Abstract. In a previous paper, a realization of the moduli space of framed torsion-free sheaves on Hirzebruch surfaces in terms of monads was given. We build upon that result to construct ADHM data for the Hilbert scheme of points of the total space of the line bundles $\mathcal{O}(-n)$ on $\mathbb{P}^1$, for $n \geq 1$, i.e., the resolutions of the singularities of type $\mathbb{A}_n(1,1)$. Basically by implementing a version of the special McKay correspondence, this ADHM description is in turn used to realize these Hilbert schemes as irreducible connected components of quiver varieties. We obtain in this way new examples of quiver varieties which are not of the Nakajima type.

1. Introduction

If $X$ is a smooth, quasi-projective surface over $\mathbb{C}$, the Hilbert scheme of points $\text{Hilb}^c(X)$, which parameterizes 0-dimensional subschemes of $X$ of length $c$, is quasi-projective [19] and smooth of dimension $2c$ [12]. In this paper we study the Hilbert schemes of points of the total spaces of the line bundles $\mathcal{O}_{\mathbb{P}^1}(-n)$ (which admit the Hirzebruch surfaces $\Sigma_n$ as projective compactifications). These spaces are resolutions of the singularities of type $\frac{1}{n}(1, 1)$. Our main results are a description of these Hilbert schemes in terms of ADHM data, and a consequence, their realization as irreducible connected components of the moduli spaces of representations of suitable quivers. It is worth pointing out that the representation varieties we obtain in this way are not Nakajima quiver varieties.

1.1. Motivations and general background.

Among the many occurrences of Hilbert schemes of points in algebraic geometry, a remarkable one is the role played by the Hilbert schemes of points of noncompact (usually hyperkähler) surfaces in geometric representation theory. Examples of such spaces are the Hilbert schemes of points of $\mathbb{C}^2$, and of the minimal resolutions $X_{n,n-1}$ of toric singularities of type $\frac{1}{n}(1, n-1)$, with $n \geq 2$.

One of the main links with geometric representation theory is the description of these Hilbert schemes as Nakajima quiver varieties. This basically requires two steps: to consider a space of complex representations of a suitable quiver with relations, and then to construct a GIT (Geometric Invariant Theory) quotient of this with respect to a suitable semistability condition for the representations, in King’s sense [21]. More precisely, let us denote by $Q$ the Jordan quiver $A^{(1)}_0$, that is, the quiver with one vertex and one loop, or the affine Dynkin quiver $A^{(1)}_{n-1}$, for $n \geq 2$; one can frame the quiver by doubling the vertices and adding arrows from the old vertices to the new ones, and double it, by duplicating the arrows, with the new arrows going the opposite direction. The space $\text{Rep}(Q^{\text{fr, double}}, \vec{v}, \vec{w})$ of representations of the double framed quiver associated with $Q$ (see [16] and Sections 2 and 4 in this paper for notation and precise definitions) has a natural symplectic structure, which is preserved by an action of the group $\prod_i \text{GL}(v_i)$, giving rise to a moment map; the previously mentioned space of complex representations is indeed the space of representations of $Q^{\text{fr, double}}$ satisfying the relations that define the moment map. For suitable $\vec{v}$ and $\vec{w}$ the GIT quotient of this space, taken with respect to a certain semistability parameter, is $\text{Hilb}^c(\mathbb{C}^2)$ if $Q = A^{(1)}_0$, and $\text{Hilb}^c(X_{n,n-1})$ if $Q = A^{(1)}_{n-1}$. In the latter case, the space of representations coincides with the space of left modules of the framed version of Wemyss’s reconstruction algebra associated with the toric singularity $\Sigma_n$ (Wemyss’s reconstruction algebra is a quotient of the path algebra of the relevant McKay quiver). Schiffmann and Vasserot used this description in terms of quiver varieties to define an action of the K-theoretic (or cohomological) Hall algebra associated with $\text{Rep}((A^{(1)}_0)^{\text{double}}, \vec{v})$ on the equivariant K-theory (or cohomology) of $\text{Hilb}^c(\mathbb{C}^2)$ [35, 36]. Subsequently, Negut extended this construction to $\text{Hilb}^c(X_{n,n-1})$ [32]. This construction is quite important in geometric representation theory, as it can be used to obtain geometric representations of quantum groups, Yangians, vertex algebras, etc. (see loc. cit. and references therein).

In this paper we provide a quiver variety description of the Hilbert schemes of points of the total spaces $X_n$ of the line bundles $\mathcal{O}_{\mathbb{P}^1}(-n)$, with $n \geq 1$. For $n \geq 2$, the surface $X_n$ is the minimal resolution of the toric singularity of type $\frac{1}{n}(1, 1)$; it admits the $n$-th Hirzebruch surface $\Sigma_n$ as a projective compactification. These spaces have been considered in physics in connection with brane
counting for string theory compactifications on “local” Calabi-Yau manifolds \cite{[11] [13] [17] [31] [9]},
gauge theory on Hirzebruch surfaces and applications to the computation of invariants, such as the
Betti numbers of moduli spaces of sheaves on Hirzebruch surfaces \cite{[7] [24] [6]} (see also \cite{[5] App. D}
for some mathematical developments), topological strings and Gromov-Witten invariants (see \cite{[37]}
for a review).

Thus, we supply a new example of a quiver variety outside the universe of the Nakajima quiver
varieties. (Other examples of quiver varieties that are not of the Nakajima type are for instance
the affine Laumon spaces, see e.g. \cite{[31]} and references therein, and those associated with the
quivers recently studied by Nakajima himself \cite{[30]}. This quiver variety is obtained by regarding
\text{Hilb}^c(X_n) as the moduli space of rank one torsion-free sheaves on the projective closure \Sigma_n
(Hirzebruch surface) of \Sigma_n that are trivial on the compactifying divisor, and following the two
above mentioned steps: we consider a space \text{Rep}(B_n^\mu, \vec{v}, \vec{w}) of representations of the framed version
B_n^\mu of a quotient B_n of the path algebra of a certain quiver \mathcal{Q}_n, and realize \text{Hilb}^c(X_n) as a suitable
GIT quotient of it. Here \mathcal{Q}_n, for \( n \geq 2 \), is the special McKay quiver associated with the toric
singularity of type \( \frac{1}{1}(1, 1) \), and \( B_n \) is the corresponding Wemyss’s reconstruction algebra. Thus we
provide a new example of a moduli space of sheaves in a minimal resolution of a toric singularity
that can be realized as a quiver variety associated with the corresponding special McKay quiver.

As we already mentioned, the Nakajima variety corresponding to any quiver carries a natural
symplectic structure. This is essentially due to the fact that the quiver variety is concocted from
the associated double quiver. Now, the quiver we associate with the variety \( X_2 \) is a double, so
that the quiver space we consider, and the Hilbert space \text{Hilb}^c(X_2), are symplectic holomorphic
varieties. On the contrary, the quivers \( \mathcal{Q}_n^\text{fr} \) are not doubles for \( n \neq 2 \). A result of Bottacin \cite{[5]}
implies, however, that \text{Hilb}^c(X_n) carries, for all \( n \geq 1 \), a Poisson structure whose rank is generically
maximal.

1.2. Contents of the paper. The ADHM description of a moduli space is usually the starting
point of its realization as a quiver variety, in that it is the ADHM description which suggests the
quiver to consider. For Hilbert schemes of points this description is available in the case of \( \mathbb{C}^2 \)
\cite{[28]} and for the multi-blowups of \( \mathbb{C}^2 \), as provided by the work of A. A. Henni \cite{[20]} specialized to
the rank one case. So, in the first part of this paper we construct ADHM data for the Hilbert
schemes of points of the total space \( X_n \) of the line bundle \( \mathcal{O}_{\mathbb{P}^1}(-n) \). We identify the space
\text{Hilb}^c(X_n) with the moduli space \( \mathcal{M}^n(1, 0, c) \) of framed sheaves on the \( n \)-th Hirzebruch surface
\( \Sigma_n \) that have rank 1, vanishing first Chern class, and second Chern class \( c_2 = c \) (the framing is
a fixed isomorphism with the trivial rank 1 bundle on a divisor linearly equivalent to the section
of \( \Sigma_n \to \mathbb{P}^1 \) of positive self-intersection). By exploiting the description of \( \mathcal{M}^n(1, 0, c) \) in terms of
monads given in \cite{[2]}, we prove (Theorem 1.3) that the moduli space \( \mathcal{M}^n(1, 0, c) \) is isomorphic to the
quotient \( P^n(c)/\text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C}) \), where \( P^n(c) \) is a quasi-affine variety contained in the
linear space \( \text{End}(\mathbb{C}^c)^{\otimes n+2} \oplus \text{Hom}(\mathbb{C}^c, \mathbb{C}) \). We show this by using the fact that the partial quotient
\( P^n(c)/\text{GL}(c, \mathbb{C}) \) can be assembled by glueing \( c+1 \) open sets, each one isomorphic to the space of
ADHM data for \( \text{Hilb}^c(\mathbb{C}^2) \) (Propositions 1.2 and 1.7).

In the second part of this paper we show (Theorem 4.5) that these Hilbert schemes are irreducible
connected components of quiver varieties, namely, they are embedded as irreducible connected components
into varieties of representations of a quiver naturally associated with the ADHM data describing the
Hilbert schemes, for a suitable choice of the stability parameter.
More precisely, we prove:

**Theorem.** For every \( n, c \geq 1 \), the variety \( \text{Hilb}^c(X_n) \) is isomorphic to an irreducible connected component of the quotient

\[
\text{Rep}(B_n^{fr}, \vec{v}_c, 1)_{\vartheta_c}^{ss} / \vartheta_c \times \text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C}),
\]

where \( \vec{v}_c = (c, c) \) and \( \vartheta_c = (2c, -2c + 1) \).

Here \( \text{Rep}(B_n^{fr}, \vec{v}_c, 1)_{\vartheta_c}^{ss} \) is a representation space associated, as we sketched above, with the framed quiver

(for \( n = 2 \) there are no \( \ell \) arrows).

This result includes the particular case of the Hilbert scheme of points of \( X_2 \), which is isomorphic, as a complex variety, to the ALE space \( A_1 \). Kuznetsov has provided, from a different point of view, a description of the Hilbert schemes of the ALE spaces \( A_k \) as quiver varieties [22]. We check indeed (Corollary 4.12) that for \( n = 2 \) our representation coincides with that of Kuznetsov for \( A_1 \).

Finally, Appendix A is devoted to proving the rather technical Proposition 3.2.

1.3. **Further developments.** Among the many possible developments of the constructions described in this paper, one is the study of the chamber structure for the stability parameter used to define the quiver variety. More generally, the results in this paper should open the way to a number of interesting questions in geometric representation theory, such as the existence of a K-theoretic (cohomological) Hall algebra associated with \( \text{Rep}(B_n, \vec{v}) \), with an action of this algebra on the equivariant K-theory (cohomology) of \( \text{Hilb}^c(X_n) \). On another line, an interesting and challenging problem is the characterization of the Poisson structure of these Hilbert schemes in purely quiver-theoretic terms, perhaps by generalizing the approaches in [4, 38].

