Abstract

Doubly special relativity (DSR) is an effective model for encoding quantum gravity in flat space-time. As a result of the nonlinearity of the Lorentz transformation, the energy-momentum dispersion relation is modified. One simple way to import DSR to curved spacetime is “Gravity’s rainbow”, where the spacetime background felt by a test particle would depend on its energy. Focusing on the “Amelino-Camelia dispersion relation” which is $E^2 = m^2 + p^2 [1 - \eta (E/m_p)^n]$ with $n > 0$, we investigate the thermodynamical properties of a Schwarzschild black hole and a static uncharged black string for all possible values of η and n in the framework of rainbow gravity. It shows that there are non-vanishing minimum masses for these two black holes in the cases with $\eta < 0$ and $n \geq 2$. Considering effects of rainbow gravity on both the Hawking temperature and radius of the event horizon, we use the geometric optics approximation to compute luminosities of a 2D black hole, a Schwarzschild one and a static uncharged black string. It is found that the luminosities can be significantly suppressed or boosted depending on the values of η and n .

I. INTRODUCTION

The Hawking radiation was a remarkable prediction of quantum field theory in curved spacetime. As Stephen Hawking demonstrated[1], a Schwarzschild black hole emits radiation just like an ordinary blackbody at temperature $T = \hbar\kappa/2k_B\pi$, where κ is the surface gravity. Soon after this discovery, it was realized that there might be the "trans-Planckian" problem[2]. It appears that the Hawking radiation originates from the modes with huge initial frequencies, well beyond the Planck mass m_p , which undergo exponential high gravitational red-shifting near the horizon. As a result, the Hawking's prediction relies on the validity of quantum field theory in curved spacetime to arbitrary high energies. On the other hand, quantum field theory is considered more like an effective field theory of an underlying theory whose nature remains unknown. This observation poses the question of whether any unknown physics at the Planck scale could strongly influence the Hawking radiation.

Although a complete understanding of the trans-Planckian problem requires a full theory of quantum gravity, there are various attempts using effective models to address this problem. Among them is Doubly Special Relativity (DSR)[3–6], where the transformation laws of special relativity are modified at very high energies. In DSR, the energy-momentum dispersion relation for a massive particle of mass m is modified to

$$E^2 f^2(E/m_p) - p^2 g^2(E/m_p) = m^2, \quad (1)$$

where m_p is the Planck mass, and $f(x)$ and $g(x)$ are two unknown functions with the following properties

$$\lim_{x \rightarrow 0} f(x) = 1 \text{ and } \lim_{x \rightarrow 0} g(x) = 1. \quad (2)$$

It has been shown that the modified dispersion relation (MDR) might play a role in astronomical and cosmological observations, such as the threshold anomalies of ultra high energy cosmic rays and TeV photons[7–12]. Moreover, thermodynamics of black holes have been explored in the framework of the MDR[13–18].

One of the most popular choice for the functions $f(x)$ and $g(x)$ has been proposed by Amelino-Camelia et al.[19, 20], which gives

$$f(x) = 1 \text{ and } g(x) = \sqrt{1 - \eta x^n}. \quad (3)$$

Usually one has $n > 0$. As shown in [20], this formula is compatible with some of the results obtained in the Loop-Quantum-Gravity approach and reflects the results obtained in κ -Minkowski and other noncommutative spacetimes. Phenomenological implications of this “Amelino-Camelia (AC) dispersion relation” are also reviewed in [20].

Nevertheless, the non-linear realization of the Lorentz transformation in the framework of DSR results in a very complicated definition of the dual position space. To circumvent this difficulty, Magueijo and Smolin[21] proposed the “Gravity’s rainbow”, where the spacetime background felt by a test particle would depend on its energy. Consequently, the energy of the test particle deforms the background geometry and hence the dispersion relation. As regards the metric, it would be replaced by a one parameter family of metrics which depends on the energy of the test particle, forming a “rainbow metric”. Specifically, for the Schwarzschild solution, the corresponding “rainbow metric” is

$$ds^2 = \left(1 - \frac{2GM}{r}\right) \frac{dt^2}{f^2(E/m_p)} - \frac{1}{g^2(E/m_p)} \left[\frac{dr^2}{1 - \frac{2GM}{r}} + r^2 (d\theta^2 + \sin^2 \theta d\phi^2) \right], \quad (4)$$

which is the spherically symmetric solution to the distorted Einstein's Field equations given in [21]. Note that E is the energy of the probing particle. To obtain the modified Schwarzschild metric from the usual one, it appears from eqn. (4) that we can simply make replacements $dt \rightarrow dt/f(E/m_p)$ for the time coordinate and $dx^i \rightarrow dx^i/g(E/m_p)$ for all spatial coordinates. In fact, such procedure also works for the black objects besides the Schwarzschild metric[22]. The rainbow gravity formalism has received a lot of attentions recently, for instance, in cosmology[23–26] and black hole physics[27–34].

In this paper, we will study thermodynamics and luminosities of black holes in the framework of rainbow gravity. The remainder of our paper is organized as follows. In section II, the deformed Hamilton-Jacobi equations for scalars, spin 1/2 fermions and vector bosons are derived in the framework of rainbow gravity. We then solve the Hamilton-Jacobi equations to obtain tunneling rates. The temperatures and entropies of a rainbow Schwarzschild black hole and a rainbow static uncharged black string is computed in section III. In section IV, we calculate the luminosities of a 2D rainbow black hole, a 4D rainbow spherically symmetric one, and a 4D rainbow cylindrically symmetric one. Section V is devoted to our conclusion. Throughout the paper we take Geometrized units $c = G = 1$, where the Planck constant \hbar is square of the Planck mass m_p .

II. HAMILTON-JACOBI METHOD

After the Hawking's original derivation, there have been some other methods proposed to understand the Hawking radiation. Recently, a semiclassical method of modeling Hawking radiation as a tunneling process has been developed and attracted a lot of attention. This method was first proposed by Kraus and Wilczek[35, 36], which is known as the null geodesic method. They employed the dynamical geometry approach to calculate the imaginary part of the action for the tunneling process of s-wave emission across the horizon and related it to the Hawking temperature. Later, the tunneling behaviors of particles were investigated using the Hamilton-Jacobi method[37–39]. In the Hamilton-Jacobi method, one ignores the self-gravitation of emitted particles and assumes that its action satisfies the relativistic Hamilton-Jacobi equation. The tunneling probability for the classically forbidden trajectory from inside to outside the horizon is obtained by using the Hamilton-Jacobi equation to calculate the imaginary part of the action for the tunneling process.

In this section, the Hamilton-Jacobi equations for scalars, spin 1/2 fermions and vector bosons in the rainbow metric are derived. The particles' tunneling rates across the event horizon $r = r_h$ of the rainbow metric (6) are then computed by solving the Hamilton-Jacobi equations. We here consider a static black hole with the line element

$$ds^2 = B(r) dt^2 - \frac{dr^2}{B(r)} - C(r^2) h_{ab}(x) dx^a dx^b, \quad (5)$$

whose rainbow metric is obtained by $dt \rightarrow dt/f(E/m_p)$, $dr \rightarrow dr/g(E/m_p)$, and $dx_i \rightarrow dx_i/g(E/m_p)$

$$ds^2 = \frac{B(r) dt^2}{f^2(E/m_p)} - \frac{dr^2}{g^2(E/m_p) B(r)} - \frac{C(r^2) h_{ab}(x) dx^a dx^b}{g^2(E/m_p)}. \quad (6)$$

The function $B(r)$ has a simple zero at $r = r_h$ with $B'(r_h)$ being finite and nonzero. The vanishing of $B(r)$ at point $r = r_h$ indicates the presence of an event horizon. For simplicity, we assume that the particles are massless.

