# EQUIVARIANT EMBEDDINGS OF COMMUTATIVE LINEAR ALGEBRAIC GROUPS OF CORANK ONE 

IVAN ARZHANTSEV AND POLINA KOTENKOVA

#### Abstract

Let $\mathbb{K}$ be an algebraically closed field of characteristic zero, $\mathbb{G}_{m}=(\mathbb{K} \backslash\{0\}, \times)$ be its multiplicative group, and $\mathbb{G}_{a}=(\mathbb{K},+)$ be its additive group. Consider a commutative linear algebraic group $\mathbb{G}=\left(\mathbb{G}_{m}\right)^{r} \times \mathbb{G}_{a}$. We study equivariant $\mathbb{G}$-embeddings, i.e. normal $\mathbb{G}$-varieties $X$ containing $\mathbb{G}$ as an open orbit. We prove that $X$ is a toric variety and all such actions of $\mathbb{G}$ on $X$ correspond to Demazure roots of the fan of $X$. In these terms, the orbit structure of a $\mathbb{G}$-variety $X$ is described.

## 1. Introduction

Let $\mathbb{K}$ be an algebraically closed field of characteristic zero, $\mathbb{G}_{m}=(\mathbb{K} \backslash\{0\}, \times)$ be its multiplicative group, and $\mathbb{G}_{a}=(\mathbb{K},+)$ be its additive group. It is well known that any connected commutative linear algebraic group $\mathbb{G}$ over $\mathbb{K}$ is isomorphic to $\left(\mathbb{G}_{m}\right)^{r} \times\left(\mathbb{G}_{a}\right)^{s}$ with some non-negative integers $r$ and $s$, see [19, Theorem 15.5]. We say that $r$ is the rank of the group $\mathbb{G}$ and $s$ is the corank of $\mathbb{G}$.

The aim of this paper is to study equivariant embeddings of commutative linear algebraic groups. Let us recall that an equivariant embedding of an algebraic group $G$ is a pair ( $X, x$ ), where $X$ is an algebraic variety equipped with a regular action $G \times X \rightarrow X$ and $x \in X$ is a point with the trivial stabilizer such that the orbit $G x$ is open and dense in $X$. We assume that the variety $X$ is normal. If $X$ is supposed to be complete, we speak about equivariant compactifications of $G$. For the study of compactifications of reductive groups, see e.g. [25]. More generally, equivariant embeddings of homogeneous spaces of reductive groups is a popular object starting from early 1970th. Recent survey of results in this field may be found in [26].

Let us return to the case $\mathbb{G}=\left(\mathbb{G}_{m}\right)^{r} \times\left(\mathbb{G}_{a}\right)^{s}$. If $s=0$ then $\mathbb{G}$ is a torus and we come to the famous theory of toric varieties, see [13], [22], [17], [12]. Another extreme $r=0$ corresponds to embeddings of a commutative unipotent (=vector) group. This case is also studied actively during last decades, see [18], [8], [3], [16], [14]. The next natural step is to study the mixed case $r>0$ and $s>0$ and to combine advantages of both torus and additive group actions.

The present paper deals with the case $s=1$, i.e. from now on $\mathbb{G}$ is a connected commutative linear algebraic group of corank one. In other words, $\mathbb{G}=\left(\mathbb{G}_{m}\right)^{n-1} \times \mathbb{G}_{a}$, where $n=\operatorname{dim} X$.

Let $X$ be a toric variety with the acting torus $\mathbb{T}$. Consider an action $\mathbb{G}_{a} \times X \rightarrow X$ normalized by $\mathbb{T}$. Then $\mathbb{T}$ acts on $\mathbb{G}_{a}$ by conjugation with some character $e$. Such a character is called a Demazure root of $X$. If $T=\operatorname{Ker}(e)$, then the group $\mathbb{G}:=T \times \mathbb{G}_{a}$ acts on $X$ with an open orbit, and $X$ is a $\mathbb{G}$-embedding, see Proposition 6. Our main result (Theorem 2) states that all $\mathbb{G}$-embeddings can be realized this way. To this end we prove

[^0]that for any $\mathbb{G}$-embedding $X$ the $\left(\mathbb{G}_{m}\right)^{n-1}$-action on $X$ can be extended to an action of a bigger torus $\mathbb{T}$ which normalizes the $\mathbb{G}_{a}$-action and $X$ is toric with respect to $\mathbb{T}$.

This result can not be generalized to groups of corank two; examples of non-toric surfaces which are equivariant compactifications of $\mathbb{G}_{a}^{2}$ can be found in [14]. Similar examples are constructed in [14], [15] for semidirect products $\mathbb{G}_{m} \curlywedge \mathbb{G}_{a}$. Such groups can be considered as non-commutative groups of corank one.

If two toric varieties are isomorphic as abstract varieties, then they are isomorphic as toric varieties [10, Theorem 4.1]. This shows that the structure of a torus embedding on a toric variety is unique up to isomorphism. A structure of a $\mathbb{G}$-embedding on a given variety may be non-unique, see Examples 2, 4. Such structures are given by Demazure roots and thus the number of structures is finite if $X$ is complete, and it is at most countable for arbitrary $X$. At the same time, $\mathbb{G}_{a}^{6}$-embeddings into $\mathbb{P}^{6}$ admit a non-trivial moduli space [18, Example 3.6].

The paper is organized as follows. Section 2 contains preliminaries on torus actions on affine varieties. We recall basic facts on affine toric varieties and introduce a description of affine $T$-varieties in terms of proper polyhedral divisors due to Altmann and Hausen [1]. A correspondence between $\mathbb{G}_{a}$-actions on $X$ normalized by $T$ and homogeneous locally nilpotent derivations (LNDs) of the algebra $\mathbb{K}[X]$ is explained. We define Demazure roots of a cone and use them to describe homogeneous LNDs on $\mathbb{K}[X]$, where $X$ is toric. Also we give a description of homogeneous LNDs of horizontal type on algebras with grading of complexity one obtained by Liendo [21].

In Section 3 we show that if $X$ is a normal affine $T$-variety of complexity one and the algebra $\mathbb{K}[X]$ admits a homogeneous LND of degree zero, then $X$ is toric with an acting torus $\mathbb{T}, T$ is a subtorus of $\mathbb{T}$, and $\mathbb{T}$ normalizes the corresponding $\mathbb{G}_{a}$-action. This gives the result for affine $\mathbb{G}$-embeddings. Moreover, Proposition 3 provides an explicit description of affine $\mathbb{G}$-embeddings.

Section 4 deals with compactifications of $\mathbb{G}$. Here we use the Cox construction and a lifting of the action of $\mathbb{G}$ to the total coordinate space $\bar{X}$ of $X$ to deduce the result from the affine case.