**Acknowledgments.** We thank the referee for the careful reading of the manuscript and for very useful suggestions, which have led to a substantial improvement of the exposition. We also thank Alberto Tacchella for valuable advice. U.B.’s stay at UFSC was supported by the grant 310002/2015-0 from “Conselho Nacional de Desenvolvimento Científico e Tecnológico” (CNPq), Brazil. 2. Background material

The construction of the ADHM data is based on the description of the moduli spaces of framed sheaves on the Hirzebruch surfaces $\Sigma_n$ in terms of monads that was worked out in [2]. We briefly review the basic ingredients of that construction. The $n$-th Hirzebruch surface $\Sigma_n$ is the projective closure of the total space $X_n$ of the line bundle $O_p(-n)$; we shall assume $n > 0$. We denote by $F$ the class in $\text{Pic}(\Sigma_n)$ of the fibre of the natural ruling $\Sigma_n \to \mathbb{P}^1$, and by $H$ and $E$ the classes of the sections squaring to $n$ and $-n$, respectively. We shall denote $O_{\Sigma_n}(p, q) = O_{\Sigma_n}(pH + qF)$.

We fix a curve $\ell_\infty \simeq \mathbb{P}^1$ in $\Sigma_n$ belonging to the class $H$ and call it the "line at infinity." A framed sheaf on $\Sigma_n$ is a pair $(E, \theta)$, where $E$ is a torsion-free sheaf which is trivial along $\ell_\infty$, and $\theta : E|_{\ell_\infty} \sim \rightarrow O_{\ell_\infty}^{\oplus r}$ is an isomorphism, where $r$ is the rank of $E$. A morphism between framed sheaves $(E, \theta), (E', \theta')$ is by definition a morphism $\lambda : E \rightarrow E'$ such that $\theta' \circ \lambda|_{\ell_\infty} = \theta$. The moduli space parameterizing isomorphism classes of framed sheaves $(E, \theta)$ on $\Sigma_n$ with Chern character $\text{ch}(E) = (r, aE, -c - \frac{1}{2} na^2)$, where $r, a, c \in \mathbb{Z}$ and $r \geq 1$, will be denoted $\mathcal{M}^n(r, a, c)$. We normalize the framed sheaves so that $0 \leq a \leq r - 1$.

We recall (see e.g. [33, Definition II.3.1.1]) that a monad $M$ on a scheme $X$ is a three-term complex of locally free $O_X$-modules of finite rank, having nontrivial cohomology only in the middle term:

$$M : \quad 0 \rightarrow \mathcal{U} \stackrel{a}{\rightarrow} \mathcal{V} \stackrel{b}{\rightarrow} \mathcal{W} \rightarrow 0.$$  

The cohomology of the monad is a coherent $O_X$-module. A morphism (isomorphism) of monads is a morphism (isomorphism) of complexes.

As proved in [2], a framed sheaf $(E, \theta)$ on $\Sigma_n$, having invariants $(r, a, c)$, is isomorphic to the cohomology of a monad

$$\text{(2.1)} \quad M(\alpha, \beta) : \quad 0 \rightarrow \mathcal{U}_k \stackrel{\alpha}{\rightarrow} \mathcal{V}_k \stackrel{\beta}{\rightarrow} \mathcal{W}_k \rightarrow 0,$$

where $\mathcal{U}_k$ denotes the quadruple $(n, r, a, c)$, and we have set

$$\mathcal{U}_k : = O_{\Sigma_n}(0, -1)^{\oplus k_1}, \quad \mathcal{V}_k : = O_{\Sigma_n}(1, -1)^{\oplus k_2} \oplus O_{\Sigma_n}^{\oplus k_3}, \quad \mathcal{W}_k : = O_{\Sigma_n}(1, 0)^{\oplus k_4},$$

with

$$k_1 = c + \frac{1}{2} na(a - 1), \quad k_2 = k_1 + na, \quad k_3 = k_1 + (n - 1)a, \quad k_4 = k_1 + r - a.$$

The set $L_k$ of pairs in $\text{Hom}(\mathcal{U}_k, \mathcal{V}_k) \oplus \text{Hom}(\mathcal{V}_k, \mathcal{W}_k)$ fitting into the complex (2.1), such that the cohomology of the complex is torsion-free and trivial at infinity, is a smooth algebraic variety. One can introduce a principal $\text{GL}(r, \mathbb{C})$-bundle $P_k$ over $L_k$, whose fibre at a point $(\alpha, \beta)$ is identified with the space of framings for the corresponding cohomology of (2.1). The algebraic group $G_k = \text{Aut}(\mathcal{U}_k) \times \text{Aut}(\mathcal{V}_k) \times \text{Aut}(\mathcal{W}_k)$ acts freely on $P_k$, and the moduli space $\mathcal{M}^n(r, a, c)$ can be described as the quotient $P_k/G_k$ [2 Theorem 3.4]. This space is nonempty if and only if $c + \frac{1}{2} na(a - 1) \geq 0$, and when nonempty, is a smooth algebraic variety of dimension $2rc + (r - 1)na^2$.

When $r = 1$ we can assume $a = 0$, so that the double dual $E^{**}$ of $E$ is isomorphic to the structure sheaf $O_{\Sigma_n}$. As a consequence, since $E$ is trivial on $\ell_\infty$, the mapping carrying $E$ to the schematic support of $O_{\Sigma_n}/E$ yields an isomorphism

$$\text{(2.2)} \quad M^n(1, 0, c) \simeq \text{Hilb}(\Sigma_n \setminus \ell_\infty) = \text{Hilb}(X_n),$$
where $X_n$ is the total space of the line bundle $\mathcal{O}_{\mathbb{P}^1}(-n)$. We shall freely use the isomorphism $(2.2)$ in the rest of the paper.

We also fix some notation about quiver representations (see [16] for details). A quiver $\mathcal{Q}$ is a finite oriented graph, given by a set of vertices $I$ and a set of arrows $E$. The path algebra $\mathbb{C}[\mathcal{Q}]$ is the $\mathbb{C}$-algebra with basis the paths in $\mathcal{Q}$ and with a product given by the concatenation of paths whenever possible, zero otherwise. Usually one includes among the generators of $\mathbb{C}[\mathcal{Q}]$ a complete set of orthogonal idempotents $\{e_i\}_{i \in I}$: this can be considered a subset of $E$ by regarding $e_i$ as a loop of “length zero” starting and ending at the $i$-th vertex. A (complex) representation of a quiver $\mathcal{Q}$ is a pair $(V, X)$, where $V = \bigoplus_{i \in I} V_i$ is an $I$-graded complex vector space and $X = (X_a)_{a \in E}$ is a collection of linear maps such that $X_a \in \text{Hom}_\mathbb{C}(V_i, V_j)$ whenever the arrow $a$ starts at the vertex $i$ and terminates at the vertex $j$. We say that a representation $(V, X)$ is supported by $V$, and denote by $\text{Rep}(\mathcal{Q}, V)$ the space of representations of $\mathcal{Q}$ supported by $V$. Morphisms and direct sums of representations are defined in an obvious way; it can be shown that the abelian category of complex representations of $\mathcal{Q}$ is equivalent to the category of left $\mathbb{C}[\mathcal{Q}]$-modules. In particular, a sub-representation of a given representation $(V, X)$ is a pair $(S, Y)$, where $S$ is an $I$-graded subspace of $V$ which is preserved by the linear maps $X$, and $Y$ is the restriction of $X$ to $S$.

We consider only finite-dimensional representations. If $\dim \mathbb{C}V_i = v_i$, a representation $(V, X)$ of $\mathcal{Q}$ is said to be $\vec{v}$-dimensional, where $\vec{v} = (v_i)_{i \in I} \in \mathbb{N}^I$. With an abuse of notation, after fixing a $\vec{v}$-dimensional vector space $V$, we write $\text{Rep}(\mathcal{Q}, \vec{v})$ instead of $\text{Rep}(\mathcal{Q}, V)$. When we consider a framed quiver (see Section 4 for this notion), for notational convenience we shall separately denote by $\vec{w}$ the dimension vector of the vector spaces associated with the framing vertices.

More generally one can define the representations of a quotient algebra $B = \mathbb{C}[\mathcal{Q}]/J$, for some ideal $J$ of the path algebra $\mathbb{C}[\mathcal{Q}]$. These are representations $(V, X)$ of $\mathcal{Q}$, whose linear maps $X = (X_a)_{a \in E}$ satisfy the relations given by the elements of $J$. The abelian category of complex representations of $B$ is equivalent to the category of left $B$-modules. We denote by $\text{Rep}(B, \vec{v})$ the space of representations of $B$ supported by a given $\vec{v}$-dimensional vector space $V$. There is a natural action of $\prod GL(v_i)$ on $\text{Rep}(B, \vec{v})$ given by change of basis. One would like to consider the space of isomorphism classes of $\vec{v}$-dimensional representations of $B$, but unfortunately in most cases this space is “badly behaved.” To overcome this drawback, following A. King’s approach [21], one introduces a notion of (semi)stability depending on the choice of a parameter $\vartheta \in \mathbb{R}^I$, considers the subset $\text{Rep}^ss_B(\vec{v})_\vartheta$ of $\text{Rep}(B, \vec{v})$ consisting of semistable representations, and takes the corresponding GIT quotient $\text{Rep}^ss_B(\vec{v})_\vartheta//\prod GL(v_i)$.

3. ADHM data

In this section we construct ADHM data for the Hilbert scheme of points of the total spaces $X_n$ of the line bundles $\mathcal{O}_{\mathbb{P}^1}(-n)$. First we show that the Hilbert schemes can be covered by open subsets, each of which is isomorphic to the Hilbert scheme of $\mathbb{C}^2$, and therefore admits Nakajima’s ADHM description; then we prove that these “local data” can be glued together to provide ADHM data for the Hilbert schemes of $X_n$.

We denote by $P^n(c)$ the subset of the vector space $\text{End}(\mathbb{C}^c)^{\oplus n+2} \oplus \text{Hom}(\mathbb{C}^c, \mathbb{C})$ whose elements $(A_1, A_2; C_1, \ldots, C_n; e)$ satisfy the conditions
Theorem 3.1. \( P(c) \) is a principal \( GL(c, \mathbb{C}) \times GL(c, \mathbb{C}) \)-bundle over \( \text{Hilb}^c(X_n) \).