In the rainbow metric $ds^2 = \tilde{g}_{\mu\nu}(E) dx^\mu dx^\nu$, the massless scalar field ϕ obeys the Klein-Gordon equation

$$\tilde{\nabla}^\mu \tilde{\nabla}_\mu \phi = 0, \quad (7)$$

where $\tilde{\nabla}_\mu$ is the covariant derivative associated with $\tilde{g}_{\mu\nu}(E)$ and the index μ is lowered or raised by $\tilde{g}_{\mu\nu}(E)$. Making the ansatz for ϕ which is

$$\phi = \exp\left(\frac{iI}{\hbar}\right), \quad (8)$$

substituting it into eqn. (7), and expanding eqn. (7) in powers of \hbar , the leading order gives the Hamilton-Jacobi equation for a massless scalar particle

$$\tilde{g}_{\mu\nu}(E) \partial^\mu I \partial^\nu I = 0. \quad (9)$$

The Dirac equation for a spin-1/2 fermion field ψ takes the form of

$$i\tilde{\gamma}_\mu \left(\partial^\mu + \tilde{\Omega}^\mu\right) \psi = 0, \quad (10)$$

where $\tilde{\Omega}_\mu \equiv \frac{i}{2} \tilde{\omega}_\mu^{ab} \tilde{\Sigma}_{ab}$, $\tilde{\Sigma}_{ab}$ and $\tilde{\omega}_\mu^{ab}$ are the Lorentz spinor generator and spin connection in the rainbow metric, respectively, and $\{\tilde{\gamma}_\mu, \tilde{\gamma}_\nu\} = 2\tilde{g}_{\mu\nu}(E)$. To obtain the Hamilton-Jacobi equation for the fermion, the ansatz for ψ is assumed as

$$\psi = \exp\left(\frac{iI}{\hbar}\right) v, \quad (11)$$

where v is a slowly varying spinor amplitude. Substituting eqn. (11) into eqn. (10), we find to the lowest order of \hbar

$$\tilde{\gamma}_\mu \partial^\mu I v = 0. \quad (12)$$

Multiplying both sides of eqn. (12) from the left by $\tilde{\gamma}_\nu \partial^\nu I$, one gets

$$[\tilde{g}_{\mu\nu}(E) \partial^\mu I \partial^\nu I] v = 0. \quad (13)$$

Since v is nonzero, the Hamilton-Jacobi equation for a massless fermionic particle is also given by eqn. (9).

The Maxwell's equations for a massless vector field A_μ is

$$\tilde{\nabla}^\mu \tilde{F}_{\mu\nu} = 0, \quad (14)$$

where $\tilde{F}_{\mu\nu} = \tilde{\nabla}_\mu A_\nu - \tilde{\nabla}_\nu A_\mu$. We then make the WKB ansatz

$$A_\mu = a_\mu \exp\left(\frac{iI}{\hbar}\right), \quad (15)$$

where a_μ is the polarization vector and I is the action. Plugging the WKB ansatz into eqn. (14), we find that leading order of \hbar gives

$$\tilde{g}^{\nu\sigma}(E) (a_\nu \partial_\sigma I \partial_\mu I - a_\mu \partial_\sigma I \partial_\nu I) = 0. \quad (16)$$

To simplify eqn. (16), one could impose the Lorentz gauge in the curved spacetime

$$\tilde{\nabla}^\mu A_\mu = 0, \quad (17)$$

where the leading order is

$$\tilde{g}^{\nu\sigma}(E) a_\nu \partial_\sigma I = 0. \quad (18)$$

By plugging eqn. (18) into eqn. (16), it shows that the Hamilton-Jacobi equation for a massless vector boson is also given by eqn. (9).

From eqn. (9), one finds that the Hamilton-Jacobi equation for a massless particle in the rainbow metric (6) becomes

$$f^2(E/m_p) \frac{(\partial_t I)^2}{B(r)} = g^2(E/m_p) \left[B(r) (\partial_r I)^2 + \frac{h^{ab}(x) \partial_a I \partial_b I}{C(r^2)} \right]. \quad (19)$$

To solve the Hamilton-Jacobi equation for the action I , we can employ the following ansatz

$$I = -Et + W(r) + \Theta(x), \quad (20)$$

where E is the particle's energy. Plugging the ansatz into eqn. (19), we have differential equations for $W(r)$ and $\Theta(x)$

$$h^{ab}(x) \partial_a \Theta(x) \partial_b \Theta(x) = \lambda,$$

$$\partial_r W_{\pm}(r) \equiv p_r^{\pm} = \frac{\pm 1}{B(r)} \sqrt{\frac{E^2 f^2(E/m_p)}{g^2(E/m_p)} - \lambda \frac{B(r)}{C(r^2)}}, \quad (21)$$

where $+/-$ denotes the outgoing/ingoing solutions and λ is a constant. Using the residue theory for the semi circle, we get

$$\text{Im } W_{\pm}(r) = \frac{\pm \pi}{2\kappa} \frac{E f(E/m_p)}{g(E/m_p)}, \quad (22)$$

where $\kappa = \frac{B'(r_h)}{2}$. As shown in [40], the probability of a particle tunneling from inside to outside the horizon is

$$P_{emit} \propto \exp \left[-\frac{2}{\hbar} (\text{Im } W_+ - \text{Im } W_-) \right]. \quad (23)$$

There is a Boltzmann factor in P_{emit} with an effective temperature, which is

$$T_{eff} = T_0 \frac{g(E/m_p)}{f(E/m_p)}, \quad (24)$$

where we define $T_0 = \frac{\hbar \kappa}{2\pi}$ and take $k_B = 1$.

III. THERMODYNAMICS OF BLACK HOLES IN RAINBOW GRAVITY

We now use the Heisenberg uncertainty principle to estimate the black hole's temperature. For a massless particle, the modified dispersion relation (1) becomes

$$\frac{x f(x)}{g(x)} = y, \quad (25)$$

where $x = E/m_p \geq 0$ and $y = p/m_p \geq 0$. To obtain the black hole's temperature from eqn. (24), eqn. (25) is needed to be solved for x in terms of y . In fact, one could have for x

$$x = y h(y), \quad (26)$$

where eqn. (25) is inverted to get the function $h(y)$ and $\lim_{y \rightarrow 0} h(y) = 1$. The Heisenberg uncertainty principle gives a relation between the momentum p of an emitted particle and the event horizon radius r_h of the black hole[41, 42]

$$y = p/m_p \sim \delta p/m_p \sim \hbar/m_p \delta x \sim m_p/r_h. \quad (27)$$

Substituting eqn. (27) into eqn. (24), we have for the black hole's temperature

$$T = T_0 \frac{E}{p} = T_0 h \left(\frac{m_p}{r_h} \right). \quad (28)$$

The range of the left-hand side(LHS) of eqn. (25) determines the ranges of the values of r_h . Specifically, the maximum value of the LHS of eqn. (25), which is denoted by y_{cr} , gives that $r_h \geq \frac{m_p}{y_{cr}}$. If y_{cr} is finite, it always predicts the existence of the black hole's remnant. For some functions $f(x)$ and $g(x)$, the domain of the LHS of eqn. (25) might be $[0, x_{cr}]/[0, x_{cr})$ with x_{cr} being finite rather than $[0, \infty)$. Thus, it gives that the energy of the particle $E \leq m_p x_{cr}$. If the domain is $[0, \infty)$, we simply set $x_{cr} = \infty$.

For the AC dispersion relation given in eqn. (3), eqn. (25) becomes

$$\frac{x}{\sqrt{1 - \eta x^n}} = y. \quad (29)$$

If $\eta > 0$, we find that $y_{cr} = 0$. However, there is an upper bound $x_{cr} = \eta^{-1/n}$ on x to make the LHS of eqn. (29) real. If $\eta < 0$, we have $x_{cr} = \infty$ and $y_{cr} = \infty$ for $0 < n < 2$ and $x_{cr} = \infty$ and $y_{cr} = (-\eta)^{-1/2}$ for $n = 2$. For the case with $\eta < 0$ and $n > 2$, the LHS of eqn. (29) has a global maximum value y_0 at x_0 , where we define

$$\begin{aligned} x_0 &= \left(\frac{2-n}{2} \eta \right)^{-1/n}, \\ y_0 &= \sqrt{\frac{n-2}{n}} \left(\frac{2-n}{2} \eta \right)^{-1/n}. \end{aligned} \quad (30)$$

Thus, it would appear that $y \leq y_0$ and $x < \infty$ since x can go to infinity. In FIG. 1, we plot an example with $\eta = -1$ and $n = 4$. If one solves eqn. (29) for $y < y_0$ in terms of x , there are always two solutions x_S and x_L , where $x_S < x_0 < x_L$. However, only the solution x_S is Taylor expandable in η . The solution x_L is a "runaways" solution since it does not exist in the limit of $\eta \rightarrow 0$. In [43], it has been argued that "runaways" solutions are not physical and hence should be discarded. A similar argument was also given in the framework of the Generalized Uncertainty Principle in [44]. Therefore, we will discard "runaways" solutions and keep only the solution x_S in this paper. In this case, we have $x_{cr} = x_0$ instead of $x_{cr} = \infty$. We list x_{cr} and y_{cr} for various choices of n and η in TABLE I.

