ON THE RELATION BETWEEN BINOMIAL THEOREM AND DISCRETE CONVOLUTION OF PIECEWISE DEFINED POWER FUNCTION

PETRO KOLOSOV

Abstract. In this manuscript we establish a relation between Binomial theorem and discrete convolution of piecewise defined power function. We show that Binomial expansion of $s$-powered sum $(a + b)^s$, $s \geq 1$, $a + b \geq 1$ is equivalent to the sum of consequent discrete convolutions of piecewise defined power function multiplied by the certain real coefficients. In addition, we generalise relation between Binomial theorem and discrete convolution of piecewise defined power function to Multinomial case.

1. Introduction

In this paper we reveal a relation between famous Binomial theorem [AS72] and discrete convolution of piecewise defined power function $f_t^r(n)$, see (1.1) for $f_t^r(n)$. The content of the manuscript reaches the main aim of the work through the following milestones. Firstly, we perform a detailed discussion on $2m$-degree integer-valued polynomials $P_{a,b}^m(n)$, see (1.3). We show all the implicit forms of the polynomials $P_{a,b}^m(n)$ and discuss their main properties. Finally, for the first milestone, we arrive to the identity between odd-powered Binomial (and...
Multinomial) expansions and partial case of $P_{a,b}^m(n)$. As next step, we establish a relation between the polynomials $P_{a,b}^m(n)$ and discrete convolution of the power function $f_t^r(n)$. This relation is consequence of the following claims:

- $P_{a,b}^m(n)$ is in relation with the power sum $Q_b^r(n)$, see (1.2) for $Q_b^r(n)$.
- Discrete convolution of power function $f_t^r(n)$ is partial case of the power sum $Q_b^r(n)$.
- Polynomials $P_{a,b}^m(n)$ are in relation with the discrete convolution of power function $f_t^r(n)$.

Then, in the subsection (3.1) we particularise obtained results to show the relation between Binomial (and Multinomial) theorem and the discrete convolution of piecewise defined power function.

1.1. Notation and conventions. We now set the following notation, which remains fixed for the remainder of this paper:

- We strongly believe to D. Knuth’s words in [Knu92]

I realized long ago that "boundary conditions" on indices of summation are often a handicap and a waste of time.

For example, instead of writing

$$2^n = \sum_{k=0}^n \binom{n}{k}$$

it is much better to write

$$2^n = \sum_k \binom{n}{k}$$

the sum now extends over all integers $k$, but only finitely many terms are nonzero.

- We believe to [GKP94] that exponential function $0^x$ should be defined for all $x$ as

$$0^x = 1.$$

- $[P(k)]$ is the Iverson’s convention [Ive62], where $P(k)$ is logical sentence depending on $k$

$$[P(k)] = \begin{cases} 1, & P(k) \text{ is true}, \\ 0, & \text{otherwise} \end{cases}$$

- $f_t^r(n)$ is a power function defined on the set $\mathbb{Z}$ of integers

$$(1.1) \quad f_t^r(n) := n^r [n \geq t], \quad n \in \mathbb{Z}.$$

- $(f \ast f)[n]$ is discrete convolution transform [BDM11] of the real defined on the set $\mathbb{Z}$ of integers function $f(n)$

$$(f \ast f)[n] = \sum_k f[k] f[n - k].$$
• \(A_{m,r}\) is a real coefficient defined recursively as
\[
A_{m,r} := \begin{cases} 
(2r + 1)\binom{2r}{r}, & \text{if } r = m, \\
(2r + 1)\binom{2r}{r} \sum_{d=2r+1}^{m} A_{m,d} \frac{(-1)^{d-1}}{d-r} B_{2d-2r}, & \text{if } 0 \leq r < m, \\
0, & \text{if } r < 0 \text{ or } r > m.
\end{cases}
\]
where \(B_t\) are Bernoulli numbers [Wei]. We assume that \(B_1 = \frac{1}{2}\). For \(m \geq 11\) the \(A_{m,r}\) takes the fractional values for certain \(r\).

