0^{\text{dy}} &= -\gamma \xi \rho_0^{\text{dy}} + \beta \xi \rho_1^{\text{dy}}, \\ \dot{\rho}_a^{\text{dy}} &= \beta \rho_{a-1}^{\text{dy}} - \gamma \xi \rho_a^{\text{dy}} + \beta (\xi - 1) \rho_{a+1}^{\text{dy}}, \quad a > 0, \end{aligned} \quad (16)$$

which can be written as

$$\dot{\rho}_a^{\text{dy}} = h_a^b \rho_b^{\text{dy}}, \quad (17)$$

where

$$\begin{aligned} h_0^b &= -\gamma \xi \delta_0^b + \beta \xi \delta_1^b, \\ h_a^b &= \beta \delta_a^{b+1} - \gamma \xi \delta_a^b + \beta (\xi - 1) \delta_a^{b-1}, \quad a > 0. \end{aligned} \quad (18)$$

3 The initial value problem

To solve the initial value problem for the dynamic solution, one way is to use the Green's function method. Denoting the Green's function by $\mathbf{G}$, one would have

$$\rho_i^{\text{dy}}(t) = \sum_j \mathbf{G}_i^j(t) \rho_j^{\text{dy}}(0), \quad (19)$$

$$\dot{\mathbf{G}}_i^j(t) = \mathbf{h}_i^l \mathbf{G}_l^j(t), \quad (20)$$

$$\mathbf{G}_i^j(0) = \delta_i^j. \quad (21)$$

The initial value configuration for the Green's function $\mathbf{G}$ is directionally-symmetric (with respect to the point j). So the evolution of $\mathbf{G}$ is governed by an equation similar to (17). To be more specific,

$$\mathbf{G}_{i,j} = G_{d(i,j)}^0, \quad (22)$$

where $d(i, j)$ is the distance of i from j , and G satisfies

$$\dot{G}_a^b(t) = h_a^c G_c^b(t), \quad (23)$$

$$G_a^b(0) = \delta_a^b. \quad (24)$$

The solution to the initial value problem for ρ^{dy} would then be

$$\rho_i^{\text{dy}}(t) = \sum_j G_{d(i,j)}^0(t) \rho_j^{\text{dy}}(0). \quad (25)$$

Of course G can also be used to solve the directionally-symmetric initial value problem:

$$\rho_a^{\text{dy}}(t) = G_a^b(t) \rho_b(0). \quad (26)$$

Comparing these, one arrives at

$$G_a^b = \sum_{j \in \mathbf{N}_b(0)} \mathbf{G}_{i,j}, \quad i \in \mathbf{N}_a(0). \quad (27)$$

To find the Green's function G , one could use the usual method of finding the eigenvectors of h :

$$h \psi_E = E \psi_E, \quad (28)$$

where ψ_E is the eigenvector of h corresponding to the eigenvalue E . An ansatz for ψ_E is

$$\psi_{E,a} = \sum_{\nu} C_{\nu} (z_{\nu})^a, \quad (29)$$

where z_{ν} 's are the roots of the function $(f - E)$ with

$$f(z) := \frac{\beta}{z} + \beta(\xi - 1)z - \gamma\xi. \quad (30)$$

The function $(f - E)$, has obviously two roots, and

$$z_1 z_2 = \frac{1}{\xi - 1}. \quad (31)$$

The analog of (15) for ψ_E , then results in

$$C_1 \left(z_1 - \frac{1}{z_1} \right) + C_2 \left(z_2 - \frac{1}{z_2} \right) = 0. \quad (32)$$