To calculate the black hole's temperature from eqn. (28), we need to solve eqn. (29) for

$h(y)$. Nevertheless, it is non-trivial to get $h(y)$ for a general n . For $n = 1, 2, 4$, we have

$$h(y) = \begin{cases} \frac{1}{2} \left(-\eta y + \sqrt{4 + \eta^2 y^2} \right) & n = 1 \\ (1 + \eta y^2)^{-1/2} & n = 2 \\ y^{-2} \sqrt{\frac{\sqrt{1+4\eta y^4} - 1}{2\eta}} & n = 3 \end{cases}. \quad (31)$$

If $y \ll 1$, one has $x \ll 1$ and hence eqn. (29) becomes

$$y = x \left(1 + \frac{\eta x^n}{2} + \mathcal{O}(x^{2n}) \right), \quad (32)$$

which gives

$$h(y) = 1 - \frac{\eta y^n}{2} + \mathcal{O}(y^{2n}). \quad (33)$$

Since $x = E/m_p$ and $y = p/m_p$, the AC dispersion relation for a massless particle (29) leads to the group velocity of the particle

$$\frac{1}{v_g} = \frac{\partial y}{\partial x} = \frac{1}{\sqrt{1 - \eta x^n}} + \frac{n\eta x^n}{2(1 - \eta x^n)^{3/2}}. \quad (34)$$

If $\eta > 0$, eqn. (34) gives $v_g < 1$, which means the particle is subluminal. If $\eta < 0$, $v_g > 1$ and hence the particle is superluminal.

We now calculate the temperatures and entropies of a Schwarzschild black hole and a static uncharged black string with negative cosmological constant.

TABLE I: The values of x_{cr} , y_{cr} , M_{cr}^{SC} , T_{cr}^{SC}/m_p , M_{cr}^{BS} , and T_{cr}^{BS}/m_p for various values of (n, η) . The superscripts SC and BS stand for the Schwarzschild black hole and black string, respectively.

FIG. 1: Plot of the curve of $\frac{x}{\sqrt{1-\eta x^n}}$ with $\eta = -1$ and $n = 4$. The curve has a maximum value $y_0 = \frac{1}{\sqrt{2}}$ at $x_0 = 1$. For $y < y_0$, there are x_S and x_L with $x_S < x_L$ satisfying $\frac{x_{L/S}}{\sqrt{1+x_{L/S}^4}} = y$. The solution x_L is considered runaways since it does not exist in the limit of $\eta \rightarrow 0$. Thus, only the solution x_S is considered in the paper.

A. Schwarzschild Black Hole

For a Schwarzschild black hole with mass M , one has $B(r) = 1 - \frac{2M}{r}$ and $r_h = 2M$. Thus, the temperature is

$$T^{SC} = \frac{m_p^2}{8\pi M} h\left(\frac{m_p}{2M}\right). \quad (35)$$

If $M \gg m_p$, we have from eqn. (33) that

$$T^{SC} = \frac{m_p^2}{8\pi M} \left[1 - \frac{\eta}{2^{n+1}} \frac{m_p^n}{M^n} + \mathcal{O}\left(\frac{m_p^{2n}}{M^{2n}}\right) \right]. \quad (36)$$

The minimum mass M_{cr}^{SC} of the black hole is given by

$$M_{cr}^{SC} = \frac{m_p}{2y_{cr}}. \quad (37)$$

When the mass M reaches M_{cr}^{SC} , the temperature of the black hole is denoted by T_{cr}^{SC} . Eqn. (38) gives that

$$T_{cr}^{SC} = \frac{x_{cr} m_p}{4\pi}. \quad (38)$$

For $\eta < 0$ and $n \geq 2$, y_{cr} is finite and hence the black hole should have non-vanishing minimum mass M_{cr}^{SC} . This implies an existence of black hole remnant due to rainbow

FIG. 2: Plot of the temperature T^{SC}/m_p against the mass M/m_p for a Schwarzschild black hole. All the lines asymptotically approach $T^{SC} = 0$ as $M/m_p \rightarrow \infty$. The blue line is usual case, where T^{SC} blows up as $M \rightarrow 0$. The red dot is the end of the red solid line, where the black hole has a remnant $M_{cr}^{SC} = 1/\sqrt{2}m_p$. In this case, T^{SC} does not blow up as $M \rightarrow M_{cr}^{SC}$. The black dotted line is the asymptotic line of the red dashed line as $M \rightarrow M_{cr}^{SC} = 0.5m_p$, which is the black hole's remnant. In this case, T^{SC} blows up as $M \rightarrow M_{cr}^{SC}$.

gravity. By eqn. (38), we find that T_{cr}^{SC} for $n = 2$ is infinite while T_{cr}^{SC} for $n > 2$ is $\frac{x_0 m_p}{4\pi}$, which is finite. For $\eta < 0$ and $0 < n < 2$, we find that $M_{cr}^{SC} = 0$ and $T_{cr}^{SC} = \infty$. In this case, the black hole would evaporate completely while its temperature increases and finally becomes infinity during evaporation, just like the standard Hawking radiation. For $\eta > 0$, the black hole would also evaporate completely. However, the temperature of the black hole is a finite value $\frac{\eta^{-1/n} m_p}{4\pi}$ at the end of the evaporation process. We list M_{cr}^{SC} and T_{cr}^{SC} for all the possible values of η and n in TABLE I. In FIG. 2, we plot the temperature T^{SC}/m_p against the black hole mass M/m_p (both in Planck units), for examples with $(\eta, n) = (1, 2)$, $(\eta, n) = (-1, 1)$, $(\eta, n) = (-1, 2)$, and $(\eta, n) = (-1, 4)$. The standard Hawking radiation is also plotted as a blue line in FIG. 2.

From the first law of black hole thermodynamics $dS = dM/T^{SC}$, the entropy associated with the temperature (35) can be given by

$$S = \int_{M_{cr}^{SC}}^M \frac{dM}{T^{SC}} = 2\pi \int_{\frac{m_p}{2M}}^{y_{cr}} \frac{dy}{y^3 h(y)}, \quad (39)$$

FIG. 3: Plot of the entropy S against the mass M/m_p for a Schwarzschild black hole.

FIG. 4: Plot of the entropy of a Plank length sm_p against the mass per unit length M for a static uncharged black string.

where we use $y_{cr} = \frac{m_p}{2M_{cr}^{SC}}$. For $\eta = 0$, we have $h(y) = 1$ and $y_{cr} = \infty$. Thus, eqn. (39) gives the Bekenstein-Hawking entropy

$$S = \frac{4\pi M^2}{m_p^2} = \frac{A}{4\hbar}. \quad (40)$$

where $A = 4\pi r_h^2$ is the area of the black hole. If $M \gg m_p$ ($A \gg \hbar$), eqn. (39) gives the entropy up to the subleading term

$$S \sim \begin{cases} \frac{A}{4\hbar} + \frac{\pi\eta}{2-n} \left(\frac{A}{4\pi\hbar}\right)^{\frac{2-n}{2}} & 0 < n < 2 \\ \frac{A}{4\hbar} + \frac{\pi\eta}{2} \ln \frac{A}{4\pi\hbar} & n = 2 \\ \frac{A}{4\hbar} + S_0 & n > 2 \end{cases}, \quad (41)$$

where S_0 is a constant and we use eqn. (33). The leading terms of eqn. (41) are the familiar Bekenstein-Hawking entropy. For $n = 2$, we obtain the logarithmic subleading term. In FIG. 3, we plot the entropy S against the black hole mass M/m_p , for examples with $\eta = 0$, $(\eta, n) = (1, 2)$, $(\eta, n) = (-1, 1)$, $(\eta, n) = (-1, 2)$, and $(\eta, n) = (-1, 4)$.

In [34], the temperature and entropy of a rainbow Schwarzschild black hole has also been computed in the case with $\eta > 0$ and $n = 2$. The temperature and logarithmic subleading term of the entropy obtained in our paper are the same as those in [34]. By contrast, the temperature and entropy were calculated in the case with $\eta > 0$ in [33], where it was found that the black hole had a non-vanishing minimum mass and the temperature was zero at the minimum mass. As pointed out in [34], the difference between the results in our paper and [34] and those in [33] stems from the fact the MDR was partially used in [33]. In fact,

the author in [33] used the MDR to get T_{eff} while the ordinary dispersion relation rather than the MDR was used to obtain the relation between the energy E of an emitted particle and the event horizon radius r_h .

B. Static Uncharged Black String

We consider the Einstein-Hilbert action in four dimensions with a negative cosmological constant Λ , which is given by

$$S = \frac{1}{16\pi} \int d^4x \sqrt{-g} (R - 2\Lambda), \quad (42)$$

where g is the determinant of the metric and R the Ricci scalar. If we assume that the solution of the Einstein equations is cylindrically symmetric and time-independent, the line element for a static uncharged black string becomes[45]

$$ds^2 = \left(\alpha^2 r^2 - \frac{b}{\alpha r} \right) dt^2 - \left(\alpha^2 r^2 - \frac{b}{\alpha r} \right)^{-1} dr^2 - r^2 (d\theta^2 + \alpha^2 dz^2), \quad (43)$$

where

$$\alpha^2 = -\frac{\Lambda}{3}, \quad b = 4M$$

$$-\infty < t < \infty, \quad 0 \leq r < \infty, \quad -\infty < z < \infty, \quad 0 \leq \theta \leq 2\pi. \quad (44)$$

Here, M is the mass per unit length of the z line of black string.