• \(Q_{r,a,b}(n)\) is the power sum defined as
\[
Q_{r,a,b}(n) := \sum_{a \leq k < b} k^r (n - k)^r, \quad (n, r) \in \mathbb{Z}.
\]

Notation \(Q_{r,b}(n)\) is an equivalent to \(Q_{r,a,b}(n)\) with set \(a = 0\), i.e \(Q_{r,b}(n) \equiv Q_{r,0,b}(n)\).

• \(S_p(n)\) is a common power sum
\[
S_p(n) = \sum_{0 \leq k < n} k^p.
\]

• \(L_m(n, k)\) are polynomials of degree \(2m\) in \(n, k\) defined involving coefficients \(A_{m,r}\)
\[
L_m(n, k) := \sum_{r} A_{m,r} k^r (n - k)^r, \quad m \in \mathbb{N}, \quad (n, k) \in \mathbb{Z}.
\]

• \(P_{a,b}^m(n)\) are polynomials of degree \(2m\), \(m \geq 0\) in \(a, b, n\)
\[
P_{a,b}^m(n) := \sum_{a \leq k < b} L_m(n, k).
\]

Notation \(P_{b}^m(n)\) is an equivalent to \(P_{a,b}^m(n)\) with set \(a = 0\), i.e \(P_{b}^m(n) \equiv P_{0,b}^m(n)\).

• \(H_{m,t}(k)\) are real coefficients defined in terms of Bernoulli numbers \(B_t\), Binomial coefficients \(\binom{j}{t}\) and \(A_{m,r}\)
\[
H_{m,t}(k) := \sum_{j \geq t} \binom{j}{t} A_{m,j} \frac{(-1)^j}{2j - t + 1} \binom{2j - t + 1}{k} B_{2j-t+1-k}, \quad 0 \leq t \leq m,
\]
where \(B_1 = \frac{1}{2}\).

• \(X_t^m(a, b)\) are polynomials of degree \(2m - t\) in \(a, b\) defined as
\[
X_t^m(a, b) := (-1)^m \sum_{k=1}^{2m-t+1} H_{m,t}(k) (b^k - a^k), \quad 0 \leq t \leq m.
\]

Notation \(X_t^m(b)\) is an equivalent to \(X_t^m(a, b)\) with set \(a = 0\), i.e \(X_t^m(b) \equiv X_t^m(0, b)\).
2. Polynomials $P_{a,b}^m(n)$ and their properties

We’d like to begin our discussion from defined above polynomial $P_{a,b}^m(n)$. Polynomial $P_{a,b}^m(n)$ is $2m + 1$ degree polynomial in $a, b, n$. Polynomial $P_{a,b}^m(n)$ is defined as finite sum of $2m$ degree polynomial $L_m(n, k)$ over $k$. Being a summation, by means of associativity the polynomials $P_{a,b}^m(n)$ can be split

$$P_{a,b}^m(n) = P_{b}^m(n) - P_{a}^m(n).$$

Polynomials $P_{a,b}^m(n)$ implicitly involve the polynomials $Q_{a,b}^r(n)$, $X_{k}^m(a, b)$, $H_{m,t}(k)$ and common power sum $S_p(n)$, see Notation and conventions. In extended form the polynomials $P_{a,b}^m(n)$ are

$$P_{a,b}^m(n) = \sum_{a \leq k < b} L_m(n, k) = \sum_k A_{m,k}Q_{a,b}^k(n) = \sum_k A_{m,k}(Q_{b}^k(n) - Q_{a}^k(n))$$

$$= \sum_k X_{k}^m(a, b)(-1)^{m-k}n^k = \sum_k(X_{k}^m(b) - X_{k}^m(a))(-1)^{m-k}n^k$$

$$= \sum_k \sum_{j \geq k} (-1)^{2m+j-k}A_{m,j}(\binom{j}{k})(S_{2j-k}(b) - S_{2j-k}(a))n^k$$

$$= \sum_k (-1)^{2m-k} \sum_{\ell=1}^{2m-k+1} H_{m,k}(\ell)(b^{\ell} - a^{\ell})n^k.$$