In Section 5 we recall basic facts on toric varieties and introduce the notion of a Demazure root of a fan following Demazure [13]. The action of the corresponding one-parameter subgroup on the toric variety is also described there.

Let $\Sigma$ be a fan and $e$ be a Demazure root of $\Sigma$. In Section 6 we define a $\mathbb{G}$-embedding associated to the pair $(\Sigma, e)$ and study the $\mathbb{G}$-orbit structure of $X$. It turns out that the number of $\mathbb{G}$-orbits on $X$ is finite.

Finally, in Section 7 we prove that any $\mathbb{G}$-embedding is associated with some pair $(\Sigma, e)$. The idea is to reduce the general case to the complete one via equivariant compactification. At the end several explicit examples of $\mathbb{G}$-embeddings are given.

Some results of this paper appeared in preprint [5]. They form a part of the Ph.D. thesis of the second author [20].

## 2. $\mathbb{G}_{a}$-ACTIONS ON AFFINE $T$-varieties

Let $X$ be an irreducible affine variety with an effective action of an algebraic torus $T$, $M$ be the character lattice of $T, N$ be the lattice of one-parameter subgroups of $T$, and $A=\mathbb{K}[X]$ be the algebra of regular functions on $X$. It is well known that there is a bijective correspondence between effective $T$-actions on $X$ and effective $M$-gradings on $A$. In fact, the algebra $A$ is graded by a semigroup of lattice points in some convex polyhedral cone
$\omega \subseteq M_{\mathbb{Q}}=M \otimes_{\mathbb{Z}} \mathbb{Q}$. So we have

$$
A=\bigoplus_{m \in \omega_{M}} A_{m} \chi^{m}
$$

where $\omega_{M}=\omega \cap M$ and $\chi^{m}$ is the character corresponding to $m$.
A derivation $\partial$ on an algebra $A$ is said to be locally nilpotent (LND) if for each $f \in A$ there exists $n \in \mathbb{N}$ such that $\partial^{n}(f)=0$. For any LND $\partial$ on $A$ the map $\varphi_{\partial}: \mathbb{G}_{a} \times A \rightarrow A$, $\varphi_{\partial}(s, f)=\exp (s \partial)(f)$, defines a structure of a rational $\mathbb{G}_{a}$-algebra on $A$. In fact, any regular $\mathbb{G}_{a}$-action on $X=\operatorname{Spec} A$ arises this way. A derivation $\partial$ on $A$ is said to be homogeneous if it respects the $M$-grading. If $f, h \in A \backslash \operatorname{ker} \partial$ are homogeneous, then $\partial(f h)=f \partial(h)+\partial(f) h$ is homogeneous too and $\operatorname{deg} \partial(f)-\operatorname{deg} f=\operatorname{deg} \partial(h)-\operatorname{deg} h$. So any homogeneous derivation $\partial$ has a well defined degree given as $\operatorname{deg} \partial=\operatorname{deg} \partial(f)-\operatorname{deg} f$ for any homogeneous $f \in$ $A \backslash \operatorname{ker} \partial$. It is easy to see that an LND on $A$ is homogeneous if and only if the corresponding $\mathbb{G}_{a}$-action is normalized by the torus $T$ in the automorphism group $\operatorname{Aut}(X)$.

Any derivation on $\mathbb{K}[X]$ extends to a derivation on the field of fractions $\mathbb{K}(X)$ by the Leibniz rule. A homogeneous LND $\partial$ on $\mathbb{K}[X]$ is said to be of fiber type if $\partial\left(\mathbb{K}(X)^{T}\right)=0$ and of horizontal type otherwise. In other words, $\partial$ is of fiber type if and only if the general orbits of corresponding $\mathbb{G}_{a}$-action on $X$ are contained in the closures of $T$-orbits.

Let $X$ be an affine toric variety, i. e. a normal affine variety with a generically transitive action of a torus $T$. In this case

$$
A=\bigoplus_{m \in \omega_{M}} \mathbb{K} \chi^{m}=\mathbb{K}\left[\omega_{M}\right]
$$

is the semigroup algebra. Recall that for given cone $\omega \subset M_{\mathbb{Q}}$, its dual cone is defined by

$$
\sigma=\left\{n \in N_{\mathbb{Q}} \mid\langle n, p\rangle \geqslant 0 \forall p \in \omega\right\}
$$

where $\langle$,$\rangle is the pairing between dual lattices N$ and $M$. Let $\sigma(1)$ be the set of rays of a cone $\sigma$ and $n_{\rho}$ be the primitive lattice vector on the ray $\rho$. For $\rho \in \sigma(1)$ we set

$$
S_{\rho}:=\left\{e \in M \mid\left\langle n_{\rho}, e\right\rangle=-1 \text { and }\left\langle n_{\rho^{\prime}}, e\right\rangle \geqslant 0 \quad \forall \rho^{\prime} \in \sigma(1), \rho^{\prime} \neq \rho\right\} .
$$

One easily checks that the set $S_{\rho}$ is infinite for each $\rho \in \sigma(1)$. The elements of the set $\mathfrak{R}:=\bigsqcup_{\rho} S_{\rho}$ are called the Demazure roots of $\sigma$. Let $e \in S_{\rho}$. Then $\rho$ is called the distinguished ray of the root $e$. One can define the homogeneous LND on the algebra $A$ by the rule

$$
\partial_{e}\left(\chi^{m}\right)=\left\langle n_{\rho}, m\right\rangle \chi^{m+e} .
$$

In fact, every homogeneous LND on $A$ has a form $\alpha \partial_{e}$ for some $\alpha \in \mathbb{K}, e \in \mathfrak{R}$, see [21, Theorem 2.7]. In other words, $\mathbb{G}_{a}$-actions on $X$ normalized by the acting torus are in bijection with Demazure roots of the cone $\sigma$.

Clearly, all homogeneous LNDs on a toric variety are of fiber type.
Example 1. Consider $X=\mathbb{A}^{k}$ with the standard action of the torus $\left(\mathbb{K}^{\times}\right)^{k}$. It is a toric variety with the cone $\sigma=\mathbb{Q}_{\geqslant 0}^{k}$ having rays $\rho_{1}=\langle(1,0, \ldots, 0)\rangle_{\mathbb{Q}_{\geqslant 0}}, \ldots, \rho_{k}=\langle(0,0, \ldots, 0,1)\rangle_{\mathbb{Q}_{\geqslant 0}}$. The dual cone $\omega$ is $\mathbb{Q}_{\geqslant 0}^{k}$ as well. In this case

$$
S_{\rho_{i}}=\left\{\left(c_{1}, \ldots, c_{i-1},-1, c_{i+1}, \ldots, c_{k}\right) \mid c_{j} \in \mathbb{Z}_{\geqslant 0}\right\} .
$$

