

Limiting two-Higgs-doublet models

Eung Jin Chun*

Korea Institute for Advanced Study, Seoul 130-722, Korea

Updating various theoretical and experimental constraints on the four different types of two-Higgs-doublet models (2HDMs), we find that only the “lepton-specific” (or “type X”) 2HDM can explain the present muon $(g-2)$ anomaly in the parameter region of large $\tan\beta$, a light CP-odd Higgs boson, and heavier CP-even and charged Higgs bosons which are almost degenerate. The severe constraints on the models come mainly from the consideration of vacuum stability and perturbativity, the electroweak precision data, B physics observables like $b \rightarrow s\gamma$ as well as the 125 GeV Higgs boson properties measured at the LHC.

I. OUTLINE

Since the first measurement of the muon anomalous magnetic moment $a_\mu = (g-2)_\mu/2$ by the E821 experiment at BNL in 2001 [1], much progress has been made in both experimental and theoretical sides to reduce the uncertainties by a factor of two or so establishing a consistent 3σ discrepancy

$$\Delta a_\mu \equiv a_\mu^{\text{EXP}} - a_\mu^{\text{SM}} = +262(85) \times 10^{-11} \quad (1)$$

which is in a good agreement with the different group’s determinations. Since the 2001 announcement, there have been quite a few studies in the context of 2HDMs [2–4] restricted only to the type I and II models. However, the type X model [5] has some unique features in explaining the a_μ anomaly while evading all the experimental constraints.

Among many recent experimental results further confirming the Standard Model (SM) predictions, the discovery of the 125 GeV Brout-Eglnert-Higgs boson, which is very much SM-like, particularly motivates us to revisit the issue of the muon $g-2$ in favor of the type X 2HDM.

The key features in confronting 2HDMs with the muon $g-2$ anomaly can be summarized as follows [6–9].

- The Barr-Zee two loop [10] can give a dominant (positive) contribution to the muon $g-2$ for a light CP-odd Higgs boson A and large $\tan\beta$ in the type II and X models.
- In the type II model, a light A has a large bottom Yukawa coupling for large $\tan\beta$, and thus is strongly constrained by the collider searches which have not been able to cover a small gap of $25(40)$ GeV $< M_A < 70$ GeV at the $2(1)\sigma$ range of the muon $(g-2)$ explanation [3].
- In the type II (and Y) model, the measured $\bar{B} \rightarrow X_s\gamma$ branching ratio pushes the charged Higgs boson H^\pm high up to 480 (358) GeV at 95 (99) % C.L. [11], which requires a large separation between M_A and M_{H^\pm} putting a strong limitation on the model due to the ρ parameter bound [4].
- Consideration of the electroweak precision data (EWPD) combined with the theoretical constraints from the vacuum stability and perturbativity requires the charged Higgs boson almost degenerate with the heavy Higgs boson H [12] (favoring $M_{H^\pm} > M_H$) and lighter than about 250 GeV in “the SM limit”; $\cos(\beta - \alpha) \rightarrow 0$. This singles out the type X model in favor of the muon $g-2$ [6].
- In the favored low m_A region, the 125 GeV Higgs decay $h \rightarrow AA$ has to be suppressed kinematically or by suppressing the trilinear coupling λ_{hAA} which is generically order-one. This excludes the 1σ range of the muon $g-2$ explanation in the SM limit [6].

*Electronic address: ejchun@kias.re.kr

However, the latest development [7–9] revealed more interesting possibilities in the “wrong-sign” domain (negative hbb or $h\tau\tau$ coupling) of 2HDMs [13].

- A cancellation in λ_{hAA} can be arranged to suppress arbitrarily the $h \rightarrow AA$ decay only in the wrong-sign limit with the heavy Higgs masses in the range of $M_{H^\pm} \sim M_H \approx 200 - 600$ GeV [7].
- The lepton universality affected by a large $H^+\tau\nu_\tau$ coupling turns out to severely constrain the large $\tan\beta$ and light H^\pm region of the type X (and II) model and thus only a very low M_A and $\tan\beta$ region is allowed at 2σ to explain the a_μ anomaly [8].

