Abstract

We address the problem of enumerating paths in square lattices, where allowed steps include (1, 0) and (0, 1) everywhere, and (1, 1) above the diagonal \(y = x\). We consider two such lattices differing in whether the (1, 1) steps are allowed along the diagonal itself. Our analysis leads to explicit generating functions and an efficient way to compute terms of many sequences in the Online Encyclopedia of Integer Sequences, proposed by Clark Kimberling almost two decades ago.

1 Introduction

The Catalan numbers \(C_n = \frac{1}{n+1} \binom{2n}{n}\) (sequence \text{A000108} in the OEIS \cite{OEIS}) enumerate among other combinatorial objects \cite{Com} the paths from \((0,0)\) to \((n,n)\) in the integer lattice bounded by lines \(y = 0\) and \(y = x\) with unit steps \((0,1)\) and \((1,0)\), called Dyck paths. We represent these restrictions as a directed diagram, which we will refer to as the Dyck diagram \(D_D\) (Fig. 1 left panel). If we allow diagonal steps \((1,1)\) in this lattice, the paths in it become known as Schröder paths \cite{Sch}, and the number of such paths from \((0,0)\) to \((n,n)\) is given by the large Schröder numbers \(S_n\) (sequence \text{A006318} in the OEIS). We similarly represent these restrictions as a directed diagram, which refer to as the Schröder diagram \(D_S\) (Fig. 1 right panel).

In 1999, Clark Kimberling contributed the sequences \text{A026769}–\text{A026790} to the OEIS \cite{OEIS}, concerning a composition of the Dyck and Schröder diagrams that below the diagonal \(y = x\) represents the Dyck diagram and above the diagonal represents the transposed Schröder diagram. There are two such diagrams \(D_{DS}\) and \(D_{DS}^*\), where the \((1,1)\) steps along the diagonal are allowed and disallowed, respectively (Fig. 2). In the present work, we address the problem of enumerating Dyck–Schröder paths, i.e., paths in the diagrams \(D_{DS}\) and \(D_{DS}^*\). We begin our analysis by recalling some useful facts about the Dyck and Schröder diagrams.

The generating functions for Catalan and Schröder numbers are given by

\[
C(x) = \sum_{n=0}^{\infty} C_n \cdot x^n = \frac{1}{2x} \left(1 - \sqrt{1 - 4x}\right)
\]

and

\[
S(x) = \sum_{n=0}^{\infty} S_n \cdot x^n = \frac{1}{2x} \frac{1 - x - \sqrt{1 - 6x + x^2}}{1 - x} = \frac{1}{1 - x} \cdot C\left(\frac{x}{(1 - x)^2}\right),
\]

respectively \cite{Knuth}. So the number of paths from \((0,0)\) to \((n,n)\) in \(D_D\) and \(D_S\) is given by \([x^n] C(x)\) and \([x^n] S(x)\), respectively, where \([x^n]\) denotes the operator of taking the coefficient of \(x^n\).

We will need the following lemma, which states well-known facts about the number of paths and the number of subdiagonal paths (i.e., paths that lay below the line \(y = x\), except possibly for their endpoints) from \((0,0)\) to \((n,k)\) in \(D_D\) and \(D_S\).
Lemma 1. For any integers \( n \geq k \geq 0 \),

(i) the number of paths from \((0, 0)\) to \((n, k)\) in \(\mathcal{D}_D\) and \(\mathcal{D}_S\) equals \([x^k] \mathcal{C}(x)^{n-k+1}\) and \([x^k] \mathcal{S}(x)^{n-k+1}\), respectively.

(ii) the number of subdiagonal paths from \((0, 0)\) to \((n, n)\) in \(\mathcal{D}_D\) and \(\mathcal{D}_S\) equals \([x^{n-1}] \mathcal{C}(x)\) and \([x^{n-1}] \mathcal{S}(x)\), respectively.

(iii) for \( n > k \), the number of subdiagonal paths from \((0, 0)\) to \((n, k)\) in \(\mathcal{D}_D\) and \(\mathcal{D}_S\) equals \([x^k] \mathcal{C}(x)^{n-k}\) and \([x^k] \mathcal{S}(x)^{n-k}\), respectively.