For the static uncharged black string, we have $B(r) = \alpha^2 r^2 - \frac{b}{\alpha r}$, $r_h = b^{1/3}/\alpha$, and $\kappa = \frac{3\alpha}{2} b^{1/3}$. Thus, eqn. (28) leads to the black string temperature

$$\frac{T^{BS}}{m_p} = \frac{3\alpha m_p b^{1/3}}{4\pi} h \left(\frac{\alpha m_p}{b^{1/3}} \right). \quad (45)$$

If $b^{1/3} \gg \alpha m_p$ ($M \gg \alpha^3 m_p^3$), we have for the temperature

$$T^{BS} = \frac{3\alpha m_p b^{1/3}}{4\pi} \left[1 - \frac{\eta}{2^{n+1}} \frac{\alpha^n m_p^n}{b^{n/3}} + \mathcal{O} \left(\frac{\alpha^{2n} m_p^{2n}}{b^{2n/3}} \right) \right]. \quad (46)$$

If $n > 1$, one has

$$T^{BS} \rightarrow T_0 \quad \text{as} \quad M \rightarrow \infty,$$

where $T_0 = \frac{3\alpha m_p b^{1/3}}{4\pi}$ is the black string temperature in the usual case. Since $r_h \geq \frac{m_p}{y_{cr}}$, the minimum mass per unit length M_{cr}^{BS} of the black string is given by

$$M_{cr}^{BS} = \frac{\alpha^3 m_p^3}{4y_{cr}^3}. \quad (47)$$

FIG. 5: Plot of the temperature T^{BS}/m_p against the mass per unit length M for a static uncharged black string. The lines with $n > 1$ asymptotically approach the blue line as $M \rightarrow \infty$. The blue line is the usual case, where $T^{SC} \rightarrow 0$ as $M \rightarrow 0$. The red dot is the end of the red solid line, where the black string has a remnant $M_{cr}^{BS} = 1/\sqrt{2}$. The black dotted line is the asymptotic line of the red dashed line as $M \rightarrow M_{cr}^{BS} = 0.25$, which is the black string's remnant. In this case, T^{BS} blows up as $M \rightarrow M_{cr}^{BS}$.

When M reaches M_{cr}^{SC} , the temperature of the black string becomes

$$\frac{T_{cr}^{BS}}{m_p} = \frac{3\alpha^2 m_p^2 x_{cr}}{4\pi y_{cr}^2}. \quad (48)$$

For the usual case with $\eta = 0$, we have $h(y) = 1$ and $y_{cr} = \infty$. The minimum mass per unit length $M_{cr}^{BS} = 0$ and T^{BS} goes to zero as $M \rightarrow 0$. For $\eta < 0$ and $n \geq 2$, y_{cr} is finite and hence the black string should have non-vanishing minimum mass per unit length M_{cr}^{BS} , which indicates an existence of black string remnant. Using eqn. (48), we can show that T_{cr}^{BS} for $n = 2$ is infinity while T_{cr}^{BS} for $n > 2$ is finite. For $\eta > 0$, the black string would evaporate completely with T^{BS} goes to zero as $M \rightarrow 0$, which is the same as in the usual case. For $\eta < 0$ and $0 < n < 2$, the minimum mass per unit length M_{cr}^{BS} is zero. Nevertheless, we find that $T_{cr}^{BS} = \infty$ for $0 < n < 1$, $T_{cr}^{BS} = -\eta \frac{3\alpha^2 m_p^3}{4\pi}$ for $n = 1$, and $T_{cr}^{BS} = 0$ for 0 . We list M_{cr}^{BS} and T_{cr}^{BS} for various values of η and n in TABLE I. In FIG. 5 where we set $\alpha m_p = 1$, we plot the temperature T^{BS}/m_p against the mass per unit length M , for examples with $\eta = 0$, $(\eta, n) = (1, 2)$, $(\eta, n) = (-1, 1)$, $(\eta, n) = (-1, 2)$, and $(\eta, n) = (-1, 4)$.

Using the first law of black hole thermodynamics, we have for the entropy per unit length

associated with the temperature (45)

$$s = \int_{M_{cr}^{SC}}^M \frac{dM}{T^{SC}} = \frac{\pi \alpha m_p}{m_p} \int_{\frac{\alpha m_p}{(4M)^{1/3}}}^{y_{cr}} \frac{dy}{y^3 h(y)}. \quad (49)$$

If $M \gg 1$, eqn. (49) gives the entropy per unit length up to the subleading term

$$s \sim \begin{cases} \frac{\pi \alpha}{2} \frac{b^{2/3}}{\alpha^2 m_p^2} + \frac{\alpha \pi \eta}{2(2-n)} \frac{b^{(2-n)/3}}{(\alpha m_p)^{2-n}} & 0 < n < 2 \\ \frac{\pi \alpha}{2} \frac{b^{2/3}}{\alpha^2 m_p^2} + \frac{\pi \alpha \eta}{2} \ln \frac{b^{1/3}}{\alpha m_p} & n = 2 \\ \frac{\pi \alpha}{2} \frac{b^{2/3}}{\alpha^2 m_p^2} + s_0 & n > 2 \end{cases}, \quad (50)$$

where s_0 is a constant. In FIG. 3, we plot $m_p S$ against M , for examples with $\eta = 0$, $(\eta, n) = (1, 2)$, $(\eta, n) = (-1, 1)$, $(\eta, n) = (-1, 2)$, and $(\eta, n) = (-1, 4)$.

IV. LUMINOSITIES OF BLACK HOLES IN RAINBOW GRAVITY

For particles emitted in a wave mode labelled by energy E and quantum numbers i , we find that

(Probability for a black hole to emit a particle in this mode)

$$= \exp\left(-\frac{E}{T_{eff}}\right) \times (\text{Probability for a black hole to absorb a particle in the same mode}),$$

where T_{eff} is given by eqn. (24). The above relation for the usual dispersion relation was obtained by Hartle and Hawking [46] using semiclassical analysis. Neglecting back-reaction, detailed balance condition requires that the ratio of the probability of having N particles in a particular mode to the probability of having $N - 1$ particles in the same mode is $\exp\left(-\frac{E}{T_{eff}}\right)$. One then follows the argument in [40] to get the average number $n_{E,i}$ in the mode with E and i

$$n_{E,i} = n\left(\frac{E}{T_{eff}}\right), \quad (51)$$

where we define

$$n(x) = \frac{1}{\exp x - (-1)^\epsilon}. \quad (52)$$

Note that $\epsilon = 0$ for bosons and $\epsilon = 1$ for fermions.

As discussed in section III, there is an upper bound $m_p x_{cr}$ on the energy E of the particle. Moreover, another upper bound comes from the requirement that nothing can be emitted that lowers the energy below the remnant mass of a black hole. Thus, one has $E \leq M - M_{cr}$,

where M is the mass of the black hole and M_{cr} is the remnant mass. Considering both upper bounds, we have for E

$$E \leq E_{\max} \equiv \min \{m_p x_{cr}, M - M_{cr}\}. \quad (53)$$

In [40, 47, 48], we have found that the total luminosity in the MDR case is given by

$$L = \sum_i \int |T_i(E)|^2 \omega n_{E,i} \frac{dE}{2\pi\hbar}. \quad (54)$$

where E is the energy of the particle, i are quantum numbers needed to specify a mode besides E , and $|T_i(E)|^2$ is the greybody factor. Usually, $T_i(E)$ represents the transmission coefficient of the black hole barrier which in general can depend on E and i . The relevant radiations usually have the energy of order $\hbar M^{-1}$ for a black hole with the mass M and one hence needs to use the wave equations to compute $T_i(E)$. However, solving the wave equations for $T_i(E)$ could be complex. On the other hand, we can use the geometric optics approximation to estimate $|T_i(E)|^2$. In the geometric optics approximation, we assume $E \gg M$ and high energy waves will be absorbed unless they are aimed away from the black hole. Hence $|T_i(E)|^2 = 1$ for all the classically allowed E and i , while $|T_i(E)|^2 = 0$ otherwise. For the usual dispersion relation, the well-known Stefan's law for black holes is obtained in this approximation.

In the remaining of the section, we will use the geometric optics approximation to calculate luminosities of a 2D rainbow black hole, a 4D rainbow spherically symmetric one, and a 4D rainbow cylindrically symmetric one. For simplicity, we assume that the particles are massless.

