DEFINITION OF CYLINDRICAL CONTACT HOMOLOGY IN DIMENSION THREE

ERKAO BAO AND KO HONDA

ABSTRACT. In this paper we give a rigorous definition of cylindrical contact homology for contact 3-manifolds that admit nondegenerate contact forms with no contractible Reeb orbits, and show that the cylindrical contact homology is an invariant of the contact structure.

1. INTRODUCTION

The goal of this paper is to give a rigorous definition of cylindrical contact homology for contact 3-manifolds that admit nondegenerate hypertight contact forms, i.e., contact forms with no contractible Reeb orbits. By “defining cylindrical contact homology” we mean the following:

**Theorem 1.0.1.** Let $(M, \xi)$ be a closed oriented contact 3-manifold that admits nondegenerate hypertight contact forms.

1. There is an assignment of a $\mathbb{Q}$-vector space $HC(D)$ to each auxiliary data

   $$D = (\alpha, \{L_i\}, \{\varphi_i\}, \{J_i\}, \{J_i\}),$$

   where $\alpha$ is a nondegenerate contact form for $\xi$ with no contractible Reeb orbits, $L_i \to \infty$, $i = 1, 2, \ldots$, $\varphi_i : M \to \mathbb{R}^+$ is a smooth function, $\varphi_i \alpha$
has no elliptic orbits of action $< L_i$, and the rest of $\mathcal{D}$ is described in Section 5.3.

(2) $HC(\mathcal{D})$ is the direct limit of homologies of chain complexes generated by good Reeb orbits of $\varphi_\alpha$ of action $< L_i$ whose differential counts Fredholm index 1 holomorphic cylinders.

(3) Given two data $\mathcal{D}_1$ and $\mathcal{D}_2$ for $(M, \xi)$ there exists a natural isomorphism

$$\Phi_{\mathcal{D}_2\mathcal{D}_1} : HC(\mathcal{D}_1) \xrightarrow{\sim} HC(\mathcal{D}_2)$$

satisfying the property $\Phi_{\mathcal{D}_3\mathcal{D}_2} \circ \Phi_{\mathcal{D}_2\mathcal{D}_1} = \Phi_{\mathcal{D}_3\mathcal{D}_1}$.

The notion of contact homology was proposed by Eliashberg-Givental-Hofer in [EGH] over a decade ago, but a rigorous definition had not been written down yet, even for cylindrical contact homology for contact 3-manifolds. This is starting to change with our work and also the recent work of Hutchings-Nelson [HN] towards defining cylindrical contact homology in dimension three.

There are earlier “abstract perturbation” approaches which are much broader in scope and are likely to give a definition of contact homology: polyfolds of Hofer-Wysocki-Zehnder [HWZ3], Kuranishi structures of Fukaya-Ono [FO], and work of Liu-Tian [LT] and Ruan [Ru]. Our approach is quite different (and closer in spirit to [HN]) in that we do not use any type of abstract perturbation theory: we try to minimize the analysis by more carefully using asymptotic eigenfunctions in the spirit of Hutchings-Taubes [HT1, HT2]. We expect that cylindrical contact homology, once it is defined via abstract perturbation theory, will be isomorphic to the one in this paper.

Remark 1.0.2. The assumption of the theorem is designed to simplify the possible degenerations that we need to analyze. Taking away the assumption would lead to the next level of difficulty: defining full contact homology in dimension three.

Remark 1.0.3. Since the first version of this paper was submitted, other approaches (cf. Pardon [Pa] and Bao-Honda [BH]) have appeared which define full contact homology in all dimensions using abstract perturbation theory. One of the usual properties of abstract perturbation theory is that, when perturbations are not needed (i.e., the relevant moduli spaces are already transversely cut out) the counts of holomorphic curves without perturbations agrees with the counts with perturbations. Hence the definition of cylindrical contact homology in this paper agrees with those of [Pa] and [BH].

We also make some remarks on computations:

(1) Currently the only case that can be explicitly computed using the definition of cylindrical contact homology given in this paper is the unit cotangent bundle of a hyperbolic surface. This is because the definition relies on replacing elliptic orbits by hyperbolic ones. It is an interesting problem to determine how to explicitly replace elliptic orbits by a countable collection of hyperbolic orbits (and holomorphic curves connecting them).
(2) If we want to compute $HC(D)$ up to a given action $L_1$, we take a contact form $\varphi_1 \alpha$ that is nice up to $L_1$, take $\varphi_i \alpha, i > 1$, such that $\varphi_i = \varphi_1$ on fixed neighborhoods of the Reeb orbits of $\varphi_1 \alpha$ of action $\leq L_1$ and $\varphi_i$ is $C^0$-close to $\varphi_1$, and form the direct limit of chain complexes induced by cobordisms from $\varphi_i \alpha$ to $\varphi_{i+1} \alpha$. Then the cobordism maps are induced by isomorphisms of chain complexes up to $L_1$ since we can take the almost complex structure to be very close to an $\mathbb{R}$-invariant one.

Outline of proof. Starting with a nondegenerate contact form $\alpha$ with no contractible Reeb orbits for $(M, \xi)$, it is possible to eliminate all its elliptic orbits up to a given action $L > 0$ by taking a small perturbation $\varphi \alpha$ of $\alpha$. Such a perturbed contact form (with some extra normalizations near the hyperbolic orbits) will be called $L$-supersimple. The elimination of elliptic orbits will be reviewed in Section 2.

The advantage of using an $L$-supersimple contact form is that, if $v$ is an $m$-fold branched cover of a finite energy holomorphic map $u$ with $b$ simple branch points, then the Fredholm index $\text{ind}$, given by Equation (3.3.1), satisfies

$$\text{ind}(v) = m \text{ind}(u) + b;$$

see Lemma 3.3.2. In particular, if $\text{ind}(u) \geq 0$, then $\text{ind}(v) \geq 0$.

Remark 1.0.4. Using $L$-supersimple contact forms is mostly a matter of convenience, used to reduce the number of possible cases that we need to consider. It is expected (although not worked out in this paper) that elliptic orbits can be treated in a similar manner.

The chain groups $CC^L(M, \varphi \alpha, J)$ are generated by the good Reeb orbits of action $< L$ for $\varphi \alpha$ and the differential $\partial$ counts $J$-holomorphic maps of $\text{ind} = 1$ as usual. Here we require $(\varphi \alpha, J)$ to be an $L$-supersimple pair; see Section 3.2 for the definition. Its significance will be explained later in this section.

We need to verify the following:

(i) $\partial^2 = 0$;

(ii) an exact symplectic cobordism gives rise to a chain map; and

(iii) a homotopy of cobordisms gives rise to a chain homotopy.

The contact homology group $HC(D)$ is then defined as the direct limit of groups $HC^{L_i}(\varphi_i \alpha, J_i)$ as $L_i \to \infty$. For suppersimple contact forms, (i) and (ii) are not difficult with the aid of automatic transversality techniques of Wendl [We]. Automatic transversality will be reviewed in Section 4 and (i) and (ii) will be proven in Section 5.

In order to prove (iii), we need to make one type of obstruction bundle calculation using the setup of Hutchings-Taubes [HT2], which takes up the rest of the paper. The prototypical gluing problem is the following (there are a few variations, but all of them can be understood in the same way, as explained in Sections 7 and 8):
**Prototypical gluing problem.** Let $\mathcal{T}^\tau$, $\tau \in [0, 1]$, be a 1-parameter family of almost complex structures adapted to a 1-parameter family of completed exact symplectic cobordisms $(\tilde{X}^\tau, \tilde{\alpha}^\tau)$, $\tau \in [0, 1]$, and let $J_{\pm}$ be the adapted almost complex structures which agree with $\mathcal{T}^\tau$ at the positive/negative symplectization ends. Let $v_0 \cup v_1$ be a two-level SFT building, arranged from bottom to top as we go from left to right.

1. $v_1$ is a holomorphic cylinder from $\gamma$ to $\gamma''$ and $v_0$ is a holomorphic cylinder from $\gamma''$ to $\gamma'$
2. we assume that $\gamma''$ is negative hyperbolic and $\gamma'$ is positive hyperbolic;
3. $v_0$ maps to a cobordism $(X^{\tau_0}, \alpha^{\tau_0}, \mathcal{T}^{\tau_0})$ for some $\tau_0 \in (0, 1)$ and $v_1$ maps to a symplectization;
4. $\text{ind}(v_0) = -k$, $\text{ind}(v_1) = k$, $k > 1$;
5. $v_0$ is a $k$-fold unbranched cover of a transversely cut out (in a 1-parameter family) cylinder $u_0$ with $\text{ind}(u_0) = -1$ and $v_1$ is regular; and we write $v_0 = u_0 \circ \pi$, where $\pi$ is the covering map.

The curves $v_0$ and $v_1$ are also equipped with asymptotic markers at the positive and negative ends; this will be described more precisely later. Let $\mathcal{M} = \mathcal{M}_{\mathcal{T}_+}$ be the moduli space of $v_1$’s from $\gamma$ to $\gamma''$ satisfying the above. We want to glue $v_0$ to $\mathcal{M}/\mathbb{R}$ (or its compactification $\overline{\mathcal{M}/\mathbb{R}}$). See Figure 1.

![Figure 1](attachment:figure1.png)

**Figure 1.** The degeneration to the limit $v_0 \cup v_1$. The numbers on the holomorphic curves represent Fredholm indices.

By a slight modification of [HT2], there is an obstruction bundle

$$\mathcal{O} \to [R, \infty) \times \overline{\mathcal{M}/\mathbb{R}}, \quad R \gg 0,$$

whose fiber over $(T, v_1)$ is

$$\mathcal{O}(T, v_1) = \text{Hom}(\ker((D^{N^2}_{v_0})^*)/\mathbb{R}, \mathbb{R}).$$

---

1. More precisely, “tame”, which is defined in Section 3.1.
2. This will be our usual convention.
3. By a curve from $\gamma_+$ to $\gamma_-$ we mean a curve which is asymptotic to $\gamma_+$ at the positive end and to $\gamma_-$ at the negative end.
and a section $s$ of the bundle whose zeros we are trying to count as they correspond to curves in $\mathcal{M}/\mathbb{R}$ that are “gluable” to $v_0$. Here we assume that $v_0$ is immersed for notational convenience, $D^N_{v_0}$ is the linearized normal $\bar{\partial}$-operator of $v_0$ (i.e., the linearized $\bar{\partial}$-operator projected to the normal direction), $(D^N_{v_0})^*$ is its $L^2$-adjoint, and $Y$ is a nonzero element of $\text{coker}(D^N_{v_0})$ which satisfies the following: The linearizations of the operators $\bar{\partial}\tau_0(\exp_{v_0} \xi_0)$ and $\bar{\partial}\tau_0(\exp_{v_0} \xi)$, projected to the normal direction, can be written as $D^N_{v_0} \xi_0 + (\tau - \tau_0) Y_0'$ and $D^N_{v_0} \xi + (\tau - \tau_0) Y'$, respectively, where $Y' = \pi^* Y_0'$. If $\Pi_{u_0}$ and $\Pi_{v_0}$ are orthogonal projections to $\text{ker}(D^N_{u_0})^*$ and $\text{ker}(D^N_{v_0})^*$, then $Y_0 = \Pi_{u_0} Y_0'$, $Y = \Pi_{v_0} Y'$, and $Y = \pi^* Y_0$.

Remark 1.0.5. In general, if $v_0$ is not immersed, we must replace $D^N_{v_0}$ by the full linearized $\bar{\partial}$-operator, which is usually denoted by $D_{v_0}$. For immersed $v_0$, $D_{v_0}$ and $D^N_{v_0}$ have isomorphic kernels and cokernels and have Fredholm index equal to $\text{ind}(v_0)$ as given by Equation (3.3.1).

Suppose $\gamma''$ is an $m(\gamma'')$-fold cover of a simple orbit $\gamma_0''$. Let $\gamma_0'' \times D^2$ be a neighborhood of $\gamma_0''$ and let $(\mathbb{R}/\mathbb{Z}) \times D^2 \to \gamma_0'' \times D^2$ be its $m(\gamma'')$-fold cover with coordinates $(t, z = x + iy)$ such that $\{z = 0\}$ corresponds to $\gamma''$. Also let $\mathbb{R} \times (\mathbb{R}/\mathbb{Z}) \times D^2$ be the cylinder over $(\mathbb{R}/\mathbb{Z}) \times D^2$ with coordinates $(s, t, z = x + iy)$. We parametrize $\mathbb{R}/\mathbb{Z}$ such that the asymptotic marker of $v_1$ at the negative end corresponds to $t = 0$.

We consider the negative end of $v_1 \in \mathcal{M}$ and write it as a graph $\eta_1(s, t)$ over a subset of $\mathbb{R} \times (\mathbb{R}/\mathbb{Z})$; a map of the form $(s, t) \mapsto (s, t, \eta_1(s, t))$ will be called a graphical over $\gamma''$. Let

$$A = -j_0 \frac{\partial}{\partial t} - S(t) : W^{1,2}(\mathbb{R}/\mathbb{Z}, \mathbb{R}^2) \to L^2(\mathbb{R}/\mathbb{Z}, \mathbb{R}^2)$$

be the asymptotic operator of $\gamma''$, where $j_0 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ and $S(t)$ is a family of symmetric matrices. The sign convention for $A$ is consistent with [HWZ1] [HWZ2] but opposite to that of [HT1] [HT2]. Asymptotic eigenfunctions will be discussed in more detail in Sections 4 and 6.

In an idealized situation, $\eta_1 \in \mathcal{M}$ admits a “Fourier expansion”

$$\eta_1(s, t) = \sum_{i \in \mathbb{Z} - \{0\}} c_i(s)e^{\lambda_i s}f_i(t),$$

where $f_i(t)$ is an eigenfunction of the asymptotic operator $A$ corresponding to $\gamma''$ with unit $L^2$-norm, $\lambda_i$ is the corresponding eigenvalue,

$$\cdots \leq \lambda_{-2} \leq \lambda_{-1} < 0 < \lambda_1 \leq \lambda_2 \leq \cdots,$$

$\{f_i(t)\}_{i \in \mathbb{Z} - \{0\}}$ forms an orthonormal basis of $L^2(\mathbb{R}/\mathbb{Z}, \mathbb{R}^2)$, and $c_i(s)$ limits to a constant $c_i$ as $s \to -\infty$ with $c_i = 0$ for $i < 0$. (If there are multiple eigenvalues, then we will make specific, convenient choices for $f_i(t)$.) Hence there would be an evaluation map

$$\text{ev}^k : \mathcal{M} \to \mathbb{R}^k,$$

$$v_1 \mapsto (c_1, \ldots, c_k),$$
which can be shown to miss the origin, and a corresponding quotient
\[ \tilde{e}^v_k : \mathcal{M}/\mathbb{R} \to (\mathbb{R}^k - \{0\})/\mathbb{R}^+ \simeq S^{k-1} \]
given by \( \mathbb{R} \)-translation.

In reality, unless the \( \partial J \)-equation is linear, i.e., of the form
\[ \frac{\partial \eta}{\partial s} + j_0 \frac{\partial \eta}{\partial t} + S(t) \eta = 0 \]
for curves that are close to and graphical over \( \mathbb{R} \times \gamma'' \), the nonlinear terms seem to interfere with the definition of the higher-order terms in the evaluation map and perhaps the best one can do is Siefring’s asymptotic analysis \( [S1] \). This now brings us to the key reason for using \( L \)-supersimple pairs \((\varphi_\alpha, J)\): For \((\varphi_\alpha, J)\) supersimple, \( \partial J \) is linear near \( \gamma'' \) and we are able to define the evaluation map; in fact \( c_i(s) = c_i \) for all \( s \ll 0 \).

The following lemma, proved in Section 4.3 is a consequence of automatic transversality:

**Lemma 1.0.6.** Suppose (C1)–(C4) hold. Then there exists a basis \( \{\sigma_1, \ldots, \sigma_k\} \) for \( \ker(D_0^N)^* \), such that the positive ends of \( \sigma_i, i = 1, \ldots, k \), are of the form
\[ \sigma_i(s, t) = e^{-\lambda_i s} f_i(t) \]
modulo \( f_{k+1}, f_{k+2}, \ldots \) and \( \sigma_k = Y \) modulo \( f_{k+1}, f_{k+2}, \ldots \) (up to a nonzero constant multiple).

Note that \( D_{v_0}^N \) is given locally by \( \frac{\partial}{\partial s} - A \) and \( (D_{v_0}^N)^* \) by \( \frac{\partial}{\partial s} + A \), when \( v_0 \) is close to and graphical over \( \mathbb{R} \times \gamma'' \).

The section \( s \) of the obstruction bundle \( O \) is homotopic to a section \( s_0 \) which is given by:
\[ s_0(T, v_1)(s_i) = e^{-2\lambda_i T} c_i, \]
where \( e^v_k(v_1) = (c_1, \ldots, c_k), i = 1, \ldots, k - 1 \). In other words, on each slice \( \{T\} \times \mathcal{M}/\mathbb{R}, s_0 \) is more or less an evaluation map. It is important that the zeros of the homotopy \( s_0, \zeta \in [0, 1] \), stay away from the boundary \( [R, \infty) \times \partial(\mathcal{M}/\mathbb{R}) \) as we go from \( s = s_1 \) to \( s_0 \). This is proved in Section 8.7.

In Section 6 we prove the transversality of \( \tilde{e}^v_k \) for generic \( J \) (Theorem 6.0.4). By the transversality of \( \tilde{e}^v_k \) and Equation (1.0.3), the zero set \( s_0^{-1}(0) \) is given by \( [R, \infty) \times (\tilde{e}^v_k)^{-1}(\{(0, \ldots, 0, 1, \pm 1)\}) \). Now, let \( \nu \) be a generic embedded path in \( S^{k-1} \) from \((0, \ldots, 0, 1)\) to \((0, \ldots, 0, -1)\). An analysis of \((\tilde{e}^v_k)^{-1}(\nu) \) yields a chain homotopy term \( K' \circ \partial \), where \( K' \) is part of the full chain homotopy \( K \). This will be carried out in Section 7. □

**Acknowledgements.** The second author thanks Michael Hutchings for various discussions over the years and Vincent Colin and Paolo Ghiggini for ideas leading to using only hyperbolic orbits. Also the authors owe an enormous mathematical debt to the work of Hutchings-Taubes \( [HT2] \) which is used throughout this paper. Finally, we thank Michael Hutchings again for pointing out some errors in earlier versions of the paper and the referees for extensive lists of comments.
2. Elimination of elliptic orbits

Convention 2.0.1. In this paper an “orbit” or “Reeb orbit” is a closed Reeb orbit, unless stated otherwise. Also, a Reeb orbit may be a multiple cover of a simple orbit.

In what follows, $M$ is a closed oriented 3-manifold. Given a contact form $\alpha$ on $M$, we denote its Reeb vector field by $R_\alpha$. The $\alpha$-action of an orbit $\gamma$ is given by $A_\alpha(\gamma) = \int_{\gamma} \alpha$.

We first review the Conley-Zehnder index and the classification of Reeb orbits into three types: positive hyperbolic, negative hyperbolic, and elliptic. Let $\gamma$ be an orbit of $R_\alpha$ with $\alpha$-action $\ell$ and $\tau$ be a framing for $\xi$ along $\gamma$. The Conley-Zehnder index $\mu_\tau(\gamma)$ of $\gamma$ with respect to $\tau$ is given as follows: Let $\phi_t, t \in [0, \ell]$, be the time-$t$ flow of $R_\alpha$ and let $p$ be a point on $\gamma$. We consider the path $d\phi_\ell(p) : \xi_p \xrightarrow{\sim} \xi_{\phi_\ell(p)}, t \in [0, \ell]$, of $d\alpha$-symplectic linear maps and in particular the first return map $d\phi_\ell(p) : \xi_p \xrightarrow{\sim} \xi_p$.

1. If the eigenvalues of $d\phi_\ell(p)$ are positive real numbers and $d\phi_\ell(v)$ winds $k$ times around the origin with respect to $\tau$, where $v \neq 0 \in \xi_p$ is an eigenvector of $d\phi_\ell(p)$, then $\mu_\tau(\gamma) = 2k$. Such an orbit $\gamma$ is positive hyperbolic.

2. If the eigenvalues are negative real numbers and $d\phi_\ell(v)$ winds $k$ and a half times around the origin with respect to $\tau$, where $v \neq 0 \in \xi_p$ is an eigenvector of $d\phi_\ell(p)$, then $\mu_\tau(\gamma) = 2k + 1$. Such an orbit $\gamma$ is negative hyperbolic.

3. If the eigenvalues are not real and $d\phi_\ell(w)$ winds between $k$ and $k + 1$ times around the origin with respect to $\tau$ for any $w \neq 0 \in \xi_p$, then $\mu_\tau(\gamma) = 2k + 1$. Such an orbit $\gamma$ is elliptic.

The definition of $\mu_\tau(\gamma)$ is independent of the choice of $p$.

The starting point of the work is the following theorem:
Theorem 2.0.2 (Elimination of elliptic orbits). Let \( \alpha \) be a nondegenerate contact form for \((M, \xi)\). Then for any finite \( L > 0 \) and \( \varepsilon > 0 \) there exists a smooth function \( \varphi : M \to \mathbb{R}^+ \) such that:

1. \( \varphi \) is \( \varepsilon \)-close to 1 with respect to a fixed \( C^1 \)-norm;
2. all the orbits of \( R_{\varphi \alpha} \) of \( \varphi \alpha \)-action less than \( L \) are hyperbolic;
3. each positive hyperbolic orbit \( \gamma \) of \( \varphi \alpha \)-action less than \( L \) has a neighborhood \((\mathbb{R}/\mathbb{Z}) \times D_{\delta_0}^2\) with coordinates \( t, x, y \) such that:
   - \( D_{\delta_0}^2 = \{ x^2 + y^2 \leq \delta_0 \}, \delta_0 > 0 \) small,
   - \( \varphi \alpha = Hdt + \beta \),
   - \( H = c(\gamma) - \varepsilon xy \) with \( c(\gamma) \), \( \varepsilon > 0 \) and \( c(\gamma) \gg \varepsilon \),
   - \( \beta = 2xdy + ydx \), and
   - \( \gamma = \{ x = y = 0 \} \); and
4. each negative hyperbolic orbit \( \gamma \) of \( \varphi \alpha \)-action less than \( L \) has a neighborhood \((0, 1] \times D_{\delta_0}^0) / \sim \) with coordinates \( t, x, y \) and identification \((1, x, y) \sim (0, -x, -y)\) satisfying (a)-(e).

Idea of proof. (1) and (2) are proved in [CGH1, Theorem 2.5.2]. We will explain the idea behind the proof.

Given a simple elliptic orbit \( \gamma \) with \( A_\alpha(\gamma) = \ell < L \), there exists a sufficiently small neighborhood \( N(\gamma) \) of \( \gamma \) and a perturbation of \( \alpha \) (which we still call \( \alpha \)) such that:

1. \( N(\gamma) \simeq D_\delta^2 \times \mathbb{R}/\ell \mathbb{Z} \) with cylindrical coordinates \((r, \theta, z)\), where \( \delta > 0 \) is small;
2. \( \alpha = f(r)dz + \frac{1}{\varepsilon}r^2 d\theta \) and \( f(r) = 1 - \frac{1}{2}ar^2 \) for some \( a > 0 \);
3. \( R_\alpha \) is parallel to \( X_0 = \frac{\partial}{\partial z} + a \frac{\partial}{\partial r} \) on \( \partial D_\delta^2 \) and \( X_1 = (\frac{\partial}{\partial \ell} + \varepsilon') \frac{\partial}{\partial \theta} \) on \( D_{\delta/2}^2 \), where \( \varepsilon' > 0 \) is small. This means that the first return map of \( X_1 \) is a rotation slightly larger than \( \pi \) on \( D_{\delta/2}^2 \). Next view \( D_{\delta/2}^2 \times \mathbb{R}/\ell \mathbb{Z} \) as \((D_{\delta/2}^2 \times [0, \ell])/(r, \theta, \ell) \sim (r, -\theta, 0)\), also with coordinates \((r, \theta, z)\). Then \( X_1 = \frac{\partial}{\partial \ell} + Y_1', Y_1' = \varepsilon' \frac{\partial}{\partial \theta} \), with respect to the latter identification. Finally modify \( Y_1' \) to \( Y_2' \) as given in Figure 3.

(3) and (4) are standard modifications that can be done in a neighborhood of any hyperbolic orbit.

Definition 2.0.3. Let \( L > 0 \). Then a contact form \( \alpha \) is:

1. \( L \)-nondegenerate if all the Reeb orbits of action < \( L \) are nondegenerate;
(2) $L$-supersimple if $\alpha$ is $L$-nondegenerate and all the Reeb orbits of action $< L$ are hyperbolic with neighborhoods that are given in Theorem \ref{thm:2.0.2}(3) and (4);

(3) $L$-hypertight if $\alpha$ is $L$-nondegenerate and has no contractible Reeb orbits of action $< L$; and

(4) $L$-monotone if $\alpha$ is $L$-nondegenerate and has no contractible Reeb orbits of action $< L$ and Conley-Zehnder index $\leq 3$ with respect to any bounding disk.

Given a nondegenerate contact form $\alpha$ for $(M, \xi)$, we choose positive increasing sequences $L_1, L_2, \ldots$ and $\varepsilon_1, \varepsilon_2, \ldots$ such that $\lim_i L_i = \infty$ and $\lim_i \varepsilon_i = \varepsilon$ for some $\varepsilon > 0$. Then there exists a sequence $\varphi_1, \varphi_2, \ldots$ of functions $\varphi_i : M \to \mathbb{R}^+$ where $\varphi_i$ is $\varepsilon_i$-close to 1 and $\varphi_i(\alpha)$ is $L_i$-supersimple. The sequences $\{L_i\}_i$ and $\{\varphi_i\}_i$ are parts of additional data that we choose in order to define cylindrical contact homology.

3. Almost complex structures and moduli spaces

Let $\alpha$ be a contact form and $R_\alpha$ be its Reeb vector field. We write $\gamma = (\gamma_1, \ldots, \gamma_l)$ for some ordered tuple of (not necessarily simple) Reeb orbits of $R_\alpha$.

Warning 3.0.1. Unlike the case of embedded contact homology \cite{Hu}, $\gamma_i$ may be multiply-covered.

3.1. $\alpha$-tame almost complex structures. The almost complex structures on $\mathbb{R} \times M$ that we use are slight variants of almost complex structures which are commonly known as “adapted to” or “compatible with” a contact form $\alpha$ for the contact manifold $(M, \xi)$.

Definition 3.1.1. An almost complex structure $J$ on $\mathbb{R} \times M$ with coordinates $(s, x)$ is $\alpha$-tame if

- $J$ is $\mathbb{R}$-invariant,
- $J \partial_s = g(x) R_\alpha$, where $g$ is a smooth positive function on $M$ and

\footnote{Unfortunately, in general the limit $\lim_i \varphi_i$ is not a smooth function.}
\( J(\xi') = \xi' \) for some oriented 2-plane field \( \xi' \) of \( M \) on which \( d\alpha \) is symplectic and \( d\alpha(v, Jv) > 0 \) for nonzero \( v \in \xi' \). Note that we are not requiring \( \xi' = \xi \).

Note that \( d\alpha|_{\xi'} \) being symplectic is equivalent to \( R_\alpha \) being positively transverse to \( \xi' \). Also observe that if \( J \) is \( \alpha \)-tame, then \( d(e^{\delta s} \alpha) \) is tamed by \( J \) for sufficiently small \( \delta > 0 \).

**Remark 3.1.2** (Failure of maximum principle). An \( \alpha \)-tame \( J \) does not necessarily satisfy the maximum principle for \( J \)-holomorphic curves. However the \( \alpha \)-tameness of \( J \) is sufficient to guarantee that the moduli space of “finite energy” \( J \)-holomorphic curves satisfies SFT compactness; see Section [3.4]

The space of all \( \alpha \)-tame \( J \) in the class \( C^\infty \) will be denoted by \( J(\alpha) \) or by \( J \) if \( \alpha \) is understood.

3.2. **\( L \)-supersimple pairs.** When \( \alpha \) is \( L \)-supersimple, we choose a \( \alpha \)-tame \( J \) which satisfies the following on each neighborhood \((\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0} \) of a positive hyperbolic orbit of action \( < L \) given in Theorem [2.0.2] (3) (and an analogous condition for each neighborhood of a negative hyperbolic orbit):

\((J1)\) \( \xi' = \xi \) on \((\mathbb{R}/\mathbb{Z}) \times (D^2_{\delta_0} - D^2_{2\delta_0/3}), \xi' = TD^2_{\delta_0} \) on \((\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0/3}, \) and \( \xi' \) is \( C^0 \)-close to \( \xi \) on \((\mathbb{R}/\mathbb{Z}) \times (D^2_{2\delta_0/3} - D^2_{\delta_0/3}); \)
\((J2)\) \( J : \partial_s \mapsto \partial_t + X_H = \partial_t - \varepsilon(x\partial_x - y\partial_y) = HR_\alpha \) and \( \partial_x \mapsto \partial_y \) on \((\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0/3}. \)

The subset of such \( J \) will be denoted by \( J_{\ast L}(\alpha) \) or \( J_{\ast}(\alpha) \) when \( L \) is understood. Finally, a pair \((\alpha, J)\) consisting of an \( L \)-supersimple \( \alpha \) and a tame \( J \) satisfying the above will be called an \( L \)-supersimple pair.