2 Enumeration of Dyck–Schröder paths

Theorem 2. Let \( f_n \) and \( f_n^* \) be the number of paths from \((0, 0)\) to \((n, n)\) in the diagrams \(\mathcal{D}_{DS}\) and \(\mathcal{D}_{DS}^*\), respectively. Then

\[
\mathcal{F}^*(x) = \sum_{n=0}^{\infty} f_n^* \cdot x^n = \frac{1}{1 - x \cdot (\mathcal{C}(x) + \mathcal{S}(x))}
\]

and

\[
\mathcal{F}(x) = \sum_{n=0}^{\infty} f_n \cdot x^n = \frac{1}{1 - x \cdot (\mathcal{C}(x) + \mathcal{S}(x) + 1)} = \frac{\mathcal{S}(x)}{1 - x \cdot \mathcal{C}(x) \cdot \mathcal{S}(x)}.
\]

Proof. Any path from \((0, 0)\) to \((n, n)\) in \(\mathcal{D}_{DS}^*\) consists of subdiagonal and/or supdiagonal\(^1\) subpaths from \((p_0, p_0)\) to \((p_1, p_1)\), from \((p_1, p_1)\) to \((p_2, p_2)\), \ldots, from \((p_{m-1}, p_{m-1})\) to \((p_m, p_m)\), where \(m \geq 0\) and \(0 = p_0 < p_1 < \cdots < p_m = n\) are integers (in other words, \(p_i\) represent the coordinates of vertices where the path visits

\(^1\)Similarly to subdiagonal paths, we define supdiagonal paths as those that lay above the diagonal \(y = x\), except possibly for their endpoints.
the diagonal). By Lemma 1 for any $k = 0, 1, \ldots, m - 1$, the number of subdiagonal and/or supdiagonal paths from $(p_k, p_k)$ to $(p_{k+1}, p_{k+1})$ equals

$$[x^{p_{k+1}-p_k-1}] (\mathcal{C}(x) + \mathcal{S}(x)).$$

Indeed, every such path is either subdiagonal (enumerated by $\mathcal{C}(x)$) or supdiagonal (enumerated by $\mathcal{S}(x)$).

Hence, the total number of paths in from $(0, 0)$ to $(n, n)$ in $\mathcal{D}_{DS}$ equals

$$\sum_{m=0}^{\infty} \sum_{0 < p_1 < \cdots < p_m < n} \prod_{k=0}^{m-1} [x^{p_{k+1}-p_k-1}] (\mathcal{C}(x) + \mathcal{S}(x))$$

$$= \sum_{m=0}^{\infty} [x^{n-m}] (\mathcal{C}(x) + \mathcal{S}(x))^m = [x^n] \sum_{m=0}^{\infty} (x \cdot (\mathcal{C}(x) + \mathcal{S}(x)))^m$$

$$= [x^n] \frac{1}{1 - x \cdot (\mathcal{C}(x) + \mathcal{S}(x))}.$$

In the diagram $\mathcal{D}_{DS}$, in addition to subdiagonal and/or supdiagonal subpaths, we need to account for single diagonal steps (when $p_{k+1} = p_k + 1$), which brings the additional summand 1 to $\mathcal{C}(x) + \mathcal{S}(x)$. That is, the total number of paths in from $(0, 0)$ to $(n, n)$ in $\mathcal{D}_{DS}$ equals the coefficient of $x^n$ in

$$\frac{1}{1 - x \cdot (\mathcal{C}(x) + \mathcal{S}(x) + 1)} = \frac{\mathcal{S}(x)}{1 - x \cdot \mathcal{C}(x) \cdot \mathcal{S}(x)}.$$