A. 2D Black Hole

Suppose the metric of a 2D black hole is given by

$$ds^2 = B(r) dt^2 - \frac{1}{B(r)} dr^2, \quad (55)$$

where $B(r)$ has a simple zero at $r = r_h$. In this case, we have $|T(E)|^2 = 1$ when $E \leq E_{\max}$ and $|T(E)|^2 = 0$ otherwise. By eqn. (54), the luminosity of a 2D black hole is

$$L = g_s \int_0^{E_{\max}} E n \left(\frac{E f(E/m_p)}{T_0 g(E/m_p)} \right) \frac{dE}{2\pi\hbar}, \quad (56)$$

where we use eqn. (24) for T_{eff} and $T_0 = \frac{m_p^2 \kappa}{2\pi}$ with $\kappa = \frac{B'(r_h)}{2}$. Note g_s is the number of polarization which is 1 for scalars and 2 for spin-1/2 fermion and vector bosons. Defining

$$u = \frac{E}{T_0} \frac{f(E/m_p)}{g(E/m_p)}, \quad (57)$$

we find

$$E = T_0 u h\left(\frac{u T_0}{m_p}\right). \quad (58)$$

Using eqn. (57) to change variables in eqn. (56), we have for the luminosity

$$L = \frac{g_s T_0^2}{2\pi m_p^2} \int_0^{u_{\max}} h\left(\frac{u T_0}{m_p}\right) \left[h\left(\frac{u T_0}{m_p}\right) + \left(\frac{u T_0}{m_p}\right) h'\left(\frac{u T_0}{m_p}\right) \right] u n(u) du, \quad (59)$$

where we define

$$u_{\max} = \frac{E_{\max}}{T_0} \frac{f\left(\frac{E_{\max}}{m_p}\right)}{g\left(\frac{E_{\max}}{m_p}\right)}. \quad (60)$$

Note that the change of variables given in eqn. (57) is legitimate for the integral (59) if the function $\frac{xf(x)}{g(x)}$ is monotonic over $(0, x_{cr})$, which is the case for the AC dispersion relation.

Now investigate properties of the luminosity for the AC dispersion relation given in eqn. (3). If $T_0 \ll m_p$, eqn. (59) becomes

$$L \approx \frac{g_s T_0^2}{2\pi m_p^2} \int_0^\infty \left[1 - \frac{n+2}{2} \eta \left(\frac{u T_0}{m_p}\right)^n \right] u n(u) du \quad (61)$$

where we set $u_{\max} = \infty$. For the emission of n_s species of massless particles of spin s , we have

$$L \approx \frac{\pi}{12} \left(\frac{T_0}{m_p}\right)^2 \left\{ (n_0 + 2n_1 + n_{1/2}) - \frac{3(n+1)!(n+2)}{\pi^2} \left(\frac{T_0}{m_p}\right)^n \eta \left[Li_{n+2}(1)(n_0 + 2n_1) + \frac{2-2^{-n}}{n+2} \zeta(n+2) n_{1/2} \right] \right\}, \quad (62)$$

where $Li_s(z)$ is the polylogarithm of order s and argument z and $\zeta(z)$ is the zeta function. If $\eta > 0$ ($\eta < 0$), the luminosity becomes smaller (larger) than that in the usual case with $\eta = 0$. This is expected from eqn. (24) where T_{eff} is lowered (raised) due to rainbow gravity if $\eta > 0$ ($\eta < 0$).

During the late stage of the black hole evaporation process when $\frac{M-M_{cr}}{m_p} \ll \min\{1, x_{cr}\}$, one has $\frac{E_{\max}}{m_p} = \frac{M-M_{cr}}{m_p} \ll 1$ and hence

$$u_{\max} \approx \frac{m_p}{T_0} \frac{M-M_{cr}}{m_p} \left[1 + \frac{\eta}{2} \left(\frac{M-M_{cr}}{m_p}\right)^n \right]. \quad (63)$$

The luminosity of radiation of one species of bosons is

$$L = \frac{g_s T_0}{2\pi m_p} \frac{M - M_{cr}}{m_p} \left[1 - \frac{\eta}{2} \frac{1}{n+1} \left(\frac{M - M_{cr}}{m_p} \right)^n + \mathcal{O} \left(\left(\frac{M - M_{cr}}{m_p} \right)^{2n} \right) \right], \quad (64)$$

and that of radiation of one species of fermions is

$$L = \frac{g_s}{4\pi} \left(\frac{M - M_{cr}}{m_p} \right)^2 \left[1 + \mathcal{O} \left(\left(\frac{M - M_{cr}}{m_p} \right)^{2n} \right) \right], \quad (65)$$

where g_s is the number of polarization. From eqns. (64) and (65), we find that the black hole evaporates mostly via bosons in the late stage of the black hole evaporation process.

B. 4D Spherically Symmetric Black Hole

For a 4D spherically symmetric black hole with $h_{ab}(x) dx^a dx^b = d\theta^2 + \sin^2 \theta d\phi^2$ in eqn. (5), we have found λ in eqn. (21) is given by [40]

$$\lambda = \left(l + \frac{1}{2} \right)^2 \hbar^2, \quad (66)$$

where $l = 0, 1, \dots$ is the angular momentum. Since p_r in eqn. (21) is always a real number in the geometric optics approximation, one has an upper bound on λ

$$\lambda \leq \frac{C(r^2)}{B(r)} \frac{f^2(E/m_p)}{g^2(E/m_p)} E^2. \quad (67)$$

Suppose $\frac{C(r^2)}{B(r)}$ has a minimum at r_{\min} . If the particles overcome the angular momentum barrier and get absorbed by the black hole, one has

$$\lambda \leq \lambda_{\max} \equiv \frac{C(r_{\min}^2)}{B(r_{\min})} \frac{f^2(E/m_p)}{g^2(E/m_p)} E^2. \quad (68)$$

The luminosity is

$$\begin{aligned} L &= g_s \sum_l (2l+1) \int E n_{E,l} \frac{dE}{2\pi \hbar} \\ &= g_s \int_0^{E_{\max}} \frac{E dE}{2\pi \hbar^3} n \left(\frac{E}{T_0} \frac{f(E/m_p)}{g(E/m_p)} \right) \int_0^{\lambda_{\max}} d \left[\left(l + \frac{1}{2} \right)^2 \right] \\ &= \frac{g_s}{2\pi \hbar^3} \frac{C(r_{\min}^2)}{B(r_{\min})} \int_0^{E_{\max}} n \left(\frac{E}{T_0} \frac{f(E/m_p)}{g(E/m_p)} \right) \frac{f^2(E/m_p)}{g^2(E/m_p)} E^3 dE, \end{aligned} \quad (69)$$

where we use eqn. (51) for $n_{E,l}$. Making change of variables for eqn. (69)

$$u = \frac{E}{T_0} \frac{f(E/m_p)}{g(E/m_p)}, \quad (70)$$

the luminosity of a 4D spherically symmetric black hole becomes

$$L = \frac{g_s T_0^4}{2\pi m_p^4} \frac{C(r_{\min}^2)}{B(r_{\min}) m_p^2} \int_0^{u_{\max}} h\left(\frac{uT_0}{m_p}\right) \left[h\left(\frac{uT_0}{m_p}\right) + \left(\frac{uT_0}{m_p}\right) h'\left(\frac{uT_0}{m_p}\right) \right] u^3 n(u) du. \quad (71)$$

In what follows, we focus on the AC dispersion relation. If $T_0 \ll m_p$, eqn. (71) becomes

$$L \approx \frac{g_s T_0^4}{2\pi m_p^4} \frac{C(r_{\min}^2)}{B(r_{\min}) m_p^2} \int_0^\infty \left[1 - \frac{n+2}{2} \eta\left(\frac{uT_0}{m_p}\right)^n \right] u^3 n(u) du, \quad (72)$$

where we set $u_{\max} = \infty$. For the emission of n_s species of massless particles of spin s , we have

$$L \approx \frac{\pi^3}{30} \left(\frac{T_0}{m_p}\right)^4 \frac{C(r_{\min}^2)}{m_p^2 B(r_{\min})} \left\{ \left(n_0 + 2n_1 + \frac{7}{4}n_{1/2} \right) - \frac{15(n+3)!(n+2)}{2\pi^4} \left(\frac{T_0}{m_p}\right)^n \eta \left[Li_{n+4}(1)(n_0 + 2n_1) + (2 - 2^{-n-2}) \zeta(n+4) n_{1/2} \right] \right\}, \quad (73)$$

where $Li_s(z)$ is the polylogarithm of order s and argument z and $\zeta(z)$ is the zeta function. In the late stage of the black hole evaporation process with $\frac{M-M_{cr}}{m_p} \ll \min\{1, x_{cr}\}$, one finds that the luminosity of radiation of one species of bosons is

$$L = \frac{g_s T_0}{6\pi m_p} \frac{C(r_{\min}^2)}{m_p^2 B(r_{\min})} \left(\frac{M-M_{cr}}{m_p}\right)^3 \left[1 + \frac{3\eta}{2(n+3)} \left(\frac{M-M_{cr}}{m_p}\right)^n + \mathcal{O}\left(\left(\frac{M-M_{cr}}{m_p}\right)^{2n}\right) \right], \quad (74)$$

and that of radiation of one species of fermions

$$L = \frac{g_s}{8\pi} \frac{C(r_{\min}^2)}{m_p^2 B(r_{\min})} \left(\frac{M-M_{cr}}{m_p}\right)^4 \left[1 + \frac{4\eta}{n+4} \left(\frac{M-M_{cr}}{m_p}\right)^n + \mathcal{O}\left(\left(\frac{M-M_{cr}}{m_p}\right)^{2n}\right) \right], \quad (75)$$

where g_s is the number of polarization. Similar to a 2D black hole, the evaporation via bosons dominates the 4D spherically symmetric black hole evaporation process in the late stage.

