#### Abstract

Linear quasi-cyclic product codes over finite fields are investigated. Given the generating set in the form of a reduced Gröbner basis of a quasi-cyclic component code and the generator polynomial of a second cyclic component code, an explicit expression of the basis of the generating set of the quasicyclic product code is given. Furthermore, the reduced Gröbner basis of a one-level quasi-cyclic product code is derived.

Index Terms-Cyclic code, Gröbner basis, module minimization, product code, quasi-cyclic code, submodule

## I. Introduction

A linear block code of length $\ell m$ over a finite field $\mathbb{F}_{q}$ is a quasi-cyclic code if every cyclic shift of a codeword by $\ell$ positions, for some integer $\ell$ between one and $\ell m$, results in another codeword. Quasi-cyclic codes are a natural generalization of cyclic codes (where $\ell=1$ ), and have a closely linked algebraic structure. In contrast to cyclic codes, quasi-cyclic codes are known to be asymptotically good (see Chen-Peterson-Weldon [1]). Several such codes have been discovered with the highest minimum distance for a given length and dimension (see Gulliver-Bhargava [2] as well as Chen's and Grassl's databases [3, 4]). Several good LDPC codes are quasi-cyclic (see e.g. [5]) and the connection to convolutional codes was investigated among others in [6-8].

Recent papers of Barbier et al. [9, 10], Lally-Fitzpatrick [8, 11, 12], Ling-Solé [13-15], Semenov-Trifonov [16], GüneriÖzbudak [17] and ours [18] discuss different aspects of the algebraic structure of quasi-cyclic codes including lower bounds on the minimum Hamming distance and efficient decoding algorithms.

The focus of this paper is on a simple method to combine two given quasi-cyclic codes into a product code. More specifically, we give a description of a quasi-cyclic product code when one component code is quasi-cyclic and the second one is cyclic.

The work of Wasan [19] first considers quasi-cyclic product codes while investigating the mathematical properties of the wider class of quasi-abelian codes. Some more results were published in a short note by Wasan and Dass [20]. Koshy proposed a so-called "circle" quasi-cyclic product codes in [21].

Our work considers quasi-cyclic product codes that generalize the results of Burton-Weldon [22] and Lin-Weldon [23]
A. Zeh has been supported by the German research council (Deutsche Forschungsgemeinschaft, DFG) under grant Ze1016/1-1. S. Ling has been supported by NTU Research Grant M4080456.
(see also [24, Chapter 18]) based on the reduced Gröbner basis representation of Lally-Fitzpatrick [11] of the quasi-cyclic component code. We derive a representation of the generating set of a quasi-cyclic product code, where one component code is quasi-cyclic and the other is cyclic (in Thm. 7) and we give a reduced Gröbner basis for the special class of one-level quasicyclic product codes (in Thm. 8).

The paper is structured as follows. In Section II, we give necessary preliminaries on quasi-cyclic codes over finite fields. We outline relevant basics of the reduced Gröbner basis representation of Lally-Fitzpatrick [11]. Furthermore, the special class of $r$-level quasi-cyclic codes is defined in this section. Section III contains the main result on quasi-cyclic product codes, where the row-code is quasi-cyclic and the columncode is cyclic. Moreover, an explicit expression of the basis of a 1-level quasi-cyclic product code is derived in Section III. For illustration, we explicitly give an example of a binary $\overline{2-}$ quasi-cyclic product code in Section IV. Section V concludes this paper.

## II. Preliminaries

Let $\mathbb{F}_{q}$ denote the finite field of order $q$ and $\mathbb{F}_{q}[X]$ the polynomial ring over $\mathbb{F}_{q}$ with indeterminate $X$. Let $a, b$ with $b>a$ be two positive integers and denote by $[a, b)$ the set of integers $\{a, a+1, \ldots, b-1\}$ and by $[b)=[0, b)$. A vector of length $n$ is denoted by a lowercase bold letter as $\mathbf{v}=$ $\left(v_{0} v_{1} \cdots v_{n-1}\right)$ and an $m \times n$ matrix is denoted by a capital bold letter as $\mathbf{M}=\left(m_{i, j}\right)_{i \in[m)}^{j \in[n)}$.

A linear $[\ell \cdot m, k, d]_{q}$ code $\mathcal{C}$ of length $\ell m$, dimension $k$ and minimum Hamming distance $d$ over $\mathbb{F}_{q}$ is $\ell$-quasi-cyclic if every cyclic shift by $\ell$ of a codeword is again a codeword of $\mathcal{C}$, more explicitly if:

$$
\begin{array}{llll}
\left(c_{0,0} \cdots c_{\ell-1,0}\right. & c_{0,1} \cdots c_{\ell-1,1} & \cdots & \left.c_{\ell-1, m-1}\right) \in \mathcal{C} \\
& \Rightarrow & & \\
\left(c_{0, m-1} \cdots c_{\ell-1, m-1}\right. & c_{0,0} \cdots c_{\ell-1,0} & \ldots & \left.c_{\ell-1, m-2}\right) \in \mathcal{C}
\end{array}
$$

We can represent a codeword of an $[\ell \cdot m, k, d]_{q} \ell$-quasi-cyclic code as $\mathbf{c}(X)=\left(c_{0}(X) c_{1}(X) \cdots c_{\ell-1}(X)\right) \in \mathbb{F}_{q}[X]^{\ell}$, where

$$
\begin{equation*}
c_{i}(X) \stackrel{\text { def }}{=} \sum_{j=0}^{m-1} c_{i, j} X^{j}, \quad \forall i \in[\ell) \tag{1}
\end{equation*}
$$

Then, the defining property of $\mathcal{C}$ is that each component $c_{i}(X)$ of $\mathbf{c}(X)$ is closed under multiplication by $X$ and reduction modulo $X^{m}-1$.