3.3. **Moduli spaces.** Let \( \alpha \) be a nondegenerate contact form on \( M \) and let \( J \) be an \( \alpha \)-tame almost complex structure.

**Definition 3.3.1.** Let \( \gamma_+ = (\gamma_{+,1}, \ldots, \gamma_{+,p_+}) \) and \( \gamma_- = (\gamma_{-,1}, \ldots, \gamma_{-,p_-}) \) be ordered tuples for \( \alpha \) and let \( J \) be \( \alpha \)-tame. We say a \( J \)-holomorphic map \( u : \hat{F} \to \mathbb{R} \times M \) is from \( \gamma_+ \) to \( \gamma_- \) if it is asymptotic to \( \gamma_+ \) at the positive end and to \( \gamma_- \) at the negative end. Here \( F \) is a closed Riemann surface, \( p = p_+ \sqcup p_- \) is a finite ordered subset of \( F \) (whose points are called punctures), \( p_+ \) corresponds to \( \gamma_+ \) in order, \( p_- \) corresponds to \( \gamma_- \) in order, and \( \hat{F} = F - p \).

**Fredholm index.** The Fredholm index of \( u \) is given by:

\begin{equation}
\text{ind}(u) = -\chi(\hat{F}) + \mu_\tau(\gamma_+) - \mu_\tau(\gamma_-) + 2\epsilon_1(u^*\xi, \tau),
\end{equation}

where \( \tau \) is a framing for \( \xi \) defined along \( \gamma_+ \) and \( \gamma_- \), \( \mu_\tau(\gamma_{\pm}) := \sum_i \mu_\tau(\gamma_{\pm,i}) \), and \( \epsilon_1(u^*\xi, \tau) \) is the first Chern class of \( u^*\xi \) with respect to \( \tau \). (Here we are viewing \( \xi \) as a 2-plane field of \( M \) and also \( \mathbb{R} \times M \).) Here ind keeps track of both the variations of complex structures of \( \hat{F} \) and the infinitesimal automorphisms of \( \hat{F} \).

The most important aspect of working with \( L \)-supersimple \( \alpha \) is the following:
Lemma 3.3.2. Let $u$ be a $J$-holomorphic map from $\gamma_+$ to $\gamma_-$, where all the orbits of $\gamma_+$ and $\gamma_-$ are hyperbolic. If $v$ is a $k$-fold branched cover of $u$ with total branching multiplicity $b$, then $\text{ind}(v) = k\text{ind}(u) + b$.

Here $b$ is the sum over all the branch points of the order of multiplicity minus one; in particular, if all the branch points are double points, then $b$ is the number of branch points.

Proof: Follows immediately from observing that the Conley-Zehnder indices of hyperbolic orbits behave multiplicatively when we take multiple covers of Reeb orbits. \hfill \Box

Definition of $\mathcal{M}_J(\gamma_+, \gamma_-)$. Pick a point $x_\gamma$ on each simple Reeb orbit $\gamma$ of $R_\alpha$. Let $(u, r)$ be a pair consisting of a $J$-holomorphic map $u : \hat{F} \to \mathbb{R} \times M$ from $\gamma_+$ to $\gamma_-$ and an ordered set $r = r_+ \sqcup r_-$ of asymptotic markers, where

$$r_+ = (r_{+1}, \ldots, r_{+l_+}) \quad \text{and} \quad r_- = (r_{-1}, \ldots, r_{-l_-})$$

correspond to punctures $p_+$ and $p_-$, the marker $r_{\pm i}$ is “mapped to” $x_{\gamma_{\pm i}}$, and $\gamma_{\pm i}$ is the simple orbit corresponding to $\gamma_{\pm i}$. Here an asymptotic marker at a puncture $z$ of $F$ is an element of $(\mathcal{Z} \setminus \{\emptyset\})/\mathbb{R}^+$. The moduli space $\mathcal{M}_J(\gamma_+, \gamma_-)$ is the space of $(u, r)$, modulo biholomorphisms of the domain that take markers to markers.

For convenience we will suppress $r$ from $(u, r)$ when there is no confusion.

If $\gamma_\pm = (\gamma_{\pm 1})$, then we also write $\gamma_\pm = \gamma_\pm$ and $\mathcal{M}_J(\gamma_+, \gamma_-) = \mathcal{M}_J(\gamma_+, \gamma_-)$; similarly, if $r_\pm = (r_{\pm 1})$, then we also write $r_\pm = r_\pm$. We write $\mathcal{M}_J^s(\gamma_+, \gamma_-)$ to denote the subset of $\mathcal{M}_J(\gamma_+, \gamma_-)$ satisfying $s$. In particular, $\text{ind} = k$ means “Fredholm index $k$”, $s$ means “simple (= non-multiply-covered)”, $A$ means “in the homology class $A \in H_2(M; \mathbb{Z})$”, sing means “singular”, i.e., non-immersed, and cyl means we only count cylinders.

A generic $J \in \mathcal{J}$ is regular, i.e, the moduli spaces $\mathcal{M}_J^s(\gamma_+, \gamma_-)$ are transversely cut out for all $\gamma_+, \gamma_-$. Let $\mathcal{J}^{\text{reg}} \subset \mathcal{J}$ be the subset of regular $J$ and let $\mathcal{J}^{<L, \text{reg}} \subset \mathcal{J}$ be the subset of $J$ for which $\mathcal{M}_J^s(\gamma_+, \gamma_-)$ is transversely cut out for all $\gamma_+, \gamma_-$ with action $< L$. The space $\mathcal{J}_L^{<L, \text{reg}} = \mathcal{J}_L^{<L, \text{reg}}$ of regular $L$-supersimple almost complex structures (with respect to a fixed $\alpha$) is defined similarly. We sometimes use the superscript $\delta_0$ on $\mathcal{J}$ to indicate the radius of $D^2$ in (J1) and (J2).

Remark 3.3.3. We sometimes say that a curve is regular if it is transversely cut out (in the sense of including variations of the complex structure on the domain). This should not be confused with a curve being singular, which means the curve is not an immersion.

Finally, we use the coherent orientation system for all $\mathcal{M}_J(\gamma_+, \gamma_-)$ as described in Bourgeois-Mohnke [BM].
3.4. Compactness. Since the class of $\alpha$-tame almost complex structures that we use is slightly different from the one in [BEHWZ], i.e., is not stable Hamiltonian, the SFT compactness results (Theorem 10.1, 10.2, and 10.3 in [BEHWZ]) for our case do not follow automatically from their paper. In this subsection we show that they still hold in our setting by a slight modification of their proofs.

**Theorem 3.4.1.** Suppose that $J$ is an $\alpha$-tame almost complex structure. Then the moduli space $\mathcal{M}(\gamma_+ , \gamma_-)$ can be compactified by adding holomorphic buildings (see Section 8 and 9 of [BEHWZ] for the definition of the holomorphic buildings and the topology of the compactified space).

**Sketch of proof.** The proof follows the general outline of [Ho, HWZ1, BEHWZ] with the following modifications to adjust to the slightly different choice of almost complex structures.

Let $K > 0$ and let $C_K$ be the set of “slow growth” smooth functions $\phi : \mathbb{R} \to [1, 2]$ such that $\phi(s) = 1$ for $s \ll 0$, $\phi(s) = 2$ for $s \gg 0$, and $0 \leq \phi'(s) \leq K$ for all $s$.

**Lemma 3.4.2.** There exists $K > 0$ small such that, all $\phi \in C_K$, $d(\phi\alpha)(v, Jv) \geq 0$ for all $v$ and $d(\phi\alpha)(v, Jv) > 0$ for all nonzero $v$ on the region $\phi'(s) > 0$.

**Proof of Lemma 3.4.2** Write $v = X + a\partial_s + bJ\partial_s = X + a\partial_s + bg\partial_\alpha$, where $X \in \xi'$. Then we have $Jv = JX - b\partial_s + ag\partial_\alpha$ and

$$d(\phi\alpha)(v, Jv) = \phi'(s)(a^2 + b^2)g + a\alpha(JX) + b\alpha(X) + \phi d\alpha(X, JX).$$

Here $d\alpha(X, JX) > 0$ if $X \neq 0$. Also note that $d\alpha(X, JX)$ is bounded below by $C_0 \cdot |X|^2$ for some constant $C_0 > 0$; $|\alpha(X)|$ and $|\alpha(JX)|$ are bounded above by $C_1 \cdot |X|$ for some constant $C_1 > 0$, where the norm $|\cdot|$ is measured with respect to some fixed Riemannian metric on $M$; and $g \geq \kappa_0 > 0$. Therefore, by the Cauchy-Schwarz lemma we have

$$d(\phi\alpha)(v, Jv) \geq \phi'(s)((a^2 + b^2)\kappa_0 - \frac{1}{2}(\kappa_0a^2 + \frac{1}{\kappa_0}C_1^2|X|^2) - \frac{1}{2}(\kappa_0b^2 + \frac{1}{\kappa_0}C_1^2|X|^2)) + \phi C_0|X|^2 = \phi'(s)(a^2 + b^2)\kappa_0 + (\phi C_0 - \frac{1}{\kappa_0}\phi'(s)C_1^2)|X|^2.$$

Since $\phi \geq 1$, the lemma follows by taking $0 \leq \phi'(s) < K$ for $K$ small. 

Let $u : \hat{F} \to \mathbb{R} \times M$ be a $J$-holomorphic map. The $d\alpha$-energy of $u$ is defined as usual by

$$E_{d\alpha}(u) = \int_{\hat{F}} u^* d\alpha$$
and the $\alpha$-energy of $u$ is defined slightly differently by

$$E_\alpha(u) = \sup_{\phi \in C_K} \int_F u^*(\phi'(s) ds \wedge \alpha).$$

where $K > 0$ is the constant given by Lemma 3.4.2. The total energy is defined as

$$E(u) = \sup_{\phi \in C_K} \int_F u^* d(\phi \alpha),$$

and we have the energy bounds

$$(3.4.3) \quad E_{da}(u) + E_\alpha(u) \leq E(u) \leq 2 \cdot E_{da}(u) + E_\alpha(u).$$

Remark 3.4.3 (Energy bounds). If $u$ is a $J$-holomorphic map from $\gamma_+$ to $\gamma_-$, then

$$E(u) = 2A_\alpha(\gamma_+) - A_\alpha(\gamma_-) \quad \text{and} \quad E_{da}(u) = A_\alpha(\gamma_+) - A_\alpha(\gamma_-).$$

Then Equation (3.4.3) implies:

$$(3.4.4) \quad A_\alpha(\gamma_-) \leq E_\alpha(u) \leq A_\alpha(\gamma_+).$$

With our choice of $J$ and energy (the curves $u$ under consideration will have finite $E(u)$ and $E_{da}(u)$, or, equivalently, finite $E_\alpha(u)$ and $E_{da}(u)$), the following key arguments in [Ho] carry over:

1. The removal of singularities and monotonicity follow from the “$J$-tameness” of the 2-forms $d(\phi \alpha)$ for $\phi \in C_K$, which is the content of Lemma 3.4.2.

2. The ends of a holomorphic curve $u : \hat{F} \to \mathbb{R} \times M$ with finite $E_{da}(u)$ and $E(u)$ limit to cylinders over closed orbits (discussed in the next paragraph).

3. In particular, the maximum principle is not necessary (cf. Remark 3.1.2), since the control of the $d\alpha$-energy $E_{da}(u)$ and (2) imply that there are no holomorphic curves with no positive end.

We will sketch the proof of (2), following [Ho, Section 3.1]. If $E_{da}(u) = 0$, then $u$ maps to a cylinder over a (not necessarily closed) Reeb trajectory $\gamma$. If $\hat{F} = \mathbb{C}$ in addition, then the little Picard theorem applied to $\tilde{u} : \mathbb{C} \to \mathbb{R} \times \tilde{\gamma}$ and the finiteness of $E(u)$ imply that $u$ is a constant map. (This is a simplification of the argument of [Ho, Lemma 28].) Here $\tilde{\gamma}$ is the universal cover of $\gamma$ and $\tilde{u}$ is the lift of $u : \mathbb{C} \to \mathbb{R} \times \gamma$. Note that using a smaller class $C_K$ of “slow growth” test functions does not alter this argument or any other argument where $E_\alpha$ is used.

Next, as in the proof of [Ho, Proposition 27], $u$ with finite $E(u)$ and $E_{da}(u)$ does not have gradient blow-up at the ends of $\hat{F}$, since otherwise we can construct a nonconstant finite energy plane with $E_{da} = 0$ using the “Hofer lemma” ([Ho, Lemma 26]) and the taming of $J$ by $d(\phi \alpha)$, $\phi \in C_K$, on compact regions. (Here the gradient is measured with respect to some $\mathbb{R}$-invariant Riemannian metric on $\mathbb{R} \times M$ and a cylindrical metric on the ends of $u$.) The gradient bound implies that if $E_{da}(u) = 0$, $\hat{F} = \mathbb{R} \times S^1$, and $u$ is nonconstant, then $u$ maps to a cylinder over a closed orbit $\gamma$ and

$$u : \hat{F} \to \mathbb{R} \times \gamma = \mathbb{R} \times (\mathbb{R}/\mathbb{Z}),$$

$$(s', t') \mapsto (s' + c, mt' + d),$$
where \( c, d \in \mathbb{R} \) and \( m \in \mathbb{Z}^+ \) (this follows from the fact that an entire holomorphic function with bounded derivative is a linear map). Finally, the gradient bound, the \( E_\alpha \)-bound, and the taming of \( J \) together imply that \( u|_E \) (here \( E \) is an end) converges either to a cylinder over a Reeb orbit or to a removable singularity. Having controlled the behavior of holomorphic curves at the ends (and analogously on the necks), the rest of the SFT compactness argument from [BEHWZ, Section 10.2] then carries over. This completes the sketch of proof of Theorem 3.4.1. □

4. Automatic Transversality and Applications

4.1. Calculation of asymptotic eigenvalues and eigenfunctions. For simplicity of notation, in this section we only look at the orbits of action 1. Let \( S^1 = \mathbb{R}/\mathbb{Z} \) with coordinate \( t \). In this subsection we explicitly calculate the eigenvalues and eigenfunctions for certain asymptotic operators

\[ A : W^{1,2}(\mathbb{R}/\mathbb{Z}, \mathbb{R}^2) \to L^2(\mathbb{R}/\mathbb{Z}, \mathbb{R}^2), \]

\[ A = -j_0 \frac{\partial}{\partial t} - S(t), \]

where \( j_0 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \) and \( S(t) \) is a family of symmetric matrices. This is mostly for reference (especially the elliptic case, which is never used) and is completely standard.

4.1.1. Elliptic case. Let \( S(t) = \begin{pmatrix} \varepsilon & 0 \\ 0 & \varepsilon \end{pmatrix} \), where \( 0 < \varepsilon < 2\pi \). If we view \( \mathbb{R}^2 = \mathbb{C} \), then \( J \) is multiplication by \( i \) and \( S(t) \) is multiplication by \( \varepsilon \). If \( f \) is an eigenfunction of \( A \) with eigenvalue \( \lambda \), then

\[ Af = -i \frac{\partial f}{\partial t} - \varepsilon f = \lambda f \]

and \( f'(t) = i(\lambda + \varepsilon)f \). Hence \( \lambda + \varepsilon = 2\pi n \) for \( n \in \mathbb{Z} \) and \( \lambda = 2\pi n - \varepsilon \); the corresponding asymptotic eigenfunction is \( f(t) = ce^{2\pi int}, c \in \mathbb{C} \). We write

\[ f_{2n-1}(t) = e^{2\pi int}, f_{2n}(t) = ie^{2\pi int}, \]

\[ \lambda_{2n-1} = \lambda_{2n} = 2\pi n - \varepsilon, \]

for \( n \geq 1 \) and

\[ f_{2n-2}(t) = e^{2\pi int}, f_{2n-1}(t) = ie^{2\pi int}, \]

\[ \lambda_{2n-2} = \lambda_{2n-1} = 2\pi n - \varepsilon, \]

for \( n \leq 0 \)\(^5\)

Note that \( \lambda_{2n-1} = \lambda_{2n} \) is a multiple eigenvalue and the corresponding eigenspace is a complex vector space \( \mathbb{C}(f_{2n-1}(t)) \).

\(^5\)We choose this slightly strange numbering so it is consistent with Equation (1.0.1).
4.1.2. Positive hyperbolic case. Let \( S(t) = \begin{pmatrix} 0 & \varepsilon \\ \varepsilon & 0 \end{pmatrix} \), where \( \varepsilon \) is a small positive number. Then \( Af = \lambda f \) can be written as:

\[
\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} \lambda & \varepsilon \\ \varepsilon & \lambda \end{pmatrix} f = \begin{pmatrix} -\varepsilon & -\lambda \\ \lambda & \varepsilon \end{pmatrix} f.
\]

We diagonalize the matrix \( P = \begin{pmatrix} -\varepsilon & -\lambda \\ \lambda & \varepsilon \end{pmatrix} \): We solve for \( \mu \) in

\[
\det \begin{pmatrix} -\varepsilon - \mu & -\lambda \\ \lambda & \varepsilon - \mu \end{pmatrix} = \mu^2 + (\lambda^2 - \varepsilon^2) = 0.
\]

Case \(|\lambda| > \varepsilon\). The eigenvalues of \( P \) are \( \mu = \pm i \sqrt{\lambda^2 - \varepsilon^2} \) and the eigenvectors are

\[
v = \begin{pmatrix} \varepsilon - i \sqrt{\lambda^2 - \varepsilon^2} \\ -\lambda \end{pmatrix}, \quad \overline{v} = \begin{pmatrix} \varepsilon + i \sqrt{\lambda^2 - \varepsilon^2} \\ -\lambda \end{pmatrix}.
\]

In order for \( f(0) = f(1) \), we require \( \sqrt{\lambda^2 - \varepsilon^2} = 2\pi n \). Hence \( \lambda = \pm \sqrt{(2\pi n)^2 + \varepsilon^2} \). Here \( n > 0 \) since we are assuming that \(|\lambda| > \varepsilon\). Then \( f \) is the real or imaginary part of \( e^{i \sqrt{\lambda^2 - \varepsilon^2}} v = e^{i2\pi nt} v \). Then for \( n > 0 \) we obtain

\[
\begin{align*}
(4.1.1) \quad f_{\pm 2n}(t) &= \left( \varepsilon \cos(2\pi nt) + 2\pi n \sin(2\pi nt) \right) \\
(4.1.2) \quad f_{\pm(2n+1)}(t) &= \left( -2\pi n \cos(2\pi nt) + \varepsilon \sin(2\pi nt) \right).
\end{align*}
\]

In particular, we have multiple eigenvalues.

Case \(|\lambda| \leq \varepsilon\). The eigenvalues are real, and in order for \( f(0) = f(1) \) we require \( \lambda = \pm \varepsilon \). We obtain

\[
f_{-1}(t) = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad f_1(t) = \begin{pmatrix} 1 \\ -1 \end{pmatrix}, \quad \lambda_{-1} = -\varepsilon, \quad \lambda_1 = \varepsilon.
\]

4.1.3. Negative hyperbolic case. We identify a neighborhood of a negative hyperbolic orbit with \(((\mathbb{R}/\mathbb{Z}) \times \mathbb{R}^2)/\sim\), where \((t, x)\) are coordinates on \([0, 1] \times \mathbb{R}^2\) and \((1, x) \sim (0, -x)\). With respect to these coordinates we write \( A = -j_0 \frac{\partial}{\partial t} - S(t) \) with \( S(t) = \begin{pmatrix} 0 & \varepsilon \\ \varepsilon & 0 \end{pmatrix} \). The calculations are similar to the positive hyperbolic case and for \( n \geq 1 \) we obtain

\[
\begin{align*}
(4.1.3) \quad f_{\pm(2n-1)}(t) &= \left( \varepsilon \cos((2n-1)\pi t) + (2n-1)\pi \sin((2n-1)\pi t) \right) \\
(4.1.4) \quad f_{\pm 2n}(t) &= \left( -(2n-1)\pi \cos((2n-1)\pi t) + \varepsilon \sin((2n-1)\pi t) \right).
\end{align*}
\]

\[
\lambda_{\pm(2n-1)} = \lambda_{\pm 2n} = \pm \sqrt{(2n-1)^2 + \varepsilon^2}.
\]
4.2. **Automatic transversality.** In this subsection we summarize the parts of the proof of the automatic transversality theorem of Wendl [We] which are used later. Automatic transversality was originally due to Gromov [Gr] and worked out carefully by Hofer-Lizan-Sikorav [HLS] for closed $J$-holomorphic curves. In this section $J \in \mathcal{J}(\alpha)$.

A Reeb orbit is even (resp. odd) if its Conley-Zehnder index is even (resp. odd) with respect to any trivialization $\tau$. Recall that the parity of the Conley-Zehnder index is independent of the choice of trivialization $\tau$. Note that a Reeb orbit is even if and only if it is positive hyperbolic, and an even multiple cover of a negative hyperbolic Reeb orbit is even. Given a $J$-holomorphic curve $u$, let $\# \Gamma_1(u)$ be the number of ends that limit to an even orbit and $\# \Gamma_1(u)$ be the number of ends that limit to an odd orbit.

The following is a special case of [We, Theorem 1]:

**Theorem 4.2.1** (Automatic transversality). Let $u : \hat{F} \to \mathbb{R} \times M$ be an element of $\mathcal{M}_J(\gamma, \gamma')$. If $u$ is an immersion, then $u$ is regular if

\[
\text{ind}(u) > 2 g(F) - 2 + \# \Gamma_0(u).
\]

**Proof.** Let $u \in \mathcal{M}_J(\gamma, \gamma')$ be an immersion and let $N \to \hat{F}$ be a normal bundle to $u(\hat{F}) \subset \mathbb{R} \times M$ such that $N = TD^3_\delta$ on the ends of $u$ for $\delta' > 0$ small. Here each Reeb orbit has a neighborhood of the form $(\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0}$ as described in Theorem 2.0.2. Let

\[
D^N_u : W^{k+1,p}(\hat{F}, N) \to W^{k,p}(\hat{F}, \Lambda^{0,1} T^* \hat{F} \otimes \mathcal{J} N)
\]

be the linearized normal $\mathcal{J}$-operator for $u$ and $(D^N_u)^*$ be its adjoint. The Fredholm index of $D^N_u$ is equal to the Fredholm index $\text{ind}(u)$ of the full linearized $\mathcal{J}$-operator. Since $\text{coker} D^N_u \simeq \ker(D^N_u)^*$, it suffices to show $\ker(D^N_u)^* = 0$ in order to prove Theorem 4.2.1.

Let $\tau$ be a trivialization of $\xi$ along $\gamma$ and $\gamma'$. Given a nontrivial element $\eta \in \ker D^N_u$, we define the winding number \(\text{wind}_\tau(\eta, p)\) of $\eta$ near a puncture $p$ of $F$ to be the winding number of the leading asymptotic eigenfunction of $\eta$ (projected to $TD^3_\delta$) with respect to $\tau$, viewed as a trivialization of $TD^3_\delta$. We also define the total winding number

\[
\text{wind}_\tau(\eta) = \sum_{p_+ \in \mathcal{P}_+} \text{wind}_\tau(\eta, p_+) - \sum_{p_- \in \mathcal{P}_-} \text{wind}_\tau(\eta, p_-).
\]

For each positive puncture $p$ that limits to $\gamma$, $2 \text{wind}_\tau(\eta, p) \leq \mu_\tau(\gamma)$ and equality is possible if and only if $\gamma$ is even; similarly, for each negative puncture that limits to $\gamma$, $2 \text{wind}_\tau(\eta, p) \geq \mu_\tau(\gamma)$ and equality is possible if and only if $\gamma$ is even. Hence

\[
2 \text{wind}_\tau(\eta) \leq \mu_\tau(\gamma) - \mu_\tau(\gamma') - \# \Gamma_1(u)
\]

\[
= \mu_\tau(\gamma) - \mu_\tau(\gamma') + \# \Gamma_0(u) - k,
\]

where $k$ is the total number of punctures.
The intersection number of \( \eta \) with the zero section of \( N \) is given by \( \text{wind}_r(\eta) + c_1(N, \tau) \) and the positivity of intersections in dimension 4 implies that:

**Claim 4.2.2.** If \( \eta \in \ker D_u^N \) is nonzero, then \( \text{wind}_r(\eta) + c_1(N, \tau) \geq 0 \).

**Claim 4.2.3.** If

\[
2c_1(N, \tau) + \mu_r(\gamma) - \mu_r(\gamma') + \#\Gamma_0(u) - k < 0,
\]

then \( \ker D_u^N = 0 \).

Similarly, if we replace \( N \) by \( \Lambda^{0,1}T^*\hat{F} \otimes N \) and note that the leading term of \( (D_u^N)^* \) is the \( \partial \)-operator, we obtain:

**Claim 4.2.4.** If \( \zeta \in \ker (D_u^N)^* \) is nonzero, then

\[
2 \text{wind}_r(\zeta) \geq \mu_r(\gamma) - \mu_r(\gamma') + \#\Gamma_1(u),
\]

\[
\text{wind}_r(\zeta) + c_1(\Lambda^{0,1}T^*\hat{F} \otimes N, (ds - idt) \otimes \tau) \leq 0,
\]

where \( ds - idt \) is the trivialization of \( \Lambda^{0,1}T^*\hat{F} \) on the ends of \( u \) induced by \( ds - idt \). Here \( (s, t) \) are the first two coordinates of \( \mathbb{R} \times (\mathbb{R}/\mathbb{Z}) \times D_{80}^2 \).

**Claim 4.2.5.** If

\[
2c_1(\Lambda^{0,1}T^*\hat{F} \otimes N, (ds - idt) \otimes \tau) + \mu_r(\gamma) - \mu_r(\gamma') + k - \#\Gamma_0(u) > 0,
\]

then \( \ker (D_u^N)^* = 0 \).

Since

\[
\chi(\hat{F}) = 2 - 2g(\hat{F}) - k = c_1(T\hat{F}, ds - idt) = c_1(\Lambda^{0,1}T^*\hat{F}, ds - idt)
\]

and

\[
c_1(\Lambda^{0,1}T^*\hat{F} \otimes N, (ds - idt) \otimes \tau) = c_1(\xi, \tau),
\]

Inequality (4.2.7) can be rephrased as:

\[
\text{ind}(u) = -\chi(\hat{F}) + 2c_1(\xi, \tau) + \mu_r(\gamma) - \mu_r(\gamma')
\]

\[= -\chi(\hat{F}) + 2c_1(\Lambda^{0,1}T^*\hat{F} \otimes N, (ds - idt) \otimes \tau) + \mu_r(\gamma) - \mu_r(\gamma')
\]

\[> -\chi(\hat{F}) + \#\Gamma_0(u) - k = 2g(\hat{F}) - 2 + \#\Gamma_0(u),
\]

which implies the theorem.

The following theorem, due to Hutchings-Taubes [HT2, Theorem 4.1] will also be used frequently in conjunction with Theorem 4.2.1.

**Theorem 4.2.6.** If \( J \) is generic, then for each \( \gamma, \gamma' \), the set of non-immersed \( u \in \mathcal{M}_J^a(\gamma, \gamma') \) has real codimension at least two. More precisely, it is the image of a smooth map \( \phi : \mathcal{Z} \to \mathcal{M}_J^a(\gamma, \gamma') \), where \( \mathcal{Z} \) is a manifold of dimension \( \dim \mathcal{M}_J^a(\gamma, \gamma') - 2 \).

Intuitively, \( du(p) = 0 \) with \( p \in \hat{F} \) fixed is a real codimension four condition for a \( J \)-holomorphic map \( u \) and \( \hat{F} \) is real two-dimensional.
Remark 4.2.7. [HT2, Theorem 4.1] states a less general theorem, but its proof (in particular the discussion of the first paragraph of [HT2, p. 31]) implies Theorem 4.2.6.

4.3. Proof of Lemma 1.0.6. As an application of the automatic transversality technique, we prove the following lemmas, which are slight strengthenings of Lemma 1.0.6 and which will be used in the proof of the chain homotopy.

We are assuming (C1)–(C4). As before, at the positive end $\gamma''$ of $v_1$, let $f_i(t), i \in \mathbb{Z} - \{0\}$, be the eigenfunctions of the asymptotic operator such that

(D1) the corresponding eigenvalues $\lambda_i$ satisfy
\[
\cdots \leq \lambda_{-2} < \lambda_{-1} < 0 < \lambda_1 \leq \lambda_2 \leq \ldots,
\]

(D2) $\{f_i(t)\}_{i \in \mathbb{Z} - \{0\}}$ forms an orthonormal basis of $L^2(\mathbb{R}/\mathbb{Z}; \mathbb{R}^2)$. At the negative end $\gamma'$ of $v_0$, let $g_i(t), i \in \mathbb{Z} - \{0\}$, be the eigenfunctions of the asymptotic operator such that

(E1) the corresponding eigenvalues $\lambda'_i$ satisfy
\[
\cdots \leq \lambda'_{-2} < \lambda'_{-1} < 0 < \lambda'_1 \leq \lambda'_2 \leq \ldots,
\]

(E2) $\{g_i(t)\}_{i \in \mathbb{Z} - \{0\}}$ forms an orthonormal basis of $L^2(\mathbb{R}/\mathbb{Z}; \mathbb{R}^2)$.