II. FOUR TYPES OF 2HDMs

Non-observation of flavour changing neutral currents restricts 2HDMs to four different classes which differ by how the Higgs doublets couple to fermions [14]. They are organized by a discrete symmetry Z_2 under which different Higgs doublets and fermions carry different parities. These models are labeled as type I, II, “lepton-specific” (or X) and “flipped” (or Y). Having two Higgs doublets $\Phi_{1,2}$, the most general Z_2 symmetric scalar potential takes the form:

$$V = m_{11}^2|\Phi_1|^2 + m_{22}^2|\Phi_2|^2 - m_{12}^2(\Phi_1^\dagger\Phi_2 + \Phi_1\Phi_2^\dagger) + \frac{\lambda_1}{2}|\Phi_1|^4 + \frac{\lambda_2}{2}|\Phi_2|^4 + \lambda_3|\Phi_1|^2|\Phi_2|^2 + \lambda_4|\Phi_1^\dagger\Phi_2|^2 + \frac{\lambda_5}{2}[(\Phi_1^\dagger\Phi_2)^2 + (\Phi_1\Phi_2^\dagger)^2], \quad (2)$$

where a (soft) Z_2 breaking term m_{12}^2 is introduced. Minimization of the scalar potential determines the vacuum expectation values $\langle\Phi_{1,2}^0\rangle \equiv v_{1,2}/\sqrt{2}$ around which the Higgs doublet fields are expanded as

$$\Phi_{1,2} = \left[\eta_{1,2}^\dagger, \frac{1}{\sqrt{2}}(v_{1,2} + \rho_{1,2} + i\eta_{1,2}^0) \right]. \quad (3)$$

The model contains the five physical fields in mass eigenstates denoted by H^\pm, A, H and h . Assuming negligible CP violation, H^\pm and A are given by

$$H^\pm, A = s_\beta \eta_1^{\pm,0} - c_\beta \eta_2^{\pm,0} \quad (4)$$

where the angle β is determined from $t_\beta \equiv \tan\beta = v_2/v_1$, and their orthogonal combinations are the corresponding Goldstone modes $G^{\pm,0}$. The neutral CP-even Higgs bosons are diagonalized as

$$h = c_\alpha \rho_1 - s_\alpha \rho_2, \quad H = s_\alpha \rho_1 + c_\alpha \rho_2 \quad (5)$$

where $h(H)$ denotes the lighter (heavier) state.

The gauge couplings of h and H are given schematically by $\mathcal{L}_{\text{gauge}} = g_V m_V (s_{\beta-\alpha} h + c_{\beta-\alpha} H) VV$ where $V = W^\pm$ or Z . When h is the 125 GeV Higgs boson, the SM limit corresponds to $s_{\beta-\alpha} \rightarrow 1$. Indeed, LHC finds, $c_{\beta-\alpha} \ll 1$ in all the 2HDMs confirming the SM-like property of the 125 GeV boson [15].

	y_u^A	y_d^A	y_l^A	y_u^H	y_d^H	y_l^H	y_u^h	y_d^h	y_l^h

TABLE I: The normalized Yukawa couplings for up- and down-type quarks and charged leptons.

Normalizing the Yukawa couplings of the neutral bosons to a fermion f by m_f/v where $v = \sqrt{v_1^2 + v_2^2} = 246$ GeV, we have the following Yukawa terms:

$$\begin{aligned}
 -\mathcal{L}_{\text{Yukawa}}^{2\text{HDMs}} = & \sum_{f=u,d,l} \frac{m_f}{v} (y_f^h h \bar{f} f + y_f^H H \bar{f} f - i y_f^A A \bar{f} \gamma_5 f) \\
 & + \left[\sqrt{2} V_{ud} H^+ \bar{u} \left(\frac{m_u}{v} y_u^A P_L + \frac{m_d}{v} y_d^A P_R \right) d + \sqrt{2} \frac{m_l}{v} y_l^A H^+ \bar{\nu} P_R l + h.c. \right]
 \end{aligned} \quad (6)$$

where the normalized Yukawa couplings $y_f^{h,H,A}$ are summarized in Table I for each of these four types of 2HDMs.