The last equality follows from the algebraic identity:

$$x \cdot \mathcal{S}(x)^2 - (1 - x) \cdot \mathcal{S}(x) + 1 = 0.$$
Theorem 3. For integers \(n, k\), the number of paths from \((0, 0)\) to \((n, k)\) in \(\mathcal{D}_{DS}\) equals

\[
\begin{cases} 
[x^n] \mathcal{F}(x) \cdot \mathcal{C}(x)^{n-k}, & \text{if } n \geq k; \\
[x^n] \mathcal{F}(x) \cdot \mathcal{S}(x)^{k-n}, & \text{if } n \leq k.
\end{cases}
\]

Similarly, the number of paths from \((0, 0)\) to \((n, k)\) in \(\mathcal{D^*_DS}\) equals

\[
\begin{cases} 
[x^n] \mathcal{F}^*(x) \cdot \mathcal{C}(x)^{n-k}, & \text{if } n \geq k; \\
[x^n] \mathcal{F}^*(x) \cdot \mathcal{S}(x)^{k-n}, & \text{if } n \leq k.
\end{cases}
\]

Proof. Any path from \((0, 0)\) to \((n, k)\) in \(\mathcal{D}_{DS}\) is formed by a path from \((0, 0)\) to \((m, m)\) for some \(m \geq 0\) and a path from \((m, m)\) to \((n, k)\) that never visits the diagonal again. Clearly, this decomposition is unique and so is \(m\). The number of paths from \((0, 0)\) to \((m, m)\) equals \([x^m] \mathcal{F}(x)\). If \(n > k\), then the number of paths from \((m, m)\) to \((n, k)\) avoiding the diagonal equals the number of subdiagonal paths from \((0, 0)\) to \((n-m, k-m)\) in \(\mathcal{D}_S\), which is \([x^{k-m}] \mathcal{C}(x)^{n-k}\) (by Lemma 1). In this case, the number of paths \((0, 0)\) to \((n, k)\) in \(\mathcal{D}_{DS}\) equals

\[
\sum_{m=0}^{\infty} [x^m] \mathcal{F}(x) \cdot [x^{n-m}] \mathcal{C}(x)^{n-k} = [x^n] \mathcal{F}(x) \cdot \mathcal{C}(x)^{n-k}.
\]

Similarly, if \(n < k\), then the number of paths from \((m, m)\) to \((n, k)\) avoiding the diagonal equals the number of subdiagonal paths from \((0, 0)\) to \((k-m, n-m)\) in \(\mathcal{D}_S\), which is \([x^{n-m}] \mathcal{S}(x)^{k-n}\) (by Lemma 1). In this case, the number of paths \((0, 0)\) to \((n, k)\) in \(\mathcal{D}_{DS}\) equals \([x^n] \mathcal{F}(x) \cdot \mathcal{S}(x)^{k-n}\). It is easy to see that the formulae in both cases are also consistent with the case \(n = k\), where the number of paths equals \([x^n] \mathcal{F}(x)\) by the definition of \(\mathcal{F}(x)\).

The diagram \(\mathcal{D^*_DS}\) is considered similarly.

3 Sequences in the OEIS

Below we derive formulae for sequences \texttt{A026769–A026779} (concerning the diagram \(\mathcal{D}_{DS}\)) and sequences \texttt{A026780–A026790} (concerning the diagram \(\mathcal{D}_{DS}\)) in the Online Encyclopedia of Integer Sequences \cite{OEIS}.

3.1 Sequences A026769 and A026780

\texttt{A026769}(n, k) and \texttt{A026780}(n, k) give the number of paths from \((0, 0)\) to \((k, n-k)\) in the diagrams \(\mathcal{D}_{DS}\) and \(\mathcal{D}_{DS}\), respectively. Formulae for these numbers are given in Theorem 3.

3.2 Sequences A026770–A026774 and A026781–A026785

The \(n\)-th term of \texttt{A026770–A026774} enumerate paths in \(\mathcal{D^*_DS}\) from \((0, 0)\) to \((n, n), (n-1, n+1), (n-2, n+2), (n-1, n), \) and \((n-2, n+1)\), respectively. By Theorem 3, the ordinary generating function for the number of such paths is \(\mathcal{F}^*(x)\), \(x \cdot \mathcal{F}^*(x) \cdot \mathcal{S}(x)^2\), \(x^2 \cdot \mathcal{F}^*(x) \cdot \mathcal{S}(x)^3\), \(x \cdot \mathcal{F}^*(x) \cdot \mathcal{S}(x)^4\), and \(x^2 \cdot \mathcal{F}^*(x) \cdot \mathcal{S}(x)^5\), respectively.