Lemma 1. Let $\left(c_{0}(X) c_{1}(X) \cdots c_{\ell-1}(X)\right)$ be a codeword of an $\ell$-quasi-cyclic code $\mathcal{C}$ of length $m \ell$, where the components are defined as in (1). Then a codeword in $\mathcal{C}$ represented as one univariate polynomial of degree smaller than $m \ell$ is

$$
\begin{equation*}
c(X)=\sum_{i=0}^{\ell-1} c_{i}\left(X^{\ell}\right) X^{i} \tag{2}
\end{equation*}
$$

Proof: Substitute (1) into (2):

$$
c(X)=\sum_{i=0}^{\ell-1} c_{i}\left(X^{\ell}\right) X^{i}=\sum_{i=0}^{\ell-1} \sum_{j=0}^{m-1} c_{i, j} X^{j \ell+i}
$$

Lally and Fitzpatrick [11, 25] showed that this enables us to see a quasi-cyclic code as an $R$-submodule of the algebra $R^{\ell}$, where $R=\mathbb{F}_{q}[X] /\left\langle X^{m}-1\right\rangle$. The code $\mathcal{C}$ is the image of an $\mathbb{F}_{q}[X]$-submodule $\widetilde{\mathcal{C}}$ of $\mathbb{F}_{q}[X]^{\ell}$ containing $\widetilde{K}=\left\langle\left(X^{m}-1\right) \mathbf{e}_{j}, j \in[\ell)\right\rangle$ (where $\mathbf{e}_{j}$ is the standard basis vector with one in position $j$ and zero elsewhere) under the natural homomorphism

$$
\begin{aligned}
& \phi: \mathbb{F}_{q}[X]^{\ell} \rightarrow R^{\ell} \\
&\left(c_{0}(X) \cdots c_{\ell-1}(X)\right) \mapsto\left(c_{0}(X)+\left\langle X^{m}-1\right\rangle \cdots\right. \\
&\left.c_{\ell-1}(X)+\left\langle X^{m}-1\right\rangle\right)
\end{aligned}
$$

It has a generating set of the form $\left\{\mathbf{a}_{i}, i \in[z),\left(X^{m}-1\right) \mathbf{e}_{j}, j \in\right.$ $[\ell)\}$, where $\mathbf{a}_{i} \in \mathbb{F}_{q}[X]^{\ell}$ and $z \leq \ell$ (see e.g. [26, Chapter 5] for further information). Therefore, its generating set can be represented as a matrix with entries in $\mathbb{F}_{q}[X]$ :

$$
\mathbf{M}(X)=\left(\begin{array}{cccc}
a_{0,0}(X) & a_{0,1}(X) & \cdots & a_{0, \ell-1}(X)  \tag{3}\\
a_{1,0}(X) & a_{1,1}(X) & \cdots & a_{1, \ell-1}(X) \\
\vdots & \vdots & \ddots & \vdots \\
a_{z-1,0}(X) & a_{z-1,1}(X) & \cdots & a_{z-1, \ell-1}(X) \\
X^{m}-1 & & & \mathbf{0} \\
& X^{m}-1 & & 0 \\
0 & & \ddots & \\
& & & X^{m}-1
\end{array}\right)
$$

Every matrix $\mathbf{M}(X)$ as in (3) of the preimage $\widetilde{\mathcal{C}}$ can be transformed into a reduced Gröbner basis (RGB) with respect to the position-over-term order (POT) in $\mathbb{F}_{q}[X]^{\ell}$ (see [11, 25]). This basis can be represented in the form of an upper-

$$
\mathbf{G}(X)=\left(\begin{array}{cccc}
g_{0,0}(X) & g_{0,1}(X) & \cdots & g_{0, \ell-1}(X)  \tag{4}\\
& g_{1,1}(X) & \cdots & g_{1, \ell-1}(X) \\
0 & \ddots & \vdots \\
0 & & g_{\ell-1, \ell-1}(X)
\end{array}\right)
$$

where the following conditions must be fulfilled:

$$
\begin{aligned}
g_{i, j}(X) & =0, & & \forall 0 \leq j<i<\ell \\
\operatorname{deg} g_{j, i}(X) & <\operatorname{deg} g_{i, i}(X), & & \forall j<i, i \in[\ell) \\
g_{i, i}(X) & \mid\left(X^{m}-1\right), & & \forall i \in[\ell) \\
\text { if } g_{i, i}(X) & =X^{m}-1 \text { then } & & \\
g_{i, j}(X) & =0, & & \forall j \in[i+1, \ell)
\end{aligned}
$$

The rows of $\mathbf{G}(X)$ with $g_{i, i}(X) \neq X^{m}-1$ (i.e., the rows
that do not map to zero under $\phi$ ) are called the reduced generating set of the quasi-cyclic code $\mathcal{C}$. A codeword of $\mathcal{C}$ can be represented as $\mathbf{c}(X)=\mathbf{i}(X) \mathbf{G}(X)$ and it follows that $k=m \ell-\sum_{i=0}^{\ell-1} \operatorname{deg} g_{i, i}(X)$. Let us recall the following definition (see also [25, Thm. 3.2]).
Definition 2 ( $r$-level Quasi-Cyclic Code). We call an $\ell$-quasicyclic code $\mathcal{C}$ of length $\ell m$ an $r$-level quasi-cyclic code if there is an index $r \in[\ell)$ for which the RGB/POT matrix as defined in (4) is such that $g_{r-1, r-1}(X) \neq X^{m}-1$ and $g_{r, r}(X)=$ $\cdots \equiv g_{\ell-1, \ell-1}(X)=X^{m}-1$.