There is another boundary condition, which is ϱ_a should not blow up at $a \rightarrow \infty$. This can be realized by introducing some N and demanding ϱ_N be zero, and then sending N to infinity. So the other boundary condition would be

$$C_1(z_1)^N + C_2(z_2)^N = 0. \quad (33)$$

If $|z_1| > |z_2|$, the above boundary condition would result in the vanishing of C_2 at $N \rightarrow \infty$; and (31) would mean that $|z_2| < 1$, so that (32) would result in C_2 being zero too. So in order that ψ_E be non vanishing,

$$|z_2| = |z_1|, \quad (34)$$

which, defining

$$\eta := \frac{1}{2} \ln(\xi - 1), \quad (35)$$

results in

$$\begin{aligned} z_{1,2}(\theta) &= \frac{1}{\sqrt{\xi-1}} \exp(\pm i\theta), \\ &= \exp(-\eta \pm i\theta), \end{aligned} \quad (36)$$

$$\begin{aligned} E(\theta) &= 2\beta \exp(\eta) \cos \theta - \gamma \xi, \\ &= 2\beta \exp(\eta) \cos \theta - 2\gamma \exp(\eta) \cosh \eta, \end{aligned} \quad (37)$$

$$\psi_{\theta a} = \sinh(\eta + i\theta) \exp[a(-\eta + i\theta)] - \sinh(\eta - i\theta) \exp[a(-\eta - i\theta)], \quad (38)$$

where (32) has been used and a change of notation has been made from ψ_E to ψ_θ . It is seen that η is nonnegative, and it is zero only for $\xi = 2$, which corresponds to a one-dimensional chain (instead of the Cayley tree).

To solve the initial value problem for ϱ^{dy} , one expands the $\varrho^{\text{dy}}(0)$ in terms of the eigenvectors of h . To do so, it is helpful to find the right eigenvectors of h . Denoting these by ϕ , one has

$$\begin{aligned} (\phi h)^0 &= -\gamma \xi \phi^0 + \beta \phi^1, \\ (\phi h)^1 &= \beta \xi \phi^0 - \gamma \xi \phi^1 + \beta \phi^2, \\ (\phi h)^b &= \beta (\xi - 1) \phi^{b-1} - \gamma \xi \phi^b + \beta \phi^{b+1}, \quad b > 1. \end{aligned} \quad (39)$$

So ϕ_θ , the right eigenvector of h corresponding to the eigenvalue $E(\theta)$, would satisfy

$$\begin{aligned} [E(\theta)] \phi_\theta^0 &= -\gamma \xi \phi_\theta^0 + \beta \phi_\theta^1, \\ [E(\theta)] \phi_\theta^1 &= \beta \xi \phi_\theta^0 - \gamma \xi \phi_\theta^1 + \beta \phi_\theta^2, \\ [E(\theta)] \phi_\theta^b &= \beta (\xi - 1) \phi_\theta^{b-1} - \gamma \xi \phi_\theta^b + \beta \phi_\theta^{b+1}, \quad b > 1. \end{aligned} \quad (40)$$

The last equation suggests

$$\phi_\theta^b = D_1(z_1)^{-b} + D_2(z_2)^{-b}, \quad b > 0. \quad (41)$$

Putting this in the remaining equations, one arrives at

$$\begin{aligned}\phi_\theta^0 &= \frac{\xi - 1}{\xi} (D_1 + D_2), \\ \xi \left(\frac{D_1}{z_1} + \frac{D_2}{z_2} \right) &= (\xi - 1) (D_1 + D_2) \left(\frac{1}{z_1} + \frac{1}{z_2} \right).\end{aligned}\quad (42)$$

So,

$$\phi_\theta^b = A \left(1 - \frac{1}{\xi} \delta_0^b \right) \{ \sinh(\eta - i\theta) \exp[b(\eta - i\theta)] - \sinh(\eta + i\theta) \exp[b(\eta + i\theta)] \}, \quad (43)$$

where A is some normalization constant. Using

$$\sum_{a=0}^{\infty} \exp(i a \chi) = \text{pf} \left[\frac{1}{1 - \exp(i \chi)} \right] + \pi \delta(\chi), \quad (44)$$

one obtains

$$\sum_{a=0}^{\infty} \phi_\theta^a \psi_{\theta'}^a = 2\pi A \sinh(\eta + i\theta) \sinh(\eta - i\theta) [\delta(\theta - \theta') - \delta(\theta + \theta')]. \quad (45)$$