Let us now recall that the tau Yukawa coupling $y_\tau \equiv y_l^h$ in Type X ($y_b \equiv y_d^h$ in Type II) can be expressed as

$$y_\tau = -\frac{s_\alpha}{c_\beta} = s_{\beta-\alpha} - t_\beta c_{\beta-\alpha} \quad (7)$$

which allows us to have the wrong-sign limit $y_\tau \sim -1$ compatible with the LHC data [13] if $c_{\beta-\alpha} \sim 2/t_\beta$ for large $\tan\beta$ favoured by the muon $g-2$. Later we will see that a cancellation in λ_{hAA} can be arranged only for $y_\tau^h < -1$ to suppress the $h \rightarrow AA$ decay.

III. ELECTROWEAK CONSTRAINTS

FIG. 1: The parameter space allowed in the M_A vs. $\Delta M_H = M_H - M_{H^\pm}$ plane by EW precision constraints. The green, yellow, gray regions satisfy $\Delta\chi_{\text{EW}}^2(M_A, \Delta M) < 2.3, 6.2, 11.8$, corresponding to 68.3, 95.4, and 99.7% confidence intervals, respectively.

Let us first consider the constraints arising from EWPD on 2HDMs. In particular, we compare the theoretical 2HDMs predictions for M_W and $\sin^2\theta_{\text{eff}}^{\text{lept}}$ with their present experimental values via a combined χ^2 analysis. These quantities can be computed perturbatively by means of the following relations

$$M_W^2 = \frac{M_Z^2}{2} \left[1 + \sqrt{1 - \frac{4\pi\alpha_{\text{em}}}{\sqrt{2}G_F M_Z^2} \frac{1}{1 - \Delta r}} \right] \quad (8)$$

$$\sin^2\theta_{\text{eff}}^{\text{lept}} = k_l(M_Z^2) \sin^2\theta_W, \quad (9)$$

where $\sin^2\theta_W = 1 - M_W^2/M_Z^2$, and $k_l(q^2) = 1 + \Delta k_l(q^2)$ is the real part of the vertex form factor $Z \rightarrow \bar{l}l$ evaluated at $q^2 = M_Z^2$. We then use the following experimental values:

$$\begin{aligned}
 M_W^{\text{EXP}} &= 80.385 \pm 0.015 \text{ GeV}, \\
 \sin^2\theta_{\text{eff}}^{\text{lept,EXP}} &= 0.23153 \pm 0.00016.
 \end{aligned} \quad (10)$$

The results of our analysis are displayed in Fig. 1 confirming a custodial symmetry limit of our interest $M_A \ll M_H \sim M_{H^\pm}$ (or $M_H \ll M_A \sim M_{H^\pm}$) [12].

IV. THEORETICAL CONSTRAINTS ON THE SPLITTING M_A - M_{H^\pm}

Although any value of M_A is allowed by the EW precision tests in the limit of $M_H \sim M_{H^\pm}$, a large separation between M_{H^\pm} and M_A is strongly constrained by theoretical requirements of vacuum stability, global minimum, and perturbativity:

$$\lambda_{1,2} > 0, \quad \lambda_3 > -\sqrt{\lambda_1 \lambda_2}, \quad |\lambda_5| < \lambda_3 + \lambda_4 + \sqrt{\lambda_1 \lambda_2}, \quad (11)$$

$$m_{12}^2(m_{11}^2 - m_{22}^2 \sqrt{\lambda_1/\lambda_2})(\tan \beta - (\lambda_1/\lambda_2)^{1/4}) > 0, \quad (12)$$

$$|\lambda_i| \lesssim |\lambda_{\max}| = \sqrt{4\pi}, 2\pi, \text{ or } 4\pi. \quad (13)$$

Taking λ_1 as a free parameter, one can have the following expressions for the other couplings in the large t_β limit [9]:

$$\lambda_2 v^2 \approx s_{\beta-\alpha}^2 M_h^2 \quad (14)$$

$$\lambda_3 v^2 \approx 2M_{H^\pm}^2 - (s_{\beta-\alpha}^2 + s_{\beta-\alpha} y_\tau) M_H^2 + s_{\beta-\alpha} y_\tau M_h^2 \quad (15)$$

$$\lambda_4 v^2 \approx -2M_{H^\pm}^2 + s_{\beta-\alpha}^2 M_H^2 + M_A^2 \quad (16)$$

$$\lambda_5 v^2 \approx s_{\beta-\alpha}^2 M_H^2 - M_A^2 \quad (17)$$

where we have used the relation (7) neglecting the terms of $\mathcal{O}(1/t_\beta^2)$.