We recall [25, Corollary 3.3] for the case of a 1-level quasicyclic code in the following.
Corollary 3 (1-level Quasi-Cyclic Code). The generator matrix in RGB/POT form of a 1-level $\ell$-quasi-cyclic code $\mathcal{C}$ of length $\ell m$ is:

$$
\mathbf{G}(X)=\left(\begin{array}{llll}
g(X) & g(X) f_{1}(X) & \cdots & g(X) f_{\ell-1}(X)
\end{array}\right)
$$

where $g(X) \mid\left(X^{m}-1\right)$ and $f_{1}(X), \ldots, f_{\ell-1}(X) \in \mathbb{F}_{q}[X]$.
To describe quasi-cyclic codes explicitly, we need to recall the following facts of cyclic codes. A $q$-cyclotomic coset $M_{m}^{\langle i\rangle}$ is defined as: $M_{m}^{\langle i\rangle} \stackrel{\text { def }}{=}\left\{i q^{j} \bmod m \mid j \in[a)\right\}$, where $a$ is the smallest positive integer such that $i q^{a} \equiv i \bmod m$. The minimal polynomial in $\mathbb{F}_{q}[X]$ of the element $\alpha^{i} \in \mathbb{F}_{q^{r}}$ is given by

$$
\begin{equation*}
m_{m}^{\langle i\rangle}(X)=\prod_{j \in M_{m}^{\langle i\rangle}}\left(X-\alpha^{j}\right) \tag{5}
\end{equation*}
$$

The following fact is used in Section III.
Fact 4. Let four nonzero integers $y, a, \ell, m$ be such that

$$
y \equiv a \ell \quad \bmod m \ell
$$

holds. Then $\ell \mid y$ and $y / \ell \equiv a \bmod m$.

## III. Quasi-Cyclic Product Code

Throughout this section we consider a linear product code $\mathcal{A} \otimes \mathcal{B}$, where $\mathcal{A}$ is the row-code and $\mathcal{B}$ the column-code, respectively. Furthermore, w.l.o.g. let $\mathcal{A}$ be an $\left[\ell \cdot m_{A}, k_{A}, d_{A}\right]_{q}$ $\ell$-quasi-cyclic code with reduced Gröbner basis in POT form as defined in (4):

$$
\mathbf{G}^{A}(X)=\left(\begin{array}{cccc}
g_{0,0}^{A}(X) & g_{0,1}^{A}(X) & \cdots & g_{0, \ell-1}^{A}(X)  \tag{6}\\
& g_{1,1}^{A}(X) & \cdots & g_{1, \ell-1}^{A}(X) \\
0 & \ddots & \vdots \\
& & & g_{\ell-1, \ell-1}^{A}(X)
\end{array}\right)
$$

and let $\mathcal{B}$ be an $\left[m_{B}, k_{B}, d_{B}\right]_{q}$ cyclic code with generator polynomial $g^{B}(X)$ of degree $m_{B}-k_{B}$.

Throughout the paper, we assume that $\operatorname{gcd}\left(\ell m_{A}, m_{B}\right)=1$ and we furthermore assume that the two integers $a$ and $b$ are such that

$$
\begin{equation*}
a \ell m_{A}+b m_{B}=1 \tag{7}
\end{equation*}
$$

We recall the lemma of Wasan [19], that generalizes the result of Burton-Weldon [22, Theorem I] for cyclic product codes to
the case of an $\ell$-quasi-cyclic product code of an $\ell$-quasi-cyclic code $\mathcal{A}$ and a cyclic code $\mathcal{B}$. A codeword of $\mathcal{A} \otimes \mathcal{B}$ represented as univariate polynomial $c(X)$ can then be obtained from the matrix representation $\left(m_{i, j}\right)_{i \in\left[m_{B}\right)}^{j \in\left[\ell m_{A}\right)}$ as follows:

$$
\begin{equation*}
c(X) \equiv \sum_{i=0}^{m_{B}-1} \sum_{j=0}^{\ell m_{A}-1} m_{i, j} X^{\mu(i, j)} \bmod X^{\ell m_{A} m_{B}}-1 \tag{8}
\end{equation*}
$$

where

$$
\begin{equation*}
\mu(i, j) \stackrel{\text { def }}{=} i a \ell m_{A} \ell+j b m_{B} \quad \bmod \ell m_{A} m_{B} \tag{9}
\end{equation*}
$$

Lemma 5 (Mapping to a Univariate Polynomial [19]). Let $\mathcal{A}$ be an $\ell$-quasi-cyclic code of length $\ell m_{A}$ and let $\overline{\mathcal{B} \text { be a cyclic }}$ code of length $m_{B}$. The product code $\mathcal{A} \otimes \mathcal{B}$ is an $\ell$-quasicyclic code of length $\ell m_{A} m_{B}$ if $\operatorname{gcd}\left(\ell m_{A}, m_{B}\right)=1$.

Proof: Let $\left(m_{i, j}\right)_{i \in\left[m_{B}\right)}^{j \in\left[\ell m_{A}\right)}$ be a codeword of the product code $\mathcal{A} \otimes \mathcal{B}$, where each row is a codeword of $\mathcal{A}$ and each column is a codeword of $\mathcal{B}$. The entry $m_{i, j}$ is the coefficient $c_{\mu(i, j)}$ of the codeword $\sum_{i} c_{i} X^{i}$ as in (8). In order to prove that $\mathcal{A} \otimes \mathcal{B}$ is $\ell$-quasi-cyclic it is sufficient to show that a shift by $\ell$ positions of a codeword serialized to a univariate polynomial by (9) of $\mathcal{A} \otimes \mathcal{B}$ is again a codeword of $\mathcal{A} \otimes \mathcal{B}$.