The sequences \texttt{A026771–A026775} enumerate similar paths in \(\mathcal{D}_{DS}\) and have ordinary generating functions \(\mathcal{F}(x)\), \(x \cdot \mathcal{F}(x) \cdot \mathcal{S}(x)^2\), \(x^2 \cdot \mathcal{F}(x) \cdot \mathcal{S}(x)^3\), \(x \cdot \mathcal{F}(x) \cdot \mathcal{S}(x)^4\), and \(x^2 \cdot \mathcal{F}(x) \cdot \mathcal{S}(x)^5\), respectively.
3.3 Sequences A026775 and A026786

The terms A026775(n) and A026786(n) give the number of paths from (0, 0) to \([\lceil n/2 \rceil, \lfloor n/2 \rfloor]\) in the diagrams \(D_{DS}^1\) and \(D_{DS}^2\), respectively. By Theorem 3, these are the coefficients of \(x^{\lceil n/2 \rceil}\) in \(F^*(x) \cdot S(x)^{n \mod 2}\) and \(F(x) \cdot S(x)^{n \mod 2}\), which are the same as the coefficients of \(x^n\) in \(F^*(x^2) \cdot (1 + x \cdot S(x^2))\) and \(F(x) \cdot (1 + x \cdot S(x^2))\).

3.4 Sequences A026776 and A026787

The terms A026776(n) and A026787(n) give the total number of paths from (0, 0) to \((i, n - i)\), where \(i = 0, 1, \ldots, n\), in the diagrams \(D_{DS}^1\) and \(D_{DS}^2\), respectively.

**Theorem 4.** The ordinary generating function for A026776 is

\[
F^*(x^2) \cdot \left( \frac{1}{1 - x \cdot S(x^2)} + \frac{1}{1 - x \cdot C(x^2)} - 1 \right),
\]

The ordinary generating function for A026787 is

\[
F(x^2) \cdot \left( \frac{1}{1 - x \cdot S(x^2)} + \frac{1}{1 - x \cdot C(x^2)} - 1 \right).
\]

**Proof.** By Theorem 3, A026776(n) equals

\[
\sum_{i=0}^{\lfloor n/2 \rfloor} [x^i] F^*(x) \cdot S(x)^{n-2i} + \sum_{i=\lceil n/2 \rceil+1}^{n} [x^{n-i}] F^*(x) \cdot C(x)^{2i-n}
\]

\[
= \sum_{i=0}^{\lfloor n/2 \rfloor} [x^{2i}] F^*(x^2) \cdot S(x^2)^{n-2i} + \sum_{i=\lceil n/2 \rceil+1}^{n} [x^{2n-2i}] F^*(x^2) \cdot C(x^2)^{2i-n}
\]

\[
= [x^n] F^*(x^2) \cdot \left( \sum_{i=0}^{\lfloor n/2 \rfloor} (x \cdot S(x^2))^{n-2i} + \sum_{i=\lceil n/2 \rceil+1}^{n} (x \cdot C(x^2))^{2i-n} \right).
\]

We notice that in the first sum, the powers of \(x \cdot S(x^2)\) go over the nonnegative integers up to \(n\) of the same oddness as \(n\). Since we are interested only in the coefficient of \(x^n\), we can drop both these restrictions. Namely, the powers above \(n\) have the coefficient of \(x^n\) equal zero, while the power \(m\) of the opposite oddness than \(n\) may have nonzero coefficients only for \(x\) in powers of the same oddness as \(m\). The same arguments apply for the powers of \(x \cdot C(x^2)\), except that in this case they go over the positive integers. That is, the above expression simplifies to

\[
[x^n] F^*(x^2) \cdot \left( \sum_{m=0}^{\lfloor n/2 \rfloor} (x \cdot S(x^2))^m \sum_{m=1}^{\lceil n/2 \rceil} (x \cdot C(x^2))^m \right)
\]

\[
= [x^n] F^*(x^2) \cdot \left( \frac{1}{1 - x \cdot S(x^2)} + \frac{1}{1 - x \cdot C(x^2)} - 1 \right),
\]

which gives the ordinary generating function for A026776.