Lemma 4.3.1. Suppose (C1)–(C4) hold. Then there exists a basis $\{\sigma_1, \ldots, \sigma_k\}$ for $\ker(D^N_{v_0})$ such that the following hold:

1. The positive ends of $\sigma_i, i = 1, \ldots, k$, are of the form
\[
\sigma_i(s, t) = e^{-\lambda_i s} f_i(t) \mod f_{k+1}, f_{k+2}, \ldots
\]

2. The negative ends of $\sigma_i, i = 1, \ldots, k$, span $\mathbb{R}(e^{-\lambda'_i s} g_j(t))_{j=-k}^{-1} \mod g_{-k-1}, g_{-k-2}, \ldots$

3. The negative end of $\sigma_i, i = 1, \ldots, k$ projects nontrivially to
\[
\mathbb{R}(e^{-\lambda'_i s} g_j(t))_{j=-k+i-2}^{-1} \mod g_{-k-1}, g_{-k-2}, \ldots
\]
if $\lambda'_{-k+i-2} = \lambda'_{-k+i-1}$ and to
\[
\mathbb{R}(e^{-\lambda'_i s} g_j(t))_{j=-k+i-1}^{-1}
\]
if $\lambda'_{-k+i-2} < \lambda'_{-k+i-1}$.

4. The negative end of $\sigma_k$ is of the form
\[
\sigma_k(s, t) = d_{k-1} e^{-\lambda'_1 s} g_{-1}(t) \mod g_{-k-1}, g_{-k-2}, \ldots
\]
where $d_{k-1}$ is nonzero.

5. $\sigma_k = Y$, up to a nonzero constant multiple.

Convention 4.3.2. From now on, we may suppress the upper index “$N$” from $D^N_{v_0}$ for simplicity.
Proof. (1) We consider the linearized normal $\overline{\partial}$-operators
\[
D^\delta_{v_0} = D^{N,\delta}_{v_0} : W^{k+1,p}_{\delta}(\hat{F}, N) \to W^{k+1,p}_{\delta}(\hat{F}, \Lambda^{0,1} T^* \hat{F} \otimes N),
\]
where $N \to \hat{F}$ is the normal bundle to $v_0 : \hat{F} \to \hat{X}_{0}$ and we are using weights $\chi_\delta(s)$, i.e., $\zeta \in W^{k+1,p}_{\delta}$ if and only if $\chi_\delta(s) \zeta \in W^{k+1,p}_{\delta}$. Here $\chi_\delta : \mathbb{R} \to \mathbb{R}^> 0$ is a smooth function such that $\chi_\delta(s) = 1$ for $s \leq 0$ and $\chi_\delta(s) = e^{-\delta s}$ for $s \gg 0$.

Suppose $k$ is odd; the case of $k$ even is similar (but slightly harder) and will be omitted. By the asymptotic eigenfunction calculations from Section 4.1.3.

\[
\text{ind}(D^0_{v_0}) = \text{ind}(D^0_{v_0}) = -k, \quad \text{ind}(D^1_{v_0}) = -k+2, \quad \cdots, \quad \text{ind}(D^{(k/2)}_{v_0}) = -1,
\]
where $\delta_j = 2\pi j$. By Claim 4.2.2,
\[
\ker(D^0_{v_0}) = \cdots = \ker(D^{(k/2)}_{v_0}) = 0.
\]
Hence we obtain
\[
\dim \ker((D^0_{v_0})^*) = k, \quad \dim \ker((D^1_{v_0})^*) = k - 2, \quad \cdots, \quad \dim \ker((D^{(k/2)}_{v_0})^*) = 1.
\]

Now consider $\sigma_1, \sigma_2 \in \ker((D^0_{v_0})^*)$, whose projections span
\[
\ker((D^0_{v_0})^*) / \ker((D^1_{v_0})^*).
\]
For $i = 1, 2$, let us write
\[
\sigma_i = c_1(\sigma_i) e^{-\lambda_1 s} f_1(t) + c_2(\sigma_i) e^{-\lambda_2 s} f_2(t) \quad \text{modulo } f_3, f_4, \cdots
\]
at the positive end. Then $(c_1(\sigma_1), c_2(\sigma_1))$ and $(c_1(\sigma_2), c_2(\sigma_2))$ are linearly independent, since otherwise a nontrivial linear combination of $\sigma_1$ and $\sigma_2$ will be in $\ker((D^1_{v_0})^*)$ and this contradicts the fact that $\ker((D^0_{v_0})^*) / \ker((D^1_{v_0})^*)$ is 2-dimensional. By induction, row reduction, and possibly renaming the $\sigma_i$, we eventually obtain the basis $\{\sigma_1, \ldots, \sigma_k\}$ which satisfies Equation (1.0.2).

(2) follows from the argument of (1).

(3) follows from Claim 4.2.4.

(4), (5) By the regularity of $u_0$ in a 1-parameter family $\mathcal{F}$, $\ker((D^0_{v_0})^*)$ is 1-dimensional and is generated by $Y_0$ which comes from the variation of $\mathcal{F}$. Choose a trivialization $\tilde{\tau}$ along $\gamma''$ and $\gamma'$ so that $\mu_\tilde{\tau}(\gamma'') = -1$ and $\mu_\tilde{\tau}(\gamma') = 0$. By Claim 4.2.4, $Y_0$ has wind $\tilde{\tau} = 0$ at both ends. Hence its pullback $Y = \pi^* Y_0$ to $\ker((D^0_{v_0})^*)$ also has wind $\tilde{\tau} = 0$ at both ends and is a multiple of $\sigma_k$. This proves (5). Moreover, since $Y$ is a pullback, it does not have any terms $d_{i,j} e^{-\lambda_j s} g_j(t)$ at the negative end, where $j \neq -1$ modulo $k$. This proves (4). \hfill \Box

Lemma 4.3.3. Suppose (C1)–(C4) hold. After modifying $\{g_i(t)\}_{i \in \mathbb{Z}^{-}\{0\}}$ subject to (E1) and (E2), there exists a basis $\{\sigma_1, \ldots, \sigma'_{k-1}, \sigma'_k = \sigma_k\}$ for $\ker(D^N_{v_0})^*$ such that the following hold:

1. The positive ends of $\sigma'_i$, $i = 1, \ldots, k$, are of the form
\[
\sigma'_i(s, t) = e^{-\lambda_i s} f_i(t) + \sum_{j > i} c_{i,j} e^{-\lambda_j s} f_j(t).
\]
(2) The negative ends of $\sigma'_i$, $i = 1, \ldots, k - 1$, are of the form

$$\sigma'_i(s, t) = d_{i, -k+i+1} e^{-\lambda'_{k+i+1} s} g_{-k+i-1}(t) + \sum_{j < -k+i-1} d_{i,j} e^{-\lambda_j s} g_j(t),$$

where $d_{i, -k+i+1}$ is nonzero.

(3) The negative end of $\sigma'_{k}$ is of the form

$$\sigma'_{k}(s, t) = d_{k, -1} e^{-\lambda'_{-1} s} g_{-1}(t) \pmod{g_{-k-1}, g_{-k-2}, \ldots},$$

where $d_{k, -1}$ is nonzero.

(4) $\sigma'_k = Y$, up to a nonzero constant multiple.

**Proof.** Let $\{\sigma_1, \ldots, \sigma_k\}$ be as in Lemma 4.3.1. We construct $\sigma'_i$ by induction, starting with $\sigma'_k = \sigma_k$, which satisfies (3) and (4) by Lemma 4.3.1. Suppose $\sigma'_{i+1}$ satisfies (1) and (2) and is of the form $\sigma_{i+1} + \sum_{j > i+1} k_j \sigma'_j$. We take $\sigma'_i$ of the form $\sigma_i + \sum_{j > i} k_j \sigma'_j$ so that (1) and (2) are satisfied, with the possible exception of $d_{i, -k+i+1}$ being nonzero. If $\lambda'_{k+i-2} < \lambda'_{k+i-1}$, then $d_{i, -k+i-1} \neq 0$ is a consequence of Claim 4.2.4. On the other hand, if $\lambda'_{k+i-2} = \lambda'_{k+i-1}$, then $(d_{i, -k+i-1}, d_{i, -k+i-2}) \neq 0$ by Claim 4.2.4 and modifying $g_{-k+i-1}$ and $g_{-k+i-2}$ subject to (E1) and (E2) gives $d_{i, -k+i+1} \neq 0$. □

5. THE DEFINITION OF $HC(D)$

5.1. The differential. Let $(M, \alpha)$ be $L$-supersimple and $L$-monotone. Recall that an orbit $\gamma$ of $R_\alpha$ is bad if it is an even multiple cover of a negative hyperbolic orbit and is good if it is not bad. Let $\mathcal{P}^L_{\alpha, \text{bad}}$ (resp. $\mathcal{P}^L_{\alpha, \text{good}}$) be the set of bad (resp. good) Reeb orbits of $R_\alpha$ of action $< L$. We write $\mathcal{P}^L_\alpha := \mathcal{P}^L_{\alpha, \text{good}} \sqcup \mathcal{P}^L_{\alpha, \text{bad}}$. Given $J \in \mathcal{J}^{< L, \text{reg}}(\alpha)$, let $\text{CC}^L(M, \alpha, J)$ be the $\mathbb{Q}$-vector space generated by $\mathcal{P}^L_{\alpha, \text{good}}$.

If $\gamma$ is an $m$-fold cover of a simple orbit, then we define the multiplicity $m(\gamma)$ of $\gamma$ to be $m$. The differential $\partial$ of $\text{CC}^L(M, \alpha, J)$ is given by

\begin{equation}
\partial \gamma = \sum_{\gamma' \in \mathcal{P}^L_{\alpha, \text{good}}} \#(\mathcal{M}^\text{ind=1,cyl}_J(\gamma, \gamma')) \frac{1}{m(\gamma')} \cdot \gamma',
\end{equation}

where $\#$ refers to the signed count using the coherent orientation system from [BM]; see Section 9.1 for more details on orientations.

**Remark 5.1.1.** Although there is a denominator $\frac{1}{m(\gamma')}$ in the definition of $\partial$, the coefficient of $\gamma'$ is always an integer; the same holds for coefficients in chain maps. For example, when $(u, r) \in \mathcal{M}^\text{ind=1,cyl}_J(\gamma, \gamma')$ and $u$ is not multiply-covered (which is automatic by Lemma 3.3.2), the contribution of all the $(u, r)$ with the same image towards

$$\#(\mathcal{M}^\text{ind=1,cyl}_J(\gamma, \gamma')) \frac{1}{m(\gamma')}$$

as we range over $r$ is $\pm m(\gamma)$.
Remark 5.1.2. One can also define the differential by

\[ \partial' \gamma = \sum_{\gamma' \in \mathcal{P}_{\alpha, \text{good}}} \#(\mathcal{M}_j^{\text{ind}=1, \text{cyl}}(\gamma, \gamma'))/\mathbb{R} \frac{1}{m(\gamma)} : \gamma'. \]

The homologies with respect to \( \partial \) and \( \partial' \) are isomorphic only over \( \mathbb{Q} \).

Remark 5.1.3. In view of Remark 5.1.1, \( \text{CC}^L(M, \alpha, J) \) can be defined over \( \mathbb{Z} \). Similarly, the chain maps \( \Phi_{X, \alpha, J} \) can be defined over \( \mathbb{Z} \). What is not defined over \( \mathbb{Z} \) are the chain homotopy maps \( K_{\pm} \).

Theorem 5.1.4. If \( J \) is generic, \( \alpha \) is \( L \)-supersimple and \( L \)-monotone, and \((\alpha, J)\) is an \( L \)-supersimple pair, then \( \partial \) is defined (i.e., the moduli space \( \mathcal{M}_j^{\text{ind}=1, \text{cyl}}(\gamma, \gamma')/\mathbb{R} \) in Equation (5.1.1) is transversely cut out, compact, and oriented) and \( \partial^2 = 0 \).

Proof: We give a proof modulo orientation considerations that are postponed until Section 9.1. We first state a couple of preliminary lemmas.

Lemma 5.1.5. The moduli space \( \mathcal{M}^i := \mathcal{M}_j^{\text{ind}=i, \text{cyl}}(\gamma, \gamma') \), where \( \gamma' = (\gamma'_1, \ldots, \gamma'_i) \) and \( \gamma, \gamma'_1, \ldots, \gamma'_i \in \mathcal{P}_{\alpha, \text{cyl}}^L \), is empty if \( i < 0 \) and consists of possibly multiple covers of trivial cylinders if \( i = 0 \).

Proof of Lemma 5.1.5. A simply-covered \( J \)-holomorphic curve is regular by the genericity of \( J \). Hence there are no simply-covered curves of \( \text{ind} \leq 0 \) besides trivial cylinders. Lemma 3.3.2 then implies that \( \mathcal{M}^{i<0} \) is empty and \( \mathcal{M}^0 \) consists of possibly multiple covers of trivial cylinders. \( \square \)

Lemma 5.1.6. For \( i = 1, 2 \), the moduli space \( \mathcal{M}^i := \mathcal{M}_j^{\text{ind}=i, \text{cyl}}(\gamma, \gamma') \) is transversely cut out if \( \gamma, \gamma' \in \mathcal{P}_{\alpha, \text{cyl}}^L \). All the curves of \( \mathcal{M}^1 \) are simply-covered.

Proof of Lemma 5.1.6. When \( i = 1 \), any \( u \in \mathcal{M}^1 \) is simply-covered by Lemma 3.3.2 and hence is transversely cut out.

When \( i = 2 \), either \( u \in \mathcal{M}^2 \) is simply-covered or double covers a simple \( u' \) with \( \text{ind}(u') = 1 \) and no branch points. By Theorem 4.2.6, \( u' \) is an immersion, so \( u \) is also an immersion. By Theorem 4.2.1, \( u \) is regular. \( \square \)

By Lemmas 5.1.5 and 5.1.6 and the additivity of \( \text{ind} \), \( \mathcal{M}_j^{\text{ind}=1, \text{cyl}}(\gamma, \gamma')/\mathbb{R} \) is compact and transversely cut out. This implies the finiteness of \( \#(\mathcal{M}_j^{\text{ind}=1, \text{cyl}}(\gamma, \gamma'))/\mathbb{R} \).

For \( \partial^2 = 0 \), we consider \( \text{ind} = 2 \) moduli space \( \mathcal{M}^2 := \mathcal{M}_j^{\text{ind}=2, \text{cyl}}(\gamma, \gamma') \), which is transversely cut out by Lemma 5.1.6. By Lemma 5.1.5, every element \( u^\infty \) of \( \partial \mathcal{M} \) is a two-level building \( u_1 \cup u_2 \), where \( u_2 \) is above \( u_1 \), \( u_i, i = 1, 2, \text{ind}(u_i) = 1 \), and \( u_1, u_2 \) are a priori not necessarily cylindrical. By the monotonicity of \( \alpha \), every holomorphic plane in \( u^\infty \) must have \( \text{ind} \geq 3 \), which is a contradiction. This implies that all the irreducible components of \( u^\infty \) are cylinders.

It remains to consider the case where \( u_2 \) is a curve from \( \gamma \) to \( \gamma'' \) and \( u_1 \) is a curve from \( \gamma'' \) to \( \gamma' \), where \( \gamma'' \) is a bad Reeb orbit. By Lemma 5.1.6, \( u_1 \) and \( u_2 \) are simply-covered. Since \( \gamma'' \) is an even multiple cover of a negative hyperbolic orbit, the gluing occurs in canceling pairs. (Recall from [BM] that the orientation
is reversed under a \( \mathbb{Z}/2 \)-deck transformation if \( \gamma'' \) is an even multiple of a negative hyperbolic orbit.)

5.2. Chain maps. Let \( (X^4, \alpha) \) be a compact, connected, exact symplectic cobordism, where \( d\alpha \) is symplectic, \( \partial X = M_+ - M_- \), and \( \alpha_\pm = \alpha|_{M_\pm} \) is a contact form on \( M_\pm \). Let \( (\hat{X}, \hat{\alpha}) \) be the completion of \( (X, \alpha) \), obtained by attaching the symplectization ends \( [0, \infty) \times M_+ \) and \( (-\infty, 0] \times M_- \), and let \( \mathcal{T} \) be an almost complex structure which tames \( (\hat{X}, \hat{\alpha}) \) and which restricts to \( \alpha_\pm \)-tame almost complex structures \( J_\pm \) at the positive and negative ends. Also let \( \mathcal{M}_\mathcal{T}(\gamma_+, \gamma_-) \) be the moduli space of \( \mathcal{T} \)-holomorphic maps in \( \hat{X} \) from \( \gamma_+ \) to \( \gamma_- \) with markings, defined in a manner analogous to that of \( (\mathbb{R} \times M, J) \).

**Theorem 5.2.1.** If \( \mathcal{T} \) is generic, \( (M_+, \alpha_+) \) and \( (M_-, \alpha_-) \) are \( L \)-supersimple and \( L \)-monotone, and \( (\alpha_+, J_+) \) and \( (\alpha_-, J_-) \) are \( L \)-supersimple pairs, then \( (X, \alpha, \mathcal{T}) \) induces a chain map

\[
\Phi_{(X, \alpha, \mathcal{T})} : CC^L(M_+, \alpha_+, J_+) \to CC^L(M_-, \alpha_-, J_-),
\gamma_+ \mapsto \sum_{\gamma_- \in \mathcal{P}_{\alpha_-}\text{-good}^{\mathcal{T}}} \#(\mathcal{M}_\mathcal{T}^{\text{ind}=0, \text{cyl}}(\gamma_+, \gamma_-)) \frac{1}{m(\gamma_-)} \cdot \gamma_-.
\]

In particular, the moduli spaces \( \mathcal{M}_\mathcal{T}^{\text{ind}=0, \text{cyl}}(\gamma_+, \gamma_-) \) are compact, transversely cut out, and oriented.

**Proof.** The proof is given in three steps.

**Step 1.** We first start with the following analogs of Lemmas 5.1.5 and 5.1.6.

**Lemma 5.2.2.** The moduli space \( \mathcal{M}_\mathcal{T}^{\text{ind}=1}(\gamma_+, \gamma_-) \), where \( \gamma_- = (\gamma_{-,1}, \ldots, \gamma_{-,\ell}) \), \( \gamma_+ \in \mathcal{P}_{\alpha_+}\text{-cyl}^{\mathcal{T}} \) and \( \gamma_{-,1}, \ldots, \gamma_{-,\ell} \in \mathcal{P}_{\alpha_-}\text{-cyl} \), is empty if \( i < 0 \).

The proof of Lemma 5.2.2 is the same as that of Lemma 5.1.5.

**Lemma 5.2.3.** For \( i = 0, 1 \), the moduli space \( \mathcal{M}_\mathcal{T}^{\text{ind}=i, \text{cyl}}(\gamma_+, \gamma_-) \) is transversely cut out for \( \gamma_+ \in \mathcal{P}_{\alpha_+}\text{-cyl}^{\mathcal{T}} \) and \( \gamma_- \in \mathcal{P}_{\alpha_-}\text{-cyl} \), away from curves \( u \in \mathcal{M}^0 \) that are even multiple covers of cylinders between (odd multiples of) negative hyperbolic orbits. All the curves of \( \mathcal{M}^1 \) are simply-covered.

**Proof of Lemma 5.2.3** When \( i = 1 \), any \( u \in \mathcal{M}^1 \) is simply-covered by Lemma 5.1.8 and hence regular.

Suppose \( i = 0 \). Since simple curves in \( \mathcal{M}^0 \) are regular, it remains to prove that \( v \in \mathcal{M}^0 \) which is an unbranched \( m \)-fold cover of a simple \( u \) from \( \gamma \) to \( \gamma' \) is regular. By Theorem 4.2.6, we may assume that \( u \) is immersed. Let \( F_1 \) and \( F_0 \) be the domains of \( v \) and \( u \) and let \( \pi : \hat{F}_1 \to \hat{F}_0 \) be the covering map such that \( v = u \circ \pi \).

Let \( N \) be a normal bundle of \( v \) as described in Section 4 and let \( \tau \) be a trivialization of \( N \) so that either \( \mu_\tau(\gamma) = \mu_\tau(\gamma') = 0 \) or \( \mu_\tau(\gamma) = \mu_\tau(\gamma') = 1 \).
Suppose that \( \mu_+ (\gamma) = \mu_+ (\gamma') = 1 \). If \( m \) is even, then \( \gamma_+ \) and \( \gamma_- \) are even multiples of \( \gamma \) and \( \gamma' \) which are odd multiples of negative hyperbolic orbits. This contradicts our assumption. Hence \( m \) is odd and \( \# \Gamma_0 (v) = 0 \). Theorem 4.2.1 then implies that \( v \) is regular.

Next suppose that \( \mu_+ (\gamma) = \mu_+ (\gamma') = 0 \). By assumption \( u \) is regular. If \( v \) is not regular, then \( 0 \neq \zeta \in \ker (D_N^N)^* \). This contradicts our assumption. Hence \( v \) is finite. By Lemma 5.2.3, \( \Phi = \Phi \).

Let \( (u, r) \in M \). Suppose that \( v \) is multiply-covered. (By the monotonicity of \( \Phi \), \( \Phi \) is transversely cut out and compact, and hence finite. By Lemma 5.2.3, \( M \) is transversely cut out and compact, and hence finite. By Lemma 5.2.3, \( M \) is transversely cut out. By the SFT compactness theorem [BEHWZ], if \( M \) is not compact, then there is a sequence \( u_1, u_2, \ldots \in M \) that limits to an SFT building \( u^\infty \) of \( \geq 2 \) levels. By Lemma 5.1.5, all the levels of \( u^\infty \) that map to \( \mathbb{R} \times M_\pm \) have \( \ind > 0 \) and by Lemma 5.1.6, the level of \( u^\infty \) that maps to the cobordism has \( \ind \geq 0 \). Hence \( u^\infty \) is a 1-level building in \( M \) and we get a contradiction.

Step 3: \( \partial \circ \Phi = \Phi \circ \partial \). First, \( M^1 \) is regular by Lemma 5.2.3. We consider the boundary \( \partial M^1 \) of \( M^1 \). If \( u^\infty \in \partial M^1 \), then by Lemmas 5.1.5 and 5.2.2, we have \( u^\infty = v_0 \cup v_1 \) or \( v_{-1} \cup v_0 \), where \( v_0 \) is a cylinder that maps to \( \hat{X} \) and \( v_i \), \( i \neq 0 \), is a cylinder that maps to \( \mathbb{R} \times M_\pm \); the levels are arranged from bottom to top as \( i \) increases; \( \ind (v_i) = 1 \), \( i \neq 0 \), and \( \ind (v_0) = 0 \); and by Lemma 5.1.6, \( v_i \), \( i \neq 0 \), is simple and \( v_0 \) may be multiply-covered. (By the monotonicity of \( \alpha_\pm \), every holomorphic plane in \( u^\infty \) must have \( \ind \geq 3 \). Since \( \ind > 0 \) for every nontrivial curve in \( \mathbb{R} \times M_\pm \) and \( \ind \geq 0 \) for every nontrivial curve in \( \hat{X} \), there can be no planes. This implies that each irreducible component of \( u^\infty \) is a cylinder.) By Lemmas 5.1.6 and 5.2.3, each component of \( u^\infty \) is regular since \( \gamma_+ \) and \( \gamma_- \) are good by assumption and one of the ends of \( v_0 \) cannot limit to a bad orbit.

Suppose that \( u^\infty = v_0 \cup v_1 \); the considerations for \( u^\infty = v_{-1} \cup v_0 \) are analogous. Suppose that \( v_0 \) limits to a bad orbit at its positive end. Then, as above, \( v_0 \) is not an even multiple cover of a cylinder between (odd multiples of) negative hyperbolic orbits since otherwise \( \gamma_- \) is bad. By [BM] this is sufficient to ensure that there is an even number of ways to glue \( v_0 \) and \( v_1 \) and they result in canceling pairs.

The orientation considerations are similar to those of Theorem 5.1.4. \( \square \)
5.3. Definition of $HC(D)$. We are now in a position to define the cylindrical contact homology group $HC(D)$. Given $(M, \xi)$, let

$$D = (\alpha, \{L_i\}, \{\varphi_i\}, \{J_i\}, \{\tilde{J}_i\})$$

be a tuple consisting of a nondegenerate $\alpha$ for $(M, \xi)$ with no contractible Reeb orbits, sequences $\{L_i\}$ and $\{\varphi_i\}$ given at the end of Section 2, a sequence $\{(\varphi_i, \alpha, J_i)\}$ of $L_i$-supersimple pairs, and a sequence $\{\tilde{J}_i\}$ of generic almost complex structures that are tamed by exact symplectic cobordisms on $\mathbb{R} \times M$ from $\varphi_i \alpha$ to $\varphi_{i+1} \alpha$ and that agree with $J_i$ and $J_{i+1}$ at the positive and negative ends.

The symplectic cobordisms together with $\tilde{J}_i$ induce chain maps

$$\Phi_i : CC^{L_i}(\varphi_i \alpha, J_i) \to CC^{L_{i+1}}(\varphi_{i+1} \alpha, J_{i+1}),$$

and we define $HC(D)$ as the direct limit of the induced maps $(\Phi_i)_*$ on homology.

## 6. The Evaluation Map

The goal of this section is to introduce and discuss the properties of the evaluation map. We consider an $L$-supersimple pair $(\alpha, J)$ as defined in Section 3.2.

Suppose that $\gamma$ is a positive hyperbolic orbit of action $< L$; the situation of $\gamma$ negative hyperbolic is similar.

Let $\gamma$ be an $m(\gamma)$-fold cover of a simple orbit $\gamma_0$, let $\gamma_0 \times D^2_{\delta_0/3}$ be a neighborhood of $\gamma_0$, where $\delta_0$ is as in Section 3.2, and let $(\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0/3} \to \gamma_0 \times D^2_{\delta_0/3}$ be its $m(\gamma)$-fold cover with coordinates $(t, z = x + iy)$ such that $\{z = 0\}$ corresponds to $\gamma$. Also let $\mathbb{R} \times (\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0/3}$ be the cylinder over $(\mathbb{R}/\mathbb{Z}) \times D^2$ with coordinates $(s, t, z = x + iy)$.

Let

$$\cdots \leq \lambda_{-2} \leq \lambda_{-1} < 0 < \lambda_1 \leq \lambda_2 \leq \cdots$$

be the eigenvalues of $A = -j_0 \frac{\partial}{\partial t} - S$ with $S = \begin{pmatrix} 0 & \varepsilon \\ \varepsilon & 0 \end{pmatrix}$ and let $f_i(t)$ be an eigenfunction corresponding to $\lambda_i$ with $L^2$-norm 1 so that $\{f_i(t)\}_{i \neq 0}$ is an orthonormal basis for $L^2(S^1, \mathbb{R}^2)$.

**Fact 6.0.1.** If $J \in J_\ast^{<L, \text{reg}}$ and

$$u : (-\infty, R] \times S^1 \to \mathbb{R} \times M$$

is a $J$-holomorphic half-cylinder which is negatively asymptotic to $\gamma$ for some $R$, then there exists $R' \ll 0$ such that $u(s, t)$, after reparametrization of the domain and lifting to the $m(\gamma)$-fold cover $\mathbb{R} \times (\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0/3}$, can be written on $\{s \leq R'\}$ as:

$$\tilde{u}(s, t) = \left( s, t, \sum_{i=1}^{\infty} c_i e^{\lambda_i s} f_i(t) \right) \in \mathbb{R} \times (\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0/3}.$$

By abuse of notation we will usually not distinguish between $u$ and $\tilde{u}$. We refer to Equation (6.0.2) as the “Fourier series” for $u$. The real constants $c_i$ will
be referred to as the “Fourier coefficients”. We also define the order $k$ Fourier polynomial $P_k(u)$ of $u$ as:

$$P_k(u) = \sum_{i=1}^{k} c_i e^{\lambda_i s} f_i(t).$$

Let $J \in \mathcal{J}^{<L}_{\ast,\text{reg}}$ and let $\mathcal{A}_{\alpha_+}(\gamma_+), \mathcal{A}_{\alpha_+}(\gamma_+') < L$. We define the order $k$ evaluation map at the negative end

$$ev^k_{-}(\gamma_+, \gamma_+', J) : \mathcal{M}_{\text{cyl}}^k(\gamma_+, \gamma_+) \to \mathbb{R}^k$$

$$(u, r_+, r_-) \mapsto (c_1, \ldots, c_k),$$

where $u$ agrees with a $J$-holomorphic half-cylinder $(-\infty, R] \times S^1 \to \mathbb{R} \times M$ which is negatively asymptotic to $\gamma_+'$ for some $R$ and has Fourier coefficients $c_1, \ldots, c_k$. Here we parametrize $\mathbb{R}/\mathbb{Z}$ such that the asymptotic marker $r_-$ at the negative end corresponds to $t = 0$.