In the geometric optics approximation, a 4D spherically symmetric black hole can be described as a black sphere for absorbing particles. The total luminosity are determined

by the radius of the black sphere R and the temperature of the black hole T . For the AC dispersion relation, we have for massless particles

$$R = \sqrt{\frac{\lambda_{\max}}{E^2}} = \frac{C(r_{\min}^2)}{B(r_{\min})} \frac{1}{1 - \eta(E/m_p)^n} \text{ and } T = T_{eff} = T_0 \sqrt{1 - \eta(E/m_p)^n}. \quad (76)$$

If $\eta > 0$ ($\eta < 0$), the radius R becomes larger(smaller) than that in the usual case while the effective temperature becomes lower(higher) due to rainbow gravity. For the subluminal case with $\eta > 0$ (the superluminal case with $\eta < 0$), the competition between the increased(decreased) radius and the decreased(increased) temperature determines whether the luminosity would increase or decrease. For $T_0 \ll m_p$, it appears from eqn. (73) that the effects of decreased(increased) temperature wins the competition and hence the luminosity tends to become smaller(larger). However for the late stage of the evaporation process, it seems from eqns. (74) and (75) that the effects of increased(decreased) radius wins the competition and hence the luminosity becomes larger(smaller).

We now work with a Schwarzschild black hole to investigate more properties of the black hole's luminosity. For a Schwarzschild black hole, one has $B(r) = 1 - \frac{2M}{r}$, $r_h = 2M$, $\kappa = \frac{1}{4M}$, $T_0 = \frac{m_p^2}{8\pi M}$, $r_{\min} = 3M$ and $\frac{C(r_{\min}^2)}{B(r_{\min})} = 27M^2$. For $M \gg m_p$, it shows from eqn. (73) that the corrections to the luminosity from rainbow gravity effects are around $\mathcal{O}\left(\frac{m_p}{M}\right)^n$. Nevertheless, these corrections begin to become appreciable around $M \lesssim M_* \equiv \frac{c_n^{1/n}}{8\pi} |\eta|^{1/n} m_p$ when the second term in the bracket of eqn. (73) becomes comparable to 1. Here c_n is the numerical factor in front of n_s of the second term in the bracket and $c_n^{1/n} \sim 5 - 10$ for $1 \leq n \leq 10$. If $M_{cr}^{SC} = 0$, in the late stage of the evaporation process with $\frac{M}{m_p} \ll \min\{1, x_{cr}\}$, the corrections to the luminosity are around $\mathcal{O}\left(\frac{M^n}{m_p^n}\right)$. Similarly, these corrections are important when $M \gtrsim M_{**} \equiv |\eta|^{-1/n} m_p$. Thus, we can conclude that for cases with $M_{cr}^{SC} = 0$, the effects of rainbow gravity impacts the black hole's luminosity noticeably when $M_{**} \lesssim M \lesssim M_*$. For cases with non-vanishing M_{cr}^{SC} , the black hole's luminosity deviates from that in the usual case appreciably when $M \lesssim M_*$. In FIG. 6, we plot the luminosity L of radiation of one species of bosons against M/m_p for examples with $\eta = 0$, $(\eta, n) = (1, 2)$, $(\eta, n) = (-1, 1)$, $(\eta, n) = (-1, 2)$, and $(\eta, n) = (-1, 4)$. Note that the effects of rainbow gravity does not change the black hole's luminosity appreciably in FIG. 6 since $M_* \sim |\eta|^{1/n} m_p = |\eta|^{-1/n} m_p \sim M_{**}$ for $|\eta| = 1$. Due to the requirement that the energy E of emitted particles could not exceed $M - M_{cr}^{SC}$, the luminosities in all cases approach zero as $M \rightarrow M_{cr}^{SC}$.

FIG. 6: Plot of the luminosity L of radiation of one species of bosons against the mass M/m_p for a Schwarzschild black hole. The blue line is the usual case. All the other lines asymptotically approach the blue line as $M \gg 1$. For the cases with the minimal mass $M_{cr}^{SC} = 0$, the black lines asymptotically approach the blue line as $M \rightarrow 0$. For all the lines, the luminosities approach zero as $M \rightarrow M_{cr}^{SC}$.

To study the sensitivity of the BH dynamics to the parameter η , we plot the luminosity L of radiation of one species of bosons against M/m_p for different values of η in FIG. 7. Since $M_* \sim |\eta|^{1/n} m_p$ and $M_{**} \sim |\eta|^{-1/n} m_p$, we find that the larger $|\eta|$ is, the more apparent the effects of rainbow gravity on the luminosities become. In FIG. 7, we plot three cases as follows:

- (a) Subluminal cases where $\eta > 0$ and $M_{cr}^{SC} = 0$. An example with $n = 2$ is plotted in FIG. 7(a) for $\eta = 1, 10, 100$, and 1000 . The red solid line ($\eta = 1000$) can be barely seen since it is too close to the horizontal axis. It is evident that the luminosity for $M_{**} \lesssim M \lesssim M_*$ gets more suppressed as the parameter η becomes larger. In other words, the effects of rainbow gravity could dramatically slow down the evaporation process of the black hole for large enough η . Hence, the corresponding characteristic time scale for the black hole to evaporate from M_* to M_{**} could be much longer than in the usual case.
- (b) Superluminal cases with the non-vanishing remnant mass M_{cr}^{SC} where $\eta < 0$ and $n \geq 2$. An example with $n = 4$ is plotted in FIG. 7(b) for $\eta = -1, -10, -100$, and