Denote $x_{1}=\chi^{(1,0, \ldots, 0)}, \ldots, x_{k}=\chi^{(0, \ldots, 0,1)}$. Then $\mathbb{K}[X]=\mathbb{K}\left[x_{1}, \ldots, x_{k}\right]$. It is easy to see that the homogeneous LND corresponding to the root $e=\left(c_{1}, \ldots, c_{k}\right) \in S_{\rho_{i}}$ is

$$
\partial_{e}=x_{1}^{c_{1}} \ldots x_{i-1}^{c_{i-1}} x_{i+1}^{c_{i+1}} \ldots x_{k}^{c_{k}} \frac{\partial}{\partial x_{i}}
$$

This LND gives rise to the $\mathbb{G}_{a}$-action

$$
x_{i} \mapsto x_{i}+s x_{1}^{c_{1}} \ldots x_{i-1}^{c_{i-1}} x_{i+1}^{c_{i+1}} \ldots x_{k}^{c_{k}}, \quad x_{j} \mapsto x_{j}, \quad j \neq i, \quad s \in \mathbb{G}_{a} .
$$

Let us recall that the complexity of an action of a torus $T$ on an irreducible variety $X$ is the codimension of a general $T$-orbit on $X$, or, equivalently, the transcendence degree of the field of rational invariants $\mathbb{K}(X)^{T}$ over $\mathbb{K}$. In particular, actions of complexity zero are precisely actions with an open $T$-orbit.

Now we recall a description of normal affine $T$-varieties of complexity one in terms of proper polyhedral divisors. Let $N$ and $M$ be two mutually dual lattices with the pairing denoted by $\langle\rangle,, \sigma$ be a strongly convex cone in $N_{\mathbb{Q}}$, and $\omega \subseteq M_{\mathbb{Q}}$ be the dual cone. A polyhedron $\Delta \subseteq N_{\mathbb{Q}}$, which can be decomposed as Minkowski sum of a bounded polyhedron and the cone $\sigma$, is called $\sigma$-tailed. Let $C$ be a smooth curve. A $\sigma$-polyhedral divisor on $C$ is a formal sum

$$
\mathfrak{D}=\sum_{z \in C} \Delta_{z} \cdot z,
$$

where $\Delta_{z}$ are the $\sigma$-tailed polyhedra and only finite number of them are not equal to $\sigma$. The divisor $\mathfrak{D}$ is trivial, if $\Delta_{z}=\sigma$ for all $z \in C$.

The finite set Supp $\mathfrak{D}:=\left\{z \in C \mid \Delta_{z} \neq \sigma\right\}$ is called the support of $\mathfrak{D}$. For every $m \in \omega_{M}$ we can obtain the $\mathbb{Q}$-divisor $\mathfrak{D}(m)=\sum_{z \in C} h_{z}(m) \cdot z$, where $h_{z}(m):=\min _{p \in \Delta_{z}}\langle p, m\rangle$. So a $\sigma$ polyhedral divisor is just a piecewise-linear function from $\omega_{M}$ to the group of $\mathbb{Q}$-divisors on $C$. One can define the $M$-graded algebra

$$
A[C, \mathfrak{D}]=\bigoplus_{m \in \omega_{M}} A_{m} \chi^{m}, \text { where } A_{m}=H^{0}(C, \mathfrak{D}(m)):=\{f \in \mathbb{K}(X) \mid \operatorname{div} f+\mathfrak{D}(m) \geqslant 0\}
$$

where the multiplication of homogeneous elements is given as in $\mathbb{K}(X)$.
A $\sigma$-polyhedral divisor on smooth curve $C$ is called proper if either $C$ is affine, or $C$ is projective and the polyhedron $\operatorname{deg} \mathfrak{D}:=\sum_{z \in C} \Delta_{z}$ is a proper subset of $\sigma$.

The next theorem expresses the main results of [1] specialized to the case of torus actions of complexity one.

Theorem 1. (1) Let $C$ be a smooth curve and $\mathfrak{D}$ a proper $\sigma$-polyhedral divisor on $C$. Then the $M$-graded algebra $A[C, \mathfrak{D}]$ is a normal finitely generated effectively graded (rk $M+1$ )-dimensional domain. Conversely, for each normal finitely generated domain A with a grading of complexity one there exist a smooth curve $C$ and a proper $\sigma$-polyhedral divisor $\mathfrak{D}$ on $C$ such that $A$ is isomorphic to $A[C, \mathfrak{D}]$.
(2) The $M$-graded domains $\operatorname{Spec} A[C, \mathfrak{D}]$ and $\operatorname{Spec} A\left[C, \mathfrak{D}^{\prime}\right]$ are isomorphic if and only if for every $z \in C$ there exists a lattice vector $v_{z} \in N$ such that

$$
\mathfrak{D}=\mathfrak{D}^{\prime}+\sum_{z}\left(v_{z}+\sigma\right) \cdot z,
$$

and for all $m \in \omega_{M}$ the divisor $\sum_{z}\left\langle v_{z}, m\right\rangle \cdot z$ is principal.
The following result is obtained in [1, Section 11].
Proposition 1. Let $\mathfrak{D}$ be a proper $\sigma$-polyhedral divisor on a smooth curve $C, X=$ Spec $A[C, \mathfrak{D}]$, and $T \times X \rightarrow X$ be the corresponding torus action. Then this action can be realized as a subtorus action an a toric variety if and only if either $C=\mathbb{A}^{1}$ and $\mathfrak{D}$ can be chosen supported in at most one point, or $C=\mathbb{P}^{1}$ and $\mathfrak{D}$ can be chosen supported in at most two points.

Also we need a description of homogeneous LNDs of horizontal type for a $T$-variety $X$ of complexity one from [21]. Below we follow the approach given in [7]. We have $\mathbb{K}[X]=A[C, \mathfrak{D}]$ for some $C$ and $\mathfrak{D}$. It turns out that $C$ is isomorphic to $\mathbb{A}^{1}$ or $\mathbb{P}^{1}$ whenever there exists a homogeneous LND of horizontal type on $A[C, \mathfrak{D}]$, see [21, Lemma 3.15].