The remainder of this Section is devoted to proving Theorem 3.1. At first, we provide an ADHM description for each open set of an open cover of Hilb\(^c\). If we fix \( c + 1 \) distinct fibres \( F_0, \ldots, F_c \in F \), for any \( [(\mathcal{E}, \theta)] \in \text{Hilb}^c(X_n) \) there exists at least one \( m \in \{0, \ldots, c\} \) such that \( \mathcal{E}|_{F_m} \simeq \mathcal{O}_{F_m} \). We choose the fibres \( F_m \) as the closed subvarieties cut in

\[
\Sigma_m = \{ ([y_1, y_2], [x_1, x_2, x_3]) \in \mathbb{P}^1 \times \mathbb{P}^2 \mid x_1 y_1^n = x_2 y_2^n \}
\]

by the equations

\[
F_m = \{ [y_1, y_2] = [c_m, s_m] \}, \quad m = 0, \ldots, c,
\]

where

\[
c_m = \cos \left( \frac{m}{c + 1} \right), \quad s_m = \sin \left( \frac{m}{c + 1} \right).
\]

We obtain in this way an open cover \( \{U_{m}^{n,c}\}_{m=0,\ldots,c} \) of \( \text{Hilb}^c(X_n) \) by letting

\[
U_{m}^{n,c} := \{ [(\mathcal{E}, \theta)] \in \text{Hilb}^c(X_n) \mid \mathcal{E}|_{F_m} \simeq \mathcal{O}_{F_m} \}.
\]

Each of these spaces is isomorphic to the Hilbert scheme of points of \( \mathbb{C}^2 \), so that it admits Nakajima’s ADHM description [23, Theorem. 1.9] in terms of two \( c \times c \) matrices \( b_1, b_2 \) and a row \( c \)-vector \( e \), satisfying the conditions

\[ (T1) \ [b_1, b_2] = 0; \]
(T2) for all \((z, w) \in \mathbb{C}^2\) there is no nonzero vector \(v \in \mathbb{C}^c\) such that
\[
\begin{aligned}
    b_1 v &= zv \\
    b_2 v &= wv \\
    v &\in \ker e .
\end{aligned}
\]
The space of triples \((b_1, b_2, c)\) satisfying the previous two conditions will be denoted by \(\mathcal{T}(c)\).

Elements \(\phi\) of the group \(\text{GL}(c, \mathbb{C})\) act on \(\mathcal{T}(c)\) according to the rule
\[
(3.6) \quad (b_1, b_2, c) \mapsto (\phi b_1 \phi^{-1}, \phi b_2 \phi^{-1}, c \phi^{-1}).
\]
Note that condition (T2) is the so-called co-stability condition, while Nakajima in \([25, \text{Theorem 1.9}]\) used the stability condition (which is satisfied by the transpose matrices \((b_1', b_2', e')\)). In particular, this explains the difference between \((3.5)\) and the \(\text{GL}(c, \mathbb{C})\)-action used by Nakajima.

The ADHM data for the open set \(U_{m}^{n, c}\) will be denoted by \((b_1, b_2, b_m, e_m)\); the next Proposition gives the transition functions on the intersections.

**Proposition 3.2.** The intersections \(U_{m}^{n, c} = U_{m}^{n, c} \cap U_{l}^{n, c}\) are characterized by the conditions
\[
\det (c_m - l c - s_m - l b_{1m}) \neq 0,
\]
where \(c_m\) and \(s_m\) are the numbers defined in eq. \((3.3)\). On any of these intersections, the ADHM data are related by the equations
\[
\begin{aligned}
    b_{1l} &= (c_m - l c - s_m - l b_{1m})^{-1} (s_m - l c + c_m - l b_{1m}) \\
    b_{2l} &= (c_m - l c - s_m - l b_{1m})^n b_{2m} \\
    e_l &= e_m .
\end{aligned}
\]

**Proof.** The proof of this result is given in Appendix A. \(\square\)

We introduce the matrices
\[
A_{1m} = c_m A_1 - s_m A_2 , \quad A_{2m} = s_m A_1 + c_m A_2 ,
\]
\[
(3.6) \quad E_m = \sum_{q=1}^{n} \binom{n-1}{q-1} c_m^{n-q} s_m^{q-1} C_q A_{2m} ,
\]
where \(m = 0, \ldots, c\). Since the polynomial \(\det(\nu A_1 + \nu A_2)\) has at most \(c\) distinct roots in \(\mathbb{P}^1\), the \(\text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C})\)-invariant open subsets
\[
P^n(c)_m = \{(A_1, A_2; C_1, \ldots, C_n; e) \in P^n(c) \mid \det A_{2m} \neq 0\} , \quad m = 0, \ldots, c,
\]
cover \(P^n(c)\). If we also define the matrices \(B_m = A_{2m}^{-1} A_{1m}\), the linear data \((B_m, E_m, e; A_{2m})\) provide local affine coordinates for \(P^n(c)\).

**Proposition 3.3.** The morphism
\[
\zeta_m : \quad P^n(c)_m \quad \rightarrow \quad \left(\text{End}(\mathbb{C}^c)^{\otimes 2} \otimes \text{Hom}(\mathbb{C}^c, \mathbb{C})\right) \times \text{GL}(c, \mathbb{C})
\]
\[
(A_1, A_2; C_1, \ldots, C_n; e) \quad \mapsto \quad (B_m, E_m, e; A_{2m})
\]
is an isomorphism onto \(\mathcal{T}(c) \times \text{GL}(c, \mathbb{C})\). The induced \(\text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C})\)-action is given by
\[
(B_m, E_m, e; A_{2m}) \mapsto (\phi_1 B_m \phi_1^{-1}, \phi_1 E_m \phi_1^{-1}, e \phi_1^{-1}; \phi_2 A_{2m} \phi_1^{-1}) .
\]
We divide the proof of Proposition 3.3 into a few steps. First we define the matrices $\sigma^h_m = (\sigma^h_m pq)_{0 \leq p, q \leq n}$ for all $h \geq 0$ and $m \in \mathbb{Z}$ by means of the equations

$$
(s_m \mu_1 + c_m \mu_2)^p (c_m \mu_1 - s_m \mu_2)^{h-p} = \sum_{q=0}^{h} \sigma^h_m pq^q \mu_1^{h-q}
$$

for any $(\mu_1, \mu_2) \in \mathbb{C}^2$ and $p = 0, \ldots, h$. Note that $\sigma^h_m \sigma^h_i = \sigma^h_{m+i}$ and $\sigma^h_0 = \mathbf{1}_{h+1}$. In particular, $\sigma^h_m$ is invertible for all $h \geq 0$ and $m \in \mathbb{Z}$.

**Lemma 3.4.** Assume $n > 1$. If the matrices $A_1, A_2 \in \text{End}(\mathbb{C}^n)$ satisfy condition (P2), then the system $A_1 C_q = A_2 C_{q+1}$, $q = 1, \ldots, n-1$, with $C_q \in \text{End}(\mathbb{C}^n)$, has maximal rank, namely, $(n-1)c^2$. In particular, if $\det A_{2m} \neq 0$, the general solution of the previous linear system is

$$
\begin{pmatrix}
C_1 \\
\vdots \\
C_n
\end{pmatrix} = (\sigma_m^{n-1} \otimes \mathbf{1}_c)
\begin{pmatrix}
1_c \\
B_m \\
\vdots \\
B_m^{n-1}
\end{pmatrix} D_m,
$$

where we have chosen as free parameter the matrix

$$
D_m = \sum_{q=1}^{n} \begin{pmatrix} n-1 \\ q-1 \end{pmatrix} c_m^{n-q} s_m^{q-1} C_q.
$$

Proof. The maximality of the rank of the system follows from condition (P2) by arguing as in [15, pp. 29-30]. Eq. (3.8) can be verified by direct substitution. \hfill \Box

Since $E_m = D_m A_{2m}$, the morphism $\zeta_m$ is injective.

Next we prove that $\text{Im} \zeta_m \subseteq T(c) \times \text{GL}(c, \mathbb{C})$. This follows from the next Lemma.

**Lemma 3.5.** (i) For all $(B_m, E_m, c; A_{2m}) \in \text{Im} \zeta_m$, one has $[B_m, E_m] = 0$.

(ii) Let $(A_1, A_2; C_1, \ldots, C_n; c) \in \text{End}(\mathbb{C}^c)^{\otimes (n+2)} \oplus \text{Hom}(\mathbb{C}^c, \mathbb{C})$ be an $(n+3)$-tuple such that condition (P1) is satisfied and $\det A_{2m} \neq 0$. Then

- if $[\lambda_1, \lambda_2] = [c_m, s_m]$, condition (P3) is trivially satisfied;
- if $[\lambda_1, \lambda_2] \neq [c_m, s_m]$, condition (P3) holds if and only if condition (T2) holds for the triple $(B_m, E_m, c)$.

Proof. (i) For all $n \geq 1$, condition (P1) implies

$$
0 = A_1 C_q A_2 - A_2 C_q A_1 = A_{1m} C_q A_{2m} - A_{2m} C_q A_{1m} = -A_{2m} [C_q A_{2m}, B_m]
$$

for $q = 1, \ldots, n$ and $m = 0, \ldots, c$. The thesis follows from eq. (3.6).

(ii) If $[\lambda_1, \lambda_2] = [c_m, s_m]$ one has $\lambda_2 A_1 + \lambda_1 A_2 = \lambda A_{2m}$ for some $\lambda \in \mathbb{C}^\times$. This proves the first statement.

Assume that $[\lambda_1, \lambda_2] \neq [c_m, s_m]$. One has

$$
\lambda_2 A_1 + \lambda_1 A_2 = \lambda A_{2m} (B_m - z \mathbf{1}_c) \quad \text{where} \quad z = \frac{c_m \lambda_1 + s_m \lambda_2}{s_m \lambda_1 - c_m \lambda_2}
$$

and

$$
\lambda_1^2 \mu_1 + \lambda_2^2 \mu_2 = 0 \quad \text{if and only if} \quad \begin{cases}
\mu_1 = (-1)^{n-1} (s_m z - c_m)^n w \\
\mu_2 = (-1)^n (c_m z + s_m)^n w
\end{cases}
$$

where

$$
\lambda_1^2 \mu_1 + \lambda_2^2 \mu_2 = 0 \quad \text{if and only if} \quad \begin{cases}
\mu_1 = (-1)^{n-1} (s_m z - c_m)^n w \\
\mu_2 = (-1)^n (c_m z + s_m)^n w
\end{cases}
$$
for some $\lambda \in \mathbb{C}^*$ and $w \in \mathbb{C}$. By using eqs. (3.8) and (3.9) one can prove the equivalence between the systems

\[
\begin{aligned}
(\lambda_2 A_1 + \lambda_1 A_2)v &= 0 \\
C_1 A_2 v &= -\mu_1 v \\
C_n A_1 v &= (-1)^n \mu_2 v \\
\end{aligned}
\tag{3.10}
\]

and

\[
\begin{aligned}
(\lambda_2 A_1 + \lambda_1 A_2)v &= 0 \\
C_1 A_2 v &= -\mu_1 v \\
C_n A_1 v &= (-1)^n \mu_2 v \\
\end{aligned}
\tag{3.11}
\]

The thesis follows as the polynomials $s_m z - c_m$ and $c_m z + s_m$ are coprime in $\mathbb{C}[z]$. \hfill \Box

The following result will be useful in the next section.