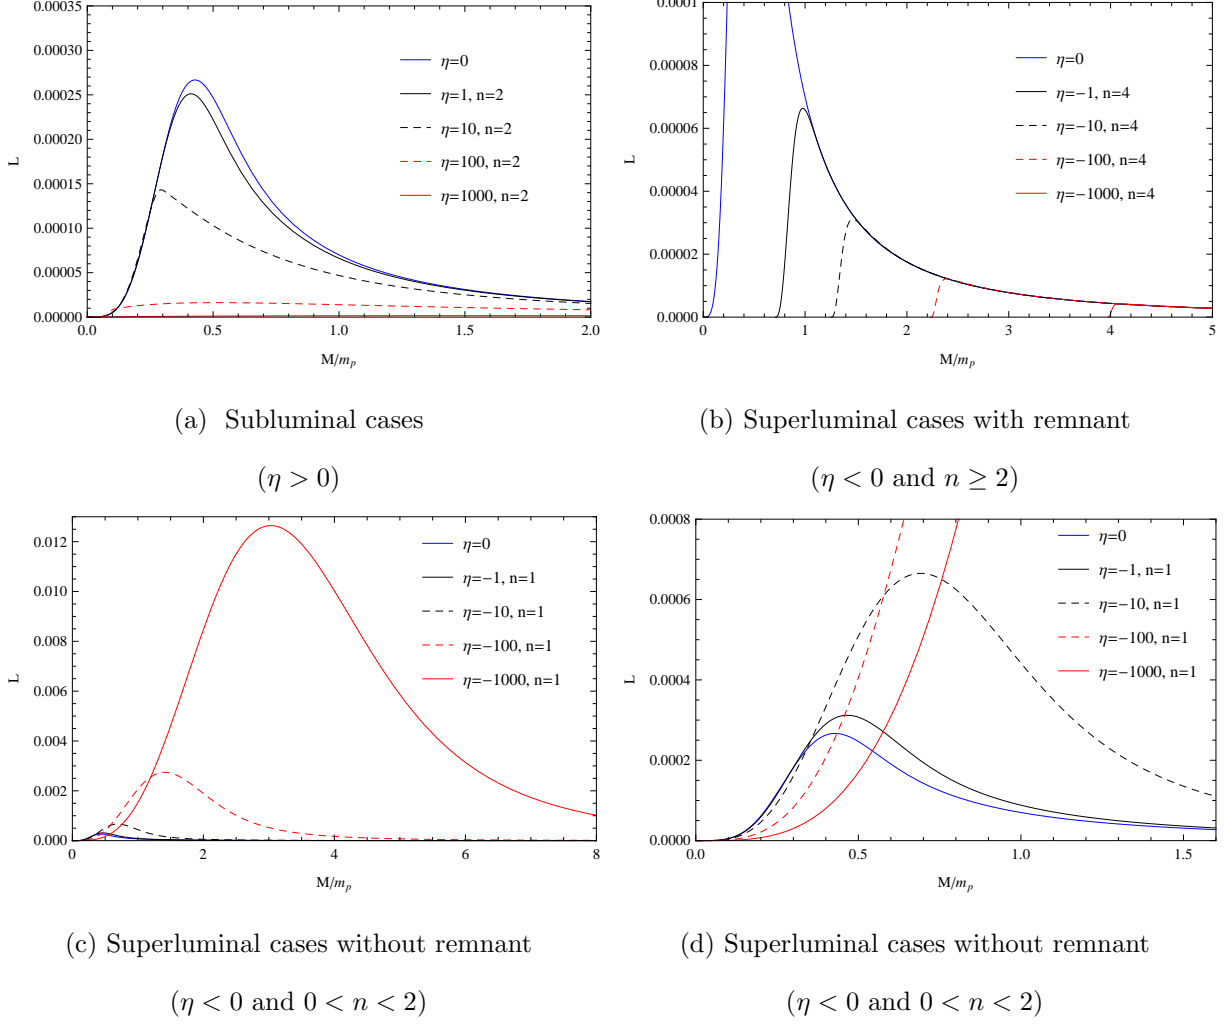

FIG. 7: Plots of the luminosity L of radiation of one species of bosons against the mass M/m_p for a Schwarzschild black hole. The luminosity L is plotted in subluminal cases and superluminal cases with and without remnant for various values of η .

-1000 . In this case, eqn. (37) gives that $M_{cr}^{SC} = \frac{m_p |\eta|^{1/n}}{\sqrt{2}} \gtrsim M_*$. It shows that the luminosity starts to deviate from that in the usual case when M is close to M_{cr}^{SC} and then decreases to zero once $M = M_{cr}^{SC}$. Note that M_{cr}^{SC} becomes larger as we increase $|\eta|$.

(c) Superluminal cases with $M_{cr}^{SC} = 0$ where $\eta < 0$ and $0 < n < 2$. An example with $n = 1$ is plotted in FIGs. 7(c) and 7(d) for $\eta = -1, -10, -100$, and -1000 . Opposite to the subluminal cases, the effects of rainbow gravity could dramatically boost the luminosity for $M_{**} \lesssim M \lesssim M_*$ in this case if $|\eta|$ is large enough. For example, the

maximum value of the luminosity for $\eta = -1000$ is approximately 10^3 times greater than that in the usual case and 10^{20} times greater for $\eta = -10^{16}$, for which the energy scale of Lorentz-invariance violation is assumed around 1TeV. The rainbow gravity speeds up the process of evaporation and hence the characteristic time scale for the black hole to evaporate from M_* to M_{**} becomes shorter than in the usual case.

The luminosity for a Schwarzschild black hole has also been calculated in the framework of rainbow gravity in [32], where massless bosons were considered and the authors used the MDR of the form of

$$E^2 - p^2 (1 - \lambda p) = m^2. \quad (77)$$

By contrast, there are a number of differences between the calculations in our paper and in [32], which are as follows:

1. The geometric optics approximation have been used to calculate the luminosity of a black hole in both papers. In such approximation, a Schwarzschild black hole can be described as a black sphere of the radius R and the temperature T . As a result, when the luminosity is calculated in the framework of rainbow gravity, we have considered effects of rainbow gravity on both R and T . On the other hand, only effects of rainbow gravity on T were considered in [32]. As discussed before, the corrections to R could play an important role in the late stage of the evaporation process. This can be illustrated by FIG. 7(d), where the corrections to R dominate over those to T and make the luminosity smaller than in the usual case for small enough M/m_p , although the corrections to T tend to increase the luminosity.
2. In our paper, we used detailed balance condition to show that the average number $n_{E,i}$ in the mode with E and i is

$$n_{E,i} = n \left(\frac{E}{T_{eff}} \right), \quad (78)$$

where T_{eff} is given in eqn. (24). In contrast, the authors of [32] assumed an average behavior for particles described by a unique average temperature, which is T^{SC} obtained in section III. Therefore in [32], the average number $n_{E,i}$ was given by

$$n_{E,i} = n \left(\frac{E}{T^{SC}} \right). \quad (79)$$

3. We have required the particles' energy $E \leq \min \{m_p x_{cr}, M - M_{cr}\}$ while only $E \leq m_p x_{cr}$ was used in [32]. The extra requirement $E \leq M - M_{cr}$ could dramatically change behaviors of the evaporation process in the late stage. In fact, for the usual case with $\eta = 0$, $x_{cr} = \infty$, and $M_{cr} = 0$, one finds the luminosity of bosons without imposing $E \leq M - M_{cr}$ is $L \sim M^{-2}$, which implies that the black hole would evaporate completely in finite time and have a final explosion at $M = 0$. However, if the requirement $E \leq M - M_{cr}$ is imposed, the luminosity $L \sim M^5$ for small enough M . Thus, it takes infinite time for the black hole to evaporate completely and death of the black hole is much milder. In our paper, since a black hole in rainbow gravity shares the similar the late-stage behaviors with that in the usual case, the lifetime of the rainbow black hole is also infinite. In contrast, the lifetime of a rainbow black hole in [32] turned out to be finite.

C. 4D Cylindrically Symmetric Black Hole

For a 4D cylindrically symmetric black hole with $h_{ab}(x) dx^a dx^b = d\theta^2 + \alpha^2 dz^2$ in eqn. (5), we have found that λ in eqn. (21) is [40]

$$\lambda = j^2 \hbar^2 + \frac{J_z^2}{\alpha^2}, \quad (80)$$

where j is the angular momentum along z -axis and J_z is a constant. To count the number of modes of radiation, we assume the length of the black string is a . Thus, the periodicity condition along z -axis gives

$$J_z = \frac{2\pi k \hbar}{a} \text{ with } k \in \mathbb{Z}. \quad (81)$$

In the geometric optics approximation, eqn. (21) puts an upper bound on λ

$$\lambda \leq \lambda_{\max} \equiv \frac{C(r_{\min}^2)}{B(r_{\min})} \frac{f^2(E/m_p)}{g^2(E/m_p)} E^2, \quad (82)$$

where $\frac{C(r^2)}{B(r)}$ has a minimum at r_{\min} . The luminosity per unit length l is

$$\begin{aligned}
l &\equiv \frac{L}{a} = \frac{g_s}{a} \sum_{j,k} \int E n \left(\frac{E}{T_0} \frac{f(E/m_p)}{g(E/m_p)} \right) \frac{dE}{2\pi\hbar} \\
&= \frac{\alpha g_s}{4\pi^2 \hbar^3} \int d(j\hbar) d\left(\frac{J_z}{\alpha}\right) \int E n \left(\frac{E}{T_0} \frac{f(E/m_p)}{g(E/m_p)} \right) dE \\
&= \frac{\alpha g_s}{2\pi \hbar^3} \frac{C(r_{\min}^2)}{B(r_{\min})} \int_0^{E_{\max}} \frac{f^2(E/m_p)}{g^2(E/m_p)} E^3 n \left(\frac{E}{T_0} \frac{f(E/m_p)}{g(E/m_p)} \right) dE \\
&= \frac{\alpha g_s T_0^4}{2\pi m_p^4} \frac{C(r_{\min}^2)}{B(r_{\min}) m_p^2} \int_0^{u_{\max}} h \left(\frac{uT_0}{m_p} \right) \left[h \left(\frac{uT_0}{m_p} \right) + \left(\frac{uT_0}{m_p} \right) h' \left(\frac{uT_0}{m_p} \right) \right] u^3 n(u) du, \quad (83)
\end{aligned}$$

where $u = \frac{E}{T_0} \frac{f(E/m_p)}{g(E/m_p)}$.