So the left eigenvectors are normalized through

$$A = \frac{1}{2\pi \sinh(\eta + i\theta) \sinh(\eta - i\theta)}, \quad (46)$$

resulting in

$$\phi_\theta^b = \frac{1}{2\pi} \left[1 - \frac{\exp(-\eta)}{2 \cosh \eta} \delta_0^b \right] \left\{ \frac{\exp[b(\eta - i\theta)]}{\sinh(\eta + i\theta)} - \frac{\exp[b(\eta + i\theta)]}{\sinh(\eta - i\theta)} \right\}, \quad (47)$$

with

$$\sum_{a=0}^{\infty} \phi_\theta^a \psi_{\theta'}^a = \delta(\theta - \theta') - \delta(\theta + \theta'). \quad (48)$$

Using these, the Green's function for the evolution (16) is seen to be

$$\begin{aligned}G_a{}^b(t) &= \int_0^\pi d\theta \psi_{\theta a} \phi_\theta^b \exp[t E(\theta)], \\ &= \frac{1}{2\pi} \left[1 - \frac{\exp(-\eta)}{2 \cosh \eta} \delta_0^b \right] \exp\{(b-a)\eta - [2\gamma \cosh \eta \exp(\eta)] t\} \\ &\quad \times \int_{-\pi}^\pi d\theta \left\{ \exp[i(a-b)\theta] + \frac{\sinh(i\theta + \eta)}{\sinh(i\theta - \eta)} \exp[i(a+b)\theta] \right\} \\ &\quad \times \exp\{[2\beta \cos \theta \exp(\eta)] t\}.\end{aligned}\quad (49)$$

Among other things, one can investigate some special or limiting cases.

3.1 Large time limit

It is seen that at large times the integral is dominated by the integrand around $\theta = 0$. Defining

$$B(\theta) := \exp[i(a-b)\theta] + \frac{\sinh(i\theta + \eta)}{\sinh(i\theta - \eta)} \exp[i(a+b)\theta], \quad (50)$$

it is seen that the behavior of B for small θ is different for η being zero or positive. In fact only the even part of B contributes to the integral, and that part behaves (for small θ) as

$$\frac{B(\theta) + B(-\theta)}{2} = \begin{cases} 2 + \dots & \eta = 0, \\ 2(a + \coth \eta)(b + \coth \eta)\theta^2 + \dots, & \eta > 0, \end{cases} \quad (51)$$

So at large times,

$$\begin{aligned} G_a^b(t) &= \frac{1}{\sqrt{\pi\beta t}} \left(1 - \frac{1}{2}\delta_0^b\right) \exp[2(\beta - \gamma)t], & \eta = 0. \\ G_a^b(t) &= \frac{(a + \coth \eta)(b + \coth \eta)}{2\sqrt{\pi}[\beta \exp(\eta)t]^3} \left[1 - \frac{\exp(-\eta)}{2\cosh \eta}\delta_0^b\right] \\ &\quad \times \exp\{(b-a)\eta + [2(\beta - \gamma \cosh \eta)\exp(\eta)]t\}, & \eta > 0. \end{aligned} \quad (52)$$