**Corollary 3.6.** Let $(A_1, A_2; C_1, \ldots, C_n) \in \text{End}(\mathbb{C}^n)^{(n+2)}$ be an $(n+2)$-tuple such that conditions (P1) and (P2) are satisfied. There exists a nonzero vector $v \in \mathbb{C}^c$ and parameters $([\lambda_1, \lambda_2], (\mu_1, \mu_2)) \in \mathbb{P}^1 \times \mathbb{C}^2$ such that

\[
\begin{aligned}
\lambda_1^a \mu_1 + \lambda_2^b \mu_2 &= 0 \\
(\lambda_2 A_1 + \lambda_1 A_2)v &= 0 \\
C_1 A_2 v &= -\mu_1 v \\
C_n A_1 v &= (-1)^n \mu_2 v \\
\end{aligned}
\tag{3.12}
\]

**Proof.** By condition (P2) there exists $m \in \{0, \ldots, c\}$ such that $\det A_{2m} \neq 0$, so that one can define $B_m$. One can also define $E_m$ according to eq. (3.5) one deduces that $B_m$ and $E_m$ commute, hence they have a common eigenvector $v \in \mathbb{C}^c$ with eigenvalues, say, $z$ and $w$, respectively. By eq. (3.10) this is equivalent to eq. (3.12), provided we define

\[
\begin{aligned}
\lambda_1 &= c_m z + s_m \\
\mu_1 &= (-1)^{n-1} (s_m z - c_m)^n w \\
\lambda_2 &= s_m z - c_m \\
\mu_2 &= (-1)^n (c_m z + s_m)^n w \\
\end{aligned}
\]

Eq. (3.11) can now be checked. \hfill \Box

Finally, we prove that $T(e) \times \text{GL}(c, \mathbb{C}) \subseteq \mathbb{I}m \zeta_m$. Let $(b_1, b_2, c; A) \in T(e) \times \text{GL}(c, \mathbb{C})$; if

\[
A_1 = A(c_m b_1 + s_m 1_c), \quad A_2 = A(-s_m b_1 + c_m 1_c)
\tag{3.13}
\]

then $(A_1, A_2; C_1, \ldots, C_n; e) \in P^c(e)_m$ and $\zeta_m(A_1, A_2; C_1, \ldots, C_n; e) = (b_1, b_2, c; A)$. One can verify by substitution that condition (P1) holds. Note now that by substituting (3.13) into eq. (3.6) one gets

\[
A_{1m} = Ab_1, \quad A_{2m} = A, \quad E_m = b_2.
\]

This shows that $A_{2m}$ is invertible, and in particular, condition (P2) holds. Since $B_m = b_1$, by Lemma 3.5 condition (P3) holds as a consequence of (T2). This concludes the proof of Proposition 3.3.
We now compute the transition functions on the intersections \( P^n(c)_{ml} = P^n(c)_m \cap P^n(c)_l \), for \( m, l = 0, \ldots, c \). First observe that

\[
\zeta_m (P^n(c)_{ml}) = T(c)_{m,l} \times \text{GL}(c, \mathbb{C})
\]
as a consequence of the identity

\[
A_{2l} = \left(s_1 c \begin{pmatrix} c_m 1_c & s_m 1_c \\ -s_m 1_c & c_m 1_c \end{pmatrix} \right) A_{1m} = A_{2m}(c_{m-l} 1_c - s_{m-l} B_m)
\]

where we have used eq. (3.8), the relation \( A_{1m} \), and Lemma 3.5. As for \( E_l \), one has

\[
E_l = \sum_{p=1}^n \sigma_{l,0,p-1}^{-1} C_p A_{2l} = \sum_{p=0}^{n-1} \sigma_{0,p}^{-1} B_m \left[ E_m A_{2m}^{-1} A_{2l} = (c_{l-m} 1_c - s_{l-m} B_m)^n E_m \right],
\]

where we have used eq. (3.14), the relation \( \sigma_{m-l}^{-1} = \sigma_{l-m}^{-1} \sigma_{m-l}^{-1} \), and Lemma 3.5.

The equivariance of \( \omega_{lm} \) is straightforward, and this completes the proof.

Proposition 3.7. One has a commutative triangle

\[
\begin{array}{c}
P^n(c)_{ml} \\
\zeta_{m,l}
\end{array}
\begin{array}{c}
T(c)_{m,l} \times \text{GL}(c, \mathbb{C}) \\
\omega_{lm}
\end{array}
\begin{array}{c}
P^n(c)_{l,m} \\
\zeta_{l,m}
\end{array}
\]

where \( \zeta_{m,l} \) and \( \zeta_{l,m} \) are the restrictions of \( \zeta_m \) and \( \zeta_l \), respectively, and

\[
\omega_{lm}(B_m, E_m, c; A_{2m}) = (\varphi_{lm}(B_m, E_m, c), A_{2m}(c_{m-l} 1_c - s_{m-l} B_m)),
\]

the functions \( \varphi_{lm} \) being defined analogously to the transition functions in Proposition 3.2. The transition functions \( \omega_{lm} \) are \( \text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C}) \)-equivariant.

Proof. We want to express \( (B_l, E_l, c; A_{2l}) \) in terms of \( (B_m, E_m, c; A_{2m}) \). We already have eq. (3.14); analogously, one can prove \( A_{2l} = A_{2m}(s_{m-l} 1_c + c_{m-l} B_m) \). It follows that \( B_l = (c_{m-l} 1_c - s_{m-l} B_m)^{-1}(s_{m-l} 1_c + c_{m-l} B_m) \). As for \( E_l \), one has

\[
E_l = \sum_{p=1}^n \sigma_{l,0,p-1}^{-1} C_p
\]

From Proposition 3.3 we have

\[
P^n(c)_{m}/\text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C}) \simeq T(c)/\text{GL}(c, \mathbb{C}) \simeq U^{m,c};
\]

moreover, there is an equivariant isomorphism \( P^n(c)_{m} \simeq T(c) \times \text{GL}(c, \mathbb{C}) \). As \( T(c) \) is a principal \( \text{GL}(c, \mathbb{C}) \)-bundle over \( T(c)/\text{GL}(c, \mathbb{C}) \), the space \( P^n(c)_{m} \) turns out to be a principal \( \text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C}) \)-bundle over \( U^{m,c} \). Propositions 3.2 and 3.4 now imply that \( P^n(c) \) is a principal \( \text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C}) \)-bundle, and this completes the proof of Theorem 3.1.

4. Hilbert schemes as quiver varieties

In this section we prove that the Hilbert schemes of points of the total space \( X_n \) of the line bundles \( \mathcal{O}_P(-n) \) are isomorphic to suitable moduli spaces of quiver representations.
4.1. **Quiver varieties.** Given two arrows $x, y$, we adopt the notation $xy$ for “$y$ followed by $x$.”

We introduce the quivers $Q_1$ and $Q_2$

![Quiver diagrams](image)

and, for $n \geq 3$, the quivers $Q_n$

![Quiver diagram](image)

Consider the relations

\begin{align}
(4.1) & \quad a_1c_1a_2 = a_2c_1a_1, \\
(4.2) & \quad a_1c_1 = a_2c_2, \quad c_1a_1 = c_2a_2, \\
(4.3) & \quad a_1c_2 = a_2\ell_1, \quad c_2a_1 = \ell_1a_2, \\
(4.4) & \quad a_1\ell_t = a_2\ell_{t+1}, \quad \ell ta_1 = \ell_{t+1}a_2 \quad \text{for} \quad t = 1, \ldots, n - 3.
\end{align}

For $n \geq 1$, we introduce the ideal $I_n$ of the path algebra $\mathbb{C}Q_n$ generated by

1. the relation (4.1) for $n = 1$;
2. the relation (4.2) for $n = 2$;
3. the relations (4.2) and (4.3) for $n = 3$;
4. the relations (4.2), (4.3) and (4.4) for $n \geq 4$.

We briefly recall the notion of *Wemyss’s reconstruction algebra* (see [39, Section 2]). First, for all integers $\alpha_i \geq 2$, one considers the labelled Dynkin diagram of type $A_l$:

![Dynkin diagram](image)

second, one associates with this diagram the double quiver of the extended Dynkin quiver, by adding a 0-th vertex. One gets

![Double quiver](image)

Finally, for any $\alpha_i > 2$, one draws $\alpha_i - 2$ additional arrows from the $i$-th vertex to the 0-th vertex. We call $Q$ the quiver we obtain at the end of this procedure. The *reconstruction algebra of type A* associated with the labels $[\alpha_1, \ldots, \alpha_l]$, with each $\alpha_i \geq 2$, was introduced in [39, Definition 2.3] as a certain quotient of the path algebra $\mathbb{C}Q$. 
As in [39, Definition 2.6], for $m_1, m_2 \in \mathbb{N}$ with $\gcd(m_1, m_2) = 1$ and $m_1 > m_2$, we denote by $\frac{1}{m_1}(1, m_2)$ the cyclic subgroup of $\text{GL}(2, \mathbb{C})$ generated by
\[
\begin{pmatrix}
\varepsilon & 0 \\
0 & e^{m_2}
\end{pmatrix},
\]
where $\varepsilon$ is a primitive $m_1$-th root of unity. Furthermore, we recall that we can associate with a pair $m_1, m_2$ as above the so-called Jung-Hirzebruch continued fraction expansion of $\frac{m_1}{m_2}$, namely
\[
\frac{m_1}{m_2} = \alpha_1 - \frac{1}{\alpha_2 - \frac{1}{\alpha_3 - \ldots}},
\]
where each $\alpha_i \in \mathbb{N} \geq 2$.

**Definition 4.1 (39 Definition 2.7).** The reconstruction algebra $A_{m_1, m_2}$ associated with the group $\frac{1}{m_1}(1, m_2)$ is the reconstruction algebra of type A corresponding to the integers of the Jung-Hirzebruch continued fraction expansion of $\frac{m_1}{m_2}$.

By comparing the definitions, for $n \geq 2$ the reconstruction algebras $A_{n,1}$ turn out to be precisely the quotients of the path algebras of our quivers $Q_n$ by the ideals $I_n$. However, there is no such correspondence for $n = 1$. In particular, we stress that, for $n \geq 2$, the quiver $Q_n$ coincides with the special McKay quiver associated with toric singularity of type $\frac{1}{n}(1,1)$.

From now on, we definitively deviate from Wemyss’s construction. We construct new quivers out of $Q_n$, by adding a “framing vertex.”

(4.5)
We call these new quivers $Q_n^\mu$, for $n \geq 1$. In what follows, any time an index runs from 1 to $n-1$, for $n = 1$ it will be understood that there is no associated object. Consider the relations

\begin{align*}
(4.6) & \quad a_1c_1a_2 = a_2c_1a_1, \\
(4.7) & \quad a_1c_1 = a_2c_2, \quad c_1a_1 + i_1j = c_2a_2, \\
(4.8) & \quad a_1c_2 = a_2c_1, \quad c_2a_1 + i_2j = c_1a_2, \\
(4.9) & \quad a_1a_t = a_2a_{t+1}, \quad a_t a_1 + i_{t+2}j = a_{t+1}a_2 \quad \text{for} \quad t = 1, \ldots, n - 3,
\end{align*}

and let $I_n^\mu$ be the ideal of the path algebra $\mathbb{C}Q_n^\mu$, generated by

1. the relation (4.6) for $n = 1$;
2. the relation (4.7) for $n = 2$;
3. the relations (4.7) and (4.8) for $n = 3$;
4. the relations (4.7), (4.8) and (4.9) for $n \geq 4$.

Note that, while $I_n^\mu$ and $I_1$ are defined by the same relation, when $n \geq 2$ we not only added a framing vertex to $Q_n$, but also “framed” the ideal $I_n$.