For a static uncharged black string (43), one has

$$T_0 = \frac{3\alpha m_p}{4\pi} b^{1/3}, \quad r_{\min} = \infty, \quad \text{and} \quad \frac{C(r_{\min}^2)}{B(r_{\min})} = \alpha^{-2},$$

where $b = 4M$. Since the length of the black string is infinite, one only has $E \leq E_{\max} \equiv m_p x_{cr}$. The luminosity per unit length for a static uncharged black string is

$$\begin{aligned}
l &= \alpha \frac{81m_p^2 \alpha^2 g_s}{512\pi^5} b^{\frac{4}{3}} \int_0^{\frac{4\pi y_{cr}}{3\alpha m_p b^{1/3}}} h \left(\frac{3\alpha m_p}{4\pi} b^{1/3} u \right) \\
&\quad \left[h \left(\frac{3\alpha m_p}{4\pi} b^{1/3} u \right) + \left(\frac{3\alpha m_p}{4\pi} b^{1/3} u \right) h' \left(\frac{3\alpha m_p}{4\pi} b^{1/3} u \right) \right] u^3 n(u) du. \quad (84)
\end{aligned}$$

In the cases with $M_{cr}^{BS} = 0$, if $T_0 \ll m_p$ ($M \ll 1$), for the emission of n_s species of massless particles of spin s , we have

$$\begin{aligned}
l &\approx \alpha \frac{81m_p^2 \alpha^2}{512\pi^5} b^{\frac{4}{3}} \left\{ (n_0 + 2n_1 + n_{1/2}) \right. \\
&\quad \left. - \frac{3(n+1)!(n+2)}{\pi^2} \left(\frac{3\alpha m_p}{4\pi} b^{1/3} u \right)^n \eta \left[Li_{n+2}(1) (n_0 + 2n_1) + \frac{2-2^{-n}}{n+2} \zeta(n+2) n_{1/2} \right] \right\}, \quad (85)
\end{aligned}$$

where $Li_s(z)$ is the polylogarithm of order s and argument z and $\zeta(z)$ is the zeta function. From eqn.(85), we find that $\frac{dM}{dt} \equiv l \sim M^{\frac{4}{3}}$ for $M \ll 1$. Consequently, just like the usual case, we have for the rainbow black string that $M \sim t^{-3}$, which means that its lifetime is infinite.

In the following, we will compute the asymptotic value of l when $T_0 \gg m_p$ ($M \gg 1$). In the usual case, the luminosity per unit length $l \propto M^{\frac{4}{3}}$. For other cases, the results show as follows:

(a) Subluminal cases where $\eta > 0$ and $M_{cr}^{BS} = 0$. Using

$$x = yh(y) \sim \eta^{-1/n} - \frac{\eta^{-3/n}}{ny^2}, \quad (86)$$

in eqn. (84), we have for the luminosity per unit length

$$l \sim \frac{\eta^{-\frac{4}{n}} g_s}{\pi n m_p^2 \alpha} \int_{\frac{4\pi}{3\alpha m_p (4M)^{1/3}}}^{\infty} \frac{n(\tilde{u})}{\tilde{u}} d\tilde{u}. \quad (87)$$

Thus, the luminosity per unit length of radiation of one species of bosons is

$$l \sim \frac{3\eta^{-\frac{4}{n}} g_s}{4n\pi^2 m_p} (4M)^{1/3}, \quad (88)$$

and that of radiation of one species of fermions is

$$l \sim \frac{\eta^{-\frac{4}{n}} g_s}{3n\pi m_p^2 \alpha} \ln M. \quad (89)$$

The luminosity per unit length l is lower than that in the usual case for large M . In addition, the radiation of bosons dominates the evaporation process for $M \gg 1$. It is evident that l becomes smaller as η is increased. An example of one species of bosons with $\eta = 1$ and $n = 2$ is plotted as a black line in FIG. 8(a). Additionally, we plot l against M for the examples with $n = 4$ in FIG. 8(b) for $\eta = 1, 10, 100$, and 1000.

(b) Superluminal cases with the non-vanishing remnant mass M_{cr}^{BS} where $\eta < 0$ and $n \geq 2$. In this case, one has for radiation of one species of bosons

$$l \sim \frac{3g_s (4M)^{1/3}}{8\pi^2 m_p} \int_0^{y_{cr}} h(y) [h(y) + yh'(y)] y^2 dy, \quad (90)$$

and radiation of one species of fermions

$$l \sim \frac{g_s}{2\pi\alpha m_p^2} \int_0^{y_{cr}} h(y) [h(y) + yh'(y)] y^3 dy. \quad (91)$$

Similar to the subluminal cases, l could become much lower than that in the usual case for large enough M and the radiation of bosons dominates the evaporation process for $M \gg 1$. An example of one species of bosons with $\eta = -1$ and $n = 4$ is plotted as a red solid line in FIG. 8(a).

(c) Superluminal cases with $M_{cr}^{BS} = 0$ where $\eta < 0$ and $0 < n < 2$. Using

$$x = yh(y) \sim (-\eta)^{\frac{1}{2-n}} y^{\frac{2}{2-n}} \quad (92)$$

(a) Subluminal cases and superluminal cases with and without remnant (b) Subluminal cases for various values of η

FIG. 8: Plots of the luminosity per unit length l of radiation of one species of bosons against the mass per unit length M for a static uncharged black string.

in eqn. (84), we find

$$l \sim \frac{(-\eta)^{\frac{2}{2-n}} g_s}{2-n} \frac{81 m_p^2 \alpha^3}{256 \pi^5} \left(\frac{3 \alpha m_p}{4 \pi} \right)^{\frac{n}{2-n}} (4M)^{\frac{8-3n}{3(2-n)}} \int_0^\infty u^2 n(u) u^{\frac{2+n}{2-n}} du. \quad (93)$$

Since $\frac{8-3n}{3(2-n)} > \frac{4}{3}$ for $0 < n < 2$, l could become much larger than that in the usual case for large enough M . The larger $|\eta|$ is, the faster the black string evaporates for $M \gg 1$. An example of one species of bosons with $\eta = -1$ and $n = 1$ is plotted as a black dashed line in FIG. 8(a).

V. CONCLUSION

In this paper, we have analyzed the effects of rainbow gravity on the temperatures, entropies and luminosities of black holes. Using the Hamilton-Jacobi method for scalars, spin 1/2 fermions and vector bosons, we first obtained the effective temperature T_{eff} of a black hole, which depends on the energy E of emitted particles. By relating the momentum p of particles to the event horizon radius r_h of the black hole, the temperatures of a rainbow Schwarzschild black hole and a rainbow static uncharged black string were calculated. Focusing on the AC dispersion relation with $f(x) = 1$ and $g(x) = \sqrt{1 - \eta x^n}$, we computed their minimum masses M_{cr} and final temperatures T_{cr} for different values of η and n . All the results were listed in TABLE I. In addition, a non-vanishing minimum mass indicates the

existence of the black hole's remnant, which could shed light on the “information paradox”. The entropies were also studied in section III.

In section IV, we used the geometric optics approximation to compute luminosities of a 2D black hole, a Schwarzschild one and a static uncharged black string in the framework of rainbow gravity. It was found that the luminosity of the rainbow Schwarzschild black hole with the mass M deviates from that in the usual case only when $M_{**} \lesssim M \lesssim M_*$ for $M_{cr}^{SC} = 0$ or $M_{cr}^{SC} \leq M \lesssim M_*$ for a non-vanishing M_{cr}^{SC} , where $M_* \sim |\eta|^{1/n} m_p$ and $M_{**} \sim |\eta|^{-1/n} m_p$. In the subluminal cases where $\eta > 0$ and $M_{cr}^{SC} = 0$, FIG. 7(a) shows that the effects of rainbow gravity could significantly suppress the luminosity for large η . In the superluminal cases with $M_{cr}^{SC} = 0$ where $\eta < 0$ and $0 < n < 2$, FIG. 7(c) shows that the luminosity could be significantly boosted for large $|\eta|$. Similar results for the rainbow static uncharged black string with the mass per unit length $M \gg 1$ were also obtained for the subluminal cases and superluminal cases with $M_{cr}^{BS} = 0$.

If the energy scale of Lorentz-invariance violation is Λ , the naturalness in effective field theories implies that $|\eta| \sim \left(\frac{\Lambda}{m_p}\right)^n$. For a Schwarzschild black hole, the effects of rainbow gravity start to play an important role when the mass of the black hole $M \lesssim |\eta|^{1/n} m_p \sim \Lambda$. If Lorentz invariance is violated by quantum gravity, the natural scale $\Lambda \sim m_p$. Currently, there are no experimental evidence that Lorentz symmetry is violated in nature, which might suggest that $1\text{TeV} \lesssim \Lambda \lesssim m_p$. The experimental and observational constraints on Lorentz-invariance violation are reviewed in [49, 50]. As a result, the rainbow gravity plays a negligible role for stellar or galactic supermassive black holes. However, the possible production of TeV-scale black holes at the LHC or ultra-high-energy cosmic ray collisions is predicted by low-scale quantum gravity[51]. Another possible source of small black holes is primordial black holes, which are created by primordial density fluctuations in the early universe and evaporate for enough long time. Future studies investigating the implications of our results on the rich phenomenology of these small black holes would be interesting.