The last line of the expression (2.1) clearly states why $P_{a,b}^m(n)$ are polynomials in $a, b, n$. Let’s show a few examples of polynomials $P_{a,b}^m(n)$

$$P_{a,b}^0(n) = -a + b.$$

$$P_{a,b}^1(n) = -3a^2 + 2a^3 + 3b^2 - 2b^3 + 3an - 3a^2n - 3bn + 3b^2n.$$

$$P_{a,b}^2(n) = -10a^3 + 15a^4 - 6a^5 + 10b^3 - 15b^4 + 6b^5 + 15a^2n - 30a^3n + 15a^4n - 15b^2n + 30b^3n - 15b^4n - 5an^2 + 15a^2n^2 - 10a^3n^2 + 5bn^2 - 15b^2n^2 + 10b^3n^2.$$
We consider the polynomials $P_{a,b}^m(n)$ because they are useful in revealing of the main topic of the manuscript. By means of partial cases of the polynomial $P_{a,b}^m(n)$ we establish a relation between the power sum $Q_{a,b}^m(n)$ and Binomial theorem. For instance, odd powers of $n$ are
\begin{equation}
(n^{2m+1} = P_{a,b}^m(n) = \sum_k A_{m,k}Q_k^m(n), \quad m \geq 0.
\end{equation}

Moreover, the Binomial expansion $(a+b)^{2m+1}$ of odd powers can be reached similarly
\begin{equation}
(a+b)^{2m+1} = \sum_k \binom{2m+1}{k} a^{2m+1-k}b^k \equiv P_{a+b}^m(a+b) \equiv \sum_k A_{m,k}Q_{a+b}^k(a+b), \quad m \geq 0.
\end{equation}

It clearly follows that Multinomial expansion of odd-powered $t$-fold sum $(a_1+a_2+\cdots+a_t)^{2m+1}$ can be reached by $P_{a,b}^m(n)$ as well
\begin{equation}
(a_1+a_2+\cdots+a_t)^{2m+1} = \sum_{k_1+k_2+\cdots+k_t=2m+1} \binom{2m+1}{k_1,k_2,\ldots,k_t} \prod_{s=1}^t a_s^{k_s}
\end{equation}

\end{equation}
\begin{equation}
\equiv P_{a_1+a_2+\cdots+a_t}^m(a_1+a_2+\cdots+a_t)
\end{equation}
\begin{equation}
= \sum_k A_{m,k}Q_{a_1+a_2+\cdots+a_t}^k(a_1+a_2+\cdots+a_t), \quad m \geq 0.
\end{equation}

Since the $n^s = n^\lfloor s \cdot \text{even} \rfloor \lfloor (s-1)/2 \rfloor$, it is easy to generalise previously obtained odd power
identity for all exponents $s \in \mathbb{N}$
\begin{equation}
n^s = n^\lfloor s \cdot \text{even} \rfloor P_n^{\lfloor s-1/2 \rfloor}(n) = n^\lfloor s \cdot \text{even} \rfloor \sum_k A_{n,\lfloor s-1/2 \rfloor,k}Q_{n,k}^k(n), \quad s \geq 1.
\end{equation}