Let $B_n^\mu = \mathbb{C}Q_n^\mu/I_n^\mu$; for every $\vec{v} := (v_0, v_1) \in \mathbb{N}^2$, $w \in \mathbb{N}$, a $(\vec{v}, w)$-dimensional representation of $B_n^\mu$ is given by the choice of three $\mathbb{C}$-vector spaces, $V_0, V_1$ and $W$, with $\dim V_i = v_i$, $\dim W = w$, together with an element $(A_1, A_2; C; f_1, \ldots, f_{n-1})$ of

$$\Hom_{\mathbb{C}}(V_0, V_1)^{\oplus 2} \oplus \Hom_{\mathbb{C}}(V_1, V_0)^{\oplus n} \oplus \Hom_{\mathbb{C}}(V_0, W) \oplus \Hom_{\mathbb{C}}(W, V_0)^{\oplus n-1}$$

compatible with the relations in (4.6)–(4.9). We will refer to the totality of the equations induced by (4.6)–(4.9) at the representation level as “condition (Q1).” The vertex $\infty$ is interpreted as a framing vertex because we regard $\text{Rep}(B_n^\mu, \vec{v}, w)$ as a $\text{GL}(v_0, \mathbb{C}) \times \text{GL}(v_1, \mathbb{C})$-variety, avoiding the change of basis action of $\text{GL}(w, \mathbb{C})$.

**Remark 4.2.** Let $Q$ be a quiver and denote by $Q^{\text{double}}$ its double, which is obtained from $Q$ by adding for any arrow a new arrow in the opposite direction. Fix $\vec{v} = (v_i) \in \mathbb{N}^I$, and let $G_{\vec{v}} = \Pi_{i \in I} \text{GL}(v_i)$. One can see [10 §4.3] that $\text{Rep}(Q^{\text{double}}, \vec{v}) \simeq T^* \text{Rep}(Q, \vec{v})$; in particular, this space carries a natural symplectic structure, the canonical one. This is the setting in which one would like to perform the so-called *Hamiltonian reduction*: the first step of this procedure consists in considering the moment map $\mu$ associated with the natural (symplectic) $G_{\vec{v}}$-action on $\text{Rep}(Q^{\text{double}}, \vec{v})$, which is given by

\begin{equation}
\text{Rep}(Q^{\text{double}}, \vec{v}) \xrightarrow{\mu} \mathfrak{g}_{\vec{v}}^* \cong \Pi_{i \in I} \text{End}(\mathbb{C}^{v_i}) \xrightarrow{X} \sum_{a \in E} (X_a \circ X_{a^*} - X_{a^*} \circ X_a),
\end{equation}

where $a^*$ is the arrow opposite to $a$. Note that the moment map is induced, at the representation level, by a moment element, which by an abuse of notation we call $\mu$ again:

\begin{equation}
\mu = \sum_{a \in E} (aa^* - a^*a) \in \mathbb{C}Q^{\text{double}}.
\end{equation}

One can see that the moment element can be decomposed as follows: $\mu = (\mu_i)_{i \in I}$, where $\mu_i \in e_i \cdot \mathbb{C}Q^{\text{double}} \cdot e_i$. The zero level set $\mu^{-1}(0)$ can be reinterpreted as $\text{Rep}(B, \vec{v})$, where $B$ is the quotient $\mathbb{C}Q^{\text{double}}/(\mu)$.

For now we only observe that the algebra $B_2^\mu$ fits into this picture. We shall return to this topic in Section [4.3]. For $n \neq 2$, although the relations defining the ideals $I_n^\mu$ look like equations for the
zero level of some “deformed (Poissonian?) moment map,” at present we are not able to interpret them from this perspective.

Definition 4.3. Fix \( \vartheta \in \mathbb{R}^2 \). A \((\vec{v}, w)\)-dimensional representation \((V_0, V_1, W)\) is said to be \( \vartheta \)-semistable if, for any sub-representation \( S = (S_0, S_1) \subseteq (V_0, V_1) \), one has:

\[
\text{if } S_0 \subseteq \ker e, \text{ then } \vartheta \cdot (\dim S_0, \dim S_1) \leq 0; \tag{4.12}
\]

\[
\text{if } S_0 \supseteq \text{Im } f_i \text{ for } i = 1, \ldots, n - 1, \text{ then } \vartheta \cdot (\dim S_0, \dim S_1) \leq \vartheta \cdot (v_0, v_1). \tag{4.13}
\]

For \( n = 1 \), the condition in \((4.13)\) must hold for any sub-representation. A \( \vartheta \)-semistable representation is \( \vartheta \)-stable if strict inequality holds in \((4.12)\) whenever \( S \neq 0 \) and in \((4.13)\) whenever \( S \neq (V_0, V_1) \).

Remark 4.4. The notion of (semi)stability introduced in Definition 4.3 is indeed a (semi)stability in the sense of GIT (depending on the parameter \( \vartheta \)). One can see this by slightly generalizing a result due to Crawley-Boevey for usual framed quivers \([11\ p. 261]\), and then referring to King’s classical paper \([21]\). This procedure is completely straightforward and will be therefore omitted. However, the scrupulous reader can find all details in \([3\ Section 3]\).

4.2. The main result. We denote by \( //_{\vartheta} \) the GIT quotient associated with the parameter \( \vartheta \). We shall prove the following result:

Theorem 4.5. For every \( n, c \geq 1 \), the variety \( \text{Hilb}^{c}(X_n) \) is isomorphic to an irreducible connected component of the quotient

\[
\text{Rep} \left( \left( B_{n}^{\text{fr}}, \vec{v}_c, 1 \right)_{ss} //_{\vartheta_c} \text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C}) \right), \tag{4.14}
\]

where \( \vec{v}_c = (c, c) \) and \( \vartheta_c = (2c, -2c + 1) \).

More precisely, this component is given by the equations \( f_1 = \cdots = f_{n-1} = 0 \). In particular, for \( n = 1 \), it coincides with the whole space.

Remark 4.6. In the case of the Hilbert scheme of \( \mathbb{C}^2 \), since the space \( W \) is 1-dimensional, and due to the stability condition, Nakajima’s map \( j \) vanishes \([28\ 14]\). In the present case, that would correspond to the fact that the equations \( f_i = 0 \) are implied by the stability conditions, and then the quotient \((4.14)\) would be irreducible. At the moment we are unable to prove this result, and we only show that the equations \( f_i = 0 \) follow from conditions (Q2) and (Q3*) (introduced below), which are a priori stronger than the stability conditions, which will be expressed by (Q2) and (Q3).

We fix \( V_0 = V_1 = \mathbb{C}^c \). The following Lemma is a direct consequence of the semistability conditions \((4.12)\) and \((4.13)\).

Lemma 4.7. An element \((A_1, A_2; C_1, \ldots, C_n; e; f_1, \ldots, f_{n-1}) \in \text{Rep}(B_{n}^{\text{fr}}, \vec{v}_c, 1)\) is \( \vartheta_c \)-semistable if and only if

- (Q2) for all sub-representations \( S = (S_0, S_1) \) such that \( S_0 \subseteq \ker e \), one has \( \dim S_0 \leq \dim S_1 \), and, if \( \dim S_0 = \dim S_1 \), then \( S = 0 \);

- (Q3) for all sub-representations \( S = (S_0, S_1) \) such that \( S_0 \supseteq \text{Im } f_i \), for \( i = 1, \ldots, n - 1 \), one has \( \dim S_0 \leq \dim S_1 \) (for \( n = 1 \), this must hold for any sub-representation).

Furthermore, \( \vartheta_c \)-semistability and \( \vartheta_c \)-stability are equivalent.
Lemma 4.11. If \( H \) hence the maximum number of linearly independent vectors in (4.16) is
\[
\dim_s(\mathbb{F}^n, \mathbb{C}) = \dim_s(\mathbb{F}^n, \mathbb{C}) \leq \dim_s(\mathbb{F}^n, \mathbb{C}) + 1.
\]

Corollary 4.8. If \((A_1, A_2; C_1, \ldots, C_n; c; f_1, \ldots, f_{n-1}) \in \mathcal{R}_n(c), \) the map \( e \) is not zero.

Proof. If \( e \) is the zero map the sub-representation \( S = (\mathbb{C}^c, \mathbb{C}^c) \) violates condition (Q2).

We observe that the action of \( \text{GL}(c, \mathbb{C}) \times \text{GL}(c, \mathbb{C}) \) on \( \mathcal{R}_n(c) \) is compatible with the action of the same group on the space of ADHM data \( P^n(e) \) we have defined in eq. (3.11). Thus, to prove Theorem II.3 we can work directly on \( P^n(c) \) and \( \mathcal{R}_n(c) \) without taking the actions into consideration.

We denote by \( Z_n(c) \) the closed subvariety of \( \mathcal{R}_n(c) \) cut by the equations \( f_1 = \cdots = f_{n-1} = 0 \) (for \( n = 1 \), \( Z_n(c) \) coincides with the whole \( \mathcal{R}_n(c) \)).

Proposition 4.9. One has \( P^n(c) = Z_n(c) \). In particular, this proves Theorem II.2 when \( n = 1 \).

The proof of this Proposition will require the next two lemmas.

Lemma 4.10. The matrices \( A_1, A_2 \) satisfy condition (P2) if and only if they satisfy the requirement
\[(Q3^*) \text{ for any subspace } S_0 \subseteq \mathbb{C}^c, \dim(A_1(S_0) + A_2(S_0)) \geq \dim S_0.\]

Proof. Suppose that condition (P2) is satisfied by \( A_1, A_2 \). Let \( S_0 \) be any subspace, and let \( \{v_1, \ldots, v_k\} \) be a basis for it. Then, for suitable \( [v_1, v_2] \in \mathbb{P}^1, \{(v_1 A_1 + v_2 A_2)v_j\}_{j=1}^k \) is a set of linearly independent vectors in \( A_1(S_0) + A_2(S_0) \). So (Q3*) is also satisfied.

To prove the converse, suppose that condition (P2) is not satisfied, i.e., the pencil \( A_1 + \lambda A_2 \) is singular. Let us consider a polynomial solution of minimal degree \( \varepsilon \) for that pencil:
\[
v(\lambda) = v_0 - \lambda v_1 + \lambda^2 v_2 + \cdots + (-1)^{\varepsilon} \lambda^\varepsilon v_\varepsilon, \quad \text{with } v_\varepsilon \neq 0.
\]
Introduce the subspace \( S_0 := \langle v_0, \ldots, v_\varepsilon \rangle \). The vectors \( v_0, \ldots, v_\varepsilon \) are linearly independent (see [15], §XII, Proof of Theorem 4), so that \( \dim S_0 = \varepsilon + 1 \). Now,
\[
A_1(S_0) + A_2(S_0) = (A_1 v_0, \ldots, A_1 v_\varepsilon, A_2 v_0, \ldots, A_2 v_\varepsilon).
\]
By substituting into the equation \( (A_1 + \lambda A_2)v(\lambda) = 0 \) and by equating to zero the coefficients of the powers of \( \lambda \), we get the \( \varepsilon + 2 \) relations
\[
A_1 v_0 = 0, \quad A_2 v_0 - A_1 v_1 = 0, \ldots, \quad A_2 v_{\varepsilon-1} - A_1 v_\varepsilon = 0, \quad A_2 v_\varepsilon = 0.
\]
Hence the maximum number of linearly independent vectors in (4.16) is
\[
2\varepsilon + 2 - (\varepsilon + 2) = \varepsilon < \varepsilon + 1.
\]

Lemma 4.11. If \((A_1, A_2; C_1, \ldots, C_n; c; f_1, \ldots, f_{n-1}) \in \mathcal{R}_n(c), \) \( \ker A_1 \cap \ker A_2 = \{0\} \).