**Fact 6.0.2.** The map $ev^k_{-}(\gamma_+, \gamma_+', J)$ is smooth.

The moduli space $\mathcal{M}_{\text{cyl}}^k(\gamma_+, \gamma_+')$ admits the usual $\mathbb{R}$-translation which corresponds to the $\mathbb{R}^+$-action on $\mathbb{R}^k$ given by:

$$(c_1, \ldots, c_k) \mapsto (c_1 e^{\lambda_1 s}, \ldots, c_k e^{\lambda_k s}).$$

Provided there is no $u$ with $(c_1, \ldots, c_k) = 0$, $ev^k_{-}(\gamma_+, \gamma_+', J)$ descends to the quotient

$$(6.0.3) \quad \tilde{ev}^k_{-}(\gamma_+, \gamma_+', J) : \mathcal{M}_{\text{cyl}}^k(\gamma_+, \gamma_+)/\mathbb{R} \to (\mathbb{R}^k - \{0\})/\mathbb{R}^+ \simeq S^{k-1}.$$  

**Remark 6.0.3.** We will make more precise the identification $(\mathbb{R}^k - \{0\})/\mathbb{R}^+ \simeq S^{k-1}$. Each path

$$c : \mathbb{R} \to \mathbb{R}^k, \quad s \mapsto (c_1 e^{\lambda_1 s}, \ldots, c_k e^{\lambda_k s})$$

with $(c_1, \ldots, c_k) \neq 0$ is transverse to the spheres $S^{k-1}_r = \{|x| \in \mathbb{R}^k \mid |x| = r\}$ since $(c'(s), c(s)) > 0$ for all $s \in \mathbb{R}$. We will take the representative of $c$ to be its intersection with $S^{k-1}_r$, where $r$ is taken to be 1 unless specified otherwise.

The maps

$$ev^k_{+}(\gamma_-, \gamma_-, J) : \mathcal{M}_{\text{cyl}}^k(\gamma_-, \gamma_-) \to \mathbb{R}^k,$$

$$\tilde{ev}^k_{+}(\gamma_-, \gamma_-, J) : \mathcal{M}_{\text{cyl}}^k(\gamma_-, \gamma_-)/\mathbb{R} \to S^{k-1}$$

are defined similarly.

The main results of this subsection concern the transversality properties of the order $k$ evaluation map, which generalizes [HT2 Proposition 3.2] in a special case. Let

$$\pi_\mathbb{R} : \mathcal{M}(\gamma_+, \gamma_+') \to \mathcal{M}(\gamma_+, \gamma_+)/\mathbb{R}$$

be the quotient map by translations in the $s$-direction.

**Theorem 6.0.4.** Given $J \in \mathcal{J}^{<L}_{\ast,\text{reg},\delta_0}$, a compact domain $K \subset \mathcal{M}^{\text{ind} = \ell, \text{cyl}, \delta}(\gamma_+, \gamma_+) / \mathbb{R}$, and a submanifold $\tilde{Z} \subset S^{k-1}$, there exist an arbitrarily close $J' \in \mathcal{J}^{<L,\text{reg},\delta_0}_{\ast}$ with $\delta' < \delta_0$ and a compact domain $K' \subset \mathcal{M}^{\text{ind} = \ell, \text{cyl}, \delta}(\gamma_+, \gamma_+)/\mathbb{R}$ such that:
Proposition 3.2. This is due to the fact that the \( \tilde{\pi} \) is transverse to \( \partial J \) near each \( \tau \). Remark 6.0.5. The proof is modeled on but is substantially easier than that of [HT2, Proposition 3.2]. This is due to the fact that the \( J \)-holomorphic equation is linear near each \( \mathbb{R} \times \gamma \). This allows us to dispense with the quadratic estimates.

Proof. Let \( J \) be the subset of \( J^{s, L, \text{reg}, \delta_0} \) consisting of \( J' \) that are \( C^1 \)-close to \( J \). Also let \( \pi : \tilde{\mathcal{M}} \to J \) be the bundle with fiber \( \pi^{-1}(J') = \mathcal{M}^{\text{cyl}}(\gamma_+, \gamma'_+) \)/\( \mathbb{R} \), \( \tilde{\pi} : \mathcal{M} \to \tilde{\mathcal{M}} \) be the bundle with fiber \( \tilde{\pi}^{-1}([u], J') = \tilde{\pi}_{\mathcal{M}}^{-1}(\gamma_+, \gamma'_+) \)/\( \mathbb{R} \), where

\[
\pi_{\mathcal{M}, J} : \mathcal{M}^{\text{cyl}}(\gamma_+, \gamma'_+) \to \mathcal{M}^{\text{cyl}}(\gamma_+, \gamma'_+) \)/\( \mathbb{R} \)
\]

is the quotient map by translations in the \( s \)-direction, and let \( \mathcal{M}^s \subset \mathcal{M} \) and \( \tilde{\mathcal{M}}^s \subset \tilde{\mathcal{M}} \) be the subsets of simple curves. Define the map

\[
Ev^k(\gamma_+, \gamma'_+) : \mathcal{M}^s \to \mathbb{R}^k,
\]

\[(u, J') \mapsto ev^k(\gamma_+, \gamma'_+)(u)\).

Choose a smooth section \( s \) of \( \tilde{\pi} : \mathcal{M} \to \tilde{\mathcal{M}} \) and denote \( N^s := s(\tilde{\mathcal{M}}^s) \).

We will show that the restriction \( Ev^k(\gamma_+, \gamma'_+)|_{N^s} \) is regular at all points over \( K \); hence \( Ev^k(\gamma_+, \gamma'_+)|_{N^s} \) is transverse to any submanifold \( Z \subset \mathbb{R}^k \). Theorem 6.0.3 then follows from Sard’s theorem: To show that \( ev^k(\gamma_+, \gamma'_+, J') \) avoids the origin \( 0 \in \mathbb{R}^k \), let \( Z = \{0\} \). Then \( Ev^k(\gamma_+, \gamma'_+)|_{N^s}(0) \) has codimension \( k \). Since each fiber of \( \pi \circ \tilde{\pi} \) has dimension \( \ell - 1 \leq k - 1 \), for a generic \( J' \in J \),

\[
(\pi \circ \tilde{\pi})^{-1}(J') \cap Ev^k(\gamma_+, \gamma'_+)|_{N^s}(0) = \emptyset,
\]

and \( ev^k_\mathcal{M}(\gamma_+, \gamma'_+, J') \) descends to \( \tilde{ev}^k_\mathcal{M}(\gamma_+, \gamma'_+, J') \). To show that \( \tilde{ev}^k_\mathcal{M}(\gamma_+, \gamma'_+, J') \) is transverse to \( \tilde{Z} \), we choose \( Z \) to be the preimage of \( \tilde{Z} \) under the projection \( \mathbb{R}^k \setminus \{0\} \to \mathbb{S}^{k-1} \).

Let \( u \in K \) and \( (\xi, Y) \in T_{u,J} \mathcal{M}^s \). With respect to the usual coordinates \( (t, x, y) \) on \( (\mathbb{R}/\mathbb{Z}) \times D^2_{\delta_0} \), the almost complex structure \( J \) maps \( \frac{\partial}{\partial s} \mapsto \frac{\partial}{\partial t} + X_H \) and \( \frac{\partial}{\partial t} \mapsto \frac{\partial}{\partial y} \) on \( D^2_{\delta_0/3} \). We assume that \( Y \) corresponds to the path \( J + \tau Y \), \( \tau \in [\varepsilon, \varepsilon] \), which maps \( \frac{\partial}{\partial s} \mapsto \frac{\partial}{\partial t} + X_H \) and leaves \( TD^2_{\delta_0/3} \) invariant. We write \( j_0 + \tau Y_0 \) for the restriction of \( J + \tau Y \) to \( TD^2_{\delta_0/3} \).

If \( \bar{D}_{J+\tau Y}(u + \tau \xi) = 0 \) for \( \tau \in [\varepsilon, \varepsilon] \), then we claim that \( (\xi, Y) \) satisfies

\[
(6.0.4) \quad \frac{\partial \xi}{\partial s} + j_0 \frac{\partial \xi}{\partial t} - j_0 \left( X_H(\xi) + Y_0(s, t, u(s, t)) \left( \frac{\partial u}{\partial s} \right) \right) = 0.
\]

Since we are only concerned with the negative end of \( u \), we assume without loss of generality that \( u \) is graphical over \( (-\infty, 0] \times (\mathbb{R}/\mathbb{Z}) \), has image in \( (-\infty, 0] \times \)
of $u$ fold cover of a simple orbit $\gamma$.

Similarly we write $\xi$ as $(s, t, \xi(s, t))$. The almost complex structure $J + \tau Y$ maps

$$
(1, 0, \frac{\partial(u + \tau \xi)}{\partial s}) \mapsto \left(0, 1, j_0 \frac{\partial(u + \tau \xi)}{\partial s} + X_H(u + \tau \xi) + \tau Y_0 \left(\frac{\partial(u + \tau \xi)}{\partial s}\right)\right),
$$

which must equal $(0, 1, \frac{\partial(u + \tau \xi)}{\partial t})$. Equating the third coordinates, using $j_0 \frac{\partial u}{\partial t} + X_H(u) = \frac{\partial u}{\partial t}$, and differentiating with respect to $\tau$, we obtain Equation (6.0.4).

**Case 1.** First suppose that $u$ does not intersect $\mathbb{R} \times \gamma_+^\prime$.

We solve for $(\xi, Y) \in T_{(u, r)} M^\theta$ in Equation (6.0.4), i.e., on the negative end, where

$$
(6.0.5) \quad j_0 Y_0(s, t, u(s, t)) \left(\frac{\partial u}{\partial s}\right) = \mu(s) f_i(t)
$$

and $\xi(s, t) = \rho(s) f_i(t)$ for $i \geq 1$, $\mu$ and $\rho$ are smooth in $s$, $\mu(s) \geq 0$ is a function with support on $[R', R]$ for some $R', R \in \mathbb{R}$ and total integral 1, and $\rho(s) = 0$ for $s > R$.

Equation (6.0.4) then becomes

$$
\rho'(s) f_i(t) - \rho(s) \lambda_i f_i(t) - \mu(s) f_i(t) = 0,
$$

$$
\rho'(s) - \lambda_i \rho(s) = \mu(s).
$$

We then pick the solution

$$
(6.0.6) \quad \rho(s) = e^{\lambda_i s} \int_R^s e^{-\lambda_i \sigma} \mu(\sigma) d\sigma.
$$

Then $\xi(s, t) = \rho(s) f_i(t)$ is equal to 0 on $s = R$ and can be written as

$$
(6.0.7) \quad \xi(s, t) = ce^{\lambda_i s} f_i(t), \quad c \geq e^{-\lambda_i R}/\lambda_i
$$

on $s \leq R'$. (Note that $R$ is a large negative number.)

We then consider the extension of $(\xi, Y)$. We extend $\xi$ to all of the domain of $u$ by setting $\xi = 0$. Let $u_T$ be the curve obtained from $u$ by translating in the $s$-direction by $T$ units. By the following claim, for sufficiently negative $R'$ and $R$, $Y$ can be extended from the annulus $\operatorname{Im} u|_{R' \leq s \leq R}$ to all of $\mathbb{R} \times M$ so that $Y$ is $s$-invariant and has support on

$$
\prod_{T \in \mathbb{R}} \operatorname{Im} u_T|_{R' \leq s \leq R} \subset \mathbb{R} \times (\mathbb{R}/\mathbb{Z}) \times \left(D_{\delta_0/3}^2 - D_{\delta_0'/3}^2\right)
$$

for some $0 < \delta'_0 < \delta_0$.

**Claim 6.0.6.** For $s_0 \ll 0$, $u|_{s=s_0}(t) = \sum_{i=1}^\infty c_i e^{\lambda_i s_0} f_i(t)$ is an embedding.

*Proof of Claim (6.0.6)* The reason the claim is not trivial is that $\gamma_+^\prime$ may be an $m$-fold cover of a simple orbit $\gamma_0$. Since $u$ is simple by assumption, the negative end of $u$ is not multiply-covered. Hence there exists an integer $j > 0$ such that:

- for each $c_i \neq 0$ with $i < j$, $f_i(t)$ is an $a$-fold cover of an asymptotic eigenfunction for $\gamma_0^{m/a}$, where $a > 1$, and
\[ \bullet \ c_j \neq 0 \text{ and } f_j(t) \text{ is a } b\text{-fold cover of an asymptotic eigenfunction for } s_{n_0}^{m/b}, \text{ where } (a, b) = 1. \]

By an explicit calculation of asymptotic eigenfunctions (i.e., Equations 4.1.1–4.1.4), it follows that \( u|_{s=s_0} \) is an embedding for \( s_0 < 0 \).

Since \( u \) does not intersect \( \mathbb{R} \times \gamma'_+ \), the support of \( Y \) intersects \( u \) only near the negative end of \( u \). Hence the pair \( (\xi, Y) \), described above and satisfying Equation 6.0.7, is indeed an element of \( T_{(u, J)} \mathcal{M}^\ast \). This implies that \( E \nu_k^\ast (\gamma_+, \gamma'_+) \) is regular at \( (u, J) \). Since all the perturbations \( (\xi, Y) \) constructed above have the form that \( \xi \) is supported near the negative end, it follows that such \( \xi \)'s are independent from the tangent vector \( \zeta \) at \( u \) corresponding to the translation in the \( s \)-direction. Hence \( E \nu_k^\ast (\gamma_+, \gamma'_+) |_{\mathcal{N}^s} \) is regular at \( (u, J) \) and the theorem holds in this case.

**Case 2.** Suppose that \( u : \tilde{F} \to \mathbb{R} \times M \) nontrivially intersects \( \mathbb{R} \times \gamma'_+ \). Let \( Y \) be as in Case 1 and let \( u^\ast Y \) be the pullback of \( Y \) to \( u^\ast \text{End}(T(\mathbb{R} \times M)) \). Then \( u^\ast Y \) can be written as \( Y' + Y'' \), where \( Y' \) is supported on the negative end of \( \tilde{F} \) and \( Y'' \) is supported on a neighborhood of \( \Theta \subset \tilde{F} \). Here \( \Theta \) is the preimage of \( u(F) \cap (\mathbb{R} \times \gamma'_+) \).

Let \( \xi' \) be the solution to \( \overline{\partial}_{J+\tau Y'}(u + \tau \xi') = 0 \) up to first order in \( \tau \), as constructed in Case 1 (the notation in Case 1 is \((\xi, Y)\)) and whose negative end satisfies Equation 6.0.7.

Let \( \xi'' \) be the solution to \( \overline{\partial}_{J+\tau Y''}(u + \tau \xi'') = 0 \) up to first order in \( \tau \), which is \( L^2 \)-orthogonal to the kernel of the linearized \( \overline{\partial} \)-operator \( D_{u,J} \). We now estimate that the solution \( \xi'' \) corresponding to \( Y'' \) is much smaller than \( \xi' \) along \( s = R' \) if \( R' \ll R \ll 0 \). We will use Morrey space norms which are defined in Section 8.3 and ideas that are used in Section 8.7. The constant \( c > 0 \) may change from line to line. We first observe that \( \xi'' = D_{u,J}^{-1}(\zeta) \), where \( ||\zeta|| \leq c ||Y||. \) Since \( D_{u,J}^{-1} \) is bounded, \( ||\xi''||_{s=0} \leq c ||Y||. \) Then, by Lemma 8.3.1, \( ||\xi''||_{s=0} \leq c ||Y||. \) Hence \( ||\xi''||_{s=R} \) has the same order of magnitude as \( ||\xi'||_{s=0} \). However, since \( \xi'' \) decays exponentially as \( s \to -\infty \),

\[ ||\xi''||_{s=R} \leq ce^{-\lambda(R-R')} ||\xi'||_{s=R}, \]

where \( \lambda = \min \{\lambda_1, |\lambda_{-1}|\}. \) This implies that \( ||\xi''||_{s=R} \ll ||\xi'||_{s=R}. \)

Since \( \xi' + \xi'' \) is a solution corresponding to \( Y' + Y'' \), the theorem follows. \( \square \)

Let us abbreviate \( \mathcal{M}^k = \mathcal{M}^\text{ind}_{J}^{k,\sigma l}(\gamma_+, \gamma'_+) \) and \( \tilde{\nu}_k = \tilde{\nu}_k^\ast (\gamma_+, \gamma'_+, J) \). We also use the superscript “\( \text{sing} \)” to denote the subset of \( \mathcal{M}^k \) consisting of curves with singularities.

**Theorem 6.0.7.** For a generic \( J \in J^{<L,\ast}_{\text{reg}} \), \( \tilde{\nu}_k^\ast : \mathcal{M}^k / \mathbb{R} \to S_{k-1} \), \( k \geq 1 \), satisfies the following:

1. The restriction of \( \tilde{\nu}_k^\ast \) to \( (\mathcal{M}^k - \mathcal{M}^{k,\text{sing}})/\mathbb{R} \) is an immersion.
2. \( \tilde{\nu}_k^\ast (\mathcal{M}^{k,\text{sing}}/\mathbb{R}) \) has codimension at least 2 and is disjoint from \( (0, \ldots, 0, \pm 1) \).
3. In particular, \((0, \ldots, 0, \pm 1)\) are regular values of \( \tilde{\nu}_k^\ast \).

Note that \( \tilde{\nu}_k^\ast \) exists by Theorem 6.0.4(2), since \( \ell = k \) in our case.
Proof: (1) Let \( u \in \mathcal{M}^k - \mathcal{M}^{k, \text{sing}} \). Since \( u \) is immersed, if \( \text{ind}(u) = k \geq 2 \), then \( u \) is regular by Theorem \([4.2.4]\). If \( k = 1 \), then \( u \) is regular by Lemma \([5.1.6]\). By the argument of Lemma \([1.0.6]\) there exists a basis \( \{e_1, \ldots, e_k\} \) for \( \ker D_u \), such that the negative ends of \( e_i \) are of the form

\[
e_i(s, t) = e^\lambda_i s f_i(t) \quad \text{modulo } f_{k+1}, f_{k+2}, \ldots.
\]

This implies the surjectivity of \( (\tilde{e}_i^k) : T_{[0]}(\mathcal{M}^k / \mathbb{R}) \rightarrow T_{\tilde{e}_i^k ([u])} S^{k-1} \).

(2) \( \mathcal{M}_k, \text{sing} \subset \mathcal{M}_k, \text{reg} \) has (real) codimension at least two by Theorem \([4.2.6]\). Hence \( \tilde{e}_i^k(\mathcal{M}_k, \text{sing} / \mathbb{R}) \) has codimension at least two and is disjoint from \( \{(0, \ldots, 0, \pm 1)\} \) by Theorem \([6.0.4]\). (We will be a little sloppy: The issue here is to find a fixed radius \( \delta_0 \) which works for all of \( \mathcal{M}_k / \mathbb{R} \). Strictly speaking, Theorem \([6.0.4]\) holds for a large compact subset \( K \subset \mathcal{M}_k, \text{sing} / \mathbb{R} \). We then apply Theorem \([6.0.4]\) to the strata of the boundary \( \mathcal{M}^k / \mathbb{R} \) to obtain Theorem \([6.0.8]\) below. This in turn allows us to use \( \mathcal{M}_k, \text{sing} / \mathbb{R} \) instead of \( K \).)

It remains to consider the multiply-covered curves in \( \mathcal{M}^k \). Writing \( \gamma_+ = \gamma_{+,0}^b \) and \( \gamma_- = (\gamma_{+,0}^b)^b \), let \( S' = \mathcal{M}^k_{\text{ind}=a, \text{cyl}}(\gamma_+, \gamma_+, 0, \gamma_{+,0}^b) \), where \( ab = k, b > 1 \), and let \( S \subset \mathcal{M}^k \) be the set of \( b \)-fold covers of curves in \( S' \). By induction, suppose that

\[
\tilde{e}_i^a(\gamma_+, \gamma_+, 0, J) : S'/\mathbb{R} \rightarrow S^{a-1}
\]

satisfies (2) with \( k \) replaced by \( a \). (As the initial step of the induction, observe that if \( k = 2 \) then \( \mathcal{M}^2 \) has no singular curves by Theorem \([4.2.6]\) and (2) holds.) Then \( \tilde{e}_i^a \) can be “lifted” to \( \tilde{e}_i^k : S/\mathbb{R} \rightarrow S^{ab-1} \) as follows: Given \( v \in S' \), suppose it is the \( b \)-fold cover of \( u \in S' \). Then \( \tilde{e}_i^k(v) = i \circ \tilde{e}_i^a(u) \), where the inclusion \( i : S^{a-1} \rightarrow S^{ab-1} \) is induced by the map

\[
(6.0.9) \quad \mathbb{R}^a \rightarrow \mathbb{R}^{ab}, \quad (x_1, \ldots, x_a) \mapsto (0, \ldots, 0, x_1, 0, \ldots, 0, x_2, 0, \ldots, 0, x_3, 0, \ldots).
\]

Here,

- the zeros are inserted in the same positions for all \( (x_1, \ldots, x_a) \) and
- \( 0, \ldots, 0 \) stands for zero or more 0’s.

While it is possible for \( \tilde{e}_i^k(S) \) to pass through \( (0, \ldots, 0, \pm 1) \in S^{k-1} \) (this may happen if the last entry of the \( ab \)-tuple is \( x_a \) in Equation \([6.0.9]\)), \( \tilde{e}_i^k(S^{\text{sing}}) \) will not pass through \( (0, \ldots, 0, \pm 1) \) by the induction hypothesis. This proves (2).

(1) and (2) then imply (3). \( \square \)

Finally we consider the extension \( \overline{e}_i^k : \overline{\mathcal{M}}^k / \mathbb{R} \rightarrow S^{k-1} \) of \( \tilde{e}_i^k \) to the compactification of \( \mathcal{M}^k / \mathbb{R} \).

Theorem 6.0.8. For a generic \( J \in \mathcal{J}_{<L, \text{reg}}^\text{reg} \) and \( k \geq 2 \), \( \overline{e}_i^k : \overline{\mathcal{M}}^k / \mathbb{R} \rightarrow S^{k-1} \) satisfies the following:

1. \( \overline{e}_i^k(\partial(\mathcal{M}^k / \mathbb{R})) \) is disjoint from \( (0, \ldots, 0, \pm 1) \).

2. If \( S \) is a (nonempty) stratum of \( \partial(\mathcal{M}^k / \mathbb{R}) \) consisting of \( l \)-level buildings \( u_1 \cup \cdots \cup u_l \) with \( \text{ind}(u_l) = a_k \), then \( 0 < a_k < k \), \( \dim(\overline{e}_i^k(S)) = a_k - 1 \), and \( S^{\text{sing}} \) has codimension at least 2 in \( S \).
As usual, $u_1$ is the lowest level and $u_t$ is the highest level.

**Proof.** By Lemma 5.1.5, we have $0 < a_i < k$. We apply Theorem 6.0.7 to the ind = $a_1$ moduli space $\mathcal{N}$ containing $u_1$ as given in the statement of (2) and the evaluation map $\tilde{ev}^{a_1} : \mathcal{N}/\mathbb{R} \to S^{a_1-1}$. We then define the map $\tilde{ev}^k : \mathcal{N}/\mathbb{R} \to S^{k-1}$ by composing $\tilde{ev}^{a_1}$ with $i : S^{a_1-1} \to S^{k-1}$ of the form given by Equation (6.0.9) to obtain (1) and (2). The details are left to the reader. \hfill \Box

7. **Chain homotopy**

7.1. **Chain homotopy.** Let $X^4$ be a compact connected 4-manifold such that $\partial X = M_+ - M_-$, let $\alpha|_{M_\pm}$ be a contact form on $M_\pm$, and let $\{\alpha^\tau\}_{0 \leq \tau \leq 1}$ be a 1-parameter family of 1-forms on $X$ such that $d\alpha^\tau$ is symplectic and $\alpha^\tau|_{M_\pm} = \alpha_\pm$, for all $\tau \in [0, 1]$. Also let $\{(\tilde{X}^\tau = \tilde{X}, \tilde{\alpha}^\tau)\}_{0 \leq \tau \leq 1}$ be a 1-parameter family of completions of $\{(X^4, \alpha^\tau)\}_{0 \leq \tau \leq 1}$ and let $\mathcal{J}$ be an almost complex structure which tames $(\tilde{X}^\tau, \tilde{\alpha}^\tau)$ and which restricts to $\alpha_\pm$-tame almost complex structures $J_\pm$ near the positive and negative ends. From now on we further require that all contact forms are $L$-hypertight.

**Theorem 7.1.1.** Suppose that $(M_-, \alpha_-)$ and $(M_+, \alpha_+)$ are $L$-supersimple and $L$-hypertight, $\{\mathcal{J}\}_{0 \leq \tau \leq 1}$ is generic as a family, and $(\alpha_+, J_+)$ and $(\alpha_-, J_-)$ are $L$-supersimple pairs. Then the chain maps $\Phi_{(X^4, \alpha^\tau, J)}$ and $\Phi_{(X^4, \alpha^0, J)}$ defined in Theorem 5.2.1 induce the same map on homology.

To prove this theorem, we show there exist linear maps

$$K_\pm : CCL(M_+ + J) \to CCL(M_-, J_-)$$

such that for any $\gamma_+ \in P^L_{\alpha_+, \text{good}}$, one has

$$\Phi_{(X^4, \alpha^\tau, J)}(\gamma_+) - \Phi_{(X^4, \alpha^0, J)}(\gamma_+) = \partial_- K_-(\gamma_+) - K_+ \partial_+(\gamma_+).$$

Let us write

$$\mathcal{M}^i := \coprod_{0 \leq \tau \leq 1} \mathcal{M}^\text{ind = i, cyl}(\gamma_+, \gamma_-).$$

We consider the 1-dimensional moduli space $\mathcal{M}^0$ and explain how each component of $\partial \mathcal{M}^0$ contributes to Equation (7.1.1).

We first establish some notation. An SFT building $u^\infty$ will be written as:

$$u^\infty = v_{-b} \cup \cdots \cup v_{-1} \cup v_0 \cup v_1 \cup \cdots \cup v_a$$

where the levels are arranged from bottom to top as we go from left to right; $v_j$, $j < 0$, maps to $(\mathbb{R} \times M, J_-)$; $v_0$ maps to $\tilde{X}^\tau$ for some $\tau$; $v_j$, $j > 0$, maps to $(\mathbb{R} \times M, J_+)$; the $v_j$’s are all holomorphic cylinders; and the pregluing of all the $v_j$ yields a cylinder of ind = 0. The only possible level with negative Fredholm index is $v_0$ by Lemma 5.1.5.

**Lemma 7.1.2.** Let $\gamma_+ \in P^L_{\alpha_+}$ and $\gamma_- \in P^L_{\alpha_-}$. 

(1) $M^{-1}$ is transversely cut out as a family and all the curves of $M^{-1}$ are simply-covered.
(2) If at least one of $\gamma_+$ and $\gamma_-$ is good, then $M^0$ is transversely cut out as a family and all the curves of each component of $M^0$ have the same multiplicity.

Proof. (1) There are no simply-covered curves of $\text{ind} < -1$ by the regularity of $J$. Hence, by Lemma 3.3.2 each $u \in M^{-1}$ must be simply-covered and regular in a family.

(2) Since simply-covered curves are regular in a generic family, it remains to consider the case where $v \in M^0$ is an unbranched $m$-fold cover of a simple $u$ with $\text{ind} = 0$. (Since we are assuming that $v$ is a cylinder, $v$ cannot be a branched cover of a simple $u$ with nonempty branch locus.) The proof of the regularity of $v$ (in a family) is similar to that of Lemma 5.2.3: Using the notation there, the only case to consider in more detail is when $\mu_\tau(\gamma') = 0$ and $\ker(D^N_\tau)*$ is generated by $Y_0$ which comes from the variation of $J$. Equation (5.2.1) implies that $\ker(D^N_\tau)*$ is at most $1$-dimensional; this must be generated by the pullback of $Y_0$ under the covering map, implying the regularity of $v$ in a family. The second assertion of (2) is immediate. □

Remark 7.1.3. While we have shown that $M^0$ is regular, the same cannot be said about the levels of $\partial M^0$. In fact, a careful analysis of $\partial M^0$ is the key part of the proof of the chain homotopy.

Simple $M^0$ case. Suppose first that no curve of $M^0$ is a multiple cover.

The boundary $\partial M^0 = M^0_1 - M^0_0$ admits a decomposition

$$\partial_1 M^0 \coprod \partial_2 M^0 \coprod \partial_3 M^0,$$

each of which will be discussed below.

Type 1. $\partial_1 M^0$ corresponds to the case when $\tau = 0$ or $1$, i.e.,

$$\partial_1 M^0 = M^0_{\text{ind}=0, \text{cyl}}(\gamma_+, \gamma_-) \coprod M^0_{\text{ind}=0, \text{cyl}}(\gamma_+, \gamma_-).$$

They contribute to

$$m(\gamma_-) \cdot \langle \Phi_{(X^1, \alpha^1, J)}(\gamma_+) - \Phi_{(X^0, \alpha^0, J)}(\gamma_+), \gamma_- \rangle.$$

Type 2. $\partial_2 M^0$ corresponds to the case when curves in $M^0$ converge to two-level holomorphic buildings: $v_0 \cup v_1$ or $v_{-1} \cup v_0$, where $v_{-1}$, $v_0$, and $v_1$ are all immersions and $v_0$ is a $k$-fold cover of a simple holomorphic cylinder $u_0$ of index $-1$. We denote the sets of these two types of two-level buildings by $\partial_2^+ M^0$ and $\partial_2^- M^0$ respectively, so that $\partial_2 M^0 = \partial_2^+ M^0 \coprod \partial_2^- M^0$.

Type 3. $\partial_3 M^0$ consists of higher codimension strata.

Case I. $v_{-1} \cup v_0$ or $v_0 \cup v_1$, where $v_{-1}$ is a singular curve in $\mathbb{R} \times M_\pm$.