FIG. 2: Theoretical constraints on the M_A - M_{H^\pm} plane. The darker to lighter gray regions in the left panel correspond to the allowed regions for $\Delta M \equiv M_H - M_{H^\pm} = \{20, 0, -30\}$ GeV and $\lambda_{\max} = \sqrt{4\pi}$. The allowed regions in the right panel correspond to $\lambda_{\max} = \{\sqrt{4\pi}, 2\pi, 4\pi\}$ and vanishing ΔM .

Consideration of all the theoretical constraints mentioned above in the SM limit corresponding to $s_{\beta-\alpha} = y_\tau = 1$ gives us Fig. 2. One can see that for a light pseudoscalar with $M_A \lesssim 100$ GeV the charged Higgs boson mass gets an upper bound of $M_{H^\pm} \lesssim 250$ GeV.

V. CONSTRAINTS FROM THE MUON G-2

Considering all the updated SM calculations of the muon g-2, we obtain

$$a_\mu^{\text{SM}} = 116591829 (57) \times 10^{-11} \quad (18)$$

comparing it with the experimental value $a_\mu^{\text{EXP}} = 116592091 (63) \times 10^{-11}$, one finds a deviation at 3.1σ : $\Delta a_\mu \equiv a_\mu^{\text{EXP}} - a_\mu^{\text{SM}} = +262 (85) \times 10^{-11}$. In the 2HDM, the one-loop contributions to a_μ of the neutral and charged Higgs bosons are

$$\delta a_\mu^{\text{2HDM}}(\text{1loop}) = \frac{G_F m_\mu^2}{4\pi^2 \sqrt{2}} \sum_j (y_\mu^j)^2 r_\mu^j f_j(r_\mu^j), \quad (19)$$

where $j = \{h, H, A, H^\pm\}$, $r_\mu^j = m_\mu^2/M_j^2$, and

$$f_{h,H}(r) = \int_0^1 dx \frac{x^2(2-x)}{1-x+rx^2}, \quad (20)$$

$$f_A(r) = \int_0^1 dx \frac{-x^3}{1-x+rx^2}, \quad (21)$$

$$f_{H^\pm}(r) = \int_0^1 dx \frac{-x(1-x)}{1-(1-x)r}. \quad (22)$$

These formula show that the one-loop contributions to a_μ are positive for the neutral scalars h and H , and negative for the pseudo-scalar and charged Higgs bosons A and H^\pm (for $M_{H^\pm} > m_\mu$). In the limit $r \ll 1$,

$$f_{h,H}(r) = -\ln r - 7/6 + O(r), \quad (23)$$

$$f_A(r) = +\ln r + 11/6 + O(r), \quad (24)$$

$$f_{H^\pm}(r) = -1/6 + O(r), \quad (25)$$

showing that in this limit $f_{H^\pm}(r)$ is suppressed with respect to $f_{h,H,A}(r)$. Now the two-loop Barr-Zee type diagrams with effective $h\gamma\gamma$, $H\gamma\gamma$ or $A\gamma\gamma$ vertices generated by the exchange of heavy fermions gives

$$\delta a_\mu^{2\text{HDM}}(2\text{loop} - \text{BZ}) = \frac{G_F m_\mu^2}{4\pi^2\sqrt{2}} \frac{\alpha_{\text{em}}}{\pi} \sum_{i,f} N_f^c Q_f^2 y_\mu^i y_f^i r_f^i g_i(r_f^i), \quad (26)$$

where $i = \{h, H, A\}$, $r_f^i = m_f^2/M_i^2$, and m_f , Q_f and N_f^c are the mass, electric charge and number of color degrees of freedom of the fermion f in the loop. The functions $g_i(r)$ are

$$g_i(r) = \int_0^1 dx \frac{\mathcal{N}_i(x)}{x(1-x)-r} \ln \frac{x(1-x)}{r}, \quad (27)$$

where $\mathcal{N}_{h,H}(x) = 2x(1-x) - 1$ and $\mathcal{N}_A(x) = 1$.