Let $C$ be $\mathbb{A}^{1}$ or $\mathbb{P}^{1}, \mathfrak{D}=\sum_{z \in C} \Delta_{z} \cdot z$ a $\sigma$-polyhedral divisor on $C, z_{0} \in C, z_{\infty} \in C \backslash\left\{z_{0}\right\}$, and $v_{z}$ a vertex of $\Delta_{z}$ for every $z \in C$. Put $C^{\prime}=C$ if $C=\mathbb{A}^{1}$ and $C^{\prime}=C \backslash\left\{z_{\infty}\right\}$ if $C=\mathbb{P}^{1}$. A collection $\widetilde{\mathfrak{D}}=\left\{\mathfrak{D}, z_{0} ; v_{z}, \forall z \in C\right\}$ if $C=\mathbb{A}^{1}$ and $\widetilde{\mathfrak{D}}=\left\{\mathfrak{D}, z_{0}, z_{\infty} ; v_{z}, \forall z \in C^{\prime}\right\}$ if $C=\mathbb{P}^{1}$ is called a colored $\sigma$-polyhedral divisor on $C$ if the following conditions hold:
$(*) v_{\mathrm{deg}}:=\sum_{z \in C^{\prime}} v_{z}$ is a vertex of $\left.\operatorname{deg} \mathfrak{D}\right|_{C^{\prime}}:=\sum_{z \in C^{\prime}} \Delta_{z} ;$
$(* *) v_{z} \in N$ for all $z \in C^{\prime}, z \neq z_{0}$.
Let $\widetilde{\mathfrak{D}}$ be a colored $\sigma$-polyhedral divisor on $C$ and $\delta \subseteq N_{\mathbb{Q}}$ be the cone generated by $\left.\operatorname{deg} \mathfrak{D}\right|_{C^{\prime}}-v_{\operatorname{deg}}$. Denote by $\widetilde{\sigma} \subseteq(N \oplus \mathbb{Z})_{\mathbb{Q}}$ the cone generated by $(\delta, 0)$ and $\left(v_{z_{0}}, 1\right)$ if $C=\mathbb{A}^{1}$, and by $(\delta, 0),\left(v_{z_{0}}, 1\right)$ and $\left(\Delta_{z_{\infty}}+v_{\text {deg }}-v_{z_{0}}+\delta,-1\right)$ if $C=\mathbb{P}^{1}$. By definition, put $d$ the minimal positive integer such that $d \cdot v_{z_{0}} \in N$. A pair ( $\left.\widetilde{\mathfrak{D}}, e\right)$, where $e \in M$, is said to be coherent if
(i) there exists $s \in \mathbb{Z}$ such that $\widetilde{e}=(e, s) \in M \oplus \mathbb{Z}$ is a Demazure root of the cone $\widetilde{\sigma}$ with distinguished ray $\widetilde{\rho}=\left(d \cdot v_{z_{0}}, d\right)$;
(ii) $\langle v, e\rangle \geqslant 1+\left\langle v_{z}, e\right\rangle$ for all $z \in C^{\prime} \backslash\left\{z_{0}\right\}$ and all vertices $v \neq v_{z}$ of the polyhedron $\Delta_{z}$;
(iii) $d \cdot\langle v, e\rangle \geqslant 1+\left\langle v_{z_{0}}, e\right\rangle$ for all vertices $v \neq v_{z_{0}}$ of the polyhedron $\Delta_{z_{0}}$;
(iv) if $Y=\mathbb{P}^{1}$, then $d \cdot\langle v, e\rangle \geqslant-1-d \cdot \sum_{z \in Y^{\prime}}\left\langle v_{z}, e\right\rangle$ for all vertices $v$ of the polyhedron $\Delta_{z_{\infty}}$.

It follows from [7, Theorem 1.10] that homogeneous LNDs of horizontal type on $A[C, \mathfrak{D}]$ are in bijection with the coherent pairs ( $\widetilde{\mathfrak{D}}, e)$. Namely, let $(\widetilde{\mathfrak{D}}, e)$ be a coherent pair. Without loss of generality we may assume that $z_{0}=0, z_{\infty}=\infty$ if $C=\mathbb{P}^{1}$, and $v_{z}=0 \in N$ for all $z \in C^{\prime} \backslash\left\{z_{0}\right\}$. Let $\mathbb{K}(C)=\mathbb{K}(t)$. Then the homogeneous LND of horizontal type corresponding to $(\widetilde{\mathfrak{D}}, e)$ is given by

$$
\begin{equation*}
\partial\left(\chi^{m} \cdot t^{r}\right)=d\left(\left\langle v_{0}, m\right\rangle+r\right) \chi^{m+e} \cdot t^{r+s} \quad \text { for all } m \in M, r \in \mathbb{Z} \tag{1}
\end{equation*}
$$

In particular, the vector $e$ is the degree of the derivation $\partial$.

## 3. The AFFINE CASE

Let $(X, x)$ be an equivariant embedding of the group $\mathbb{G}=\left(\mathbb{G}_{m}\right)^{n-1} \times \mathbb{G}_{a}$, where $n=$ $\operatorname{dim} X$. In this section we assume that $X$ is normal and affine. Let us denote the subgroup $\left(\mathbb{G}_{m}\right)^{n-1}$ of $\mathbb{G}$ by $T$. Since the action of $T$ on $X$ is effective, it has compelxity one and defines an effective grading of the algebra $\mathbb{K}[X]$ by the lattice $M$. In particular, the graded algebra $\mathbb{K}[X]$ has the form $A[C, \mathfrak{D}]$ for some smooth curve $C$ and some proper $\sigma$-polyhedral divisor on $C$, where $\sigma$ is a cone in $N_{\mathbb{Q}}$.

Since the action of the subgroup $\mathbb{G}_{a}$ commutes with $T$-action on $X$, the corresponding homogeneous LND on $\mathbb{K}[X]$ has degree zero. Moreover, the group $\mathbb{G}$ acts on $X$ with an open orbit. It implies that the $\mathbb{G}_{a}$-action on $X$ is of horizontal type, and hence either $C=\mathbb{A}^{1}$ or $C=\mathbb{P}^{1}$.
Proposition 2. Let $X=\operatorname{Spec} A[C, \mathfrak{D}]$ be a T-variety of complexity one. Suppose that there exists a homogeneous LND of horizontal type and of degree zero on $A[C, \mathfrak{D}]$. Then
(1) if $C=\mathbb{A}^{1}$, then one can assume (via Theorem 1) that $\mathfrak{D}$ is a trivial $\sigma$-polyhedral divisor;
(2) if $C=\mathbb{P}^{1}$, then one can choose $\mathfrak{D}=\Delta_{\infty} \cdot[\infty]$, where $\Delta_{\infty} \nsubseteq \sigma$ is some $\sigma$-tailed polyhedron.
Proof. Let $(\widetilde{\mathfrak{D}}, 0)$ be the coherent pair corresponding to the homogeneous LND of horizontal type. Without loss of generality we may assume that $z_{0}=0$ and $z_{\infty}=\infty$ if $C=\mathbb{P}^{1}$. By definition of a coherent pair, there exists $s \in \mathbb{Z}$ such that $(0, s)$ is a Demazure root of the cone $\widetilde{\sigma}$ with distinguished ray $\left(d v_{0}, d\right)$. It implies that $s=-1, d=1$, and hence $v_{0} \in N$. Further, the inequality $\langle v, 0\rangle \geqslant 1+\left\langle v_{z}, 0\right\rangle$ should be satisfied for every $z \in C^{\prime}$ and every vertex $v \neq v_{z}$ of $\Delta_{z}$. It means that each polyhedron $\Delta_{z}$, where $z \in C^{\prime}$, has only one vertex $v_{z}$. Replacing $\sigma$-polyhedral divisor $\mathfrak{D}$ with $\mathfrak{D}^{\prime}=\mathfrak{D}+\sum_{z \in C^{\prime}}\left(-v_{z}+\sigma\right) \cdot z$ and using Theorem 1, we obtain the assertion. The condition $\Delta_{\infty} \nsubseteq \sigma$ follows from the fact that $\mathfrak{D}$ is a proper $\sigma$-polyhedral divisor.