Proof. Suppose that there exists a nonzero vector \( v \in \mathbb{C}^c \) such that \( A_i(v) = 0 \) for \( i = 1, 2 \). For \( n = 1 \), the sub-representation \( \langle v, \{0\} \rangle \) violates condition (Q3). For \( n \geq 2 \), if \( v \in \ker e \), the sub-representation \( \langle v, \{0\} \rangle \) violates condition (Q2); if \( v \notin \ker e \), one has \( \text{Im } f_q = \langle f_q e(v) \rangle \), for

\[4\text{By polynomial solution we mean a solution } v(\lambda) \text{ of the equation } (A_1 + \lambda A_2)v(\lambda) = 0 \text{ which is a polynomial in } \lambda. \]

Such a solution always exists [13, p. 29].
Suppose indeed that $S$ implies dim $A$ conditions (P2) and (P3). Suppose that the pencil $A_1 + \lambda A_2$ is singular. Let $v(\lambda)$ be a polynomial solution of minimal degree for the pencil defined in eq. (4.15). Lemma 4.11 implies $\varepsilon \geq 1$. Set

$$S_0 := \langle v_0, \ldots, v_\varepsilon \rangle,$$

$$S_1 := A_1(V_0) + A_2(V_0),$$

$$S_2 := \sum_{q=1}^n C_q(V_1).$$

We know that dim $S_0 = \varepsilon + 1$ and dim $S_1 = \varepsilon$ [15, XII, Proof of Theorem 4]. It is not difficult to show that $S_2 = 0$. In fact, by using repeatedly condition (P1) and the relations in [14, 17], one sees that

$$S_2 = \langle C_n A_1 v_1, \ldots, C_n A_1 v_\varepsilon \rangle,$$

and, if $S_2 \neq 0$, by direct computation one can check that $\sum_{q=1}^\varepsilon (-\lambda)^{q-1} C_n A_1 v_q$ is a polynomial solution of degree smaller than $\varepsilon$. Thus, the sub-representation $S = (S_0, S_1)$ fails to satisfy (Q3). As a consequence, condition (Q2) holds in $P^n(c)$. We know that dim $S_0 = \varepsilon + 1$ for all sub-representations $S = (S_0, S_1)$ and, if $\mu$ violates condition (Q3). As for the opposite inclusion, $Z_n(c) \subseteq P^n(c)$, we have to show that any element of $Z_n(c)$ satisfies conditions (P2) and (P3). Suppose that the pencil $A_1 + \lambda A_2$ is singular. Let $v(\lambda)$ be a polynomial solution of minimal degree for the pencil defined in eq. (4.15). Lemma 4.11 implies $\varepsilon \geq 1$. Set

$$S_0 := \langle v_0, \ldots, v_\varepsilon \rangle,$$

$$S_1 := A_1(V_0) + A_2(V_0),$$

$$S_2 := \sum_{q=1}^n C_q(V_1).$$

We know that dim $S_0 = \varepsilon + 1$ and dim $S_1 = \varepsilon$ [15, XII, Proof of Theorem 4]. It is not difficult to show that $S_2 = 0$. In fact, by using repeatedly condition (P1) and the relations in [14, 17], one sees that

$$S_2 = \langle C_n A_1 v_1, \ldots, C_n A_1 v_\varepsilon \rangle,$$

and, if $S_2 \neq 0$, by direct computation one can check that $\sum_{q=1}^\varepsilon (-\lambda)^{q-1} C_n A_1 v_q$ is a polynomial solution of degree smaller than $\varepsilon$. Thus, the sub-representation $S = (S_0, S_1)$ fails to satisfy (Q3). As a consequence, condition (P2) holds in $Z_n(c)$. Finally, let $v \in \mathbb{C}^c$ be a vector violating condition (P3). Set

$$S_0 := \langle v \rangle, \quad S_1 := \langle A_1 v, A_2 v \rangle.$$

In particular, $v \neq 0$, so dim $S_0 = 1$. The conditions $\lambda A_1 v + \lambda_1 A_2 v = 0$ and Lemma 4.11 together imply dim $S_1 = 1$. We claim that

$$S_2 := \sum_{q=1}^n C_q(S_2) \subseteq \langle v \rangle.$$

Suppose indeed that $S_1 = \langle A_1 v \rangle$. Then $A_2 v = \lambda A_1 v$ for some $\lambda \in \mathbb{C}$. This implies

$$S_2 = \langle C_1 A_1 v, \ldots, C_n A_1 v \rangle.$$

Now, by hypothesis $C_n A_1 v \in \langle v \rangle$; one has

$$C_q A_1 v = C_{q+1} A_2 v = \lambda C_{q+1} A_1 v \quad \text{for } q = 1, \ldots, n - 1.$$
so that by induction one gets $C_qA_1v = \lambda^{n-q}C_nA_1v \subseteq \langle v \rangle$, for $q = 1, \ldots, n-1$. The case $S_1 = (A_2v)$ is completely analogous. Thus, the claim is proved, and as $S_0 \subseteq \ker e$ by hypothesis, $(S_0, S_1)$ is a sub-representation that violates condition (Q2). So $P^n(c) = Z_n(c)$. Note that condition (P3) holds on the whole of $\mathcal{R}_n(c)$.

\textit{Proof of Theorem 4.5} when $n \geq 2$. Having proved Proposition 4.9, it remains to show that $Z_n(c)$ is a connected component of $\mathcal{R}_n(c)$, i.e., that $Z_n(c)$ is closed and open in $\mathcal{R}_n(c)$, and it is connected. This last statement follows from the fact that $Z_n(c) = P^n(c)$ and from the connectedness of $\text{Hilb}^c(X_n)$ [12 Prop. 2.3].

We claim that the closed subvariety $Z_n(c)$ coincides with the open subset of $\mathcal{R}_n(c)$ where condition (P2) is satisfied, that is, we assume condition (P2) and prove that $Z_n(c)$ holds on the whole of $\mathcal{R}_n(c)$.

Given an element $(A_1, A_2; C_1, \ldots, C_n; e_1, \ldots, e_{n-1}) \in \mathcal{R}_n(c)$, we introduce the matrices $A_{1m}$, $A_{2m}$ and $E_m$ as in eq. (5.9); by condition (P2), we can choose $m$ such that $\det A_{2m} \neq 0$. After introducing the matrix $B_m = A_{2m}^{-1}A_{1m}$, we define

$$u_m := \sum_{q=1}^{n-1} \left(\begin{array}{c}n-2 \n q-1\end{array}\right) q^{n-1-q} c_m^{q-1} f_q,$$

and set

$$b_1 = t B_m, \quad b_2 = t E_m, \quad i = t e, \quad j = t u_m.$$

The data $b_1, b_2, i, j$ satisfy:

(i) $[b_1, b_2] + jq = 0$;

(ii) there exists no proper subspace $S \subseteq \mathbb{C}^n$ such that $b_\alpha(S) \subseteq S$ ($\alpha = 1, 2$) and $\text{Im} i \subseteq S$.

Indeed, relation (i) follows by direct computation, by suitably manipulating condition (Q1) and the expressions for the $C_q$’s given in eq. (4.3). As for condition (ii), it suffices to observe that the second statement of Lemma 3.5 which applies here too, is equivalent to the maximality of the rank of

$$\left((-b_2 - w 1_e) \ b_1 - z 1_e \right) i,$$

so that we can apply [28 Lemma 2.7 (2)]. By [28 Prop. 2.8 (1)], one has $u_m = 0$, which implies that $B_m$ and $E_m$ commute; by using this fact in combination with condition (Q1), one shows that $f_q e = 0$, for $q = 1, \ldots, n-1$. Corollary 4.8 allows one to conclude that $f_1 = \cdots = f_{n-1} = 0$, as wanted. \hfill \Box

4.3. \textbf{Comparison with Nakajima quiver varieties.} We focus now on the case $n = 2$; in particular, as a consequence of Theorem 4.5 we recover a result for ALE spaces due to Kuznetsova [22]. We recall that, according to Nakajima [26], any quiver $Q$ with vertex set $I$ is associated with a quiver variety $\mathcal{M}_\lambda, \theta(Q, \vec{v}, \vec{w})$, where $\vec{v} = (v_i), \vec{w} = (w_i) \in \mathbb{N}^I$, $\lambda = (\lambda_i) \in \mathbb{C}^I$ and $\theta \in \mathbb{R}^I$. The main steps of this construction are the following (see [16] for further details):

(i) one considers the quiver $Q^{fr}$, the framed version of $Q$, which is obtained by taking as set of vertices the disjoint union $I \sqcup I'$, where $I'$ is a copy of $I$, and by adding to the set of arrows $E$ one arrow from the $i$-th vertex to the $i'$-th vertex, for any $i \in I$. We call $\{d_i\}_{i \in I}$ these new arrows;

(ii) as in Remark 4.2, one introduces an auxiliary quiver $Q^{fr, \text{double}}$, the double of $Q^{fr}$, and consider the space $\text{Rep}(Q^{fr, \text{double}}, \vec{v}, \vec{w})$ of $(\vec{v}, \vec{w})$-dimensional representations of $\mathbb{C}Q^{fr, \text{double}}$. The group $G_\vec{v} = \prod_{i \in I} \text{GL}(v_i)$ acts naturally on this space if one regards $\text{GL}(v_i)$ as the
group of automorphisms of the vector space associated with the $i$-th vertex (of the original quiver $Q$); (iii) since the action of $G$ on $\text{Rep}(Q^{\text{fr, double}}, \vec{v}, \vec{w})$ is symplectic, one can introduce a moment map

$$
\mu = \sum_{a \in E} (X_a \circ X_{a^*} - X_{a^*} \circ X_a) + \sum_{i \in I} X_d_i^* \circ X_d_i
$$

(cf. eq. (4.10)), corresponding to a moment element, which we call again $\mu$ (analogous to eq. (4.11)); (iv) one defines the framed pre-projective algebra $\Pi^{\text{fr}}_\lambda Q$ of $Q$ with parameter $\lambda$ as the quotient $\mathbb{C}Q^{\text{fr, double}}/J$, where $J$ is the ideal of $\mathbb{C}Q^{\text{fr, double}}$ generated by the elements $\{\mu_i - \lambda_i\}_{i \in I}$. The fibre

$$
\mu^{-1}(\sum_{i \in I} \lambda_i 1_{v_i}) \subset \text{Rep}(Q^{\text{fr, double}}, \vec{v}, \vec{w})
$$

is the space of $(\vec{v}, \vec{w})$-dimensional representations of $\Pi^{\text{fr}}_\lambda Q$, which we denote $\text{Rep}(\Pi^{\text{fr}}_\lambda Q, \vec{v}, \vec{w})$; (v) one defines the quotient $M_{\lambda, \vartheta}(Q, \vec{v}, \vec{w}) := \text{Rep}(\Pi^{\text{fr}}_\lambda Q, \vec{v}, \vec{w})_{\vartheta}/G_{\vec{v}}$. We denote by $A$ the affine Dynkin quiver of type $A_1^{(1)}$, namely,

$$
0 \rightarrow a \rightarrow 1
b
$$

Corollary 4.12. For every $c \geq 1$, the variety $\text{Hilb}^c(X_2)$ is isomorphic to the Nakajima quiver variety $M_{0, \vartheta}(A, \vec{v}, \vec{w})$, where $\vartheta_c = (2c, -2c + 1)$, $\vec{v}_c = (c, c)$ and $\vec{w} = (1, 0)$.