A shift by $\ell$ in each row and a shift by one each column clearly gives a codeword in $\mathcal{A} \otimes \mathcal{B}$, because $\mathcal{A}$ is $\ell$-quasi-cyclic and $\mathcal{B}$ is cyclic. With

$$
\begin{aligned}
& \mu(i+1, j+\ell) \\
& \equiv(i+1) a \ell m_{A} \ell+(j+\ell) b m_{B} \bmod \ell m_{A} m_{B} \\
& \equiv i a \ell m_{A} \ell+j b m_{B}+\ell\left(a \ell m_{A}+b m_{B}\right) \bmod \ell m_{A} m_{B} \\
& \equiv \mu(i, j)+\ell \bmod \ell m_{A} m_{B}
\end{aligned}
$$

we obtain an $\ell$-quasi-cyclic shift of the univariate codeword obtained by (8) and (9).

Instead of representing a codeword of $\mathcal{A} \otimes \mathcal{B}$ as one univariate polynomial as in (8), we want to represent it as $\ell$ univariate polynomials as defined in (1).

Lemma 6 (Mapping to $\ell$ Univariate Polynomials). Let $\mathcal{A}$ be an $\ell$-quasi-cyclic code of length $\ell m_{A}$ and let $\mathcal{B}$ be a cyclic code of length $m_{B}$. Let the matrix $\left(m_{i, j}\right)_{i \in\left[m_{B}\right)}^{j \in\left[\ell m_{A}\right)}$ be a codeword of $\mathcal{A} \otimes \mathcal{B}$, where each row is in $\mathcal{A}$ and each column is in $\mathcal{B}$. The $\ell$ univariate polynomials of the corresponding codeword $\left(c_{0}(X) c_{1}(X) \cdots c_{\ell-1}(X)\right)$, where each component is defined as in (1), are given by:

$$
\begin{array}{r}
c_{h}(X) \equiv X^{h\left(-a m_{A}\right)} \cdot \sum_{i=0}^{m_{B}-1} \sum_{j=0}^{m_{A}-1} m_{i, j \ell+h} X^{\bar{\mu}(i, j)}  \tag{10}\\
\bmod X^{m_{A} m_{B}}-1, \quad \forall h \in[\ell)
\end{array}
$$

where

$$
\begin{equation*}
\bar{\mu}(i, j) \equiv i a \ell m_{A}+j b m_{B} \quad \bmod m_{A} m_{B} \tag{11}
\end{equation*}
$$

Proof: From Fact 4 we have for the exponents in (10):

$$
\begin{align*}
& \bar{\mu}(i, j)+h\left(-a m_{A}\right) \equiv i a \ell m_{A}+j b m_{B} \quad \bmod m_{A} m_{B} \\
& \Leftrightarrow \\
& \ell\left(\bar{\mu}(i, j)+h\left(-a m_{A}\right)\right) \\
& \equiv \ell\left(i a \ell m_{A}+j b m_{B}+h\left(-a m_{A}\right)\right) \bmod \ell m_{A} m_{B} \tag{12}
\end{align*}
$$

With $-a \ell m_{A}=b m_{B}-1$, we can rewrite (12):

$$
\begin{aligned}
\ell\left(\bar{\mu}(i, j)+h\left(-a m_{A}\right)\right) & =\ell \bar{\mu}(i, j)+\ell h\left(-a m_{A}\right) \\
& =\ell \bar{\mu}(i, j)+h b m_{B}-h
\end{aligned}
$$

and this gives with $\bar{\mu}(i, j)$ as in (11) and $\mu(i, j)$ as in (9):

$$
\begin{align*}
& \ell \bar{\mu}(i, j)+h b m_{B}-h \\
& \equiv \ell\left(i a \ell m_{A}+j b m_{B}\right)+h b m_{B}-h \\
& \equiv \ell i a \ell m_{A}+(j \ell+h) b m_{B}-h \quad \bmod \ell m_{A} m_{B} \\
& =\mu(i, j \ell+h)-h . \tag{13}
\end{align*}
$$

Inserting (13) in (2) of Lemma 1 leads to:

$$
\begin{align*}
c(X) & =\sum_{h=0}^{\ell-1} c_{h}\left(X^{\ell}\right) X^{h} \\
& =\sum_{h=0}^{\ell-1} \sum_{i=0}^{m_{B}-1} \sum_{j=0}^{m_{A}-1} m_{i, j \ell+h} X^{\mu(i, j \ell+h)} \\
& =\sum_{i=0}^{m_{B}-1} \sum_{j=0}^{\ell m_{A}-1} m_{i, j} X^{\mu(i, j)} \tag{14}
\end{align*}
$$

which equals (8).
The mapping $\bar{\mu}(i, j)$ from (11) of the $\ell$ submatrices $\left(m_{i, j \ell}\right)_{i \in\left[m_{B}\right)}^{j \in\left[m_{A}\right)},\left(m_{i, j \ell+1}\right)_{i \in\left[m_{B}\right)}^{j \in\left[m_{A}\right)}, \ldots,\left(m_{i, j \ell+\ell-1}\right)_{i \in\left[m_{B}\right)}^{j \in\left[m_{A}\right)}$ to the $\ell$ univariate polynomials $c_{0}(X), c_{1}(X), \ldots, c_{\ell-1}(X)$ is the same as the one used to map the codeword of a cyclic product code from its matrix representation to a polynomial representation (see [22, Thm. 1]).