Corollary 1. Under the conditions of Proposition 2 the variety $X$ is toric with $T$ being a subtorus of the action torus $\mathbb{T}$.

Proof. It follows immediately from Propositions 1 and 2.
The next proposition is a specification of Corollary 1. In particular, it shows that the $\mathbb{G}_{a}$-action on $X$ is normalized by the acting torus $\mathbb{T}$.
Proposition 3. Under the conditions of Proposition 2,
(1) if $C=\mathbb{A}^{1}$, then $X \cong Y \times \mathbb{A}^{1}$, where $Y$ is the toric variety corresponding to the cone $\sigma$ and $\mathbb{G}_{a}$ acts on $\mathbb{A}^{1}$ by translations;
(2) if $C=\mathbb{P}^{1}$, then $X$ is the toric variety with the cone $\widetilde{\sigma} \subset N \oplus \mathbb{Z}$ generated by $(\sigma, 0),\left(\Delta_{\infty},-1\right)$ and $(0,1)$. The $\mathbb{G}_{a}$-action on $X$ is given by Demazure root $\widetilde{e}=$ $(0,-1) \in M \oplus \mathbb{Z}$ of the cone $\widetilde{\sigma}$.
Proof. Let $\mathbb{K}(C)=\mathbb{K}(t)$. If $C=\mathbb{A}^{1}$ then $\mathfrak{D}$ is trivial and

$$
A[C, \mathfrak{D}]=\bigoplus_{m \in \omega_{M}} \mathbb{K}[t] \cdot \chi^{m}=\mathbb{K}\left[\omega_{M}\right] \otimes \mathbb{K}[t]=\mathbb{K}[Y] \otimes \mathbb{K}[t]
$$

Hence $X \cong Y \times \mathbb{A}^{1}$. Applying formula (1), we obtain that the homogeneous LND is given by

$$
\begin{equation*}
\partial\left(\chi^{m} \cdot t^{r}\right)=r \chi^{m} \cdot t^{r-1} \tag{2}
\end{equation*}
$$

for all $m \in \omega_{M}$ and $r \in \mathbb{Z}_{\geqslant 0}$. Thus $\mathbb{G}_{a}$ acts on $Y \times \mathbb{A}^{1}$ as $(y, t) \mapsto(y, t+s)$.
If $C=\mathbb{P}^{1}$ then $\mathfrak{D}=\Delta_{\infty} \cdot[\infty]$ and we obtain

$$
A[C, \mathfrak{D}]=\bigoplus_{m \in \omega_{M}} \bigoplus_{r=0}^{h_{\infty}(m)} \mathbb{K} \chi^{m} \cdot t^{r}=\bigoplus_{(m, r) \in \widetilde{\omega}_{\widetilde{M}}} \mathbb{K} \chi^{m} \cdot t^{r}=\mathbb{K}\left[\widetilde{\omega}_{\widetilde{M}}\right]
$$

where $\widetilde{M}=M \oplus \mathbb{Z}$ and $\widetilde{\omega} \subset \widetilde{M}_{\mathbb{Q}}$ is the cone dual to $\widetilde{\sigma}$. So we see that $A[C, \mathfrak{D}]$ is a semigroup algebra and $X$ is a toric variety with the cone $\widetilde{\sigma}$. In this case formula (2) gives the LND corresponding to the Demazure root $\widetilde{e}=(0,-1)$.

## 4. The complete case

In this section we study equivariant compactifications of the group $\mathbb{G}$. First we briefly recall the main ingredients of the Cox construction, see [4, Chapter 1] for more details.

Let $X$ be a normal variety with finitely generated divisor class group $\mathrm{Cl}(X)$ and only constant invertible regular functions.

Suppose that $\mathrm{Cl}(X)$ is free. Denote by $\operatorname{WDiv}(X)$ the group of Weil divisors on $X$ and fix a subgroup $K \subseteq \operatorname{WDiv}(X)$ which maps onto $\operatorname{Cl}(X)$ isomorphically. The Cox ring of the variety $X$ is defined as

$$
R(X)=\bigoplus_{D \in K} H^{0}(X, D)
$$

where $H^{0}(X, D)=\{f \in \mathbb{K}(X) \mid \operatorname{div} f+D \geqslant 0\}$ and multiplication on homogeneous components coincides with multiplication in $\mathbb{K}(X)$ and extends to $R(X)$ by linearity.

If $\mathrm{Cl}(X)$ has torsion, we choose finitely generated subgroup $K \subseteq \mathrm{WDiv}(X)$ that projects to $\mathrm{Cl}(X)$ surjectively. Denote by $K_{0} \subset K$ the kernel of this projection. Take compatible bases $D_{1}, \ldots, D_{s}$ and $D_{1}^{0}=d_{1} D_{1}, \ldots, D_{r}^{0}=d_{r} D_{r}$ in $K$ and $K_{0}$ respectively. Let us choose the set of rational functions $\mathcal{F}=\left\{F_{D} \in \mathbb{K}(X)^{\times}: D \in K_{0}\right\}$ such that $\operatorname{div}\left(F_{D}\right)=D$ and $F_{D+D^{\prime}}=F_{D} F_{D^{\prime}}$. Suppose that $D, D^{\prime} \in K$ and $D-D^{\prime} \in K_{0}$. A map $f \mapsto F_{D-D^{\prime}} f$ is an isomorphism of the vector spaces $H^{0}(X, D)$ and $H^{0}\left(X, D^{\prime}\right)$. The linear span of the elements $f-F_{D-D^{\prime}} f$ over all $D, D^{\prime}$ with $D-D^{\prime} \in K_{0}$ and all $f \in H^{0}(X, D)$ is an ideal $I(K, \mathcal{F})$ of the graded ring $T_{K}(X):=\bigoplus_{D \in K} H^{0}(X, D)$. The Cox ring of the variety $X$ is given by

$$
R(X)=T_{K}(X) / I(K, \mathcal{F})
$$

This construction does not depend on the choice of $K$ and $\mathcal{F}$, see [2, Lemma 3.1 and Proposition 3.2].