Proof. As recalled above, one wants to consider the quiver $A^{\text{fr, double}}$:

The choice $\vec{w} = (1, 0)$ implies that the linear morphisms associated with $d_1$ and $d_1^*$ vanish, and this allows one to construct $M_{\lambda, \vartheta}(A, \vec{v}, \vec{w})$ using $Q^{\text{fr}}_2$ (see (4.20)). By a general result proved by Crawley-Boevey [11], the variety $M_{0, \vartheta}(A, \vec{v}, \vec{w})$ is connected (see also [16, Theorem 5.2.2] for some comments). The thesis now follows from Theorem 4.5. □

Appendix A. Proof of Proposition 3.2

A.1. A first step. We recall from Section 2 the notation $G_\vec{k} = \text{Aut}(U_\vec{k}) \times \text{Aut}(V_\vec{k}) \times \text{Aut}(W_\vec{k})$. Moreover, there we introduced a principal $G_\vec{k}$-bundle $P_\vec{k}$ such that $\text{Hilb}^c(X_2)$ can be described as a quotient $P_\vec{k}/G_\vec{k}$ for $\vec{k} = (n, 1, 0, c)$ (from now on we fix this value of $\vec{k}$). We recall also that the group $\text{GL}(c, \mathbb{C})$ acts on the space $T(c)$ according to the rule (3.8). Moreover, by embedding
\text{GL}(c, \mathbb{C}) \to G_\mathcal{E} \text{ by the equations}
\begin{equation}
\iota: \phi \mapsto \left( t^\epsilon \phi^{-1}, \text{diag}(t^\epsilon \phi^{-1}, t^\epsilon \phi^{-1}, 1), t^\epsilon \phi^{-1} \right),
\end{equation}
the group \text{GL}(c, \mathbb{C}) also acts on \( P_k \). We can therefore state the following Lemma.

\textbf{Lemma A.1.} \textit{There is a} \( \text{GL}(c, \mathbb{C}) \)-\textit{equivariant closed immersion} \( j_m: T(c) \to P_{k,m} \), \textit{where} \( \{ P_{k,m} \} \) \textit{is the open cover of} \( P_k \) \textit{given by the inverse image of the open cover} \( \{ U_{m,c}^n \} \) \textit{of} \( \text{Hilb}^n(X_n) \) \textit{introduced in eq. (B.4)}.

This immersion induces an isomorphism
\begin{equation}
\eta_m: T(c)/\text{GL}(c, \mathbb{C}) \longrightarrow P_{k,m}/G_\mathcal{E} \simeq U_{m,c}^n.
\end{equation}
We start by introducing some constructions that will be used in the proof of this Lemma. In particular, we define the immersion \( j_m \) for any given \( m \in \{ 0, \ldots, c \} \). To this aim, after fixing homogeneous coordinates \([y_1, y_2]\) for \( \mathbb{P}^1 \) (cfr. eq. (3.1)), we introduce additional \( c \) pairs of coordinates
\begin{equation}
[y_{m,1}, y_{m,2}] = [c_m y_1 + s_m y_2, -s_m y_1 + c_m y_2], \quad m = 0, \ldots, c,
\end{equation}
where \( c_m \) and \( s_m \) are the real numbers defined in eq. (3.3). The set \( \{ y_{m,1}^{q}y_{1,m}^{n-q} \}_{q=0}^{n} \) is a basis for \( H^0(\mathcal{O}_{\Sigma_n}(0, h)) = H^0(\pi^* \mathcal{O}_{\mathbb{P}^1}(h)) \) for all \( h \geq 1 \), where \( \pi: \Sigma_n \longrightarrow \mathbb{P}^1 \) is the canonical projection. Furthermore the (unique up to homotheties) global section \( s_E \) of \( \mathcal{O}_{\Sigma_n}(E) \) induces an injection \( \mathcal{O}_{\Sigma_n}(0, n) \to \mathcal{O}_{\Sigma_n}(1, 0) \), so that the set \( \{ y_{m,1}^{q}y_{1,m}^{n-q} s_E \}_{q=0}^{n} \cup \{ s_\infty \} \) is a basis for \( H^0(\mathcal{O}_{\Sigma_n}(1, 0)) \), where \( s_\infty \) is the section characterized by the condition \( \{ s_\infty = 0 \} = \ell_\infty \). This notation allows us to expand the morphisms \( \alpha \) and \( \beta \) (see eq. (2.1)) as follows:
\begin{equation}
\alpha = \left( \begin{array}{c}
\sum_{q=0}^{n} \alpha_{1q}^{(m)} (y_{2,m}^{q}y_{1,m}^{n-q} s_E) + \alpha_{1,n+1}s_\infty \\
\alpha_{20}^{(m)} y_{1,m} + \alpha_{21}^{(m)} y_{2,m}
\end{array} \right),
\end{equation}
\begin{equation}
\beta = \left( \begin{array}{c}
\beta_{10}^{(m)} y_{1,m} + \beta_{11}^{(m)} y_{2,m} \\
\sum_{q=0}^{n} \beta_{2q}^{(m)} (y_{2,m}^{q}y_{1,m}^{n-q} s_E) + \beta_{2,n+1}s_\infty
\end{array} \right).
\end{equation}
Note that the choice of a framing for a torsion-free sheaf \( \mathcal{E} \) which is trivial at infinity, and is the cohomology of a monad of the type \( \mathcal{E} \) is equivalent to the choice of a basis for \( H^0(\mathcal{E}|_{\ell_\infty}) \simeq H^0(\ker \beta|_{\ell_\infty}) = \ker H^0(\beta|_{\ell_\infty}) \), i.e., it is given by an injective linear map \( \xi: \mathbb{C}^r \to H^0(\mathcal{V}_k|_{\ell_\infty}) \) such that \( H^0(\beta|_{\ell_\infty}) \circ \xi = 0 \).

We put \( V_k := H^0(\mathcal{V}_k|_{\ell_\infty}) \). We can define the morphism
\begin{equation}
\bar{j}_m: \text{End}(\mathcal{C}) \otimes \mathbb{C} \to \text{Hom}(H_k, V_k) \rightarrow \text{Hom}(H_k, \mathcal{V}_k) \oplus \text{Hom}(\mathcal{V}_k, W_k) \oplus \text{Hom}(\mathcal{C}, V_k)
\end{equation}
\begin{equation}
(b_1, b_2, c) \mapsto (\alpha, \beta, \xi),
\end{equation}
where
\begin{equation}
\alpha = \left( \begin{array}{c}
1_c(y_{2,m}^{n} s_E) + t^b_2 s_\infty \\
1_c y_{1,m} + t^b_1 y_{2,m}
\end{array} \right),
\end{equation}
\begin{equation}
\beta = \left( \begin{array}{c}
1_c y_{1,m} + t^b_1 y_{2,m} \\
- (1_c(y_{2,m}^{n} s_E) + t^b_2 s_\infty)
\end{array} \right) t^c s_\infty,
\end{equation}
\begin{equation}
\xi = (1_c(y_{2,m}^{n} s_E) + t^b_2 s_\infty).
\end{equation}
\[ \xi = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix}, \]

and \( j_m \) is the restriction of \( j_m \) to \( T(c) \).

**Proof of Lemma A.1.** It is quite clear that \( j_m \) is a closed immersion, so that it is enough to prove that

\[ \text{Im } j_m \cap P_{k,m} = \text{Im } j_m. \]

Let \((\alpha, \beta, \xi) = j_m(b_1, b_2, e)\) be a point in the intersection \( \text{Im } j_m \cap P_{k,m} \); the equation \( \beta \circ \alpha = 0 \) implies that the triple \((b_1, b_2, e)\) satisfies condition (T1), while the fact that \( \beta \circ k(x) \) has maximal rank for all \( x \in \Sigma_n \) entails condition (T2). It follows that

\[ \text{Im } j_m \cap P_{k,m} \subseteq \text{Im } j_m. \]

To get the opposite inclusion, note that for all \((\alpha, \beta, \xi) \in \text{Im } j_m:\)

(i) the morphism \( \alpha \otimes k(x) \) fails to have maximal rank at most at a finite number of points \( x \in \Sigma_n \); hence, \( \alpha \) is injective as a sheaf morphism;

(ii) the morphisms \( \alpha \otimes k(x) \) and \( \beta \otimes k(x) \) have maximal rank for all points \( x \in \ell_\infty \cup F_m \);

(iii) the natural morphism \( \Phi : H^0((\text{coker } \alpha)|_{\ell_\infty}(-1)) \to H^0(W_{\bar{\ell}}|_{\ell_\infty}(-1)) \) is invertible;

(iv) \( \beta_1|_{F_m} = 1_e \), where \( \beta_1 : \mathcal{O}_{\Sigma_n}(1, -1)^{\oplus k_3} \to \mathcal{O}_{\Sigma_n}(1, 0)^{\oplus k_3} \) is the first component of \( \beta \);

(v) the morphism \( \xi \) has maximal rank.

If \((\alpha, \beta, \xi) \in \text{Im } j_m \), condition (T2) implies that \( \beta \circ k(x) \) has maximal rank for all \( x \in \Sigma_n \setminus (\ell_\infty \cup F_m) \); by (ii) this is enough to ensure that \( \beta \) is surjective. Condition (T1) implies \( \beta \circ \alpha = 0 \), so that we can define \( \mathcal{E} = \ker \beta / \text{Im } \alpha \). By (i) \( \mathcal{E} \) is torsion free, by (ii) and (iii) it is trivial at infinity, and by (iv) \( \mathcal{E}|_{F_m} \) is trivial as well. The \( GL(c, \mathbb{C}) \)-equivariance of \( j_m \) is readily checked. \( \Box \)

**A.2. A technical Lemma.** The next Lemma and Corollary will be used to show that \( j_m \) induces an isomorphism between the quotients of \( T(c) \) and \( P_{k,m} \) under the actions of \( GL(c, \mathbb{C}) \) and \( G_{\ell} \), respectively (cf. eq. [A.2]). Let \( X \) be a smooth algebraic variety over \( \mathbb{C} \) with an action \( \gamma : X \times G \to X \) of a complex affine algebraic group \( G \). The set-theoretical quotient \( X/G \) has a natural structure of ringed space induced by the quotient map \( q : X \to X/G \). If the action is free, and the graph morphism \( X \times G \to X \times X \) is a closed immersion, \( X/G \) is a smooth algebraic variety, the pair \((X/G, q)\) is a geometric quotient of \( X \) modulo \( G \), and \( X \) is a (locally isotrivial) principal \( G \)-bundle over \( X/G \). This can be proved by arguing as in the proof of [2] Theorem 5.1.