In Fig. III, we illustrate the $\mu(i, j)$ as in (9) for $a=1$, $\ell=2, m_{A}=17$ and $b=-11, m_{B}=3$. Subfigure $\underline{1(a)}$ shows the values of $\mu(i, j)$. The two submatrices $\left(m_{i, j 2}\right)$ and $\left(m_{i, j 2+1}\right)$ for $i \in[3)$ and $j \in[17)$ are shown in Subfigure 1(b). Subfigure 1(c) contains the coefficients of the two univariate polynomials $c_{0}(X)$ and $c_{1}(X)$, where $\left(c_{0}(X) c_{1}(X)\right)$ is a codeword of the 2 -quasi-cyclic product code of length 102 .

The following theorem gives the basis representation of a quasi-cyclic product code, where the row-code is quasi-cyclic and the column-code is cyclic.

Theorem 7 (Quasi-Cyclic Product Code). Let $\mathcal{A}$ be an $\left[\ell \cdot m_{A}, k_{A}, d_{A}\right]_{q} \ell$-quasi-cyclic code with generator matrix $\mathbf{G}^{A}(X) \in \mathbb{F}_{q}[X]^{\ell \times \ell}$ as in (6) and let $\mathcal{B}$ be an $\left[m_{B}, k_{B}, d_{B}\right]_{q}$ cyclic code with generator polynomial $g^{B}(X) \in \mathbb{F}_{q}[X]$.

Then the $\ell$-quasi-cyclic product code $\mathcal{A} \otimes \mathcal{B}$ has a generating matrix of the following (unreduced) form:

$$
\begin{equation*}
\mathbf{G}(X)=\binom{\mathbf{G}^{0}(X)}{\mathbf{G}^{1}(X)} \tag{15}
\end{equation*}
$$

| 0 | 69 | 36 | 3 | 72 | 39 | 6 | 75 | 42 | 9 | 78 | 45 | 12 | 81 | 48 | 15 | 84 | 51 | 18 | 87 | 54 | 21 | 90 | 57 | 24 | 93 | 60 | 27 | 96 | 63 | 30 | 99 | 66 | 33 |

(a) The $3 \times(2 \cdot 17)$ codeword matrix $\left(m_{i, j}\right)$ of the 2-quasi-cyclic product code $\mathcal{A} \otimes \mathcal{B}$. Each entry contains the index of the coefficient $c_{i}$ of the univariate polynomial $c(X)=\sum_{i=0}^{101} c_{i} X^{i} \in \mathcal{A} \otimes \mathcal{B}$.

(b) The two submatrices $\left(m_{i, 2 j}\right)_{i \in[3)}^{i \in[17)}$ and $\left(m_{i, 2 j+1}\right)_{i \in[3)}^{i \in[17)}$ with entries that are the coefficients of $c_{0}\left(X^{2}\right)$ and $X c_{1}\left(X^{2}\right)$.

(c) The left submatrix contains the coefficients $c_{0, i}$ of the univariate polynomials $c_{0}(X)$ (the right one contains $c_{1, i}$ of $c_{1}(X)$, respectively).

Figure 1. Illustration of the mapping $\mu(i, j)$ (as defined in (9)) from a codeword of a quasi-cyclic product code represented as matrix to a polynomial representation. The product code $\mathcal{A} \otimes \mathcal{B}$ is 2 -quasi-cyclic. The row-code $\mathcal{A}$ is 2 -quasi-cyclic and has length $\ell m_{A}=2 \cdot 17$ and the column-code $\mathcal{B}$ is cyclic and has length $m_{B}=3$ (Subfigure $\underline{1(\mathrm{a}) \text {, here } a=1 \text { and } b=-11 \text { ). The mapping } \bar{\mu}(i, j) \text { (as in (11)) to two univariate polynomials is illustrated in Subfigure } 1(\mathrm{~b})}$ and Subfigure 1(c).
where

$$
\begin{align*}
& \mathbf{G}^{0}(X)=g^{B}\left(X^{a \ell m_{A}}\right) . \\
& \left(\begin{array}{cccc}
g_{0,0}^{A}\left(X^{b m_{B}}\right) & g_{0,1}^{A}\left(X^{b m_{B}}\right) & \cdots & g_{0, \ell-1}^{A}\left(X^{b m_{B}}\right) \\
& g_{1,1}^{A}\left(X^{b m_{B}}\right) & \cdots & g_{1, \ell-1}^{A}\left(X^{b m_{B}}\right) \\
0 & & \ddots & \vdots \\
& & g_{\ell-1, \ell-1}^{A}\left(X^{b m_{B}}\right)
\end{array}\right) \\
& \cdot \operatorname{diag}\left(1, X^{-a m_{A}}, X^{-2 a m_{A}}, \ldots, X^{-(\ell-1) a m_{A}}\right) \tag{16}
\end{align*}
$$

and

$$
\begin{equation*}
\mathbf{G}^{1}(X)=\left(X^{m_{A} m_{B}}-1\right) \mathbf{I}_{\ell}, \tag{17}
\end{equation*}
$$

where $\mathbf{I}_{\ell}$ is the $\ell \times \ell$ identity matrix.
Proof: We first give an explicit expression for each component of a codeword $\left(c_{0}(X) c_{1}(X) \quad \cdots \quad c_{\ell-1}(X)\right)$ in $\mathcal{A} \otimes \mathcal{B}$ depending on the components of a codeword $\left(a_{0}(X) a_{1}(X) \cdots a_{\ell-1}(X)\right)$ of the row-code $\mathcal{A}$ and depending the column-code $\mathcal{B}$ based on the expression of Lemma 6 . Let the $m_{B} \times \ell m_{A}$ matrix $\left(m_{i, j}\right)$ be a codeword of the $\bar{\ell}$ -quasi-cyclic product code $\mathcal{A} \otimes \mathcal{B}$ and let the polynomial

$$
\begin{equation*}
a_{i, h}(X) \stackrel{\text { def }}{=} \sum_{j=0}^{m_{A}-1} m_{i, j \ell+h} X^{j}, \quad \forall h \in[\ell), i \in\left[m_{B}\right) \tag{18}
\end{equation*}
$$