Suppose that the Cox ring $R(X)$ is finitely generated. Then $\bar{X}:=\operatorname{Spec} R(X)$ is a normal affine variety with an action of the quasitorus $H_{X}:=\operatorname{Spec} \mathbb{K}[\mathrm{Cl}(X)]$. There is an open $H_{X}$-invariant subset $\widehat{X} \subseteq \bar{X}$ such that the complement $\bar{X} \backslash \widehat{X}$ is of codimension at least two in $\bar{X}$, there exists a good quotient $p_{X}: \widehat{X} \rightarrow \widehat{X} / / H_{X}$, and the quotient space $\widehat{X} / / H_{X}$ is isomorphic to $X$. So we have the following diagram

$$
\begin{aligned}
& \widehat{X} \xrightarrow{i} \bar{X}=\operatorname{Spec} R(X) \\
& \downarrow^{/ / / H_{X}} \\
& X
\end{aligned}
$$

Let us return to equivariant compactifications of $\mathbb{G}$.

Proposition 4. Let $\mathbb{G}=T \times \mathbb{G}_{a}$ and $X$ be a normal compactification of $\mathbb{G}$. Then the $T$-action on $X$ can be extended to an action of a bigger torus $\mathbb{T}$ such that $\mathbb{T}$ normalizes $\mathbb{G}_{a}$ and $X$ is a toric variety with the acting torus $\mathbb{T}$.

Proof. The variety $X$ is rational with torus action of complexity one. By [4, Theorem 4.3.1.5], the divisor class group $\mathrm{Cl}(X)$ and the Cox ring $R(X)$ are finitely generated.

There exists a finite epimorphism $\epsilon: \mathbb{G}^{\prime} \rightarrow \mathbb{G}$ of connected linear algebraic groups and an action $\mathbb{G}^{\prime} \times \widehat{X} \rightarrow \widehat{X}$ which commutes with the quasitorus $H_{X}$ and $p_{X}\left(g^{\prime} \cdot \widetilde{x}\right)=\epsilon\left(g^{\prime}\right) \cdot p_{X}(\widetilde{x})$ for all $g^{\prime} \in \mathbb{G}^{\prime}$ and $\widetilde{x} \in \widetilde{X}$, see [4, Theorem 4.2.3.1]. The group $\mathbb{G}^{\prime}$ has a form $T^{\prime} \times \mathbb{G}_{a}$, where $\epsilon$ defines a finite epimorphism of tori $T^{\prime} \rightarrow T$ and is identical on $\mathbb{G}_{a}$.

Since $\bar{X}=\operatorname{Spec} \mathbb{K}[\widehat{X}]$, the action of $\mathbb{G}^{\prime}$ extends to the affine variety $\bar{X}$. This variety is an embedding of the group $\left(T^{\prime} H_{X}^{0}\right) \times \mathbb{G}_{a}$. By Proposition 3 , it is toric with an acting torus $\overline{\mathbb{T}}$ normalizing the $\mathbb{G}_{a}$-action and $T^{\prime} H_{X}^{0}$ is a subtorus of $\overline{\mathbb{T}}$. Since $X$ is complete, [24, Corollary 2.5] implies that the subset $\widetilde{X}$ is invariant under the torus $\overline{\mathbb{T}}$. By [4, Lemma 4.2.1.3], the action of $\overline{\mathbb{T}}$ descends to an action of the torus $\mathbb{T}:=\overline{\mathbb{T}} / H_{X}^{0}$ on $X$. Here $\mathbb{T}$ normalizes $\mathbb{G}_{a}$, its action extends the action of $T$ on $X$, and $X$ is toric with respect to $\mathbb{T}$.

## 5. Toric varieties and Demazure roots

We keep notations of Section 2. Let $X$ be a toric variety of dimension $n$ with an acting torus $\mathbb{T}$ and $\Sigma$ be the corresponding fan of convex polyhedral cones in the space $N_{\mathbb{Q}}$, see [17] or [12] for details.

As before, let $\Sigma(1)$ be the set of rays of the fan $\Sigma$ and $n_{\rho}$ be the primitive lattice vector on the ray $\rho$. For $\rho \in \Sigma(1)$ we consider the set $S_{\rho}$ of all vectors $e \in M$ such that
(1) $\left\langle n_{\rho}, e\right\rangle=-1$ and $\left\langle n_{\rho^{\prime}}, e\right\rangle \geqslant 0 \quad \forall \rho^{\prime} \in \sigma(1), \rho^{\prime} \neq \rho$;
(2) if $\sigma$ is a cone of $\Sigma$ and $\langle v, e\rangle=0$ for all $v \in \sigma$, then the cone generated by $\sigma$ and $\rho$ is in $\Sigma$ as well.
Note that condition (1) implies condition (2) if $\Sigma$ is a maximal fan with support $|\Sigma|$. This is the case if $X$ is affine or complete.

The elements of the set $\mathfrak{R}:=\bigsqcup_{\rho} S_{\rho}$ are called the Demazure roots of the fan $\Sigma$, cf. [13, Definition 4] and [22, Section 3.4]. Again elements $e \in \mathfrak{R}$ are in bijections with $\mathbb{G}_{a}$-actions on $X$ normalized by the acting torus. Let us denote the corresponding one-parameter subgroup of $\operatorname{Aut}(X)$ by $H_{e}$.

We recall basic facts from toric geometry. There is a bijection between cones $\sigma \in \Sigma$ and $\mathbb{T}$-orbits $\mathcal{O}_{\sigma}$ on $X$ such that $\sigma_{1} \subseteq \sigma_{2}$ if and only if $\mathcal{O}_{\sigma_{2}} \subseteq \overline{\mathcal{O}_{\sigma_{1}}}$. Here $\operatorname{dim} \mathcal{O}_{\sigma}=n-\operatorname{dim}\langle\sigma\rangle$. Moreover, each cone $\sigma \in \Sigma$ defines an open affine $\mathbb{T}$-invariant subset $U_{\sigma}$ on $X$ such that $\mathcal{O}_{\sigma}$ is a unique closed $\mathbb{T}$-orbit on $U_{\sigma}$ and $\sigma_{1} \subseteq \sigma_{2}$ if and only if $U_{\sigma_{1}} \subseteq U_{\sigma_{2}}$.

Let $\rho_{e}$ be the distinguished ray corresponding to a root $e, n_{e}$ be the primitive lattice vector on $\rho_{e}$, and $R_{e}$ be the one-parameter subgroup of $\mathbb{T}$ corresponding to $n_{e}$.