Let \( Y \) be a smooth closed subvariety of \( X \) and let \( H \hookrightarrow G \) be a closed subgroup of \( G \). Assume that \( H \) acts on \( Y \) and that the inclusion \( j : Y \hookrightarrow X \) is \( H \)-equivariant. We consider the quotient \( p : Y \to Y/H \) as a ringed space with the quotient topology, and structure sheaf given by the sheaf of invariant functions.

**Lemma A.2.** If the intersection of \( \text{Im } j \) with every \( G \)-orbit in \( X \) is nonempty, and for all \( G \)-orbits \( O_G \) in \( X \), one has \( \text{Stab}_G(O_G \cap \text{Im } j) = \text{Im } \iota \), then \( j \) induces an isomorphism \( \tilde{j} : Y/H \to X/G \) of algebraic varieties.

**Proof.** By [23] Prop. 0.7] the morphism \( q \) is affine. If \( U \subseteq X/G \) is an open affine subset, then \( V = q^{-1}(U) \) is affine, \( V = \text{Spec } A \), so that \( U = \text{Spec } (A^G) \), and the restricted morphism \( q|_{V} \) is
induced by the canonical injection \( q^2 : A^G \rightarrow A \). Since \( j \) is an affine morphism \([18\text{ Prop. 1.6.2.(i)}]\), the counterimage \( W = j^{-1}(V) \) is affine, \( W = \text{Spec} \, B \), and by the equivariance of \( j \) it is \( H \)-invariant.

It follows that its image \( p(W) = \text{Spec}(B^H) \) is affine, and the restricted morphism \( p|_W \) is induced by the canonical injection \( p^* : B^H \hookrightarrow B \). Let \( j^1 : A \rightarrow B \) be the homomorphism associated with \( j \). One can prove that \( \text{Im}(j^1 \circ q^2) \subseteq A^G \), and that this composition is an isomorphism, which induces \( j |_V \). Thus \( j \) is an isomorphism locally on the target, hence it is an isomorphism. \( \square \)

**Corollary A.3.** The morphism \( p : Y \rightarrow Y/H \) is an \( H \)-principal bundle, and is a reduction of the structure group of \( q : X \rightarrow X/G \). If \( X \rightarrow X/G \) is locally trivial, the same is true for \( Y \rightarrow Y/H \).

A.3. Conclusion.

**Lemma A.4.** For any \( G_\mathbb{C} \)-orbit \( O \) in \( P_{k,m} \), the intersection \( O \cap \text{Im} \, j_m \) is not empty and its stabilizer in \( G_\mathbb{C} \) coincides with \( \text{Im} \, \iota \) (the morphism \( \iota \) was defined in eq. (A.1)).

**Proof.** Let \( (\alpha, \beta, \xi) \in P_{k,m} \) be any point and let \( O \) be its \( G_\mathbb{C} \)-orbit. We call \( E \) the cohomology of \( M(\alpha, \beta) \). One can verify that the condition \( E |_{F_m} \simeq O_{F_m} \) is equivalent to the condition \( \det(\beta_{10}^{(m)}) \neq 0 \) (see eq. (A.3)). By acting with \( G_\mathbb{C} \), one can find a point in \( O \) such that

\[
\begin{align*}
\beta_{10}^{(m)} &= 1_c \\
\beta_{2q}^{(m)} &= 0 & q = 0, \ldots, n - 1.
\end{align*}
\]

We call \( O_1 \) the subvariety cut by these equations inside \( O \). The stabilizer of \( O_1 \) inside \( G_\mathbb{C} \) is the closed subgroup \( G_1 \) characterized by the conditions \( \psi_{11} = \chi \) and \( \psi_{12} = 0 \).

We put \( b_1 := t \beta_{11}^{(m)} \).

For all points in \( O_1 \) the equation \( \beta \circ \alpha = 0 \) implies

\[
\begin{align*}
\alpha_{1q}^{(m)} &= 0 & q = 0, \ldots, n - 1 \\
\alpha_{1n}^{(m)} &= -\beta_{2n}^{(m)} \alpha_{20}^{(m)}.
\end{align*}
\]

In particular, for all points in \( O_1 \), the invertibility of \( \Phi \) is equivalent to the condition \( \det(\alpha_{1n}^{(m)}) \neq 0 \), and by acting with \( G_1 \) we can find a point in \( O_1 \) such that

\[
\alpha_{1n}^{(m)} = 1_c.
\]

We call \( O_2 \) the subvariety cut by this equation inside \( O_1 \). The stabilizer of \( O_2 \) in \( G_1 \) is the closed subgroup \( G_2 \) characterized by the condition \( \gamma = \phi \).

From eq. (A.5) we deduce that \( \text{rk} \, \beta_{2n}^{(m)} = \text{rk} \, \alpha_{20}^{(m)} = c \). By acting with \( G_2 \) we can find a point in \( O_2 \) such that

\[
\alpha_{20}^{(m)} = \begin{pmatrix} 1_c \\ 0 \end{pmatrix}, \quad \beta_{2n}^{(m)} = \begin{pmatrix} 0 \\ -1_c \end{pmatrix}
\]

We call \( O_3 \) the subvariety cut by these equations inside \( O_2 \). The stabilizer of \( O_3 \) in \( G_2 \) is the closed subgroup \( G_3 \) characterized by the condition \( \psi_{22} = (\lambda^{0 \, 0 \, \omega \, 0}) \) for some \( \lambda \in \mathbb{C}^* \).

For all points in \( O_3 \) the equation \( H^0(\beta|_{E_{\omega}}) \circ \xi = 0 \) implies \( t\xi = (0, \ldots, 0, \omega) \) for some \( \omega \in \mathbb{C}^* \).

By acting with \( G_3 \) we can find a point in \( O_3 \) such that

\[
t\xi = (0, \ldots, 0, 1)
\]
We call $O_4$ the subvariety cut by this equation inside $O_3$. The stabilizer of $O_4$ in $G_4$ is the closed subgroup $G_4$ characterized by the condition $\psi_{22} = \left( \begin{smallmatrix} \alpha & 0 \\ 0 & 1 \end{smallmatrix} \right)$. One can see that $G_4 = \text{Im} \iota$. To get the thesis we have to prove that the subvariety $Z$ cut in $P_{k,m}$ by eqs. (A.4), (A.6), (A.7) and (A.8) coincides with $\text{Im} j_m$. For all points in $Z$ the equation $\beta \circ \alpha = 0$ implies
\[
\alpha_{21}^{(m)} = \left( \begin{array}{c} t \phi_1 \\ \gamma \psi_2 \end{array} \right), \quad \beta_{2,n+1} = \left( -\alpha_{1,n+1} + t \epsilon \right)
\]
and
\[
[t \alpha_{1,n+1}, b_1] + e_2 e = 0,
\]
for some $e \in \text{Hom}(\mathbb{C}^c, \mathbb{C})$ and $e_2 \in \text{Hom}(\mathbb{C}, \mathbb{C}^c)$. We put $b_2 = t \alpha_{1,n+1}$. By carefully adapting the arguments of the proof of [28] Prop. 2.8.(1) for co-stable ADHM data, one gets $e_2 = 0$. The equality $Z = \text{Im} j_m$ follows. □

So, as we anticipated, we have:

**Proposition A.5.** The morphism $j_m$ induces an isomorphism $\eta_m: \mathcal{T}(c)/\text{GL}(c, \mathbb{C}) \rightarrow P_{k,m}/G_k \simeq U_{m,c}^n$.

**Proof.** This is proved by Lemma A.22 whose hypotheses are satisfied in view of Lemma A.4. □

As a further step in the proof of Proposition A.22 we introduce the open subsets
\[
\mathcal{T}(c)_{m,l} = j_m^{-1} \left( \text{Im} j_m \cap P_{k,l} \right) \quad \text{for} \quad m, l = 0, \ldots, c.
\]
It is not difficult to see that
\[
\mathcal{T}(c)_{m,l} = \{(b_1, b_2, e) \in \mathcal{T}(c) | \det (c_{m-l} \mathbb{1}_c - s_{m-l} b_1) \neq 0 \}.
\]

To conclude our reasoning we need one more Lemma.

**Lemma A.6.** For any $l, m = 0, \ldots, c$ and for any point $\tilde{b}_m = (b_1, b_2, c_m) \in \mathcal{T}(c)_{m,l}$, there exists a unique element $\psi(\tilde{b}_m) = (\phi, \psi, \chi) \in G_k$ such that $\chi = 1_c$, and the point $(\alpha', \beta', \xi') = \psi(\tilde{b}_m) \cdot j_m(\tilde{b}_m)$ lies in the image of $j_1$. If we set
\[
(b_{1l}, b_{2l}, e_l) = j_1^{-1}(\alpha', \beta', \xi'),
\]
we have
\[
b_{1l} = (c_{m-l} \mathbb{1}_c - s_{m-l} b_1) (s_{m-l} \mathbb{1}_c + c_{m-l} b_1)^{-1} b_{2m}
\]
\[
b_{2l} = (c_{m-l} \mathbb{1}_c - s_{m-l} b_1)^n b_{2m}
\]
\[
e_l = c_m.
\]

**Proof.** If we set $(\alpha, \beta, \xi) = j_m(\tilde{b}_m)$, by expressing the coordinates $[y_{1m}, y_{2m}]$ as functions of $[y_{1l}, y_{2l}]$ we get
\[
\alpha = \left( \begin{array}{c} \sum_{q=0}^n (\sigma q \mathbb{1}_c)(y_{2l}^{q} y_{1l}^{n-q} s_E) + t b_{2m} s_\infty \\ d_{1m} y_{1m} + d_{2m} y_{2m} \\ 0 \end{array} \right),
\]
\[
\beta = \left( d_{1m} y_{1m} + d_{2m} y_{2m}, \quad -\sum_{q=0}^n (\sigma q \mathbb{1}_c)(y_{2l}^{q} y_{1l}^{n-q} s_E) - t b_{2m} s_\infty, \quad t e_m s_\infty \right),
\]
where
\[
d_{1m} = c_{m-l} \mathbb{1}_c - s_{m-l} t b_1 \quad \quad d_{2m} = s_{m-l} \mathbb{1}_c + c_{m-l} t b_1.
\]
and we have put \( \sigma_q = \sigma_{n-m,nq}^m \) for \( q = 0, \ldots, n \) (see eq. (3.7)). The explicit form of \( \psi(b_m) \) is obtained by imposing the equality

\[
(\phi, \psi, 1_c) \cdot (\alpha, \beta, \xi) = j_l(b_{1l}, b_{2l}, c_l)
\]

for some \( (b_{1l}, b_{2l}, c_l) \in T(c_l) \). One gets

\[
\phi = d_{1m}^{(n-1)}
\psi = \begin{pmatrix}
    d_{1m} & \psi_{12,1} & 0 \\
    0 & d_{1m}^{n-1} & 0 \\
    0 & 0 & 1
\end{pmatrix},
\]

where \( \psi_{12,1} = -\sum_{q=0}^{n-1} \sum_{p=0}^{n-q} \sigma_{q-p} (-d_{2m} d_{1m}^{n-q}) q! s_q y_1^{n-1-q} y_2^{n-1-q} \).

Eq. (A.11) follows from eq. (A.12). \( \square \)

Equations (A.10) and (A.11) yield a proof of Proposition 3.2.