The generating function for A026787 is be obtained by replacing \(F^*(x^2)\) with \(F(x^2)\).

3.5 Sequences A026777 and A026788

The term A026777(n) gives the total number of paths in \(D_{DS}^1\) from (0, 0) to \((i, n-i)\), where \(i = 0, 1, \ldots, \lfloor n/2 \rfloor\). The ordinary generating function for A026777 is \(\frac{F^*(x^2)}{1 - x \cdot S(x^2)}\), which can be easily obtained from our analysis of the sequence A026776 above.
The ordinary generating function for \(A026788\), which enumerates similar paths in \(D_{DS}\), equals \(\frac{F(x^2)}{1-x S(x^2)}\).

### 3.6 Sequences A026778 and A026789

The term \(A026778(n)\) gives the total number of paths in \(D_{DS}\) from \((0,0)\) to \((i,i-j)\), where \(0 \leq j \leq i \leq n\). It is easy to see that

\[
A026778(n) = \sum_{m=0}^{n} A026776(m)
\]

and thus the ordinary generating function for \(A026778\) can be obtained from the one for \(A026776\) by multiplying it by \(\frac{1}{1-x}\). That is, the ordinary generating function for \(A026778\) equals

\[
\frac{F(x^2)}{1-x} \cdot \left( \frac{1}{1-x \cdot S(x^2)} + \frac{1}{1-x \cdot C(x^2)} - 1 \right).
\]

The ordinary generating function for \(A026789\), which enumerates similar paths in \(D_{DS}\), equals

\[
\frac{F(x^2)}{1-x} \cdot \left( \frac{1}{1-x \cdot S(x^2)} + \frac{1}{1-x \cdot C(x^2)} - 1 \right).
\]

### 3.7 Sequences A026779 and A026790

The terms \(A026779(n)\) and \(A026790(n)\) give the total number of paths from \((0,0)\) to \((i,n-2i)\), where \(i=0,1,\ldots,\lfloor n/2 \rfloor\), in the diagrams \(D_{DS}\) and \(D_{DS}\), respectively.

**Theorem 5.** The ordinary generating function for \(A026779\) is

\[
F^*(x^3) \cdot \left( \frac{1}{1-x \cdot S(x^3)} + \frac{1}{1-x^2 \cdot C(x^3)} - 1 \right).
\]

The ordinary generating function for \(A026790\) is

\[
F(x^3) \cdot \left( \frac{1}{1-x \cdot S(x^3)} + \frac{1}{1-x^2 \cdot C(x^3)} - 1 \right).
\]

**Proof.** By Theorem 3 A026779\((n)\) equals

\[
\sum_{i=0}^{\lfloor n/3 \rfloor} [x^i] F^*(x) \cdot S(x)^{n-3i} + \sum_{i=\lfloor n/3 \rfloor+1}^{\lfloor n/2 \rfloor} [x^{n-2i}] F^*(x) \cdot C(x)^{3i-n}
\]

\[
= \sum_{i=0}^{\lfloor n/3 \rfloor} [x^3i] F^*(x^3) \cdot S(x^3)^{n-3i} + \sum_{i=\lfloor n/3 \rfloor+1}^{\lfloor n/2 \rfloor} [x^{3n-6i}] F^*(x^3) \cdot C(x^3)^{3i-n}
\]

\[
= [x^n] F^*(x^3) \cdot \left( \sum_{i=0}^{\lfloor n/3 \rfloor} (x \cdot S(x^3))^{n-3i} + \sum_{i=\lfloor n/3 \rfloor+1}^{\lfloor n/2 \rfloor} (x^2 \cdot C(x^3))^{3i-n} \right),
\]

from where we conclude the proof with arguments similar to those in the proof of Theorem 4.