Note the enhancement factor m_f^2/m_μ^2 of the two-loop formula in Eq. (26) relative to the one-loop contribution in Eq. (19), which can overcome the additional loop suppression factor α/π , and makes the two-loop contributions may become larger than the one-loop ones. Moreover, the signs of the two-loop functions $g_{h,H}$ (negative) and g_A (positive) for the CP-even and CP-odd contributions are opposite to those of the functions $f_{h,H}$ (positive) and f_A (negative) at one-loop. As a result, for small M_A and large $\tan\beta$ in Type II and X, the positive two-loop pseudoscalar contribution can generate a dominant contribution which can account for the observed Δa_μ discrepancy. The additional 2HDM contribution $\delta a_\mu^{2\text{HDM}} = \delta a_\mu^{2\text{HDM}}(1\text{loop}) + \delta a_\mu^{2\text{HDM}}(2\text{loop} - \text{BZ})$ obtained adding Eqs. (19) and (26) (without the h contributions) is compared with Δa_μ in Fig. 3.

Finally, let us remark that the hAA coupling is generically order one and thus can lead to a sizable non-standard decay of $h \rightarrow AA$ which should be suppressed kinematically or by making $|\lambda_{hAA}/v| \ll 1$ to meet the LHC results [7–9]. Using Eq. (14), one gets the hAA coupling, $\lambda_{hAA}/v \approx s_{\beta-\alpha}[\lambda_3 + \lambda_4 - \lambda_5]$, and thus

$$\lambda_{hAA}v/s_{\beta-\alpha} \approx -(1 + s_{\beta-\alpha}y_\tau)M_H^2 + s_{\beta-\alpha}y_\tau M_h^2 + 2M_A^2 \quad (28)$$

where we have put $s_{\beta-\alpha}^2 = 1$ [9]. It shows that, in the SM limit of $s_{\beta-\alpha}y_\tau \rightarrow 1$, the condition $\lambda_{hAA} \approx 0$ requires $M_H \sim M_h$ which is disfavoured, and thus one needs to have $M_A > M_h/2$. On the other hand, one can arrange a cancellation for $\lambda_{hAA} \approx 0$ in the wrong-sign domain $s_{\beta-\alpha}y_\tau < 0$ if the tau Yukawa coupling satisfies

$$y_\tau s_{\beta-\alpha} \approx -\frac{M_H^2 - 2M_A^2}{M_H^2 - M_h^2}. \quad (29)$$

VI. SUMMARY

The type X 2HDM provides a unique opportunity to explain the current $\sim 3\sigma$ deviation in the muon $g-2$ while satisfying all the theoretical requirements and the experimental constraints. The parameter space favourable

FIG. 3: The 1σ , 2σ and 3σ regions allowed by Δa_μ in the M_A - $\tan\beta$ plane taking the limit of $\beta - \alpha = \pi/2$ and $M_{h(H)} = 126$ (200) GeV in type II (left panel) and type X (right panel) 2HDMs. The regions below the dashed (dotted) lines are allowed at 3σ (1.4σ) by Δa_e . The vertical dashed line corresponds to $M_A = M_h/2$.

for the muon $g-2$ at 2σ is quite limited in the SM limit: $\tan\beta \gtrsim 30$ and $M_A \ll M_H \sim M_{H^\pm} \lesssim 250$ GeV. However, consideration of the $h \rightarrow AA$ decay and lepton universality [8] rules out this region. On the other hand, in the wrong-sign limit of $y_\tau \sim -1$, a cancellation for $\lambda_{hAA} \approx 0$ can be arranged for M_H up to about 600 GeV [7, 9] opening up more parameter space.

Such a light CP-odd boson A and the extra Heavy bosons can be searched for at the next run of the LHC mainly through $pp \rightarrow AH, AH^\pm$ followed by the decays $H^\pm \rightarrow \tau^\pm \nu$ and $A, H \rightarrow \tau^+ \tau^-$ [8, 9].