Case II. $v_{-l} \cup \cdots \cup v_0$ or $v_0 \cup \cdots \cup v_l$, where $l > 1$. 

Case III. \( v_{-l} \cup \cdots \cup v_0 \cup \cdots \cup v_{l'} \), where \( l, l' > 0 \).

**Lemma 7.1.4.** \( \partial_3 \mathcal{M}^0 = \emptyset \).

**Proof.** Cases I and II cannot occur by Proposition [8.8.1] Case III is eliminated in Section [8.9] \( \square \)

Now we go back to analyze the contributions from the Type 2 boundary. We will focus on \( \partial_2^+ \mathcal{M}^0 \) and show that it corresponds to the term \( (K_+(\gamma_+), \gamma_-) \). \( \partial_2^- \mathcal{M}^0 \) can be dealt with similarly and corresponds to the term \( (\partial_- K_-(\gamma_+), \gamma_-) \).

We first consider the moduli spaces of the form \( \mathcal{M}_{\mathcal{J}}^{\text{ind}=k,\text{cyl}}((\gamma_+)^{1/k}, \gamma_-) \) for \( k \geq 1 \). There are only finitely many \( \tau_l \in [0,1] \) such that \( \mathcal{M}_{\mathcal{J}}^{\text{ind}=k,\text{cyl}}((\gamma_+)^{1/k}, \gamma_-) \) is non-empty since \( \{\mathcal{J}\} \) is generic; and, for each such \( \tau_l \), if \( (v, r) \in \mathcal{M}_{\mathcal{J}}^{\text{ind}=k,\text{cyl}}((\gamma_+)^{1/k}, \gamma_-) \), then \( v \) is a \( k \)-fold cover of a simple curve \( u \), where \( (u, r') \in \mathcal{M}_{\mathcal{J}}^{\text{ind}=1,\text{cyl}}((\gamma_+)^{1/k}, \gamma_-) \), \( \gamma_+ \) is the \( k \)-fold cover of \( (\gamma_+)^{1/k} \), and \( \gamma_- \) is the \( k \)-fold cover of \( \gamma_-^{1/k} \).

**Remark 7.1.5.** For each \( \mathcal{J} \)-holomorphic cylinder from \( (\gamma_+)^{1/k} \) to \( \gamma_-^{1/k} \) of index \(-1\), without markers but after quotienting by automorphisms, there are \( m((\gamma_+)^{1/k}) \cdot m(\gamma_-^{1/k}) \) elements of \( \mathcal{M}_{\mathcal{J}}^{\text{ind}=1,\text{cyl}}((\gamma_+)^{1/k}, \gamma_-) \) and \( k \cdot m((\gamma_+)^{1/k}) \cdot m(\gamma_-^{1/k}) \) elements of \( \mathcal{M}_{\mathcal{J}}^{\text{ind}=k,\text{cyl}}((\gamma_+), \gamma_-) \).

**Lemma 7.1.6.** For each integer \( k \geq 1 \) and \( R \gg 0 \), there exists a \((k-1)\)-dimensional vector bundle

\[
\mathcal{O}_{+,k} \to [R, \infty) \times \prod_{\gamma_+ \in \mathcal{P}L_+} \left( \prod_{0 \leq \tau \leq 1} \mathcal{M}_{\mathcal{J}}^{\text{ind}=k,\text{cyl}}((\gamma_+)^{1/k}, \gamma_-) \times \mathcal{M}_{\partial_+}^{\text{ind}=k,\text{cyl}}(\gamma_+, (\gamma_+)^{1/k}) / \mathbb{R} \right),
\]

called the obstruction bundle, and an obstruction section \( s_{+,k} \) of \( \mathcal{O}_{+,k} \), for which there exists a neighborhood \( \mathcal{N} \subset \overline{\mathcal{M}^0} \) of \( \partial^+_2 \mathcal{M}^0 \) such that

\[
\mathcal{N} \setminus \partial^+_2 \mathcal{M}^0 = \bigcup_{k \geq 1} (s_{+,k})^{-1}(0).
\]

**Remark 7.1.7.** When \( k = 1 \), we have the usual gluing of \( v_0 \cup v_1 \), where \( \text{ind}(v_0) = -1 \), \( \text{ind}(v_1) = 1 \), \( v_0 \) maps to some \( \tilde{X}^{v_0} \), \( v_1 \) maps to \( \mathbb{R} \times M \), and \( v_0, v_1 \) are simple.

The explicit definitions of \( \mathcal{O}_{+,k} \) and \( s_{+,k} \) are given in Section [8.5] — they are written as \( \mathcal{O} \) and \( s \) with the understanding that \( k \) and \( (v_0, r_0) \) are fixed. The proof of Lemma [7.1.6] follows from Theorem [8.6.1].

Recall that we are viewing \( ((v_0, r_0), (v_1, r_1)) \sim ((v_0', r_0'), (v_1', r_1')) \) if there exist automorphisms \( \pi_1 \) and \( \pi_2 \) of the domains \( \tilde{F}_1 = \mathbb{R} \times S^1 \) and \( \tilde{F}_2 = \mathbb{R} \times S^1 \) such that \( v_1 = v_1' \circ \pi_1, v_2 = v_2' \circ \pi_2, \) and \( \pi_1 \) and \( \pi_2 \) take positive (resp. negative) punctures to positive (resp. negative) punctures and take markers to markers.

**Remark 7.1.8 (Source of \( \mathbb{Q} \)-coefficients).** It is tempting to instead identify

\[
((v_0, r_0), (v_1, r_1)) \sim' ((v_0', r_0'), (v_1', r_1'))
\]
if we do not require \( \pi_1 \) and \( \pi_2 \) map markers to markers, but only satisfy

\[
(r_{0+} - r_{0-}) + (r_{1+} - r_{1-}) = (r'_{0+} - r'_{0-}) + (r'_{1+} - r'_{1-}).
\]

Here the asymptotic markers are viewed as elements of \( S^1 \in \mathbb{R}/\mathbb{Z} \). In the \( k = 1 \) case, the pairs identified by \( \sim' \) represent the same boundary point of \( \mathcal{M}^0 \). However, for \( k > 1 \), unless \(( (v_0, r_0), (v_1, r_1) ) = ((v'_0, r'_0), (v'_1, r'_1) ) \), the upper level of the 2-level buildings identified by \( \sim' \) do not continue to the same component of \((ev^k_0)^{-1}(\nu) \); cf. the proof of Theorem 7.1.1. This is the source of “branching”, which in turn forces us to use \( \mathbb{Q} \)-coefficients.

Define \( n_{+,\tau_1}(\gamma_+, \gamma'_+; \gamma_-) \) as the signed count

\[
\# \left( \mathcal{M}^\text{ind} = -k, \text{cyl}(\gamma'_+, \gamma_-) \times \mathcal{M}^\text{ind} = k, \text{cyl}(\gamma_+, \gamma'_+)/\mathbb{R} \right) \frac{1}{m(\gamma_+)}
\]

for generic \( T \in [0, \infty) \). Then, in view of Lemma 7.1.1

\[
\langle \Phi_{(X^1, \alpha^1, J')}, \Phi_{(X^0, \alpha^0, \mathcal{P}')} \rangle (\gamma_+), (\gamma_-) = \sum_{k=1}^{\infty} \sum_{\gamma'_+ \in \mathcal{P}_{\gamma_+}^L} \sum_{\gamma_-} n_{+,\tau_1}(\gamma_+, \gamma'_+; \gamma_-) \frac{1}{m(\gamma_-)}
\]

\[+ \text{ terms coming from } \partial_- \mathcal{M}^0.\]

Recall the evaluation map

\[
ev_k = ev_k(\gamma_+, \gamma'_+, J^+_\gamma_+ J^-_\gamma_-) : \mathcal{M}^\text{ind} = k, \text{cyl}(\gamma_+, \gamma'_+)/\mathbb{R} \to S^{k-1}.
\]

from Section 6. Also recall that \( ev_k(\nu_1, r_{1+}, r_{1-}) \) depends on the marker \( r_{1-} \) at the negative end. Finally, the asymptotic eigenfunctions \( f_1, \ldots, f_k \) and the cokernel element \( Y \) depend on the parametrization given by \((v_0, r_{0+}, r_{0-})\).

**Lemma 7.1.9.** For any positive integer \( k \),

1. if \((\gamma'_+)^{1/k} \) is negative hyperbolic, then \( n_{+,\tau_1}(\gamma_+, \gamma'_+; \gamma_-) \) is given by

\[
\# \mathcal{M}^\text{ind} = -k, \text{cyl}(\gamma'_+, \gamma_-) : \left( \ev_k(\gamma_+, \gamma'_+; J^+_\gamma_+ J^-_\gamma_-) \right)^{-1} \left( \{ (0, \ldots, 0, \pm 1) \} \right) \frac{1}{m(\gamma'_+)}:
\]

2. if \((\gamma'_+) \) is positive hyperbolic, then we replace \((0, \ldots, 0, \pm 1) \) by \((\pm 1, 0, \ldots, 0) \).

**Proof.** The proof of Lemma 7.1.9 follows from Lemma 8.7.1 Proposition 8.7.2 and Section 8.9A.

Now we are in a position to finish the proof of Theorem 7.1.1 in the simple \( \mathcal{M}^0 \) case.

**Proof of Theorem 7.1.1 in the simple \( \mathcal{M}^0 \) case.** Let us abbreviate

\[
\mathcal{M} = \mathcal{M}^\text{ind} = k, \text{cyl}(\gamma_+, \gamma'_+)
\]

and denote the restriction of \( ev^0_k \) to the boundary \( \partial(\mathcal{M}/\mathbb{R}) \) by \( \partial ev^0_k \). We assume \((\gamma'_+) \) is negative hyperbolic; the case of \((\gamma'_+)^{1/k} \) positive hyperbolic is similar. By Theorems 6.0.7 and 6.0.8, there exists a generic embedded oriented path
\( \nu : [0, 1] \to S^{k-1} \) from \((0, \ldots, 0, -1)\) to \((0, \ldots, 0, +1)\) such that \( \nu \cap \overline{ev}_+^k \) and \( \nu \cap \partial \overline{ev}_+^k \). In particular, \( \overline{ev}_-^k \cap \nu \) consists of finitely many points. Here the path \( \nu \) is oriented with the standard orientation from \([0, 1]\), and \( \partial \nu = \{(0, \ldots, 0, \pm 1)\} \) is oriented as the boundary. We postpone further details about orientation to Section 9.2.

Let
\[
\mathcal{M}^{k-1}_+ (\zeta_+, \gamma_+) = \left\{ w \in \mathcal{M}^{\text{ind}=k-1, \text{cyl}}_J (\zeta_+, \gamma_+'); \overline{ev}_-^k (\zeta_+, \gamma_+; J_+) (w) \in \partial \overline{ev}_-^k \cap \nu \right\}.
\]

For \( k = 1 \) we define
\[
K^{k-1}_+ (\zeta_+, \gamma_-) = \sum_l \# \mathcal{M}^{\text{ind}=-1, \text{cyl}}_J (\zeta_+, \gamma_-)
\]
and for \( k \geq 2 \) we define
\[
K^{k-1}_+ (\zeta_+, \gamma_-) = \sum_l \sum_{\gamma'_- \in \mathcal{P}_{\alpha_+}} \# \mathcal{M}^{\text{ind}=-k, \text{cyl}}_J (\gamma'_-, \gamma_-) \# (\mathcal{M}^{k-1}_+ (\zeta_+, \gamma'_+) / \mathbb{R}) \frac{1}{m(\gamma'_+)}.
\]

We then define
\[
(7.1.6) \quad K_+ (\zeta_+) = \sum_{k=1}^\infty \sum_{\gamma_- \in \mathcal{P}_{\alpha_-}} K^{k-1}_+ (\zeta_+, \gamma_-) \frac{1}{m(\gamma_-)} \cdot \gamma_-.
\]

We claim that
\[
(7.1.7) \quad (\partial \overline{ev}_-^k)^{-1} (\nu) = \left( \prod_{\zeta_+} \mathcal{M}^{k-1}_+ (\zeta_+, \gamma'_+) / \mathbb{R} \times (\mathcal{M}^{\text{ind}=1, \text{cyl}}_J (\gamma_+, \zeta_+) / \mathbb{R}) \right) / \sim',
\]
where \( \sim' \) is defined as in Equations (7.1.2) and (7.1.3) with all the subscripts increased by 1. Indeed, “\( \supseteq \)” follows from the fact that the evaluation map \( \overline{ev}_-^k \) only depends on the behavior of holomorphic curves near the negative end; and “\( \subseteq \)” follows from the fact that generically there is no other boundary component by Theorem 6.0.8. Observe that \( \{(0, \ldots, 0, \pm 1)\} \cap \partial \overline{ev}_-^k = \emptyset \).

By examining the boundary of the 1-dimensional manifold \((\overline{ev}_-^k)^{-1} (\nu)\),
\[
(7.1.8) \quad \# (\overline{ev}_-^k)^{-1} (\{(0, \ldots, 0, \pm 1)\})
\]
where the right-hand side comes from Equation (7.1.7). Then Lemma 7.1.9 and Equation (7.1.8) imply that the first term on the right-hand side of Equation (7.1.4) is equal to \( (K_+ \partial_+ (\gamma_+), \gamma_-) \). This finishes the proof of Theorem 7.1.1 modulo the discussion of orientations from Section 9.2. \( \square \)
Non-simple \( \mathcal{M}^0 \) case. We explain the necessary modifications when some curve \( u \in \mathcal{M}^0 \) is multiply-covered. By Lemma 5.2.3, \( u \in \mathcal{M}^0 \) is part of a regular 1-dimensional family and all the curves in the connected component of \( \mathcal{M}^0 \) containing \( u \) are \( m \)-fold covers of a regular 1-dimensional family \( \prod_{0 \leq \tau \leq 1} \mathcal{M}^{\text{ind}=0, \text{cyl}}(\gamma', \gamma) \).

Let \( \mathcal{M} = \mathcal{M}^{\text{ind}=k, \text{cyl}}(\gamma_+, \gamma'_+) \) as before and let \( \mathcal{M}' \subset \mathcal{M} \) be the subset of curves which are \( b \)-fold covers, where \( b|k \). We then use the inclusion given by Equation (6.0.9) to argue that for generic \( J \) the evaluation map \( (\tilde{e}v')_k : \mathcal{M}'/\mathbb{R} \to S^{k-1} \) does not pass through zero and hence descends to \( (\tilde{e}v')_k : \mathcal{M}'/\mathbb{R} \to S^{k-1} \).

The rest of the argument is the same. Suppose the family \( \mathcal{M}^0 \) has boundary which consists of a two-level building \( v_0 \cup v_1 \), where \( \text{ind}(v_0) = -k \), \( \text{ind}(v_1) = -k \), \( v_0 \) is a \( k \)-fold cover, and \( v_1 \) is a \( b \)-fold cover with \( b|k \). As before, the only pairs \( v_0 \cup v_1 \) that glue satisfy \( (\tilde{e}v')_k(v_1) = (0, \ldots, 0, \pm 1) \) and we continue the family along some generic \( u \subset S^{k-1} \) from \( (0, \ldots, 0, 1) \) to \( (0, \ldots, 0, -1) \), where the evaluation map we are taking is \( \tilde{e}v_k : \mathcal{M}/\mathbb{R} \to S^{k-1} \).

7.2. \( HC(\mathcal{D}) \) is independent of \( \mathcal{D} \). To show that \( HC(\mathcal{D}) \) is independent of \( \mathcal{D} \), we study the composition of chain maps induced by a composition of symplectic cobordisms.

For \( j = 1, 2 \), let \( (X^j, \alpha^j) \) be an exact symplectic cobordism as in Section 5.2 with \( M^j_1 = M^j_2 \) and \( \alpha^j_1 = \alpha^j_2 \). We define \( X^{12} \) to be \( X^1 \cup X^2 \) identified along \( M^1_1 = M^2_2 \) and define the 1-form \( \alpha^{12} \) on \( X^{12} \) by \( \alpha^{12}|_{X^1} = \alpha^1 \) and \( \alpha^{12}|_{X^2} = \alpha^2 \).

Let \( (\tilde{X}^j, \tilde{\alpha}^j) \) be the completion of \( (X^j, \alpha^j) \) and let \( \tilde{\mathcal{J}}^j \) be an almost complex structure which tames \( (\tilde{X}^j, \tilde{\alpha}^j) \) and restricts to \( \tilde{\alpha}^j_\pm \)-tame almost complex structures \( \tilde{J}^j_\pm \) at the positive and negative ends. Similarly, let \( (\tilde{X}^{12}, \tilde{\alpha}^{12}) \) be the completion of \( (X^{12}, \alpha^{12}) \) and let \( \tilde{\mathcal{J}}^{12} \) be a generic almost complex structure on \( \tilde{X}^{12} \) which tames \( (\tilde{X}^{12}, \tilde{\alpha}^{12}) \) and coincides with \( \tilde{\mathcal{J}}^j_\pm \) at the positive and negative ends.

Theorem 7.2.1. Suppose that \( (\tilde{X}^1, \tilde{\alpha}^1, \tilde{\mathcal{J}}^1) \) and \( (\tilde{X}^{12}, \tilde{\alpha}^{12}, \tilde{\mathcal{J}}^{12}) \) satisfy the assumptions of Theorem 5.2.1 Then \( \Phi(\tilde{X}^{12}, \tilde{\alpha}^{12}, \tilde{\mathcal{J}}^{12}) \) and \( \Phi(\tilde{X}^1, \tilde{\alpha}^1, \tilde{\mathcal{J}}^1) \) induce the same map on homology.

Proof. The proof of this is essentially the same as the proof of Theorem 7.1.1 as one can construct a 1-parameter family of completed symplectic cobordisms between \( \tilde{X}^{12} \) and \( \tilde{X}^1 \cup \tilde{X}^2 \). \( \square \)

Theorem 7.1.1 and Theorem 7.2.1 imply:

Corollary 7.2.2. \( HC(\mathcal{D}) \) is independent of the auxiliary data \( \mathcal{D} \).

8. Gluing

In this section we construct the gluing map that is used in Section 7. In Section 7 we see that a sequence of curves in \( \prod_{0 \leq \tau \leq 1} \mathcal{M}^{\text{ind}=0, \text{cyl}}(\gamma'_+, \gamma_-) \) can degenerate
into a holomorphic building
\[(v_-, [v_+]) \in \left( \mathcal{M}^\text{ind} = -k, \text{cyl} (\gamma'_+), \gamma_- \right) \times \left( \mathcal{M}^\text{ind} = k, \text{cyl} (\gamma_+, \gamma'_+)/\mathbb{R} \right) / \sim \]

for some \(\tau_0\). For convenience we write \(\mathcal{M} = \mathcal{M}^\text{ind} = k, \text{cyl} \left( \gamma_+ + \gamma'_+, \gamma_+ - \gamma'_+ \right) \times \left( \mathcal{M}^\text{ind} = k, \text{cyl} \left( \gamma_+, \gamma'_+ \right)/\mathbb{R} \right) \). For most of this section we are assuming Conditions (C1)–(C4) of the prototypical gluing problem, where \(u_0, v_0, v_1, \gamma, \gamma'' \) are now called \(u_-, v_-, v_+, \gamma, \gamma_- \). At the end we will treat similar, but slightly different, cases in Section 8.9.

Certainly not every \([v_+] \in \mathcal{M}/\mathbb{R}\) can be glued with \([v_-]\) to give a holomorphic map. In this section we closely follow [HT2] (with the appropriate modifications) and define an obstruction bundle
\[O \to [R, \infty) \times \mathcal{M}/\mathbb{R}, \quad R \gg 0,\]

and a section \(s\) of \(O\) such that \(s^{-1}(0) \cap (\{T\} \times \mathcal{M}/\mathbb{R})\) are exactly the curves \([v_+]\) that glue with \([v_-]\) for \(T \gg 0\). The expressions will be substantially simpler since \((\alpha_+, J_+)\) is \(L\)-supersimple. The proofs of the results that carry over with minimal changes will be omitted.

Assume for the moment that all the curves in \(\mathcal{M}\) are immersed. In Section 8.8 we will explain how to modify the argument in the general case.

From now on we implicitly choose a smooth section of \(\mathcal{M} \to \mathcal{M}/\mathbb{R}\) and representatives of \(([v_-], [v_+])\), and write \((v_-, v_+)\) instead of \(([v_-], [v_+])\).

Also, in this section the constant \(c > 0\) may change from line to line when we are making estimates.

### 8.1. Pregluing

Fix a constant \(T_0 \gg 0\). Also let \(T \gg 2T_0\), which is allowed to vary. Let \(v_+, T(s, t) := v_+(s - 2T, t)\).

Recall the coordinates \((s, t, x, y)\) on the neighborhood \(\mathbb{R} \times \mathbb{R}/\mathbb{Z} \times D^2_0/3\) of \(\mathbb{R} \times \gamma'_+\) on which \(J\) satisfies (J1) and (J2). For sufficiently large \(T_0\), \(v_-(s, t)\) can be written in terms of these coordinates as \((s, t, \eta_-(s, t))\) on \(s \geq T_0\) and \(v_+, T(s, t)\) can be written as \((s, t, \eta_+, T(s, t))\) on \(s \leq T\).

Fix constants \(0 < h < 1\) and \(r \gg h^{-1}\). We take \(T_0 > 5r\). Choose a cutoff function \(\beta : \mathbb{R} \to [0, 1]\) such that \(\beta(s) = 0\) for \(s \leq 0\) and \(\beta(s) = 1\) for \(s \geq 1\). Let
\[\beta_{-T}(s) = \beta \left( \frac{T - s}{hr} \right)\]
and \(\beta_{+T_0}(s) = \beta \left( \frac{s - T_0}{hr} \right)\).

\[\beta_{-T}(s)\]
\[\beta_{+T_0}(s)\]
\[\beta_{+T_0}(s)\]
\[T_0 \quad T_0 + hr \quad T - hr \quad T\]

**Figure 4.** Cutoff functions.
We define the pregluing of $v_+$ and $v_-$ by

\[
v_+(s, t) = \begin{cases} 
  v_{+T}(s, t) & \text{for } s \geq T, \\
  (s, t, \beta_{+, \tau_0}(s)\eta_{+, T}(s, t) + \beta_{-, T}(s)\eta_{-, T}(s, t)) & \text{for } T_0 \leq s \leq T, \\
  v_-(s, t) & \text{for } s \leq T_0.
\end{cases}
\]

We often suppress the $T$ or $T_0$ in $\beta_{+, \tau_0}$, $\beta_{-, T}$, and $\eta_{+, T}$.

8.2. Gluing. Let $\psi_+$ be a section of the normal bundle of $v_{+, T}$ and $\psi_-$ be a section of the normal bundle of $v_-$. We deform $v_+$ to

\[
(8.2.1) \quad v = \exp_v(\beta_+ \psi_+ + \beta_- \psi_-),
\]

where $\exp_v$ is an exponential map which identifies the normal bundle to $v_+$ with a tubular neighborhood of $v_+$. The exponential maps $\exp_{v_+}$ and $\exp_{v_-}$ can be chosen such that

\[
\exp_{v_+}(\psi_+) = (s, t, \eta_+ + \psi_+) \quad \text{and} \quad \exp_{v_-}(\psi_-) = (s, t, \eta_- + \psi_-)
\]

for $s \leq T$ and $s \geq T_0$, respectively. Similarly, we assume that

\[
\exp_v(\beta_+ \psi_+ + \beta_- \psi_-) = (s, t, \eta_+ + \beta_+ \psi_+ + \beta_- \psi_-)
\]

for $T_0 \leq s \leq T$. Here $\eta_* = \beta_+ \eta_+ + \beta_- \eta_-.$

Let $\tau \in [0, 1]$ be close to $\tau_0$. The equation $\overline{\mathcal{T}}_{\mathcal{J}} v = 0$ is equivalent to:

\[
(8.2.2) \quad \beta_- \left( D_- \psi_- + (\tau - \tau_0)Y' + \frac{\partial \beta_+}{\partial s} \eta_+ + R_- \right) + \beta_+ \left( D_+ \psi_+ + \frac{\partial \beta_-}{\partial s} \eta_- + R_+ \right) = 0,
\]

where $D_-$ is the linearization of $\overline{\mathcal{T}}_{\mathcal{J_0}}$ for the normal bundle of $v_-$, $D_+$ is the linearization of $\overline{\mathcal{T}}_{\mathcal{J_0}}$ for the normal bundle of $v_{+, T}$. $Y'$ comes from the variation of the almost complex structure from $\mathcal{J}'$ to $\mathcal{J}_0$, and by abuse of notation we write $\frac{\partial \beta_+}{\partial s} \eta_+$ instead of $\frac{\partial \beta_+}{\partial s} \eta_+ \otimes (ds - i dt)$.

We will now describe the terms $R_-$ and $R_+$. Recall from [HT2 Definition 5.1] that $F(\psi)$ is type 1 quadratic if it can be written as

\[
F(\psi) = P(\psi) + Q(\psi) \cdot \nabla \psi,
\]

where $|P(\psi)| \leq c|\psi|^2$ and $|Q(\psi)| \leq c|\psi|$ for some constant $c > 0$. On $s \leq T_0$,

\[
R_- = F_-(\psi_-, \tau - \tau_0),
\]

where $F_- = F_-(\psi_-, \tau - \tau_0)$ is type 1 quadratic with respect to $\psi = (\psi_-, \tau - \tau_0)$. On $s \geq T$,

\[
R_+ = F_+(\psi_+),
\]

where $F_+ = F_+(\psi_+)$ is type 1 quadratic. In local coordinates,

\[
\frac{\partial (u + \xi)}{\partial s} + J_r(u + \xi) \frac{\partial (u + \xi)}{\partial t} = \left( \frac{\partial u}{\partial s} + J_{\tau_0}(u) \frac{\partial u}{\partial t} \right) + \left( \frac{\partial \xi}{\partial s} + J_{\tau_0}(u) \frac{\partial \xi}{\partial t} \right)
\]

\[
+ (J_r(u + \xi) - J_{\tau_0}(u)) \frac{\partial u}{\partial t} + (J_r(u + \xi) - J_{\tau_0}(u)) \frac{\partial \xi}{\partial t}.
\]
The first term on the right is zero; the second is part of the linearization $D_u \xi$; the third contributes $(\tau - \tau_0)Y'$ and a term $\nabla J_{\tau_0}(\xi) \frac{\partial}{\partial \tau}$ towards $D_u \xi$, and the remainder is quadratic and higher in $(\xi, \tau - \tau_0)$; the fourth is bounded by $|(\xi, \tau - \tau_0)| \cdot |\nabla \xi|$.

Claim 8.2.1. If $(\alpha_\pm, J_\pm)$ is $L$-supersimple and $T_0 \gg 0$, then $Y' = 0$ on $s \geq T_0$ and we can take $\mathcal{R}_\pm$ to be

$$
\mathcal{R}_- = \frac{\partial \beta_+}{\partial s} \psi_+ , \quad \mathcal{R}_+ = \frac{\partial \beta_-}{\partial s} \psi_-
$$

for $s \geq T_0$ and $s \leq T$, respectively.

Proof: Since $\mathcal{J}' = J_+$ on $s \geq T_0$ and $T_0 \gg 0$, we have $Y' = 0$.

On $T_0 \leq s \leq T$, $\mathcal{J} v = 0$ can be written as:

$$
\beta_- D_- \psi_+ + \beta_+ D_+ \psi_+ + \frac{\partial \beta_-}{\partial s} (\eta_- + \psi_-) + \frac{\partial \beta_+}{\partial s} (\eta_+ + \psi_+) = 0,
$$

where $D_- = D_+ = \frac{\partial}{\partial s} - A$. (Note that $D_- \eta_- = 0$ and $D_+ \eta_+ = 0$.) This decomposition is consistent with Equation (8.2.2) and hence we can define $\mathcal{R}_\pm$ by Equation (8.2.3) for $T_0 \leq s \leq T$.

We also define $\mathcal{R}_- = 0$ for $s \geq T$ and $\mathcal{R}_+ = 0$ for $s \leq T_0$.

We then rewrite Equation (8.2.2) as

$$
\beta_- \Theta_- (\psi_-, \psi_+, \tau) + \beta_+ \Theta_+ (\psi_-, \psi_+) = 0,
$$

by setting

$$
\Theta_- (\psi_-, \psi_+, \tau) = D_- \psi_+ + (\tau - \tau_0)Y' + \frac{\partial \beta_+}{\partial s} \eta_+ + \mathcal{R}_-, \quad \Theta_+ (\psi_-, \psi_+) = D_+ \psi_+ + \frac{\partial \beta_-}{\partial s} \eta_- + \mathcal{R}_+.
$$

We want to solve the equations $\Theta_- (\psi_-, \psi_+, \tau) = 0$ and $\Theta_+ (\psi_-, \psi_+) = 0$, subject to $\psi_\pm$ being in $(\ker(D_\pm))_\perp$ the $L^2$-orthogonal complement of $\ker(D_\pm)$. For any sufficiently small $\psi_-$, one can solve for $\psi_+ = \psi_+=(\psi_-) \in (\ker D_+)\perp$ in $\Theta_+ (\psi_-, \psi_+) = 0$, since $D_+$ is surjective; see Lemma 8.4.1.