The binomial expansion of $(a+b)^s$ for every $s \in \mathbb{N}$ is
\begin{equation}
(a+b)^s = \sum_k \binom{s}{k} a^{s-k}b^k \equiv (a+b)^\lfloor s \cdot \text{even} \rfloor P_{a+b}^{\lfloor s-1/2 \rfloor}(a+b)
\end{equation}
\begin{equation}
= (a+b)^\lfloor s \cdot \text{even} \rfloor \sum_k A_{\lfloor s-1/2 \rfloor,k}Q_{a+b}^k(a+b), \quad s \geq 1.
\end{equation}
Now we are able to generalise the expression (2.5) even more. For the \( t \)-fold \( s \)-powered sum 
\[(a_1 + a_2 + \cdots + a_t)^s; \quad s \geq 1\] we have following Multinomial expansion (2.7)
\[
(a_1 + a_2 + \cdots + a_t)^s = \sum_{k_1+k_2+\cdots+k_t=s} \binom{s}{k_1, k_2, \ldots, k_t} \prod_{\ell=1}^t a_\ell^{k_\ell}
\]
\[
\equiv (a_1 + a_2 + \cdots + a_t)^{\lfloor s/2 \rfloor} \sum_{k} \mathcal{A}_{\left\lfloor \frac{s-1}{2} \right\rfloor}^{k} \mathcal{Q}_{a_1+\cdots+a_t}^k (a_1 + \cdots + a_t).
\]

**Property 2.8.** For every \( n, k \in \mathbb{Z} \)
\[
L_m(n, k) = L_m(n - k, k).
\]

By the property (2.8)
\[
n^{2m+1} = P^m_n(n) = P^m_{1,n+1}(n).
\]

Thus, there are exist analogs of (2.2), (2.3), (2.4), (2.5), (2.6), (2.7) expressed by means of 
\( P^m_{1,n+1}(n) \). Also, it is necessary to notice that for each \( m \geq 0 \)
\[
L_m(n, 0) = 1, \quad L_m(n, n) = 1,
\]
thus
\[
(2.9) \quad n^{2m+1} = -1 + P^m_{n+1}(n), \quad n^{2m+1} = 1 + P^m_{1,n}(n).
\]

3. **Relation between the polynomials** \( P^m_{a,b}(n) \) **and discrete convolution of power function** \( f^r_t(n) \)

Previously we have established a relation between the polynomials \( P^m_{a,b}(n) \) and Binomial theorem. In this section a relation between \( P^m_{a,b}(n) \) and convolution of the power function \( f^r_t(n) \) is established. To show that \( P^m_{a,b}(n) \) implicitly involves the discrete convolution of the power function \( f^r_t(n) \) let’s refresh what \( P^m_{a,b}(n) \) is
\[
P^m_{a,b}(n) = \sum_k \mathcal{A}_{m,k} \mathcal{Q}_{a,b}^k(n).
\]

Meanwhile, the term \( \mathcal{Q}_{a,b}^k(n) \) is the convolutional power sum of the form
\[
\mathcal{Q}_{a,b}^r(n) = \sum_{a \leq k < b} k^r(n - k)^r.
\]

By definition, the discrete convolution of some integer-defined function \( f \) is
\[
(f * f)[n] = \sum_k f[k] f[n - k].
\]
Now it could be noticed immediately that the discrete convolution \((f_t^r * f_t^r)[n]\) of power function \(f_t^r(n)\) is partial case of \(Q_{a,b}^k(n)\). For instance, the discrete convolution of power function \(f_t^r(n)\) is

\[
(f_t^r * f_t^r)[n] = \sum_k f_t^r(k)f_t^r(n-k) = \sum_k k^r(n-k)^r[k \geq t][n-k \geq t]
\]

= \sum_k k^r(n-k)^r[t \leq k \leq n-t].

Thus, we have an identity between the discrete convolution \((f_t^r * f_t^r)[n]\) of piecewise defined power function \(f_t^r(n)\) and power sum \(Q_{a,b}^r(n)\)

\[
(f_t^r * f_t^r)[n] = Q_{t,n-t+1}^r(n), \quad n \geq 1.
\]

Therefore, the polynomials \(P_{a,b}^m(n)\) are in relation with discrete convolution of piecewise defined power function \(f_t^r(n)\) as follows

\[
P_{t,n-t+1}^m(n) = \sum_r A_{m,r}Q_{t,n-t+1}^r(n) \equiv \sum_r A_{m,r}(f_t^r * f_t^r)[n], \quad n \geq 1.
\]

Following this logic, we are able to find a relation between the Binomial theorem and discrete convolution of power function \(f_t^r(n)\).