It is seen that the large time behavior of the system for $\eta = 0$ (equivalent to $\xi = 2$, when the Cayley tree is a one dimensional chain) is different from that of $\eta > 0$ (corresponding to $\xi > 2$). Even the large time behavior for $\eta \rightarrow 0$ is different from the large time behavior for $\eta = 0$. The reason is that in approximating $B(\theta)$ for small values of θ , the result is different for $\eta \rightarrow 0$ and $\eta = 0$, due to the fraction in the second term. For $\eta = 0$, that fraction is equal to 1, no matter how small θ is. But if $\eta > 0$, no matter how small it is, there are values for θ which are much smaller than η , which make the fraction equal to (-1) . One can, however, find a cross-over time when such a shift in behavior occurs. This comes from the fact that for large values of t , the relevant values of θ are those which are less than a certain value θ_0 :

$$\theta_0 \sim (\beta t)^{-1/2}. \quad (54)$$

If θ_0 is much smaller than η , then the behavior corresponds to the case of $\eta > 0$. So the cross-over time t_c satisfies

$$t_c \sim (\beta \eta^2)^{-1}. \quad (55)$$

If t is large but still much smaller than t_c , then the behavior is similar to the case of $\eta = 0$.

3.2 One dimensional chain

The one dimensional chain is a Cayley tree with $\xi = 2$ (equivalently $\eta = 0$). In that case, the integration in the expression for the Green's function is readily

performed and one obtains

$$G_a^b(t) = \left(1 - \frac{1}{2} \delta_0^b\right) \exp(-2\gamma t) [\mathbf{I}_{a-b}(2\beta t) + \mathbf{I}_{a+b}(2\beta t)], \quad \xi = 2, \quad (56)$$

where $\mathbf{I}_c$ is the modified Bessel function of the first kind of order c .

3.3 Highly connected Cayley tree

The Green's function is simplified in the opposite limit (large ξ) as well. For large values of ξ (or η), the integral in the expression of the Green's function is again dominated by the value of the integrand for small θ . Hence a technique similar to what was used for the large time behavior can be used here. One arrives at

$$G_a^b(t) = \frac{(a+1)(b+1)}{2\sqrt{\pi}[\beta \exp(\eta)t]^3} \exp\{(b-a)\eta + [2\beta \exp(\eta) - \gamma \exp(2\eta)]t\},$$

$$\eta \gg 1 \text{ (equivalent to } \xi \gg 2\text{).} \quad (57)$$

3.4 directionally-symmetric initial conditions

If the initial density is directionally-symmetric, then (26) can be used to obtain the density at the time t . As an example, consider

$$\rho_a^{\text{dy}}(0) = \begin{cases} \varrho, & a \leq r \\ 0, & a > r \end{cases}, \quad (58)$$

where ϱ is a constant. One arrives at

$$\rho_a^{\text{dy}}(t) = \varrho \sum_{b=0}^r G_a^b(t). \quad (59)$$

So,

$$\begin{aligned} \rho_a^{\text{dy}}(t) &= \frac{\varrho}{2\pi} \exp\{-a\eta - [2\gamma \cosh \eta \exp(\eta)]t\} \\ &\times \left(-\frac{\exp(-\eta)}{2 \cosh \eta} \int_{-\pi}^{\pi} d\theta \exp(i a \theta) \left[1 + \frac{\sinh(i\theta + \eta)}{\sinh(i\theta - \eta)} \right] \right. \\ &+ \int_{-\pi}^{\pi} d\theta \left\{ \frac{\exp[(r+1)(\eta - i\theta)] - 1}{\exp(\eta - i\theta) - 1} \right. \\ &+ \left. \frac{\exp[(r+1)(\eta + i\theta)] - 1}{\exp(\eta + i\theta) - 1} \frac{\sinh(i\theta + \eta)}{\sinh(i\theta - \eta)} \right\} \exp(i a \theta) \Bigg) \\ &\times \exp\{[2\beta \cos \theta \exp(\eta)]t\}, \end{aligned} \quad (60)$$

where (49) has been used.

4 Concluding remarks

A system of particles was studied which move and react on a cayley tree, so that the interactions are nearest-neighbor, and autonomous. The Green's function for the initial value problem of the densities was calculated, and its behavior for large times, as well as small and large coordination numbers was studied. It was seen that the large-time behavior of the system is different for t he coordination number equal to 2, and the coordination number larger than 2.