Next we solve for $(\psi_-, \tau)$ in $\Theta_- (\psi_-, \psi_+(\psi_-), \tau) = 0$. This is equivalent to solving the following triple of equations

$$
D_- \psi_+ + (1 - \Pi) \left( (\tau - \tau_0)Y' + \frac{\partial \beta_+}{\partial s} \eta_+ + \mathcal{R}_- \right) = 0,
$$

$$
\Pi_Y \left( (\tau - \tau_0)Y' + \frac{\partial \beta_+}{\partial s} \eta_+ + \mathcal{R}_- \right) = 0,
$$

$$
\Pi' \left( \frac{\partial \beta_+}{\partial s} \eta_+ + \mathcal{R}_- \right) = 0,
$$

where $\Pi$ and $\Pi'$ are appropriate projection operators.
where $\Pi$ is the orthogonal projection to $\ker D_+^*$, $\Pi_Y$ is the orthogonal projection to $\mathbb{R}\langle Y \rangle$, and $\Pi'$ is the orthogonal projection to $\ker D_-^* \cap Y^\perp$. Here $Y = \Pi Y'$ and $Y^\perp$ is the orthogonal complement of $Y$. $Y$ is nonzero because $\{T^\tau\}_{0 \leq \tau \leq 1}$ is generic.

Given $(T, v_+)$, one can always solve for $\psi_+, \psi_-$ and $\tau$ in Equations (8.2.5), (8.2.6) and (8.2.7), subject to $\psi_+ \in (\ker D_+)^\perp$; see Lemma 8.4.4. We then set

$$v(T, v_+) := \exp_{v_+}(\beta_+ \psi_+ + \beta_- \psi_-)$$

where the right-hand side of the equation (implicitly) depends on $T$ and $v_+$.

8.3. Banach spaces. The function spaces that we use are Morrey spaces, following [HT2] Section 5.5. Let $u : \tilde{F} \to \mathbb{R} \times M$ be an immersed finite energy holomorphic curve and $N \to \tilde{F}$ be a normal bundle. On $\tilde{F}$ we choose a Riemannian metric so that the ends are cylindrical and on $N$ we use the metric induced from an $\mathbb{R}$-invariant Riemannian metric on $\mathbb{R} \times M$.

The Morrey space $\mathcal{H}_0(\tilde{F}, \Lambda^{0,1}T^*\tilde{F} \otimes N)$ is the Banach space which is the completion of the compactly supported sections of $\Lambda^{0,1}T^*\tilde{F} \otimes N$ with respect to the norm

$$\|\xi\| = \left(\int_{\tilde{F}} |\xi|^2\right)^{1/2} + \left(\sup_{x \in \tilde{F}} \sup_{\rho \in (0, 1]} \rho^{-1/2} \int_{B_\rho(x)} |\xi|^2\right)^{1/2},$$

where $B_\rho(x) \subset \tilde{F}$ is the ball of radius $\rho$ about $x$. Similarly, $\mathcal{H}_1(\tilde{F}, N)$ is the completion of the compactly supported sections of $N$ with respect to

$$\|\xi\|_* = \|\nabla \xi\| + \|\xi\|.$$

The analog of the usual Sobolev embedding theorem is the following:

**Lemma 8.3.1.** There is a bounded linear map

$$\mathcal{H}_1(\tilde{F}, N) \to C^{0,1/4}(\tilde{F}, N), \quad \xi \mapsto \xi,$$

where $C^{0,1/4}$ denotes the space of Hölder continuous functions with exponent $\frac{1}{4}$.

8.4. Some estimates. Let $\lambda = \min\{|\lambda_1|, |\lambda_{-1}|\}$. Let $\mathcal{H}_+^\perp$ be the $L^2$-orthogonal complement of $\ker D_+^*$ in $\mathcal{H}_1(\tilde{F}, N)$ corresponding to $v_+$, $\mathcal{H}_-^\perp$ be $\mathcal{H}_1(\tilde{F}, N)$ corresponding to $v_-$, and $B_{\pm}$ be the closed ball of radius $\varepsilon$ in $\mathcal{H}_\pm$ centered at 0.

The following lemma closely follows [HT2] Proposition 5.6, but the estimates are slightly different.

**Lemma 8.4.1.** There exist $r \gg 0$ and $c, \varepsilon > 0$ such that for $T \gg 0$ the following holds:

1. There is a map $P : B_- \to \mathcal{H}_+$ such that Equation (8.2.5) holds with $\psi_+ = P(\psi_-)$.
2. $\|P(\psi_-)\|_* \leq cr^{-1}(e^{-\lambda T} + \|\psi_+\|_*).$

---

Footnote: This is rather nonstandard and we chose to adopt it to avoid redoing the work in [HT2] for $W^{k,p}$-spaces.
Proof. (1) We are trying to solve for
\[ D_+ \psi_+ + \frac{\partial \beta_+}{\partial s}(\eta_- + \psi_-) + R'_+(\psi_+) = 0, \]
where \( R'_+(\psi_+) \) is type 1 quadratic. Writing
\[
(8.4.1) \quad \mathcal{I}(\psi_+) = -D_+^{-1} \left( \frac{\partial \beta_+}{\partial s}(\eta_- + \psi_-) + R'_+(\psi_+) \right),
\]
where \( D_+^{-1} \) is the bounded inverse of \( D_+|_{\mathcal{H}_+} \), we define \( P(\psi_-) \) as the unique fixed point \( \mathcal{I}(\psi_+) = \psi_+ \).

The unique fixed point is guaranteed by the contraction mapping theorem, which relies on two estimates. Our first estimate is
\[
(8.4.2) \quad \|\mathcal{I}(\psi_+)\|_* \leq cr^{-1}(e^{-\lambda T} + \|\psi_-\|_*) + c\|\psi_+\|_*_2.
\]
Indeed, since \( \frac{\partial \beta_+}{\partial s} < cr^{-1} \) for some \( c > 0, \)
\[
\|\frac{\partial \beta_+}{\partial s}(\eta_- + \psi_-)\| \leq cr^{-1}(e^{-\lambda T} + \|\psi_-\|_*)
\]
and, since \( R'_+ \) is type 1 quadratic,
\[
\|R'_+(\psi_+)\| \leq c\|\psi_+\|_*_2.
\]
The estimate follows from the boundedness of \( D_+^{-1} \); observe that the domain of \( D_+^{-1} \) uses the norm \( \|\cdot\| \) and the range of \( D_+^{-1} \) uses \( \|\cdot\|_* \). If \( r, T \gg 0 \) and \( \varepsilon > 0 \) is small, then the right-hand side of Equation (8.4.2) is \( \varepsilon \) whenever \( \|\psi_-\|_* \), \( \|\psi_+\|_* \) \( < \varepsilon \). Hence \( \mathcal{I} \) maps a radius \( \varepsilon \) ball into itself.

Our second estimate is
\[
(8.4.3) \quad \|\mathcal{I}(\psi_+) - \mathcal{I}(\psi'_+)\|_* = \|D_+^{-1}(R'_+(\psi_+) - R'_+(\psi'_+))\|_*
\]
\[
\leq c(\|\psi_+\|_* + \|\psi'_+\|_*) \cdot \|\psi_+ - \psi'_+\|_*.
\]
This follows from observing that \( D_+^{-1} \) is bounded and \( R' \) is type 1 quadratic. When \( \|\psi_+\|_* \), \( \|\psi'_+\|_* \) are sufficiently small, \( \mathcal{I} \) gives a contraction mapping. This proves (1).

(2) \( \psi_+ = P(\psi_-) \) satisfies \( \mathcal{I}(\psi_+) = \psi_+ \). Hence Equation (8.4.2) gives:
\[
\|\psi_+\|_* \leq cr^{-1}(e^{-\lambda T} + \|\psi_-\|_*) + c\|\psi_+\|_*_2.
\]
This implies (2) since \( c\|\psi_+\|_*_2 \ll \|\psi_+\|_* \) for \( \varepsilon > 0 \) small. \( \square \)

The following lemma closely follows [HT2, Proposition 5.7].

Lemma 8.4.2. There exist \( r \gg 0, c, \varepsilon > 0 \), and \( 0 < \varepsilon_0 < 1 \) such that for \( T \gg 0 \) the following holds:

(1) There is a map \( P': B_+ \times [-\varepsilon_0, \varepsilon_0] \to \mathcal{H}_- \) such that Equation (8.2.6) holds with \( \psi_- = P'(\psi_+, \tau - \tau_0) \).
(2) \( \|P'(\psi_+, \tau - \tau_0)\|_* \leq cr^{-1}(e^{-\lambda T} + \|\psi_+\|_*) + c|\tau - \tau_0| \).

Here \( \tau - \tau_0 \) is the coordinate for \( [-\varepsilon_0, \varepsilon_0] \).
Proof. (1) We are trying to solve for
\[
D_+ \psi_+ + (1 - \Pi) \left( (\tau - \tau_0)Y' + \frac{\partial \beta_+}{\partial s}(\eta_+ + \psi_+) + \mathcal{R}'_-(\psi_-, \tau - \tau_0) \right) = 0,
\]
where \( \mathcal{R}'_- \) is type 1 quadratic. Let us write
(8.4.4)
\[
I_{\psi_+, \tau - \tau_0}(\psi_-) = -D_-^{-1}(1 - \Pi) \left( (\tau - \tau_0)Y' + \frac{\partial \beta_+}{\partial s}(\eta_+ + \psi_+) + \mathcal{R}'_-(\psi_-, \tau - \tau_0) \right).
\]

We first estimate
(8.4.5)
\[
\|I_{\psi_+, \tau - \tau_0}(\psi_-)\|_* \leq c|\tau - \tau_0| + cr^{-1}(e^{-\lambda T} + \|\psi_+\|_*) + c(\|\psi_-\|^2 + |\tau - \tau_0|^2).
\]
Provided \( r, T \gg 0, \varepsilon > 0 \) is small, and \( |\tau - \tau_0| \) is small, the right-hand side is \( < \varepsilon \) whenever \( \|\psi_-\|_* \), \( \|\psi_+\|_* \) are small. Hence \( I_{\psi_+, \tau - \tau_0} \) maps a radius \( \varepsilon \) ball into itself.

Next we estimate
(8.4.6)
\[
\|I_{\psi_+, \tau - \tau_0}(\psi_-) - I_{\psi_+, \tau - \tau_0}(\psi'_-)|I_{\psi_+}(\tau - \tau_0)| - \mathcal{R}'_-(\psi_-, \tau - \tau_0)\|_* \]
\[
\leq C\|\psi_- - \psi'_-\|_*, \quad 0 < C < 1,
\]
provided \( |\tau - \tau_0| \), \( \|\psi_-\|_* \), and \( \|\psi'_-\|_* \) are small. The above estimates provide a contraction mapping.

(2) Follows from Equation (8.4.5) and \( I_{\psi_+, \tau - \tau_0}(\psi_-) = \psi_- \). \( \square \)

We also have:

Lemma 8.4.3. There exist \( r \gg 0 \) and \( \varepsilon > 0 \) such that for \( T \gg 0 \) the following holds:

1. There is a map \( P'' : \mathcal{B}_- \times \mathcal{B}_+ \rightarrow [-\varepsilon_0, \varepsilon_0] \) such that Equation (8.2.7) holds with \( \tau - \tau_0 = P''(\psi_-, \psi_+) \).

2. \( |P''(\psi_-, \psi_+)| \leq cr^{-1}(e^{-\lambda T} + \|\psi_+\|_*) + c\|\psi_-\|^2_* \).

Proof. This is proved using the contraction mapping theorem as in the proofs of Lemmas 8.4.1 and 8.4.2 and is left to the reader. \( \square \)

Putting Lemmas 8.4.1, 8.4.2, and 8.4.3 together we obtain:

Lemma 8.4.4. There exist \( r \gg 0, \varepsilon > 0 \) and \( \varepsilon_0 > 0 \) such that for \( T \gg 0 \) there is a unique solution \( (\psi_-, \psi_+, \tau - \tau_0) \in \mathcal{B}_- \times \mathcal{B}_+ \times [-\varepsilon_0, \varepsilon_0] \) to the equation \( \Theta_+(\psi_-, \psi_) = 0 \) and Equations (8.2.6) and (8.2.7). Moreover,
\[
\|\psi_-\|_*, \|\psi_+\|_*, |\tau - \tau_0| \leq cr^{-1}e^{-\lambda T}.
\]

Proof. We solve Equation (8.2.5) using Lemma 8.4.1 to obtain \( \psi_+ = P(\psi_-) \). We then plug \( \psi_+ = P(\psi_-) \) into Equation (8.2.7) and apply Lemma 8.4.3 to obtain \( \tau = P''(\psi_-, P(\psi_-)) + \tau_0 \). Finally, we plug \( \psi_+ = P(\psi_-) \) and \( \tau = P''(\psi_-, P(\psi_-)) + \tau_0 \) into Equation (8.2.6) and solve for \( \psi_-. \)

To this end, we define a map \( T : \mathcal{B}_- \rightarrow \mathcal{H}_- \) which takes \( \psi_- \) to \( I_{\psi_+, \tau - \tau_0}(\psi_-) \) as in Equation (8.4.4) with \( \psi_+ = P(\psi_-) \) and \( \tau = P''(\psi_-, P(\psi_-)) + \tau_0 \). Now we
show that \( \mathcal{I}' \) is a contraction mapping. By Estimate (8.4.5) and Lemmas 8.4.1(2) and 8.4.3(2) we get
\[
\|\mathcal{I}'(\psi_-)\|_* \leq c|\tau - \tau_0| + cr^{-1}(e^{-\lambda T} + \|\psi_+\|_*) + c\|\psi_-\|_*^2
\]
\[
\leq c \left( cr^{-1}(e^{-\lambda T} + \|\psi_+\|_*) + c\|\psi_-\|_*^2 \right)
\]
\[
+ cr^{-1}(e^{-\lambda T} + \|\psi_+\|_*) + c\|\psi_-\|_*^2
\]
\[
\leq cr^{-1}(e^{-\lambda T} + \|\psi_-\|_*) + c\|\psi_-\|_*^2,
\]
where the constant \( c > 0 \) changes from line to line. Hence \( \mathcal{I}' \) maps an \( \varepsilon \)-ball into itself.

Next we estimate
\[
(8.4.7)
\|\mathcal{I}'(\psi_-) - \mathcal{I}'(\psi'_-)|_ *
\]
\[
\leq c|\tau - \tau'| + c\|\partial_{\tau_0}(\psi_+ - \psi'_+)\|_* + c\|\mathcal{R}'_- (\psi_-, \tau - \tau_0) - \mathcal{R}'_- (\psi'_-, \tau' - \tau_0)\|_*
\]
\[
\leq c|\tau - \tau'| + cr^{-1}\|\psi_+ - \psi'_+\|_* + C \cdot (\|\psi_- - \psi'_-\|_* + |\tau - \tau'|),
\]
where \( \psi'_+ = \psi_+(\psi'_-) \), \( \tau' = \tau(\psi'_+, \psi'_-) \), and \( C \to 0 \) as
\[
\|\psi_-\|_*^2 + \|\psi'_+\|_* + |\tau - \tau_0| + |\tau' - \tau_0| \to 0.
\]
We now estimate the terms \( |\tau - \tau'| \) and \( \|\psi_+ - \psi'_+\|_* \) in Estimate (8.4.7). Starting from Equation (8.2.7) we estimate
\[
|\tau - \tau'| \leq cr^{-1}\|\psi_+ - \psi'_+\|_* + C\|\psi_- - \psi'_-\|_*.
\]
Along the lines of Estimate (8.4.3) we get
\[
\|\psi_+ - \psi'_+\|_* \leq C'\|\psi_- - \psi'_-\|_*,
\]
where \( C' \to 0 \) as \( \|\psi_-\|_* + \|\psi'_+\|_* \to 0 \). Combining these we obtain
\[
(8.4.8)
\|\mathcal{I}'(\psi_-) - \mathcal{I}'(\psi'_-)|_ * \leq C'' \cdot \|\psi_- - \psi'_-\|_*,
\]
where \( 0 < C'' < 1 \). Hence \( \mathcal{I}' \) is a contraction mapping, and it has a unique fixed point \( \psi_- = \mathcal{I}'(\psi_-) \).

Finally, the claimed estimates follow from Lemmas 8.4.1, 8.4.2 and 8.4.3. \( \square \)

8.5. Obstruction bundle and obstruction section. Let \( \mathcal{O} \) be the obstruction bundle
\[
\mathcal{O} \to [R, \infty) \times \mathcal{M}/\mathbb{R}, \quad R \gg 0,
\]
whose fiber over \((T, v_+)\) is
\[
\mathcal{O}_{T, v_+} = \text{Hom}(\ker D^*_+/\mathbb{R}(Y), \mathbb{R}).
\]

We define the section \( \sigma \) of \( \mathcal{O} \) as follows:
\[
(8.5.1) \quad \sigma(T, v_+)(\sigma) = \left( \sigma, \frac{\partial \beta_+}{\partial s} \eta_+ + \mathcal{R}_- \right),
\]
where \( \sigma \in \ker D^*_+/\mathbb{R}(Y) \) and \( \langle \cdot, \cdot \rangle \) denotes the \( L^2 \)-inner product. More precisely, given \((T, v_+)\), we solve for \( \psi_+, \psi_-, \tau \) in \( \Theta_+(\psi_-, \psi_+) = 0 \) and in Equations (8.2.6).
and (8.2.7) and evaluate the right-hand side of Equation (8.5.1) using these $\psi_+, \psi_-$, and $\tau$.

**Theorem 8.5.1 ([HT2] Lemma 6.3).** $\mathcal{s}$ is smooth for $R \gg 0$.

As in Lemma 1.0.6

\[
\dim \ker(D_-) = 0, \quad \dim \ker(D^*) = \dim \coker(D_-) = k.
\]

Therefore, we expect $\mathcal{s}^{-1}(0)$ to intersect $\{T\} \times \mathcal{M}/\mathbb{R}$ at finitely many points, for generic $T \geq 10r$.

To any $(T,v_+) \in [R, \infty) \times \mathcal{M}/\mathbb{R}$ we can associate $v(T,v_+)$ and $\tau(T,v_+)$, as described at the end of Section 8.2. When $(T,v_+) \in \mathcal{s}^{-1}(0)$, we can view $(v(T,v_+), \tau(T,v_+))$ as an element of $\prod_{0 \leq \tau \leq 1} \mathcal{M}_{\mathcal{T}}^{\text{ind}=0, \text{cyl}}(\gamma'_+ , \gamma_-)$. Hence we have the gluing map

\[
G : \mathcal{s}^{-1}(0) \to \prod_{0 \leq \tau \leq 1} \mathcal{M}_{\mathcal{T}}^{\text{ind}=0, \text{cyl}}(\gamma'_+ , \gamma_-),
\]

\[
(T,v_+) \mapsto (v(T,v_+), \tau(T,v_+)).
\]

### 8.6. Bijectivity of the gluing map.

Let $K$ be a subset of $\mathcal{M}/\mathbb{R}$. Given $\delta > 0$, let $\tilde{G}_\delta(v_-, K)$ be the set of (not necessarily holomorphic) maps that are $\delta$-close to some holomorphic building $v_+ \cup v_+$ in the sense of [HT2] Definition 7.1], where $v_+ \in K$. Let $\tilde{G}_\delta(v_- , K)$ be the subset of

\[
\prod_{0 \leq \tau \leq 1} \mathcal{M}_{\mathcal{T}}^{\text{ind}=0, \text{cyl}}(\gamma'_+ , \gamma_-)
\]

consisting of pairs $(v, \tau)$, where $v$ is a $\mathcal{T}$-holomorphic curve in $\tilde{G}_\delta(v_-, K)$. Also let $\mathcal{U}_{\delta,K} \subset [R, \infty) \times K$ be the set of $(T,v_+)$ such that $v(T,v_+) \in \tilde{G}_\delta(v_- , K)$.

**Theorem 8.6.1 ([HT2] Theorem 7.3]).** Suppose $K \subset \mathcal{M}/\mathbb{R}$ is compact.

1. For $R' > 0$ sufficiently large with respect to $\delta$, $[R', \infty) \times K \subset \mathcal{U}_{\delta,K}$.
2. For $\delta > 0$ sufficiently small, there exists a compact set $\mathcal{K} \subset \mathcal{K}' \subset \mathcal{M}/\mathbb{R}$ such that the restriction

\[
G|_{\mathcal{U}_{\delta,K'}} : \mathcal{s}^{-1}(0) \cap \mathcal{U}_{\delta,K'} \to \tilde{G}_\delta(v_, \mathcal{M}/\mathbb{R})
\]

of $G$ satisfies $\text{Im}(G|_{\mathcal{U}_{\delta,K'}}) \supset \tilde{G}_\delta(v_- , K)$. Moreover, $G|_{\mathcal{U}_{\delta,K'}}$ is a homeomorphism onto its image.

### 8.7. The linearized section $\mathcal{s}_0$. Recall the evaluation map $\tilde{\mathcal{v}}_\mathcal{R} : \mathcal{M}/\mathbb{R} \to S^{k-1}$ and also that $\dim \mathcal{M}/\mathbb{R} = k - 1$.

We define a homotopy of sections $\mathcal{s}_\zeta$, $\zeta \in [0, 1]$, as follows: For $\zeta \in \left[\frac{1}{2}, 1\right]$,

\[
\mathcal{s}_\zeta(T,v_+)(\sigma) = \left\langle \sigma, \frac{\partial\beta_+}{\partial s} \eta_+ + \beta(2\zeta - 1) \cdot \mathcal{R}_- \right\rangle,
\]

where $\beta$ is the cutoff function from Section 8.1. More precisely, given $(T,v_+)$, we solve for $\psi_+, \psi_-$, $\tau$ in $\Theta_+^{\star}(\psi_+, \psi_+)$ = 0 and in Equations (8.2.6) and (8.2.7) with $\mathcal{R}_-$ replaced by $\beta(2\zeta - 1) \mathcal{R}_-$, and evaluate the right-hand side of Equation (8.7.1).
using these $\psi_+, \psi_-$, and $\tau$. Observe that the estimates from Section 8.4 carry over with $\mathcal{R}_-$ replaced by $\beta(2\zeta - 1)\mathcal{R}_-$, allowing us to define $s_\zeta$. For $\zeta \in [0, 1]$, 

(8.7.2) 

$$s_\zeta(T, v_+)(\sigma) = \left\langle \sigma_\zeta, \frac{\partial \beta_+}{\partial s} \eta_+ \right\rangle,$$

where $\sigma_\zeta$ is the linear interpolation between $\sigma$ and $\tilde{\sigma}$, and $\tilde{\sigma}$ is $\sigma$ with the $f_{k+1}(t), f_{k+2}(t), \ldots$ terms truncated. Note that we are only concerned with the positive end of $\sigma$.

Here $s_1 = s$ and $s_0(T, v_+)(\sigma) = \left\langle \tilde{\sigma}, \frac{\partial \beta_+}{\partial s} \eta_+ \right\rangle$.

**Lemma 8.7.1.** With respect to the basis $\{\sigma_1, \ldots, \sigma_k\}$ from Lemma 1.0.6 

(8.7.3) 

$$s_0(T, v_+)(\sigma_i) = e^{-2\lambda_i T} c_i$$

where $\tilde{e}^k(v_+) = (c_1, \ldots, c_k)$ and $i = 1, \ldots, k - 1$, and 

(8.7.4) 

$$s_0^{-1}(0) = [R, \infty) \times (\tilde{e}^k)^{-1}([0, 1, 0, \pm 1]).$$

**Proof.** We compute 

$$s_0(T, v_+)(\sigma_i) = \left\langle \tilde{\sigma}_i, \frac{\partial \beta_+}{\partial s} \eta_+ \right\rangle = \left\langle e^{-\lambda_i s} f_i(t), \frac{\partial \beta_+}{\partial s} \left( \sum_j c_j e^{\lambda_j s} f_j(t) \right) \right\rangle = e^{-2\lambda_i T} c_i.$$

Recall that $\{f_j \}_{j \in \mathbb{Z} - \{0\}}$ is an $L^2$-orthonormal basis and that $\int_{-\infty}^{\infty} \frac{\partial \beta_+}{\partial s} \ ds = 1$. The calculation of $s_0^{-1}(0)$ immediately follows from Equation (8.7.3). 

The following proposition allows us to substitute $s$ for the linearized section $s_0$:

**Proposition 8.7.2.** Let $K \subset \mathcal{M}/\mathbb{R}$ be a compact $(k - 1)$-dimensional submanifold with boundary such that $\tilde{e}^k(\partial K) \cap \{(0, \ldots, 0, \pm 1)\} = \emptyset$. Then for $R \gg 0$, there are no zeros of $s_\zeta$, $\zeta \in [0, 1]$, on $[R, \infty) \times \partial K$.

**Proof.** For our purposes we take a smooth section of $\mathcal{M} \to \mathcal{M}/\mathbb{R}$ over $K$ and a constant $C > 0$ so that, for each $v_+$ representing $[v_+] \in K$,

(K1) $v_+|_{s \leq 0}$ has image in $\mathbb{R} \times (\mathbb{R}/\mathbb{Z}) \times D_{s_0/3}^2$ and is graphical over a subset of $\mathbb{R} \times \gamma'$;

(K2) if we write $v_+ = \left( s, t, \sum_{i > 0} c_i e^{\lambda_i s} f_i(t) \right)$ on $s \leq 0$, then $\sum_{i=1}^{k} c_i^2 = C^2 \delta_0^2$;

(K3) $\sum_{i=1}^{k} c_i^2 \gg \sum_{i > k} c_i^2$.

We then take $0 < \delta \ll C\delta_0$.

Let $R > 0$ be sufficiently large with respect to $\delta$. Arguing by contradiction, suppose $(T, v_+) \in s^{-1}(0) \cap ([R, \infty) \times \partial K)$. Given $(T, v_+) \in [R, \infty) \times \partial K$, 

etc.
consider \((v(T, v_+), \tau(T, v_+))\). Observe that \(v(T, v_+) = \exp_{v_+}(\psi_+)\) for \(s \geq 2T\); \(v(T, v_+) = \exp_{v_+}(\psi_-)\) for \(s \leq T_0\); and \(v(T, v_+)\) can be written as 
\[
(s, t, \beta_+(\eta_+ + \psi_+) + \beta_- (\eta_- + \psi_-))
\]
on \(T_0 \leq s \leq 2T\) by our choice of section. Recall that \(v_+\) is \(v_+\) translated up by \(2T\).

By Lemmas 8.4.4 and 8.3.1
\[
\tag{8.7.5}
|\psi_-|_{C^0}, |\psi_+|_{C^0}, |\tau - \tau_0| < cr^{-1}e^{-\lambda T},
\]
for some constant \(c > 0\). In view of the normalization of \(v_+\) along \(s = 0\) given by (K2) and (K3), we have
\[
\tag{8.7.6}
|\psi_+|_{C^0} \ll |\eta_+|_{C^0}
\]
along \(s = 2T\), provided \(R \gg 0\).

We now make some explicit calculations in local coordinates for \(\psi_+\) on the \(s \leq 2T\) region. By Claim 8.2.1 \(\psi_+\) satisfies the equation
\[
\tag{8.7.7}
D_+ \psi_+ + \frac{\partial \beta_-}{\partial s}(\eta_- + \psi_-) = 0.
\]
For the term \(\eta_- + \psi_-\) in Equation (8.7.7) we have:

**Claim 8.7.3.** If \((T, v_+) \in s^{-1}(0)\), then
\[
\eta_- + \psi_- = \sum_{i < 0} d_i e^{\lambda_i s} f_i(t)
\]
for \(s \geq T_0 + hr\).

**Proof of Claim 8.7.3** First note that \(\eta_-\) is holomorphic. On \(s \geq T_0\), \(\psi_-\) satisfies the equation
\[
D_- \psi_- + \frac{\partial \beta_+}{\partial s}(\eta_+ + \psi_+) = 0
\]
by Claim 8.2.1 Restricted to \(s \geq T_0 + hr\), this becomes \(D_- \psi_- = 0\). Since both \(\eta_-\) and \(\psi_-\) have exponential decay as \(s \to \infty\), \(\eta_- + \psi_-\) can be written as
\[
\sum_{i < 0} d_i e^{\lambda_i s} f_i(t) \text{ for } s \geq T_0 + hr.
\]

Next let us write
\[
\psi_+(s, t) = \sum_{i \in \mathbb{Z}-\{0\}} b_i(s) e^{\lambda_i s} f_i(t).
\]
Then we have the following:

**Claim 8.7.4.** If \((T, v_+) \in s^{-1}(0)\), then on \(s < 2T\):

1. for \(i > 0\), \(b_i(s)\) is constant; and
2. for \(i < 0\), \(b_i(s) = -d_i \int_{-\infty}^{s} \frac{\partial \beta_-}{\partial s} ds\).
Proof of Claim 8.7.4 Since \( \psi_\perp \) has exponential decay as \( s \to -\infty \) and \( \frac{\partial \beta}{\partial s} = 0 \) on \( s < T - hr \), \( b_i(s) \) must be constant for all \( i \) and equal to zero for \( i < 0 \) on \( s < T - hr \) by Equation (8.7.7). By a similar argument which uses Claim 8.7.3, \( b_i(s) \) is constant on \( T_0 + hr < s < 2T \) for \( i > 0 \). Therefore, \( b_i(s) \) is constant on \( s < 2T \) for \( i > 0 \), which gives (1). Solving for the Fourier coefficients for \( i < 0 \) gives (2).