denote the $h$ th component of a codeword $\left(a_{i, 0}(X) a_{i, 1}(X) \cdots a_{i, \ell-1}(X)\right)$ in $\mathcal{A}$ in the $i$ th row of the matrix $\left(m_{i, j}\right)$. Denote a codeword $b_{j}(X)$ of $\mathcal{B}$ in the $j$ th column by

$$
\begin{equation*}
b_{j}(X)=\sum_{i=0}^{m_{B}-1} m_{i, j} X^{i}, \quad \forall j \in\left[\ell m_{A}\right) \tag{19}
\end{equation*}
$$

respectively. From (10), we have for the $h$ th component of a codeword of the product code $\mathcal{A} \otimes \mathcal{B}$ :

$$
\begin{array}{r}
c_{h}(X) \equiv X^{h\left(-a m_{A}\right)} \sum_{i=0}^{m_{B}-1} \sum_{j=0}^{m_{A}-1} m_{i, j \ell+h} X^{\bar{\mu}(i, j)}  \tag{20}\\
\bmod X^{m_{A} m_{B}}-1, \quad \forall h \in[\ell)
\end{array}
$$

and with $\bar{\mu}(i, j)$ as in (11) of Lemma $\underline{6}$ we can write (20) explicitly:

$$
\begin{gather*}
c_{h}(X) \equiv X^{h\left(-a m_{A}\right)} \sum_{i=0}^{m_{B}-1} \sum_{j=0}^{m_{A}-1} m_{i, j \ell+h} X^{i a \ell m_{A}+j b m_{B}} \\
\bmod X^{m_{A} m_{B}}-1, \quad \forall h \in[\ell) \tag{21}
\end{gather*}
$$

We define a shifted component:

$$
\begin{equation*}
\widetilde{c}_{h}(X) \equiv c_{h}(X) X^{h\left(a m_{A}\right)} \quad \bmod X^{m_{A} m_{B}-1}, \forall h \in[\ell) \tag{22}
\end{equation*}
$$

Since

$$
\begin{aligned}
\sum_{i=0}^{m_{B}-1} \sum_{j=0}^{m_{A}-1} & m_{i, j \ell+h} X^{i a \ell m_{A}+j b m_{B}} \\
& =\sum_{i=0}^{m_{B}-1} X^{i a \ell m_{A}} \sum_{j=0}^{m_{A}-1} m_{i, j \ell+h} X^{j b m_{B}} \\
& =\sum_{i=0}^{m_{B}-1} X^{i a \ell m_{A}} a_{i, h}\left(X^{b m_{B}}\right), \quad \forall h \in[\ell),
\end{aligned}
$$

and from (22) and in terms of the components of the row-code as defined in (18), we obtain:

$$
\begin{align*}
\widetilde{c}_{h}(X)= & q_{h}(X)\left(X^{m_{A} m_{B}}-1\right)+ \\
& \sum_{i=0}^{m_{B}-1} X^{i a \ell m_{A}} a_{i, h}\left(X^{b m_{B}}\right), \quad \forall h \in[\ell), \tag{23}
\end{align*}
$$

for some $q_{h}(X) \in \mathbb{F}_{q}[X]$. Therefore $\widetilde{c}_{h}(X)$ is a multiple of $\sum_{i=0}^{h} \epsilon_{i}(X) g_{i, h}^{A}\left(X^{b m_{B}}\right)$ for some $\epsilon_{i}(X) \in \mathbb{F}_{q}[X]$. A codeword $b_{j}(X)$ in $\mathcal{B}$ in the $j$ th column of $\left(m_{i, j}\right)$ is a multiple of $g^{B}(X)$ and we obtain:

$$
\begin{aligned}
\sum_{i=0}^{m_{B}-1} \sum_{j=0}^{\ell m_{A}-1} & m_{i, j} X^{i a \ell m_{A}+j b m_{B}} \\
& =\sum_{j=0}^{\ell m_{A}-1} X^{j b m_{B}} \sum_{i=0}^{m_{B}-1} m_{i, j} X^{i a \ell m_{A}} \\
& =\sum_{j=0}^{\ell m_{A}-1} X^{j b m_{B}} b_{j}\left(X^{a \ell m_{A}}\right)
\end{aligned}
$$

and therefore $\widetilde{c}_{h}(X)$ is a multiple of $g^{B}\left(X^{a \ell m_{A}}\right)$ modulo $X^{m_{A} m_{B}}-1$.

Similar to the proof of [22, Thm. III], it can be shown that every shifted component $\widetilde{c}_{h} \overline{(X)}$ is a multiple of the product of $g^{B}\left(X^{a \ell m_{A}}\right)$ and $\sum_{i=0}^{h} \epsilon_{i} g_{i, h}^{A}\left(X^{b m_{B}}\right)$ modulo ( $X^{m_{A} m_{B}}-1$ ). Therefore, we can represent each codeword in $\mathcal{A} \otimes \mathcal{B}$ as:

$$
\begin{aligned}
& \left(c_{0}(X)\right. \\
& \quad c_{1}(X) \\
& \quad=\left(i_{\ell-1}(X)\right)
\end{aligned}
$$

where $\mathbf{G}(X)$ is as in (15).
The following theorem gives the reduced Gröbner basis (as defined in (4)) representation of the quasi-cyclic product code from Thm. ㄱ, where the row-code is a 1-level quasi-cyclic code.