3.1. Relation between Binomial theorem and discrete convolution of power function \(f_t^r(n)\). As it is stated previously in (3.1), the polynomials \(P_{a,b}^m(n)\) are able to be expressed in terms of discrete convolution \((f_t^r * f_t^r)[n]\) of the piecewise defined power function \(f_t^r(n)\). Consequently, by the equivalence between Binomial theorem and partial case of \(P_{a,b}^m(n)\), which is shown in (2.6), the odd Binomial expansion could be expressed in terms of discrete convolution of power function \(f_t^r(n)\) as well,

\[
(a + b)^{2m+1} = \sum_r \binom{2m+1}{r} a^{2m+1-r}b^r \equiv -1 + P_{a+b+1}^m(a + b)
\]

= \sum_r A_{m,r}Q_{a+b+1}^r(a + b)

= -1 + \sum_r A_{m,r}(f_0^r * f_0^r)[a + b], \quad m \geq 0, \ a + b \geq 1.

For the case \(t = 1\) in \(f_t^r(n)\) holds

\[
(a + b)^{2m+1} = \sum_r \binom{2m+1}{r} a^{2m+1-r}b^r \equiv 1 + P_{1,a+b}^m(a + b)
\]

= \sum_r A_{m,r}Q_{1,a+b}^r(a + b)

= 1 + \sum_r A_{m,r}(f_1^r * f_1^r)[a + b], \quad m \geq 0, \ a + b \geq 2.
An equations (3.2), (3.3) one more time proof identities (2.9). For the exponent \( s \in \mathbb{N} \) we have the following relation between Binomial theorem and discrete convolution of power function

\[
(a + b)^s = \sum_k \binom{s}{k} a^{s-k} b^k
\]

\[
\equiv (a + b)^{[s \text{ is even}]} \left( -1 + P_{\frac{s-1}{2}, a+b+1} \right)(a + b)
\]

(3.4)

\[
= (a + b)^{[s \text{ is even}]} \left( -1 + \sum_k A_{\frac{s-1}{2}, k} Q_k \right)(a + b)
\]

(3.5)

For the case \( t = 1 \) in \( f_1^r(n) \) holds

\[
(a + b)^s = \sum_k \binom{s}{k} a^{s-k} b^k
\]

\[
\equiv (a + b)^{[s \text{ is even}]} \left( 1 + P_{\frac{s-1}{2}, a+b} \right)(a + b)
\]

3.2. Relation between Multinomial theorem and discrete convolution of power function \( f_1^r(n) \). In this subsection we’d like to generalise the equations (3.2), (3.3) to Multinomial case. For the \( t \)-fold \( s \)-powered sum \((a_1 + a_2 + \cdots + a_t)^s, \ s \in \mathbb{N}, \ a_1 + a_2 + \cdots + a_t \geq 1\) we have following equality involving Multinomial expansion and discrete convolution of power function \( f_1^r(n) \)

\[
(a_1 + a_2 + \cdots + a_t)^s = \sum_{k_1, k_2, \ldots, k_t=s} \binom{s}{k_1, k_2, \ldots, k_t} \prod_{\ell=1}^t a_\ell^{k_\ell}
\]

\[
\equiv (a_1 + a_2 + \cdots + a_t)^{[s \text{ is even}]} \left( -1 + P_{\frac{s-1}{2}, a_1+a_2+\cdots+a_t+1} (a_1 + a_2 + \cdots + a_t) \right)
\]

\[
= (a_1 + a_2 + \cdots + a_t)^{[s \text{ is even}]} \left( -1 + \sum_k A_{\frac{s-1}{2}, k} Q_k \right)(a_1 + a_2 + \cdots + a_t)
\]

\[
= (a_1 + a_2 + \cdots + a_t)^{[s \text{ is even}]} \left( -1 + \sum_k A_{\frac{s-1}{2}, k} (f_1^r * f_0^r)[a_1 + a_2 + \cdots + a_t] \right)
\]