Our aim is to describe the action of $H_{e}$ on $X$.
Proposition 5. For every point $x \in X \backslash X^{H_{e}}$ the orbit $H_{e} x$ meets exactly two $\mathbb{T}$-orbits $\mathcal{O}_{1}$ and $\mathcal{O}_{2}$ on $X$, where $\operatorname{dim} \mathcal{O}_{1}=\operatorname{dim} \mathcal{O}_{2}+1$. The intersection $\mathcal{O}_{2} \cap H_{e} x$ consists of a single point, while

$$
\mathcal{O}_{1} \cap H_{e} x=R_{e} y \quad \text { for any } \quad y \in \mathcal{O}_{1} \cap H_{e} x
$$

Proof. It follows from the proof of [22, Proposition 3.14] that the affine charts $U_{\sigma}$, where $\sigma \in \Sigma$ is a cone containing $\rho_{e}$, are $H_{e}$-invariant, and the complement of their union is
contained in $X^{H_{e}}$, cf. [9, Lemma 2.4]. This reduces the proof to the case $X$ is affine. Then the assertion is proved in [6, Proposition 2.1].

A pair of $\mathbb{T}$-orbits $\left(\mathcal{O}_{1}, \mathcal{O}_{2}\right)$ on $X$ is said to be $H_{e}$-connected if $H_{e} x \subseteq \mathcal{O}_{1} \cup \mathcal{O}_{2}$ for some $x \in X \backslash X^{H_{e}}$. By Proposition $5, \mathcal{O}_{2} \subseteq \overline{\mathcal{O}_{1}}$ for such a pair (up to permutation) and $\operatorname{dim} \mathcal{O}_{2}=\operatorname{dim} \mathcal{O}_{1}+1$. Since the torus normalizes the subgroup $H_{e}$, any point of $\mathcal{O}_{1} \cup \mathcal{O}_{2}$ can actually serve as a point $x$.

Lemma 1. A pair of $\mathbb{T}$-orbits $\left(\mathcal{O}_{\sigma_{1}}, \mathcal{O}_{\sigma_{2}}\right)$ is $H_{e}$-connected if and only if e $\left.\right|_{\sigma_{2}} \leq 0$ and $\sigma_{1}$ is a facet of $\sigma_{2}$ given by the equation $\langle v, e\rangle=0$.
Proof. The proof again reduces to the affine case, where the assertion is [6, Lemma 2.2].

## 6. The orbit structure

We keep notations of the previous section. Let us begin with a construction mentioned in the Introduction. Let $X$ be a toric variety with the acting torus $\mathbb{T}$. Consider a non-trivial action $\mathbb{G}_{a} \times X \rightarrow X$ normalized by $\mathbb{T}$ and thus represented by a Demazure root $e$ of the fan $\Sigma$ of $X$. Then $\mathbb{T}$ acts on $\mathbb{G}_{a}$ by conjugation with the character $e$ and the semidirect product $\mathbb{T} \curlywedge \mathbb{G}_{a}$ acts on $X$ as well. Let $T=\operatorname{Ker}(e) \subseteq \mathbb{T}$ and consider the group $\mathbb{G}:=T \times \mathbb{G}_{a}$.
Proposition 6. The variety $X$ is an embedding of $\mathbb{G}$.
Proof. Take a point $x \in X$ whose stabilizers in $\mathbb{T}$ and $\mathbb{G}_{a}$ are trivial. It suffices to show that the stabilizer of $x$ in $\mathbb{G}$ is trivial. To this end, note that by the Jordan decomposition [19, Theorem 15.3] any subgroup of $T \times \mathbb{G}_{a}$ is a product of subgroups in $T$ and $\mathbb{G}_{a}$ respectively.

Remark 1. The $\mathbb{G}$-embedding of Proposition 6 is defined by the pair $(\Sigma, e)$.
Since $\left\langle n_{e}, e\right\rangle=-1$, we have $\mathbb{T}=T \times R_{e}$.
Lemma 2. Any $\left(T \times \mathbb{G}_{a}\right)$-invariant subset in $X$ is also $\mathbb{T}$-invariant.
Proof. Note that an orbit $\mathbb{T} x$ does not coincide with the orbit $T x$ if and only if the stabilizer of $x$ in $\mathbb{T}$ is contained in $T$. For $x \in \mathcal{O}_{\sigma}$ this condition is equivalent to $\left.e\right|_{\sigma}=0$. It shows that for every $x \in X^{\mathbb{G}_{a}}$ we have $\mathbb{T} x=T x$. If $x \in X \backslash X^{\mathbb{G}_{a}}$, then by Proposition 5 the orbit $\mathbb{G}_{a} x$ is invariant under $R_{e}$. This proves that any orbit of $\left(T \times \mathbb{G}_{a}\right)$ is $R_{e^{-}}$and $\mathbb{T}$-invariant, thus the assertion.

Proposition 7. Let $X$ be a $\mathbb{G}$-embedding given by a pair $(\Sigma, e)$. Then any $\mathbb{G}$-orbit on $X$ is either a union $\mathcal{O}_{1} \cup \mathcal{O}_{2}$ of two $\mathbb{T}$-orbits on $X$ or a unique $\mathbb{T}$-orbit; the first possibility occurs if and only if the pair $\left(\mathcal{O}_{1}, \mathcal{O}_{2}\right)$ is $H_{e}$-connected. In particular, the number of $\mathbb{G}$-orbits on $X$ is finite.

Proof. The assertion follows directly from Lemma 2 and Proposition 5.
Proposition 8. Let $X$ be a $\mathbb{G}$-embedding given by a pair $(\Sigma, e)$. Then the stabilizer of any point $x \in X$ in $\mathbb{G}$ is connected and the closure of any $\mathbb{G}$-orbit on $X$ is a (normal) toric variety. If $X$ is smooth, then the closure of any $\mathbb{G}$-orbit is smooth.

Proof. The stabilizer of a point $x$ in $\mathbb{G}$ is the direct product of stabilizers in $T$ and in $\mathbb{G}_{a}$. An algebraic subgroup of $\mathbb{G}_{a}$ is either $\{0\}$ or $\mathbb{G}_{a}$ itself, while the stabilizer in $T$ is the kernel of the (primitive) character $e$ restricted to the (connected) stabilizer of $x$ in $\mathbb{T}$. Thus the stabilizer of $x$ in $\mathbb{G}$ is connected.

Proposition 7 shows that any $\mathbb{G}$-orbit on $X$ contains an open $\mathbb{T}$-orbit, and thus the closure of a $\mathbb{G}$-orbit coincides with the closure of some $\mathbb{T}$-orbit. Now the last two assertions follow from [17, Section 3.1].
Remark 2. If $X$ contains $l$ torus invariant prime divisors, then the number of $\mathbb{G}$-invariant prime divisors on $X$ is $l-1$. On a toric variety, the closure of any torus orbit is an intersection of torus invariant prime divisors. In contrast, not every $\mathbb{G}$-orbit closure on $X$ is an intersection of $\mathbb{G}$-invariant prime divisors, see Example 3.