Claim 8.7.5. If \( R \gg 0 \), then \( \tilde{\psi}_-^k(\eta_+ + \psi_+) \) is close to \( \bar{\psi}_-^k(\eta_+) \) for all \( [T, v_+] \in [R, \infty) \times \partial K \). In particular, \( \tilde{\psi}_-^k(\eta_+ + \psi_+) \neq (0, \ldots, 0, \pm 1) \).

We will be using the identification \((\mathbb{R}^k - \{0\})/\mathbb{R}^+ \simeq S_{c_{\theta_0}^{-1}}^{k-1}\), see Remark 6.0.3. This is to take advantage of (K2).

Proof of Claim 8.7.5 If we write \( \eta_+(s, t) = \sum_{i=0}^k c_i e^{\lambda_i(s-2T)} f_i(t) \), then the order \( k \) Fourier polynomial for the negative end of \( \eta_+ + \psi_+ \) is

\[
P_k(\eta_+ + \psi_+) = \sum_{i=1}^k (c_i e^{-2\lambda_i T} + b_i) e^{\lambda_i s} f_i(t).
\]

By (K2), \( \tilde{\psi}_-^k(\eta_+) = (c_1, \ldots, c_k) \). By using Equation (8.7.6) along \( s = 2T \), we see that \( \sum_{i=1}^k c_i^2 > \sum_{i=1}^k (b_i e^{2\lambda_i T})^2 \). The claim then follows.

Claim 8.7.6. For any \( \varepsilon > 0 \), there exists \( R \gg 0 \) such that

\[
|\langle \psi_+ \rangle - P_k(\eta_+ + \psi_+)\rangle| < \varepsilon|P_k(\eta_+ + \psi_+)\rangle
\]

pointwise on \( s \leq 2T \) for all \( [T, v_+] \in [R, \infty) \times \partial K \).

Proof of Claim 8.7.6 By (K3),

\[
|\langle \psi_+ \rangle - P_k(\eta_+ + \psi_+)\rangle| < \varepsilon|P_k(\eta_+ + \psi_+)\rangle
\]

holds along \( s = 2T \). Since the error \( (\eta_+ + \psi_+) - P_k(\eta_+ + \psi_+) \) has faster exponential decay than \( P_k(\eta_+ + \psi_+) \) as \( s \) decreases, the claim follows.

Let us now consider \( \Theta_- (\psi_-, \psi_+) = 0 \), which can be written as

\[
(8.7.8) \quad \overline{\partial_T} \exp_{v_-} (\psi_-) = -\frac{\partial \beta}{\partial s}(\eta_+ + \psi_+).
\]

Consider the finite-dimensional vector space \( W = \mathbb{R} \left\langle \frac{\partial \beta}{\partial s} e^{\lambda_i s} f_i(t) \right\rangle_{i=1}^k \). We write \( Z_k = \mathbb{R} \left\langle \frac{\partial \beta}{\partial s} e^{\lambda_i s} f_k(t) \right\rangle \).

Lemma 8.7.7. If \( B \subset W \) is a sufficiently small ball centered at 0, then for all \( g \in B - Z_k \) there is no solution to the equation

\[
(8.7.9) \quad \overline{\partial_T} \exp_{v_-} (\psi_-) = g.
\]

The same is also true for all \( g \) of the form \( g' + g'' \), where \( g' \in B - Z_k \), \( g'' \in \mathcal{H}_0(\tilde{F}, \Lambda^{0,1} T^* F \otimes N) \), \( ||g'|| < \varepsilon ||g''|| \), and \( \varepsilon > 0 \) is a fixed sufficiently small number.
Proof of Lemma 8.7.7 First we claim that if \( g \in B \cap Z_k \), then there exists a pair \((\psi_+, \tau)\) which solves Equation (8.7.9): Let us write \( v_- = u_- \circ \pi \). Then \( g \in B \cap Z_k \) can be written as \( g = \pi^* g_0 \) for some \( g_0 \). There is a solution \((\psi_-, \tau)\) of

\[ \mathcal{J}_\tau \exp_{v_-}(\psi_-) = g_0, \]

since \( \ker(D^*_0) \) is 1-dimensional and is generated by \( Y_0 \) which comes from the variation of \( \mathcal{J} \). If we write \( \psi_- = \pi^* \psi_- \), then the pair \((\psi_- \circ 0^*, \tau)\) solves Equation (8.7.9).

The claim, interpreted suitably, implies the lemma: Consider the map

\[ \mathcal{J}_\tau^P : \mathcal{H}_1(\hat{F}, N) \oplus \mathbb{R} \to \mathcal{H}_0(\hat{F}, \Lambda^0 T^* \hat{F} \otimes N), \]

\[ (\psi_- \circ 0^*, \tau) \mapsto \mathcal{P}(\mathcal{J}_\tau^P \exp_{v_-}(\psi_-)), \]

where \( \mathcal{P} \) refers to a suitable parallel transport. For a sufficiently small ball \( B \) of \( \mathcal{H}_1(\hat{F}, N) \oplus \mathbb{R} \) centered at \((0, 0)\), \( \mathcal{J}_\tau^P(B) \) is a submanifold of codimension \( k - 1 \) in \( \mathcal{H}_0(\hat{F}, \Lambda^0 T^* \hat{F} \otimes N) \): this is because the linearization \( L_{(\psi_-, \tau-\tau_0)} \) of \( \mathcal{J}_\tau^P \) at any point \((\psi_-, \tau-\tau_0) \in B \) has Fredholm index \(-k + 1\), \( L_{(0,0)} \) has maximal rank, i.e., codimension \( k - 1 \), and hence \( L_{(\psi_-, \tau-\tau_0)} \) also has codimension \( k - 1 \). If \((\psi_-, \tau-\tau_0) \in B \), then \( L_{(\psi_-, \tau-\tau_0)} \) has image which is close to that \( L_{(0,0)} \). Since

\[ L_{(0,0)} = T_{(0,0)} \mathcal{J}_\tau^P(B) = \text{Im}(D_-) + \mathbb{R}\langle \sigma_k \rangle, \]

the tangent space \( T_{(\psi_-, \tau-\tau_0)} \mathcal{J}_\tau^P(B) \) is close to \( \text{Im}(D_-) + \mathbb{R}\langle \sigma_k \rangle \) when \((\psi_-, \tau-\tau_0)\) is small. If we write \( g = g^0 + g^\delta \in B - Z_k \) with \( g^0 \in Z_k \) and \( 0 \neq g^\delta \in \mathbb{R}\langle \frac{\partial}{\partial s} e^{A^s f_i(t)} \rangle_{i=1}^{k-1} \) and solve for \((\psi_-, \tau-\tau_0)\) in \( \mathcal{J}_\tau^P \exp_{v_-}(\psi_-) = g^\delta \), then the absolute value of the angle between \( g^\delta \) and \( T_{(\psi_-, \tau-\tau_0)} \mathcal{J}_\tau^P(B) \) is bounded below by a positive constant. Hence Equation (8.7.9) does not admit a solution for \( g \in B - Z_k \).

By Claims 8.7.3 and 8.7.6, the right-hand side of Equation (8.7.8) is an element of \( W \), plus a small error. Hence Equation (8.7.8) has no solution by Lemma 8.7.7 Unwinding the definition of \( s, s(T, u_+) \neq 0 \) and we have a contradiction.

The argument for \( \delta_\zeta, \zeta \in [\frac{1}{2}, 1] \), is done in exactly the same way. The estimates from Lemmas 8.4.1(2) and 8.4.2(2) carry over and the nonexistence of the solution to Equation (8.7.8) also holds for \( \Theta_- (\psi_-, \psi_+) \). Finally, \( \delta_\zeta, \zeta \in [0, \frac{1}{2}] \), is close to \( s_0 \) for \( R \gg 0 \). Hence there are no zeros of \( \delta_\zeta, \zeta \in [0, \frac{1}{2}] \), on \([R, \infty) \times \partial K \). This completes the proof of Proposition 8.7.2. \( \Box \)

8.8. The general prototypical gluing. So far we have been assuming that all the curves in \( M \) are immersed. In general we have the following proposition, which allows us to reduce to the immersed case.

Proposition 8.8.1. For \( \delta > 0 \) sufficiently small, there are no holomorphic curves in \( \prod_{0 \leq \tau \leq 1} \mathcal{M}^{ind=0, cyl}(\gamma_+, \gamma_-) \) that are:
(1) $\delta$-close to $(v_-, v_1, \ldots, v_l)$, where $v_1 \cup \cdots \cup v_l$ is an l-level building of $\partial(M/\mathbb{R})$ and $l > 1$ or

(2) $\delta$-close to $(v_-, v_+)$, where $v_+ \in M^{\text{sing}}$.

**Remark 8.8.2.** The proof of Proposition 8.8.1(1) does not require any $v_i$ to be regular.

**Proof.** (1) Suppose there is a curve $u$ satisfying (1). We will apply the proof of Proposition 8.7.2 to obtain a contradiction. Let $v_+$ be a pregluing of $v_1 \cup \cdots \cup v_l$ with gluing parameters $T_1, \ldots, T_{l-1}$ and let $v_*$ be a pregluing of $v_- \cup v_+$ with gluing parameter $T$. We focus on the neck portion $T_0 \leq s \leq 2T$ between $v_-$ and $v_+.T$, which we take to be preglued in the same way as in Sections 8.1 and 8.2.

Let $\psi_-$ be a section of the normal bundle of $v_-$, defined on $s \leq T_0$, so that $u = \exp_{v_-}(\psi_-)$. Similarly, let $\psi_+$ be a section of the normal bundle of $v_+.T$, defined on $s \geq 2T$, so that $u = \exp_{v_+.T}(\psi_+)$. (Assume without loss of generality that $v_+$ is immersed, since we only care about the negative end of $v_+$. ) If $\delta > 0$ is sufficiently small, then the sections $\psi_-$ and $\psi_+$ exist and $u$ is graphical over $[T_0, 2T] \times \mathbb{R}/\mathbb{Z}$ on the neighborhood $[T_0, 2T] \times \mathbb{R}/\mathbb{Z} \times D^2_{\delta_0/3}$ with coordinates $(s, t, x, y)$. Also let $\eta_+, \eta_-$ be as defined before.

**Claim 8.8.3.** There exist extensions of $\psi_+$ to $s \leq 2T$ and $\psi_-$ to $s \geq T_0$, viewed as functions to $D^2_{\delta_0/3}$, such that

$$\Theta_-(\psi_-, \psi_+) = D_- (\eta_- + \psi_-) + \frac{\partial \beta_+}{\partial s} (\eta_+ + \psi_+) = 0,$$

$$\Theta_+(\psi_-, \psi_+) = D_+ (\eta_+ + \psi_+) + \frac{\partial \beta_-}{\partial s} (\eta_- + \psi_-) = 0,$$

on $s \geq T_0$ and $s \leq 2T$, respectively.

**Proof.** This is proved in Lemmas 7.6 and 7.7 of [HT2].

More directly, if

$$u(s, t) = \sum_{i \in \mathbb{Z} \setminus \{0\}} c_i e^{\lambda_i s} f_i(t)$$

on $T_0 + hr \leq s \leq T - hr$, then we set

$$\eta_+ + \psi_+ = \sum_{i > 0} c_i e^{\lambda_i s} f_i(t), \quad s \leq T - hr,$$

$$\eta_- + \psi_- = \sum_{i < 0} c_i e^{\lambda_i s} f_i(t), \quad s \geq T_0 + hr.$$

We solve $\Theta_+(\psi_-, \psi_+) = 0$ on $T - hr \leq s \leq 2T$ by decomposing into eigenmodes: Writing

$$\eta_+ + \psi_+ = \sum_{i \in \mathbb{Z} \setminus \{0\}} c_i(s) e^{\lambda_i s} f_i(t),$$

$c_i(s) = c_i$ for $i > 0$. On the other hand, for $i < 0$, we have $c_i'(s) + \frac{\partial \beta_-}{\partial s} c_i = 0$ and the solution $c_i(s) = -c_i \int_{-\infty}^{s} \frac{\partial \beta_-}{\partial s}(s) \, ds$ has the right boundary conditions $c_i(T - hr) = 0$ and $c_i(2T) = c_i$. The equation $\Theta_-(\psi_-, \psi_+)$ is solved similarly. \qed
Returning to the proof of Proposition \[\text{8.8.1}\] now that we have sections $\psi_-$ and $\psi_+$ irrespective of the regularity of $v_1$, we reconsider Equation \[\text{(8.7.8)}\], which is satisfied by the pair $(\psi_-, \psi_+)$. By Theorem \[\text{6.0.8}\] $\overline{\tau}^k_{\ast} (\partial (\mathcal{M} / \mathbb{R}))$ does not pass through $(0, \ldots , 0 , \pm 1)$. Hence Claims \[\text{8.7.5}\] and \[\text{8.7.6}\] and Lemma \[\text{8.7.7}\] imply that there is no solution of Equation \[\text{(8.7.8)}\], a contradiction. Notice that in this argument we only need $v_+$ to be holomorphic near the negative end, so we only need to preglue $v_1 \cup \cdots \cup v_l$ instead of glue.

(2) is similar since $\overline{\tau}^k_{\ast} (\mathcal{M}^{\text{sing}} / \mathbb{R})$ does not intersect $(0, \ldots, 0, \pm 1)$ by Theorem \[\text{6.0.7}\]. Note that when a curve has a singular point, there is no normal bundle $N$; however, the entire argument carries over to the situation of $u^\ast T\bar{X}^\tau$ with minimal change. \hfill \qed

Let $K_1 \subset K_2 \subset \cdots \subset (\mathcal{M} - \mathcal{M}^{\text{sing}})/\mathbb{R}$ be an exhaustion of $(\mathcal{M} - \mathcal{M}^{\text{sing}})/\mathbb{R}$ by compact submanifolds of dimension $k - 1$ with boundary.

**Corollary 8.8.4.** For sufficiently small $\delta > 0$, sufficiently large $j > 0$, and sufficiently large $R > 0$, 

$$G|_{U_{\delta, K_j} : s^{-1}(0) \cap U_{\delta, K_j} \sim G_{\delta}(v_-, \mathcal{M}/\mathbb{R})}$$

is a homeomorphism.

**Proof.** Immediate from Proposition \[\text{8.8.1}\] and Theorem \[\text{8.6.1}\]. \hfill \qed

### 8.9. Other cases.

In this subsection we treat two other cases:

A. Suppose \[\text{[C1]–(C4)}\] holds with (C1) modified to (C1’) so that $\gamma'' = \gamma'_'$ is positive hyperbolic and $\gamma' = \gamma'_-$ is negative hyperbolic. Then Lemma \[\text{1.0.6}\] is modified so that $\sigma_1$ is a nonzero constant multiple of $Y$ modulo $f_{k+1}, f_{k+2}, \ldots$; this modification also carries over to Lemma \[\text{4.3.1}\]. The rest of the discussion carries over with $(0, \ldots, 0, \pm 1) \in S^{k-1}$ replaced by $(\pm 1, 0, \ldots, 0) \in S^{k-1}$.

B. Consider the 3-level SFT building $v_{-1} \cup v_0 \cup v_1$ where:

- $(\text{C1''})$ $v_1$ is a cylinder from $\gamma_+$ to $\gamma'_+$, $v_0$ is a cylinder from $\gamma'_+$ to $\gamma'_-$, and $v_{-1}$ is a cylinder from $\gamma'_-$ to $\gamma_-$; we assume that $\gamma'_+$ is negative hyperbolic and $\gamma'_-$ is positive hyperbolic;
- $(\text{C2''})$ $v_0$ maps to a cobordism $(\hat{X}^\tau_0, \hat{\alpha}^\tau_0, \hat{\mathcal{J}}^0)$ for some $\tau_0 \in (0, 1)$ and $v_{-1}$ and $v_1$ map to symplectizations;
- $(\text{C3''})$ $\text{ind}(v_{-1}) = b$, $\text{ind}(v_0) = -k$, $\text{ind}(v_1) = a$, where $a, b > 0$ and $a + b = k > 1$;
- $(\text{C4})$ $v_0$ is a $k$-fold unbranched cover of a transversely cut out (in a 1-parameter family) cylinder $u_0$ with $\text{ind}(u_0) = -1$ and $v_1$ is regular; and we write $v_0 = u_0 \circ \pi$, where $\pi$ is the covering map.

The gluing setup is similar to the previous situation: Let

$$\mathcal{M}_1 = \mathcal{M}_{J_+}^{\text{ind}=a, \text{cyl}}(\gamma_+, \gamma'_+), \quad \mathcal{M}_{-1} = \mathcal{M}_{J_-}^{\text{ind}=b, \text{cyl}}(\gamma'_-, \gamma_-).$$
We assume that all the curves in \( M_1 \) and \( M_{-1} \) are immersed; modifications can be made using the analog of Proposition [8.8.1]. The obstruction bundle is

\[
\mathcal{O} \to [R, \infty)^{\times 2} \times (M_{-1}/\mathbb{R}) \times (M_1/\mathbb{R}),
\]

whose fiber over \( (T_-, T_+, v_{-1}, v_1) \) is \( \text{Hom}(\ker D_{\gamma_0}^*/\mathbb{R}(Y), \mathbb{R}) \). The pregluing is done in exactly the same way with gluing parameters \( T_+ \) and \( T_- \), such that the pregluing between \( v_1 \) and \( v_0 \) is the same as that of Section [8.1] with parameter \( T_+ \) instead of \( T \) and the pregluing between \( v_{-1} \) and \( v_0 \) is done symmetrically about \( s = 0 \) with parameter \( T_- \). Let us write \( \eta_1 \) for the end corresponding to \( v_1(s - 2T_+, t) \) and \( \eta_{-1} \) for the end corresponding to \( v_{-1}(s + 2T_-, t) \). Define the cut-off functions

\[
\beta_1(s) = \beta \left( \frac{s-T_0}{hr} \right), \quad \beta_{-1}(s) = \beta \left( \frac{T_0-s}{hr} \right), \quad \text{and} \quad \beta_0(s) = \beta \left( \frac{s+T_{-1}}{hr} \right) - \beta \left( \frac{T_{-1}-s}{hr} \right).
\]

We then define the pregluing of \( v_{-1} \cup v_0 \cup v_1 \) by

\[
v_s(s, t) = \begin{cases} 
  v_{1,T_1}(s, t) & \text{for } T_1 \leq s, \\
  (s, t, \beta_1(s)\eta_1(s, t) + \beta_0(s)\eta_0(s, t)) & \text{for } T_0 \leq s < T, \\
  v_0(s, t) & \text{for } -T_0 \leq s < T_0, \\
  (s, t, \beta_{-1}(s)\eta_{-1}(s, t) + \beta_0(s)\eta_0(s, t)) & \text{for } -T_{-1} \leq s < -T_0, \\
  v_{-1,T_{-1}}(s, t) & \text{for } s < -T_{-1}.
\end{cases}
\]

Assume for convenience \( v_{-1}, v_0, \) and \( v_1 \) are all immersed. Otherwise, one can go through the proof of Proposition [8.8.1] to deal with the rest of the cases. Let \( \psi_1, \psi_0, \) and \( \psi_{-1} \) be sections of the normal bundles of \( \eta_{-1}, \eta_0, \) and \( \eta_1, \) respectively. We deform the \( v_s \) as before by

\[
v = \exp_{\nu_s}(\beta_1\psi_1 + \beta_0\psi_0 + \beta_{-1}\psi_{-1}).
\]

The obstruction section \( s \) is defined in a similar manner as in Section [8.5].

The linearized section is

\[
(8.9.1) \quad s_0(T_-, T_+, v_{-1}, v_1)(\sigma) = \left( \bar{\sigma}, \frac{\partial \beta_1}{\partial \eta_1} - \frac{\partial \beta_{-1}}{\partial \eta_{-1}} \right),
\]

where \( \bar{\sigma} \) is \( \sigma \) with the \( f_{k+1}(t), f_{k+2}(t), \ldots \) terms truncated at the positive end and \( g_{-k-1}(t), g_{-k-2}(t), \ldots \) truncated at the negative end. We use the basis

\[
\{ \sigma_1', \ldots, \sigma_{k-1}', \sigma_k \}
\]

from Lemma [4.3.3] to analyze \( s_0^{-1}(0) \). By Theorems [6.0.4] and [6.0.7] and our genericity assumption, there exist evaluation maps

\[
\tilde{\varepsilon}_{\gamma_+}^a(\gamma_+, \gamma_+'): M_{1}/\mathbb{R} \to S^{a-1},
\]

\[
\tilde{\varepsilon}_{\gamma_+}^b(\gamma_+, \gamma_-): M_{-1}/\mathbb{R} \to S^{b-1}.
\]

The evaluation maps will be abbreviated \( \tilde{\varepsilon}(\eta_1) \) and \( \tilde{\varepsilon}(\eta_{-1}) \) when the ends are understood.

**Lemma 8.9.1.** Let \( K \subset (M_{-1}/\mathbb{R}) \times (M_1/\mathbb{R}) \) be a compact \((k-2)\)-dimensional submanifold with boundary. Then for \( R \gg 0 \), there are no zeros of \( s_0 \) on \([R, \infty)^{\times 2} \times \partial K\).
Proof. Suppose $R \gg 0$. Let $(v_{-1}, v_1) \in K$ and let us denote their translated ends by

\[ \eta_1(s, t) = \sum_{i=1}^{\infty} c_i e^{\lambda_i (s - 2) T_+} f_i(t), \quad \eta_{-1}(s, t) = \sum_{i=-\infty}^{-1} d_i e^{\lambda_i (s + 2) T_-} g_i(t). \]

Suppose that $\lambda_a < \lambda_{a+1}$. Let us write

\[ \tilde{\sigma}_i'(s, t) = \begin{cases} i \leq j \leq k & c_i j e^{-\lambda_j T_+} f_j(t), \quad c_{i,j} = 1, \\ \sum_{-k \leq j \leq -k+i-1} d_{i,j} e^{-\lambda_j T_-} g_j(t), & d_{i,-k+i-1} \neq 0, \end{cases} \]

at the positive and negative ends. By a computation similar to that of Lemma 8.7.1

\[ \langle \tilde{\sigma}_i', \frac{\partial \beta}{\partial s} \eta_1 \rangle = \sum_{i,j \leq k} c_{i,j} c_j e^{-2\lambda_j T_+}, \tag{8.9.2} \]

\[ \langle \tilde{\sigma}_i', \frac{\partial \beta}{\partial s} \eta_{-1} \rangle = \sum_{-k \leq j \leq -k+i-1} d_{i,j} d_j e^{2\lambda_j T_-}. \tag{8.9.3} \]

Now let us write

\[ c_{i,s} = (c_{i,1}, \ldots, c_{i,k}), \quad d_{i,s} = (d_{i,-k}, \ldots, d_{i,1}), \]

where we are setting $c_{i,1} = \cdots = c_{i,i-1} = 0$ and $d_{i,-k+i} = \cdots = d_{i,-1} = 0$, and

\[ C_1 = \left( c_1 e^{-2\lambda_1 T_+}, \ldots, c_a e^{-2\lambda_a T_+} \right), \quad C_2 = \left( c_{a+1} e^{-2\lambda_{a+1} T_+}, \ldots, c_k e^{-2\lambda_k T_+} \right), \]

\[ D_{-2} = \left( d_{-k} e^{2\lambda'_{k-1} T_-}, \ldots, d_{-k+a-1} e^{2\lambda'_{k-a} T_-} \right), \quad D_{-1} = \left( d_{-b} e^{2\lambda'_{k-a-1} T_-}, \ldots, d_{-1} e^{2\lambda'_{k-1} T_-} \right). \]

Recall that $a + b = k$. Since $\lambda_a < \lambda_{a+1}$ and $(c_1, \ldots, c_a)$ and $(d_{-b}, \ldots, d_{-1})$ are nonzero, it follows that $|C_2| \ll |C_1|$ and $|D_{-2}| \ll |D_{-1}|$ for $R \gg 0$.

Suppose $i = j_0$ maximizes $(8.9.2)$, where we are ranging over $i = 1, \ldots, a$. We claim that if $s_0(\sigma_{j_0}') = 0$, then $|C_1| \leq c |D_{-2}|$ for some constant $c > 0$ which does not depend on $T_-, T_+, v_{-1}, v_1$, provided $R \gg 0$. First observe that \( \{c_{i,*}\}_{i=1}^k \) and \( \{d_{i,*}\}_{i=1}^k \) form bases of $\mathbb{R}^k$ and that $(8.9.2)$ and $(8.9.3)$ can be written as:

\[ \langle c_{i,*}, (C_1, C_2) \rangle \quad \text{and} \quad \langle d_{i,*}, (D_{-2}, D_{-1}) \rangle, \]

where we are using the standard inner product on $\mathbb{R}^k$. It is not hard to see that there exist a constant $c > 0$, which only depends on \( \{c_{i,*}\}_{i=1}^k \), and an integer $i = j_0'$, which depends on $(C_1, C_2)$, such that

\[ \langle c_{j_0'*}, (C_1, C_2) \rangle \geq c \cdot |c_{j_0'*}| \cdot |(C_1, C_2)|. \]

(Roughly speaking, some vector $c_{j_0'*}$ makes an angle with $(C_1, C_2)$ which is bounded away from $\frac{\pi}{4}$.) If $i = j_0$ maximizes $(8.9.2)$ and $s_0(\sigma_{j_0}') = 0$, then

\[ c \cdot |c_{j_0'*}| \cdot |(C_1, C_2)| \leq |(c_{j_0'*}, (C_1, C_2))| \leq |(d_{j_0'*}, (D_{-2}, D_{-1}))|. \]

Hence, by Lemma 4.3.3 and the fact that $|D_{-2}| \ll |D_{-1}|$,

\[ c \cdot |c_{j_0'*}| \cdot |C_1| \leq |d_{j_0'*}| \cdot |D_{-2}|, \]
which implies the claim.

Combining the inequalities $|C_2| \ll |C_1|$, $|C_1| \leq c|D_{-2}|$, and $|D_{-2}| \ll |D_{-1}|$, we obtain $|C_2| \ll |D_{-1}|$. On the other hand, applying the above argument to $\hat{\sigma}_{j_1}$, $a + 1 \leq j_1 < k$, such that $s_0(\sigma_{j_1}) = 0$, we obtain $|D_{-1}| \leq c|C_2|$, a contradiction. This proves the lemma when $\lambda_a < \lambda_{a+1}$.

When $\lambda_a = \lambda_{a+1}$, the only case that is not treated by the above argument is when

$$
\eta_1(s, t) = (c_a f_a(t) + c_{a+1} f_{a+1}(t)) e^{\lambda_a (s - 2T_+)},
\eta_1(s, t) = (d_{a+1} g_{a+1}(t) + d_{a+2} g_{a+2}(t)) e^{\lambda_{a+1} (s + 2T_-)},
$$

up to a small error. By the transversality of the evaluation maps, there is only a finite number of possible values for $(c_a, c_{a+1})$ and $(d_{a+1}, d_{a+2})$; moreover their genericity implies that, for each $(T_-, T_+, v_1, v_1)$, there exists $(r_a, r_{a+1})$ such that $s_0(T_-, T_+, v_1, v_1)(r_a \tilde{\sigma}_a + r_{a+1} \tilde{\sigma}_{a+1}) \neq 0$. This proves the lemma. \hfill \Box

The existence of a homotopy $s_t$ from $s_1 = s$ to $s_0$ without zeros on $[R, \infty)^{\times 2} \times \partial K$ is proved as in Proposition 8.7.2 using Lemma 8.9.1. The higher codimension strata are eliminated using the argument of Section 8.8.

9. Orientations

In this section we discuss orientations for the moduli spaces. Section 9.1 and Sections 9.2.1, 9.2.2 are standard.

9.1. $\partial^2 = 0$.

9.1.1. Signs in the definition of $\partial$. We first discuss orientations involved in the definition of $\partial$. Let $u \in M_{J}^{\text{ind}=\text{cyl}}(\gamma, \gamma')$, where we are suppressing asymptotic markers from the notation. For simplicity let us assume that $u$ is immersed. Let $D = D_u$ be the linearized normal $\partial$-operator and let

$$
det(D) = \Lambda^{\text{top}} \ker D \otimes \Lambda^{\text{top}}(\text{coker } D)^*$$

be its determinant line. We define an equivalence relation $\sim$ on $\det(D) - \{0\}$ as follows: $\xi_1 \sim \xi_2$ if $\xi_1 = c \xi_2$ for $c \in \mathbb{R}^+$. The equivalence class of $\xi \in \det(D) - \{0\}$ is denoted by $[\xi]$. Let $s(D)$ be the orientation of $\det(D)$ given by [BM]. An orientation of $\det(D)$ can be viewed as an equivalence class of $\det(D) - \{0\}$.

When $\text{ind}(u) = 1$, we can write $s(D) = [\text{sgn}(u) \cdot \partial_s]$, where $\partial_s$ refers to the section of the normal bundle corresponding to the infinitesimal translation in the $s$-direction and $\text{sgn}(u) = \pm 1$.

Sign assignment. In the definition of $\partial$, we assign the sign $\text{sgn}(u)$ to $[u] \in M_{J}^{\text{ind}=\text{cyl}}(\gamma, \gamma')/\mathbb{R}$. 