Theorem 8 (1-Level Quasi-Cyclic Product Code). Let $\mathcal{A}$ be an $\left[\ell \cdot m_{A}, k_{A}, d_{A}\right]_{q} 1$-level $\ell$-quasi-cyclic code with generator matrix in RGB/POT form:

$$
\begin{align*}
& \mathbf{G}^{A}(X) \\
& =\left(\begin{array}{lllc}
g_{0,0}^{A}(X) & g_{0,1}^{A}(X) & \cdots & g_{0, \ell-1}^{A}(X)
\end{array}\right) \\
& =\left(\begin{array}{llll}
g^{A}(X) & g^{A}(X) f_{1}^{A}(X) & \cdots & g^{A}(X) f_{\ell-1}^{A}(X)
\end{array}\right) \tag{24}
\end{align*}
$$

as shown in Corollary 3. Let $\mathcal{B}$ be an $\left[m_{B}, k_{B}, d_{B}\right]_{q}$ cyclic code with generator polynomial $g^{B}(X) \in \mathbb{F}_{q}[X]$.

Then a generator matrix of the 1-level $\ell$-quasi-cyclic product code in $R G B / P O T$ form is:

$$
\left.\begin{array}{rl}
\mathbf{G}(X)= & \left(\begin{array}{lll}
g(X) & g(X) f_{1}^{A}\left(X^{b m_{B}}\right) & \cdots
\end{array} \quad g(X) f_{\ell-1}^{A}\left(X^{b m_{B}}\right)\right.
\end{array}\right)
$$

where

$$
\begin{equation*}
g(X)=\operatorname{gcd}\left(X^{m_{A} m_{B}}-1, g^{A}\left(X^{b m_{B}}\right) g^{B}\left(X^{a \ell m_{A}}\right)\right) \tag{25}
\end{equation*}
$$

Proof: Let two polynomials $u_{0}(X), v_{0}(X) \in \mathbb{F}_{q}[X]$ be such that:

$$
\begin{align*}
g(X)=u_{0}(X) & g^{A}\left(X^{b m_{B}}\right) g^{B}\left(X^{a \ell m_{A}}\right)  \tag{26}\\
& +v_{0}(X)\left(X^{m_{A} m_{B}}-1\right)
\end{align*}
$$

We show now how to reduce the basis representation to the RGB/POT form. We denote a new Row $i$ by $\mathrm{R}[i]^{\prime}$. For ease of notation, we omit the term $\operatorname{diag}\left(1, X^{-a m_{A}}, X^{-2 a m_{A}}, \ldots, X^{-(\ell-1) a m_{A}}\right)$ and denote by $Y=X^{b m_{B}}$ and $Z=X^{a \ell m_{A}}$.

We write the basis of the submodule in unreduced form (as in (15)):

$$
\begin{align*}
& \left(\begin{array}{ccc}
g^{A}(Y) g^{B}(Z) & g^{A}(Y) f_{1}^{A}(Y) g^{B}(Z) & \cdots \\
X^{m_{A} m_{B}}-1 & X^{m_{A} m_{B}}-1 & \\
0 & & \ddots
\end{array}\right)  \tag{27}\\
& \rightarrow \mathrm{R}[0]^{\prime}=u_{0}(X) \mathrm{R}[0]+v_{0}(X) \mathrm{R}[1]+v_{0}(X) f_{1}^{A}(Y) \mathrm{R}[2] \\
& +\cdots+v_{0}(X) f_{\ell-1}^{A}(Y) \mathrm{R}[\ell] \\
& \left(\begin{array}{ccc}
g(X) & g(X) f_{1}^{A}(Y) & \cdots \\
g^{A}(Y) g^{B}(Z) & g^{A}(Y) f_{1}^{A}(Y) g^{B}(Z) & \cdots \\
X^{m_{A} m_{B}}-1 & X^{m_{A} m_{B}}-1 & \\
\mathbf{0} & & \ddots
\end{array}\right) \tag{28}
\end{align*}
$$

where the $i$ th entry in new row 0 was obtained using:

$$
\begin{align*}
& u_{0}(X) g^{A}(Y) f_{i}^{A}(Y) g^{B}(Z)+v_{0}(X) f_{i}^{A}(Y)\left(X^{m_{A} m_{B}}-1\right) \\
& =f_{i}^{A}(Y)\left(u_{0}(X) g^{A}(Y) g^{B}(Z)\right. \\
& \left.\quad \quad+v_{0}(X)\left(X^{m_{A} m_{B}}-1\right)\right) \tag{29}
\end{align*}
$$

and with (26) we obtain from (29)

$$
\begin{aligned}
& f_{i}^{A}(Y)\left(u_{0}(X) g^{A}(Y) g^{B}(Z)+v_{0}(X)\left(X^{m_{A} m_{B}}-1\right)\right) \\
& =f_{i}^{A}(Y) g(X)
\end{aligned}
$$

Clearly, $g(X)$ divides $g^{A}(Y) g^{B}(Z)$ and it is easy to check that Row 1 of the matrix in (28) can be obtained from Row 0 by multiplying by $g^{A}(Y) g^{B}(Z) / g(X)$. Therefore, we can omit the linearly dependent Row 1 in (28) and write the reduced basis as:

$$
\left(g(X) \quad g(X) f_{1}^{A}\left(X^{b m_{B}}\right) \quad \cdots \quad g(X) f_{\ell-1}^{A}\left(X^{b m_{B}}\right)\right)
$$

where we omitted the matrix $\operatorname{diag}\left(1, X^{-a m_{A}}, X^{-2 a m_{A}}, \ldots, X^{-(\ell-1) a m_{A}}\right)$ for the first row during the proof, but it will only influence the row-operations by a factor.

Note that (25) is exactly the generator polynomial of a cyclic product code. A 1-level $\ell$-quasi-cyclic product has rate greater than $(\ell-1) / \ell$ and is therefore of high practical relevance. The explicit RGB/POT form of the 1-level quasi-cyclic product code as in Thm. $\underline{8}$ allows statements on the minimum distance and to develop decoding algorithms.