## 7. The general case

We are going to show that every $\mathbb{G}$-embedding can be realized as in Proposition 6.
Theorem 2. Let $\mathbb{G}=T \times \mathbb{G}_{a}$ and $X$ be a normal equivariant $\mathbb{G}$-embedding. Then the $T$-action on $X$ can be extended to an action of a bigger torus $\mathbb{T}$ such that $\mathbb{T}$ normalizes $\mathbb{G}_{a}$ and $X$ is a toric variety with the acting torus $\mathbb{T}$. In particular, every $\mathbb{G}$-embedding comes from a pair $(\Sigma, e)$, where $\Sigma$ is a fan and $e$ is a Demazure root of $\Sigma$.

Proof. We begin with a classical result of Sumihiro. Let $X$ be a normal variety with a regular action $G \times X \rightarrow X$ of a linear algebraic group $G$. By [23, Theorem 3], there exists a normal complete $G$-variety $\mathbf{X}$ such that $X$ can be embedded equivariantly as an open subset of $\mathbf{X}$. In other words, $\mathbf{X}$ is an equivariant compactification of $X$.

Let $X$ be a normal embedding of $\mathbb{G}$ and $\mathbf{X}$ be an equivariant compactification of $X$. By Proposition 4, the $T$-action on $\mathbf{X}$ can be extended to an action of a bigger torus $\mathbb{T}$ such that $\mathbb{T}$ normalizes $\mathbb{G}_{a}$ and $\mathbf{X}$ is a toric variety with the acting torus $\mathbb{T}$. Since the subset $X \subseteq \mathbf{X}$ is $\left(T \times \mathbb{G}_{a}\right)$-invariant, it is invariant under $\mathbb{T}$, see Lemma 2. This provides the desired structure of a toric variety on $X$.

Proposition 9. A complete toric variety $X$ admits a structure of $a \mathbb{G}$-embedding if and only if $\operatorname{Aut}(X)^{0} \neq \mathbb{T}$.
Proof. The variety $X$ admits a structure of a $\mathbb{G}$-embedding if and only if $\operatorname{Aut}(X)^{0}$ contains at least one root subgroup. It is well known that the group $\operatorname{Aut}(X)^{0}$ is generated by $\mathbb{T}$ and root subgroups [13, Proposition 11], [22, Section 3.4], [11, Corollary 4.7].

Consider two structures of a $\mathbb{G}$-embedding on a variety $X$. We say that such structures are equivalent, if there is an automorphism of $X$ sending one structure to the other. Since the structure of a toric variety on $X$ is unique up to automorphism, we may assume that our two structures share the same acting torus $\mathbb{T}$ and the same fan $\Sigma$, and are given by two roots $e, e^{\prime}$ of $\Sigma$. Then the structures are equivalent if and only if $e$ can be sent to $e^{\prime}$ by an automorphism of the torus $\mathbb{T}$. This leads to the following result.
Proposition 10. Two structures of a $\mathbb{G}$-embedding given by pairs $(\Sigma, e)$ and $\left(\Sigma, e^{\prime}\right)$ are equivalent if and only if there is an automorphism $\phi$ of the lattice $N$ which preserves the fan $\Sigma$ and such that the induced automorphism $\phi^{*}$ of the dual lattice $M$ sends e to $e^{\prime}$.

Let us finish with explicit examples of $\mathbb{G}$-embeddings into a given variety.
Example 2. We find all structures of $\mathbb{G}$-embeddings on $\mathbb{A}^{2}$. The cone of $\mathbb{A}^{2}$ as a toric variety is $\mathbb{Q}_{\geqslant 0}^{2}$. The set of Demazure roots of $\mathbb{Q}_{\geqslant 00}^{2}$ is

$$
\mathfrak{R}=\left\{(-1, k) \mid k \in \mathbb{Z}_{\geqslant 0}\right\} \sqcup\left\{(k,-1) \mid k \in \mathbb{Z}_{\geqslant 0}\right\},
$$

see Example 1 . The $\mathbb{G}$-action on $\mathbb{A}^{2}$ corresponding to the root $(-1, k)$ is given by

$$
\begin{equation*}
(t, s) \circ\left(x_{1}, x_{2}\right)=\left(t^{k} x_{1}+s t^{k} x_{2}^{k}, t x_{2}\right), \tag{3}
\end{equation*}
$$

where $\left(x_{1}, x_{2}\right) \in \mathbb{A}^{2}, s \in \mathbb{G}_{a}$, and $t \in \mathbb{K}^{\times}$. If $k \neq 0$, then there is a line of $\mathbb{G}_{a}$-fixed points and the stabilizer of a non-zero point on this line is a cyclic group of order $k$. If $k=0$, then there is no $\mathbb{G}_{a}$-fixed point. So formula (3) gives non-equivalent $\mathbb{G}$-actions for different $k$. With $k \neq 0$ we have three $\mathbb{G}$-orbits on $\mathbb{A}^{2}$, while for $k=0$ there are two $\mathbb{G}$-orbits.

Note that $\mathbb{G}$-actions defined by the roots $(k,-1)$ and $(-1, k)$ are equivalent via the automorphism $x_{1} \leftrightarrow x_{2}$ of $\mathbb{A}^{2}$.

Example 3. Let $X=\mathbb{P}^{2}$. It is a complete toric variety with a fan $\Sigma$ generated by the vectors $(1,0),(0,1)$ and $(-1,-1)$ :

The set of Demazure roots is

$$
\mathfrak{R}=\left\{e_{1}=(1,0), e_{2}=(1,-1), e_{3}=(0,-1), e_{4}=(-1,0), e_{5}=(-1,1), e_{6}=(0,1)\right\}
$$

We see that for any $i$ and $j$ there exists isomorphism of the fan $\Sigma$ sending $e_{i}$ to $e_{j}$. So any $\mathbb{G}$-embedding into $\mathbb{P}^{2}$ is equivalent to

$$
(t, s) \circ\left[z_{0}: z_{1}: z_{2}\right]=\left[t z_{0}+s t z_{1}: t z_{1}: z_{2}\right] .
$$

This time seven $\mathbb{T}$-orbits glue to five $\mathbb{G}$-orbits.
Example 4. Consider the Hirzebruch surface $\mathbb{F}_{1}$. The corresponding complete fan $\Sigma$ is generated by the vectors $(1,0),(0,1),(0,-1)$, and $(-1,1)$ :

The set of Demazure roots is

$$
\mathfrak{R}=\left\{e_{1}=(1,0), e_{2}=(-1,0), e_{3}=(0,1), e_{4}=(1,1)\right\} .
$$

By an automorphism, we can send $e_{1}$ to $e_{2}$ and $e_{3}$ to $e_{4}$. For the first equivalence class we have six $\mathbb{G}$-orbits, while in the second one the number of $\mathbb{G}$-orbits in seven.