9.1.2. $\partial^2 = 0$. Next we discuss orientations in the proof of $\partial^2 = 0$. We are gluing/pregluing $u_1 \in \mathcal{M}_J^{\text{ind}=1,\text{cyl}}(\gamma'', \gamma')$ and $u_2 \in \mathcal{M}_J^{\text{ind}=1,\text{cyl}}(\gamma, \gamma'')$. Assume $u_1$ and $u_2$ are regular. Let $u_1 \# u_2$ be a pregluing of $u_1$ and $u_2$ and let $D_{u_1 \# u_2}$ be the linearized normal $\overline{\partial}$-operator for $u_1 \# u_2$. We assume that the “neck length” $T$ is sufficiently large. Then by the gluing property for coherent orientations from [BM], there is an isomorphism

$$\det(D_{u_1 \# u_2}) \simeq \det(D_{u_1}) \otimes \det(D_{u_2})$$

which is natural up to a positive constant and

$$\sigma(D_{u_1 \# u_2}) = \sigma(D_{u_1}) \otimes \sigma(D_{u_2}),$$

where the right-hand side is defined as follows: We use cutoff functions $\beta_i : \mathbb{R} \to [0, 1], i = 1, 2$, that are analogous to $\beta_\pm$ from Section 8.1. Given $\xi_i \in \ker D_{u_i}$, we translate by $\pm T$ and damp it out at the positive or negative end (as appropriate) by multiplying by $\beta_i$. This yields $\xi_i' = \beta_i(\xi_i) T$. Here the subscript $T$ indicates a translation which depends on $T$. We then view $\xi_i'$ as an element of the domain of $D_{u_1 \# u_2}$ and take the $L^2$-orthogonal projection to $\ker D_{u_1 \# u_2}$ to obtain $\tilde{\xi}_i$. Finally, if

$$\sigma(D_{u_1}) = [\text{sgn}(u_1) \partial_s^1] \quad \text{and} \quad \sigma(D_{u_2}) = [\text{sgn}(u_2) \partial_s^2],$$

where $\partial_s^i, i = 1, 2$, is the vector field that corresponds to translation in $s$-direction inside the moduli space inside the moduli space corresponding to $u_i$, then

$$\sigma(D_{u_1}) \otimes \sigma(D_{u_2}) := [\text{sgn}(u_1) \partial_s^1 \wedge \text{sgn}(u_2) \partial_s^2].$$

Now let $u_1 \cup u_2$ and $u_1^\# \cup u_2^\#$ be the two boundary points of a component $\mathcal{N}$ of $\mathcal{M}/\mathbb{R}$. Let $a$ be a nonsingular vector field of $\mathcal{N}$ that points away from $u_1 \cup u_2$ and towards $u_1^\# \cup u_2^\#$, and let $\partial_s^{12}$ be the vector field of $\mathcal{M}$ that corresponds to translation in the $s$-direction. If we denote $\sigma(D_{u_1 \# u_2}) = [\text{sgn}(a) \partial_s^{12} \wedge a]$, then $\partial_s^1 + \partial_s^2$ corresponds to $\partial_s^{12}$ and $\partial_s^1 - \partial_s^2$ corresponds to $a$. Therefore,

$$[\text{sgn}(u_1) \partial_s^1 \wedge \text{sgn}(u_2) \partial_s^2] = [\text{sgn}(a)(\partial_s^1 + \partial_s^2) \wedge (\partial_s^1 - \partial_s^2)],$$

and $\text{sgn}(u_1) \text{sgn}(u_2) = - \text{sgn}(a)$. The analogous computation for $u_1^\# \cup u_2^\#$ implies

$$\text{sgn}(u_1^\#) \text{sgn}(u_2^\#) = \text{sgn}(a) = - \text{sgn}(u_1) \text{sgn}(u_2).$$

This is the desired relation for $\partial^2 = 0$.

9.2. Chain homotopy.

9.2.1. A lemma. In this subsection we will make frequent use of the following standard lemma (cf. [FO3, p. 676], for example):

**Lemma 9.2.1.** If $\phi : V \to W$ is a Fredholm map and $E$ is a finite-dimensional subspace of $W$ such that $W = \text{Im} \phi + E$, then there is an isomorphism

$$\Phi_E : \det \phi \sim \det \phi^{-1}(E) \otimes \det E^*,$$

which is natural up to a positive constant.
Then, by Lemma 9.2.1, since $\beta$ where $\phi$, $F$, coker $\phi$, and $\phi(F)$ have bases $\{v_1, \ldots, v_m\}$, $\{f_1, \ldots, f_\ell\}$, $\{w_1, \ldots, w_n\}$, and $\{\phi(f_1), \ldots, \phi(f_\ell)\}$, then the isomorphism $\Phi_E$ is given by:
\[ [v_1 \wedge \cdots \wedge v_m \otimes w_n^* \wedge \cdots \wedge w_1^*] \mapsto [v_1 \wedge \cdots \wedge v_m \wedge f_1 \wedge \cdots \wedge f_\ell \otimes \phi(f_1)^* \wedge \cdots \wedge \phi(f_\ell)^* \wedge w_n^* \wedge \cdots \wedge w_1^*], \]
where $\{w_1^*, \ldots, w_n^*\}$ is the dual basis to $\{w_1, \ldots, w_n\}$ and $\{\phi(f_1)^*, \ldots, \phi(f_\ell)^*\}$ is the dual basis to $\{\phi(f_1), \ldots, \phi(f_\ell)\}$.

9.2.2. The $k = 1$ case. We mostly use the notation from Section 7.1. Let
\[ \mathcal{M}^0 = \prod_{0 \leq \tau \leq 1} \mathcal{M}^{ind=0, cyl}_{(\gamma_+, \gamma_-)} \]
and let $\pi : \mathcal{M}^0 \to [0, 1]$ be the projection to $\tau \in [0, 1]$.

Consider
\[ v_0 \cup v_1 \in \left( \mathcal{M}^{ind=-k, cyl}_{\mathcal{N}_-}(\gamma_+, \gamma_-) \times \mathcal{M}^{ind=k, cyl}_{\mathcal{N}_+}(\gamma_+, \gamma_-)/\mathbb{R} \right)/ \sim. \]

Let
\[ D_{v_0} : \mathcal{H}_1(\tilde{F}_0, N_{v_0}) \to \mathcal{H}_0(\tilde{F}_0, \Lambda^{0,1} T^* \tilde{F}_0 \otimes N_{v_0}), \]
\[ D_{v_1} : \mathcal{H}_1(\tilde{F}_1, N_{v_1}) \to \mathcal{H}_0(\tilde{F}_1, \Lambda^{0,1} T^* \tilde{F}_1 \otimes N_{v_1}), \]
be the linearized normal operator for $v_0 : \tilde{F}_0 \to \tilde{X}_\tau$ and $v_1 : \tilde{F}_1 \to \mathbb{R} \times M_+$, where $\mathcal{H}_0$ and $\mathcal{H}_1$ are the Morrey spaces described in Section 8.3. We then write
\[ \tilde{D}_{v_0} : \mathcal{H}_0(\tilde{F}_0, N_{v_0}) \oplus \mathbb{R} \to \mathcal{H}_0(\tilde{F}_0, \Lambda^{0,1} T^* \tilde{F}_0 \otimes N_{v_0}), \]
\[ (\xi, c) \mapsto D_{v_0} \xi + cY', \]
where the generator of the summand $\mathbb{R}$ is denoted by $a$.

We first consider the case $k = 1$. We define $\text{sgn}(v_0)$ and $\text{sgn}(v_1)$ by
\[ \sigma(D_{v_0}) = [\text{sgn}(v_0)(Y')^*], \quad \sigma(D_{v_1}) = [\text{sgn}(v_1)\partial_\xi]. \]

Then, by Lemma 9.2.1,
\[ \sigma(\tilde{D}_{v_0}) = [\text{sgn}(v_0)a \otimes (Y')^*] = \text{sgn}(v_0)[1], \]
since $\tilde{D}_{v_0}$ maps $a \mapsto Y'$.

Let $\tilde{D} = \tilde{D}_{v_0} \# v_1$ be the operator obtained from pregluing $\tilde{D}_{v_0}$ and $D_{v_1}$:
\[ \tilde{D} : \mathcal{H}_1(\tilde{F}_0 \# \tilde{F}_1, N_{v_0} \# v_1) \oplus \mathbb{R} \to \mathcal{H}_0(\tilde{F}_0 \# \tilde{F}_1, \Lambda^{0,1} T^* (\tilde{F}_0 \# \tilde{F}_1) \otimes N_{v_0} \# v_1), \]
\[ (\xi, c) \mapsto D_{v_0} \# v_1 \xi + c\beta_0 Y', \]
where $\beta_0, \beta_1$ are the same as the cutoff functions $\beta_-, \beta_+$ from Section 8.1. For $i = 0, 1$ we also have maps
\[ \mathcal{H}_1(\tilde{F}_i, N_{v_1}) \to \mathcal{H}_1(\tilde{F}_0 \# \tilde{F}_1, N_{v_0} \# v_1), \]
\[ \mathcal{H}_0(\tilde{F}_i, \Lambda^{0,1} T^* \tilde{F}_i \otimes N_{v_0}) \to \mathcal{H}_0(\tilde{F}_0 \# \tilde{F}_1, \Lambda^{0,1} T^* (\tilde{F}_0 \# \tilde{F}_1) \otimes N_{v_0} \# v_1), \]
\[ \xi_0 \mapsto \xi'_0 := \beta_0 \xi_0, \quad \xi_1 \mapsto \xi'_1 := \beta_1(\xi_1) t \]
which restrict to inclusions on \( \ker D_{v_0} \) and \( \coker D_{v_0} \). Here the subscript \( T \) indicates a translation which depends on \( T \) and \( \xi^i \) is viewed as a section of the appropriate bundle. For \( \xi_i \in H_1(\hat{F}_1, N_{v_i}) \), we let \( \hat{\xi}_i \) be the \( L^2 \)-orthogonal projection of \( \xi^i \) to \( \ker \hat{D} \). By abuse of notation, let \( \partial_r \) be the pullback of \( \partial_r \) under the projection \( \pi : \mathcal{M}^0 \to [0, 1] \). If \( v_0 \cup v_1 \) is on \( \partial \mathcal{M}^0 \) such that \( \partial_r \) points away from (resp. towards) \( v_0 \cup v_1 \) and towards (resp. away from) the interior of \( \mathcal{M}^0 \), then \( \partial_r \) corresponds to \( -\partial_s \) (resp. \( \partial_s \)). By the gluing property for coherent orientations we have

\[
\sigma(\hat{D}) = \sgn(v_0) \sgn(v_1)[\hat{\partial}_s] = \sgn(v_0) \sgn(v_1)[-\partial_r]
\]

(resp. \( \sigma(\hat{D}) = \sgn(v_0) \sgn(v_1)[\partial_r] \)) and the sign \( \sgn(v_0) \sgn(v_1) \) assigned to \( v_0 \cup v_1 \) agrees with the boundary orientation of \( \mathcal{M}^0 \).

9.2.3. The case \( k > 1 \). Next we consider the case \( k > 1 \). Define \( \sgn(v_0) \) and \( \sgn(v_1) \) by

\[
\sigma(D_{v_0}) = [\sgn(v_0) \sigma^*_k \wedge \cdots \wedge \sigma^*_1], \quad \sigma(D_{v_1}) = [\sgn(v_1)e_1 \wedge \cdots \wedge e_k],
\]

where \( e_i \in \ker D_{v_i}, 1 \leq i \leq k \), corresponds to \( f_i \). Then

\[
\sigma(\hat{D}_{v_0}) = [\sgn(v_0)a \otimes \sigma^*_k \wedge \cdots \wedge \sigma^*_1] = [\sgn(v_0)\sigma^*_{k-1} \wedge \cdots \wedge \sigma^*_1].
\]

Notice that \( \sgn(v_1) \) is locally constant.

We will now define \( \sigma(\hat{D}_{v_0}) \otimes \sigma(D_{v_1}) \). Let

\[
F = \mathbb{R}\langle e'_1, \ldots, e'_k \rangle, \quad E = \mathbb{R}\langle \sigma'_1, \ldots, \sigma'_k \rangle.
\]

We are assuming that \( T \gg 0 \) so that \( D_{v_0 \# v_1} \) is an isomorphism and the composition of \( \hat{D}|_F \) and the \( L^2 \)-projection \( p : \hat{D}(F) \to E \) is also an isomorphism. Then we set \( \hat{\xi} = \xi' - D^{-1}_{v_0 \# v_1}((1 - p) \hat{D}(\xi')) \) and

\[
(9.2.1) \quad \sigma(\hat{D}_{v_0}) \otimes \sigma(D_{v_1}) := \sgn(v_0) \sgn(v_1)[\hat{e}_1 \wedge \cdots \wedge \hat{e}_k \otimes (\sigma^*_{k-1})^* \wedge \cdots \wedge (\sigma^*_1)^*],
\]

which makes sense in light of Lemma 9.2.1.

The gluing property for coherent orientations (in a slightly more general form than that of [BM]) implies:

**Lemma 9.2.2.** For \( T \gg 0 \), \( \sigma(\hat{D}) = \sigma(\hat{D}_{v_0}) \otimes \sigma(D_{v_1}) \). Hence

\[
\sigma(\hat{D}) = \sgn(v_0) \sgn(v_1)[\hat{e}_1 \wedge \cdots \wedge \hat{e}_k \otimes (\sigma^*_{k-1})^* \wedge \cdots \wedge (\sigma^*_1)^*].
\]

Let \( \tilde{D}_v \) be the operator for the glued curve \( v \), given as follows:

\[
\tilde{D}_v : H_1(\hat{F}_0 \# \hat{F}_1, N_v) \oplus \mathbb{R} \to H_0(\hat{F}_0 \# \hat{F}_1, \Lambda^0 \mathcal{M}^0\ast \hat{D}(\hat{F}_0 \# \hat{F}_1) \otimes N_v),
\]

\[
(\xi, c) \mapsto D_v \xi + c \beta_0 Y',
\]

where \( D_v \) is the linearized normal \( \partial \)-operator for \( v \). Then the analog of Lemma 9.2.2 also holds for \( \tilde{D}_v \).
9.2.4. *Comparison with signs of zeros of ds.* Next we compare \(\delta(\tilde{D}_v)\) with the
signs of zeros of \(ds\). As before we write \(\mathcal{M} = \mathcal{M}^{\text{ind}=k,\text{cyl}}(\gamma_+, \gamma'_+)\). Assume that
\(T \gg 0\) is sufficiently generic so that \(s : \{T\} \times \mathcal{M}/\mathbb{R} \to \mathcal{O}\) is transverse to the
zero section. Let \(v_1 \in s^{-1}(0)\). In Section 9.2.4 only, we write \(v_+ = v_1\) so that we
have agreement with Section 8. We orient \(T_{v_+}(\mathcal{M}/\mathbb{R})\) by
\[-[e_1 \wedge \cdots \wedge e_k \otimes \partial^*_s] = -[e_1^s \wedge \cdots \wedge e_{k-1} \wedge \partial_r \otimes \partial^*_s] = [e_1^s \wedge \cdots \wedge e_k^s],\]
where \(\partial_r\) is the outward radial vector field on \(\mathbb{R}^k\) and \(e_1^s, \ldots, e_k^s\) are tangent to
\(S^{k-1} \subset \mathbb{R}^k\) at \(ev^k(v_+)\) so that \([e_1^s \wedge \cdots \wedge e_{k-1} \wedge \partial_r] = [e_1 \wedge \cdots \wedge e_k]\), and orient
the fiber \(\mathcal{O}_{T,v_+}\) by \([\sigma_{k-1}^s \wedge \cdots \wedge \sigma_1^s]\).

**Sign of ds.** We define \(\text{sgn } ds(v_+) \in \{\pm 1\}\) as the sign of \(\det(\pi_{\mathcal{O}} \circ ds(v_+))\),
where \(\pi_{\mathcal{O}}\) is the projection to the fiber \(\mathcal{O}_{T,v_+}\).

Let
\[F^\pm = \mathbb{R} \langle (e_1^\pm, \ldots, e_{k-1}^\pm) \rangle, \quad E^\pm = \mathbb{R} \langle \sigma_1^\pm, \ldots, \sigma_{k-1}^\pm \rangle,\]
and let \(D_v^\pm : F^\pm \to E^\pm\) be the composition of \(\tilde{D}_v|_{F^\pm}\) and the \(L^2\)-projection to \(E^\pm\).
Also we orient \(F^\pm\) by \([e_1^\pm \wedge \cdots \wedge (e_{k-1}^\pm)'\] and \(E^\pm\) by \([\sigma_1^\pm \wedge \cdots \wedge \sigma_{k-1}^\pm]\); these are
analogous to the orientations for \(T_{v_+}(\mathcal{M}/\mathbb{R})\) and \(\mathcal{O}_{T,v_+}\).

**Lemma 9.2.3.** \(\text{sgn } ds(v_+) = \text{sgn } \det D_v^\pm\).

**Proof.** Using the notation from Section 8 given
\[v = \exp_{v_+}(\beta_+ \psi_+ + \beta_- \psi_-),\]
we consider \(\tilde{\mathcal{O}}_v\), which equals the left-hand side of Equation (8.2.2). Here \(\beta_0 = \beta_\pm\) and \(\beta_1 = \beta_\pm\). For a zero \(v_+\) of \(s\), there exist \((\psi_+, \psi_-, \tau)\) so that
\(\tilde{\mathcal{O}}_v v = 0\); in other words, \((\psi_+, \psi_-, \tau)\) solves Equations (8.2.6)–(8.2.8).

Consider the variation \(\beta_+ \phi_+ + \phi_- \in \ker D_v^+\). We claim that
\[(9.2.2) \quad ds(v_+)(\phi_+)(\sigma) = \left(\sigma, \tilde{D}_v(\beta_+ \phi_+ + \phi_+^\pm) + \beta_- \psi_-^\pm, \tau^\pm\right),\]
where \((\psi_+, \phi_+ + \phi_+^\pm, \psi_- + \psi_-^\pm, \tau + \tau^\pm)\) satisfy Equations (8.2.6) and (8.2.7), with
\((\psi_+, \psi_-, \tau)\) replaced by \((\psi_+ + \phi_+ + \phi_+^\pm, \psi_- + \psi_-^\pm, \tau + \tau^\pm)\), and \(\sigma \in \ker D_v^-/\mathbb{R}\langle Y\rangle\).
Although strictly speaking not necessary, we write out the left-hand side of Equation (8.2.2)
for \(v_+\)
\[v_+ = \exp_{v_+}(\beta_+(\psi_+ + \phi_+ + \phi_+^\pm) + \beta_- (\psi_- + \psi_-^\pm))\]
and \(\tau + \tau^\pm\), using the fact that \(\tilde{\mathcal{O}}_v v = 0\):
\[\beta_- \left(\frac{\partial}{\partial s}(\phi_+ + \phi_+^\pm) + \Delta R_{\gamma_+}^\prime(\psi_+ + \psi_-^\pm, \tau - \tau_0 + \tau^\pm)\right)\]
\[+ \beta_+(\frac{\partial}{\partial s}(\phi_+ + \phi_+^\pm) + \Delta R_{\gamma_+}^\prime(\psi_+ + \phi_+ + \phi_+^\pm)),\]
up to first order in $\phi_+, \psi_+, \psi_-^0, \tau^0$. Here $\Delta R'_-$ has terms of the form $B(\psi_-, \psi_-^0)$, $B(\psi_-, \tau^0)$, $B(\tau - \tau_0, \psi_-^0)$, and $B(\tau - \tau_0, \tau^0)$; and $\Delta R'_+$ has terms of the form $B(\psi_+, \phi_+ + \psi_+^0)$. By $B(r_0, r_1)$ we mean a term that is linear in $r_1$ with coefficients that are functions of $r_0$. Then, by Equations (8.2.6) and (8.2.7), $d\bar{s}(v_+)(\phi_+)$ is given by

\begin{equation}
(9.2.3)
\sigma \mapsto \left\langle \sigma, \frac{\partial \beta_+}{\partial s}(\phi_+ + \psi_+^0) + \Delta R'_-(\psi_- + \psi_-^0, \tau - \tau_0 + \tau^0) \right\rangle,
\end{equation}

whereas $\langle \sigma, \bar{D}_v(\beta_+ + \psi_+^0 + \beta_- \psi_-^0, \tau^0) \rangle$ is given by

\begin{equation}
(9.2.4)
\sigma \mapsto \left\langle \sigma, \beta_- \left( \frac{\partial \beta_+}{\partial s}(\phi_+ + \psi_+^0) + \Delta R'_-(\psi_- + \psi_-^0, \tau - \tau_0 + \tau^0) \right) \right\rangle
\end{equation}

\begin{equation}
= \left\langle \sigma, \frac{\partial \beta_+}{\partial s}(\phi_+ + \psi_+^0) + \Delta R'_-(\psi_- + \psi_-^0, \tau - \tau_0 + \tau^0) \right\rangle,
\end{equation}

since $\beta_- = 1$ on the support of $\frac{\partial \beta_+}{\partial s}$ and $\Delta R'_-$. This proves the claim.

The claim, together with Lemma [9.2.2 for $\bar{D}_v$], implies the lemma. □

9.2.5. From $ds$ to $d\bar{s}_0$. The homotopy $s_\zeta$, $\zeta \in [0, 1]$, from $s = s_1$ to $s_0$ gives an oriented cobordism from $s^{-1}(0)$ to $s_0^{-1}(0)$. In view of Lemmas 9.2.2 and 9.2.3 and the facts that $\text{sgn}(v_0)$ is fixed and $\text{sgn}(v_1)$ is locally constant, it suffices to keep track of $\text{sgn} d\bar{s}_\zeta$ as we go from $s$ to $s_0$.

Let $v_1 \in s_0^{-1}(0)$. We will determine $\text{sgn} d\bar{s}_0(v_1)$, using Equation (8.7.3). There are two cases: $v_1 = v_1^+$ or $v_1^-$, where $\hat{e}_k^\pm(v_1^\pm) = (0, \ldots, 0, \pm 1)$.

Lemma 9.2.4. $\text{sgn} d\bar{s}_0(v_1^\mp) = \mp 1$.

Proof. The tangent space $T_{v_1^\pm}(M/\mathbb{R})$ is oriented by $\pm[e_1 \wedge \cdots \wedge e_{k-1}]$. For $i = 1, \ldots, k-1$, $d\bar{s}_0(v_1^+)$ maps $e_i$ to some positive multiple of $\sigma_i^+$ by Equation (8.7.3). Hence $\text{sgn} d\bar{s}_0(v_1^+) = +1$. Similarly, $\text{sgn} d\bar{s}_0(v_1^-) = -1$. □

Let $\bar{D}_{v_0\# v_1^\pm}$ be the analog of $\bar{D}_v$ for $v_0\# v_1^\pm$, with one modification: $D_{v_0\# v_1^\pm}$ is the linearization of $\bar{D}_{\bar{\gamma}_*}(v_0\# v_1^\pm)$, where the term $F_-(\psi_-, \tau - \tau_0)$ of $\mathcal{R}_-$ is set to zero. This is analogous to changing $s$ to $s_0$.

By Lemmas 9.2.2 and 9.2.3 adapted to $\bar{D}_{v_0\# v_1^\pm}$ and Lemma 9.2.4

\begin{equation}
(9.2.5)
\sigma(\bar{D}_{v_0\# v_1^\pm}) = \text{sgn}(v_0) \text{sgn}(v_1^\pm)[\hat{e}_1 \wedge \cdots \wedge \hat{e}_k \otimes (\sigma_k')^* \wedge \cdots \wedge (\sigma_1')^*]
\end{equation}

\begin{equation}
= (-1)^{k-1} \text{sgn}(v_0) \text{sgn}(v_1^\pm)[\pm \partial_r \wedge \hat{e}_1 \wedge \cdots \wedge \hat{e}_{k-1} \otimes (\sigma_k')^* \wedge \cdots \wedge (\sigma_1')^*]
\end{equation}

\begin{equation}
= (-1)^{k-1} \text{sgn}(v_0) \text{sgn}(v_1^\pm)(\pm 1) \text{sgn} d\bar{s}_0(v_1^\pm)[\pm \partial_r]
\end{equation}

where $\partial_r$ is the radial vector field for $\mathbb{R}^k$. Note that $e_k = \partial_r$ at $(0, \ldots, 0, 1)$ and $e_k = -\partial_r$ at $(0, \ldots, 0, -1)$.
9.2.6. Orientations over $\nu$. Recall that the embedded arc $\nu \subset S^{k-1}$ is oriented from $(0, \ldots, 0, 1)$ to $(0, \ldots, 0, -1)$. Let $\tilde{\nu}$ be a connected component of $(\pi\nu^{-})^{-1}(\nu)$.

Suppose $v_1^\pm$ are the endpoints of $\tilde{\nu}$ over $(0, \ldots, 0, \pm 1)$. We can view $\tilde{\nu}$ as the continuation of the tangent vector field $-\partial_r$ at $v_1^+$ and $\partial_r$ as the continuation of $\nu$ at $v_1^-$. Since $\text{sgn}(v_0)$ is constant and $\text{sgn}(v_1^+) = \text{sgn}(v_1^-)$, the orientations of $v_0 \cup v_1^+$ and $v_0 \cup v_1^-$ that come from Equation (9.2.5) are consistent with the boundary orientation of $v_0 \cup \partial \tilde{\nu}$ (up to an overall sign), i.e., the signs are opposite.

Next consider

$$w_1 \cup w_2 \in \left(\mathcal{M}_{k-1}^1(\zeta^+, \gamma^+)/\mathbb{R} \times \mathcal{M}_{2}^{\text{ind}=1, \text{cyl}}(\gamma^+, \zeta^+)/\mathbb{R}\right) / \sim,$$

i.e., $w_1 \cup w_2$ is a boundary point of $\tilde{\nu}$ that lies over the interior of $\nu$. We define $\text{sgn}(w_1)$ by

$$\sigma(D_{w_1}) = [\text{sgn}(w_1) \sigma(N) \wedge \partial_s^1],$$

where $N$ is the normal bundle to $\nu$ inside $S^{k-1}$ and $\sigma(N)$ is (a representative of) the orientation for $N$ such that $[\sigma(N) \wedge \dot{\nu} \wedge \partial_r] = [e_1 \wedge \cdots \wedge e_k]$. Also define $\text{sgn}(w_2)$ by

$$\sigma(D_{w_2}) = [\text{sgn}(w_2) \partial_s^2].$$

Then

$$\sigma(D_{w_1 \# w_2}) = \sigma(D_{w_1}) \Phi \sigma(D_{w_2}) = \text{sgn}(w_1) \text{sgn}(w_2) [\sigma(N) \wedge \partial_s^1 \wedge \partial_s^2],$$

where $\Phi$ is defined as in the discussion after Equation (9.1.1).

If $\dot{\nu}$ points from the interior of $\tilde{\nu}$ towards $w_1 \cup w_2$, then $\partial_s^1 + \partial_s^2$ corresponds to $\partial_s^{12}$ or $-\partial_r$, and $-\partial_s^1 + \partial_s^2$ corresponds to $\dot{\nu}$. Hence

$$\sigma(D_{w_1 \# w_2}) = - \text{sgn}(w_1) \text{sgn}(w_2) [\sigma(N) \wedge \dot{\nu} \wedge \partial_s^{12}]$$

$$= - \text{sgn}(w_1) \text{sgn}(w_2) [\sigma(N) \wedge \dot{\nu} \wedge -\partial_r]$$

$$= \text{sgn}(w_1) \text{sgn}(w_2) [e_1 \wedge \cdots \wedge e_k].$$

In particular, $\text{sgn}(w_1) \text{sgn}(w_2) = \text{sgn}(v_1^\pm)$, if $v_1^\pm$ is in the same component of $\overline{\mathcal{M}}/\mathbb{R}$ as $w_1 \cup w_2$. On the other hand, if $\dot{\nu}$ points from $w_1 \cup w_2$ towards the interior of $\tilde{\nu}$, then $\partial_s^1 + \partial_s^2$ corresponds to $\partial_s^{12}$ or $-\partial_r$, and $\partial_s^1 - \partial_s^2$ corresponds to $\dot{\nu}$. Hence

$$\sigma(D_{w_1 \# w_2}) = - \text{sgn}(w_1) \text{sgn}(w_2) [\sigma(N) \wedge \dot{\nu} \wedge \partial_r]$$

$$= - \text{sgn}(w_1) \text{sgn}(w_2) [e_1 \wedge \cdots \wedge e_k].$$

In particular, $- \text{sgn}(w_1) \text{sgn}(w_2) = \text{sgn}(v_1^\pm)$, if $v_1^\pm$ is in the same component of $\overline{\mathcal{M}}/\mathbb{R}$ as $w_1 \cup w_2$. The signs of $\text{sgn}(w_1) \text{sgn}(w_2)$ in Equations (9.2.6) and (9.2.7) are opposite, as desired.

Finally, we compare the signs of Equations (9.2.6) and (9.2.7) with those of Equation (9.2.5). We contract the right-hand sides of Equations (9.2.6) and (9.2.7) with $e_{k-1}^* \wedge \cdots \wedge e_1^*$ to obtain

$$(−1)^k \text{sgn}(w_1) \text{sgn}(w_2)[−\partial_r] \quad \text{and} \quad (−1)^{k-1} \text{sgn}(w_1) \text{sgn}(w_2)[\partial_r].$$
These agree with
\[
(-1)^k \text{sgn}(v^+_1)[\partial_r] \quad \text{and} \quad (-1)^k \text{sgn}(v^-_1)[\partial_r],
\]
which are obtained from Equation (9.2.5) by dividing by \text{sgn}(v_0).

This finishes the proof of Theorem 7.1.1.