## IV. Example

We consider a 2-quasi-cyclic product code with the same parameters as the one illustrated in Fig. III. In this section we investigate a more explicit example to be able to calculate the basis as given in Thm. 8.

Let $\mathcal{A}$ be a binary $\overline{2}$-quasi-cyclic code of length $\ell m_{A}=$ $2 \cdot 17=34$ and let $\mathcal{B}$ be a cyclic code of length $m_{B}=3$. We have $X^{17}-1=m_{0}^{\langle 17\rangle}(X) m_{1}^{\langle 17\rangle}(X) m_{3}^{\langle 17\rangle}(X)$, where the minimal polynomials are as defined in (5). Let the generator
matrix of $\mathcal{A}$ in RGB/POT form as in (4) be $\mathbf{G}^{A}(X)=$ $\left(g_{0,0}^{A}(X) \quad g_{0,1}^{A}(X)\right)$ where

$$
\begin{aligned}
g_{0,0}^{A}(X) & =m_{1}^{\langle 17\rangle}(X) \\
& =X^{8}+X^{7}+X^{6}+X^{4}+X^{2}+X+1 \\
g_{0,1}^{A}(X) & =m_{1}^{\langle 17\rangle}(X) \cdot m_{0}(X)^{3} \cdot\left(X^{3}+X^{2}+1\right) \\
& =X^{14}+X^{13}+X^{12}+X^{11}+X^{8}+1
\end{aligned}
$$

and $\mathcal{A}$ is a $[17 \cdot 2,9,11]_{2} 2$-quasi-cyclic code. Let $\alpha$ be a 17 th root of unity in $\mathbb{F}_{2^{8}}[X] \cong \mathbb{F}_{2}[X] /\left(X^{8}+X^{4}+X^{3}+X^{2}+1\right)$. Let $g^{B}(X)=m_{0}^{\langle 3\rangle}(X)=X+1$ be the generator polynomial of the $[3,2,2]_{2}$ cyclic code $\mathcal{B}$ and let $a=1$ and $b=-11$ be such that (7) holds. We have

$$
\begin{gathered}
X^{51}-1=m_{0}^{\langle 51\rangle}(X) m_{1}^{\langle 51\rangle}(X) m_{3}^{\langle 51\rangle}(X) m_{5}^{\langle 51\rangle}(X) m_{9}^{\langle 51\rangle}(X) \\
m_{11}^{\langle 51\rangle}(X) m_{17}^{\langle 51\rangle}(X) m_{19}^{\langle 51\rangle}(X)
\end{gathered}
$$

According to Thm. $\underline{8}$, we calculate

$$
\begin{aligned}
f_{1}^{A}\left(X^{-11 \cdot 3}\right) & \equiv f_{0,1}^{A}\left(X^{18}\right)=m_{0}\left(X^{18}\right)^{3} \cdot\left(X^{54}+X^{36}+1\right) \\
& =\left(X^{18}+1\right)^{3} \cdot\left(X^{54}+X^{36}+1\right) \\
& =X^{108}+X^{54}+X^{18}+1 \\
& \equiv X^{18}+X^{6}+X^{3}+1 \bmod \left(X^{51}+1\right)
\end{aligned}
$$

and we obtain the generator matrix $\mathbf{G}(X)=$ $\left(g_{0,0}(X) g_{0,1}(X)\right)$ of $\mathcal{A} \otimes \mathcal{B}$, where:

$$
\begin{aligned}
g_{0,0}(X)= & m_{0}^{\langle 51\rangle}(X) m_{1}^{\langle 51\rangle}(X) m_{3}^{\langle 51\rangle}(X) m_{9}^{\langle 51\rangle}(X) m_{19}^{\langle 51\rangle}(X) \\
= & X^{33}+X^{32}+X^{30}+X^{27}+X^{25}+X^{23}+X^{20} \\
& +X^{18}+X^{17}+X^{16}+X^{15}+X^{13}+X^{10}+X^{8} \\
& +X^{6}+X^{3}+X+1
\end{aligned}
$$

With Thm. 8, we obtain:

$$
\begin{aligned}
g_{0,1}(X) \equiv & a_{1}^{A}\left(X^{-11 \cdot 3}\right) g_{0,0}(X) \\
\equiv & X^{50}+X^{48}+X^{45}+X^{43}+X^{41}+X^{39}+X^{36} \\
& +X^{34}+X^{32}+X^{29}+X^{27}+X^{26}+X^{25}+X^{23} \\
& +X^{22}+X^{21}+X^{19}+X^{18}+X^{17}+X^{16}+X^{15} \\
& +X^{14}+X^{12}+X^{11}+X^{10}+X^{8}+X^{7}+X^{6} \\
& +X^{4}+X \bmod \left(X^{51}+1\right) .
\end{aligned}
$$

## V. Conclusion and Outlook

Based on the RGB/POT representation of an $\ell$-quasi-cyclic code $\mathcal{A}$ and the generator polynomial of a cyclic code $\mathcal{B}$, a basis representation of the $\ell$-quasi-cyclic product code $\mathcal{A} \otimes \mathcal{B}$ was proven. The reduced basis representation of the special case of a 1-generator quasi-cyclic product code was derived.

The general case of the basis representation of an $\ell_{A} \ell_{B^{-}}$ quasi cyclic product code from an $\ell_{A}$-quasi-cyclic code $\mathcal{A}$ and an $\ell_{B}$-quasi-cyclic code $\mathcal{B}$ as well as the reduction of the basis remains an open future work. Furthermore, a technique to bound the minimum distance of a given quasi-cyclic code by embedding it into a product code similar to [27] seems to be realizable.