\( s \geq 1, \ a_1 + a_2 + \cdots + a_t \geq 1. \)
For the case $t = 1$ in $f^t_1(a_1 + a_2 + \cdots + a_t)$ as well holds

$$(a_1 + a_2 + \cdots + a_t)^s = \sum_{k_1 + k_2 + \cdots + k_t = s} \left( \prod_{\ell=1}^t a_{k_\ell}^{k_\ell} \right)$$

$$\equiv (a_1 + a_2 + \cdots + a_t)^{[s \text{ is even}]} \left( 1 + \sum_{k} a_{-\frac{s-1}{2}, k,} Q^k_{1, a_1 + \cdots + a_t} (a_1 + a_2 + \cdots + a_t) \right)$$

$$= (a_1 + a_2 + \cdots + a_t)^{[s \text{ is even}]} \left( 1 + \sum_{k} A_{s-\frac{1}{2}, k} (f_0^r + f_0^s) [a_1 + a_2 + \cdots + a_t] \right),$$

$s \geq 1$, $a_1 + a_2 + \cdots + a_t \geq 2$.

4. Derivation of the coefficients $A_{m,r}$

Assuming that

$$n^{2m+1} = \binom{m}{n} = \sum_k A_{m,k} Q^k_n(n), \quad m \geq 0.$$

The coefficients $A_{m,r}$ could be evaluated expanding $Q^k_n(n) = \sum_{k=0}^{n-1} k^r (n-k)^r$ and using Faulhaber’s formula $\sum_{k=1}^{n} k^p = \frac{1}{p+1} \sum_{j=0}^{p} \binom{p+1}{j} B_j n^{p+1-j}$, we get

$$\sum_{k=0}^{n-1} k^r (n-k)^r$$

$$= \sum_{k=0}^{n-1} k^r \sum_{j} (-1)^j \binom{r}{j} n^{r-j} k^j = \sum_{j} (-1)^j \binom{r}{j} n^{r-j} \left( \sum_{k=0}^{n-1} k^{r+j} \right)$$

$$= \sum_{j} \binom{r}{j} n^{r-j} \frac{(-1)^j}{r+j+1} \left[ \sum_{s} \binom{r+j+1}{s} B_s n^{r+j+1-s} - B_{r+j+1} \right]$$

$$(4.1)$$

$$= \sum_{j,s} \binom{r}{j} \frac{(-1)^j}{r+j+1} \binom{r+j+1}{s} B_s n^{2r+1-s} - \sum_{j} \binom{r}{j} \frac{(-1)^j}{r+j+1} B_{r+j+1} n^{r-j}$$

$$= \sum_{s} \left\{ \sum_{j} \binom{r}{j} \frac{(-1)^j}{r+j+1} \binom{r+j+1}{s} B_s n^{2r+1-s} - \sum_{j} \binom{r}{j} \frac{(-1)^j}{s} B_{r+j+1} n^{r-j} \right\} S(r)$$

where $B_s$ are Bernoulli numbers and $B_1 = \frac{1}{2}$. Now, we notice that

$$S(r) = \sum_{j} \binom{r}{j} \frac{(-1)^j}{r+j+1} \binom{r+j+1}{s} = \begin{cases} \frac{1}{(2r+1)\binom{2r}{r}}, & \text{if } s = 0; \\ \frac{(-1)^r}{s} \binom{r}{2r-s+1}, & \text{if } s > 0. \end{cases}$$
In particular, the last sum is zero for $0 < s \leq r$. Therefore, expression (4.1) takes the form

\[
\sum_{k=0}^{n-1} k^r (n-k)^r = \frac{1}{(2r+1)(2^r)} n^{2r+1} + \sum_{s \geq 1} \frac{(-1)^r}{s} \left( \frac{r}{2r-s+1} \right) B_s n^{2r+1-s} \quad \text{(\star)}
\]

\[- \sum_{j} \binom{r}{j} \frac{(-1)^j}{r+j+1} B_{r+j+1} n^{r-j} \quad \text{(\circ)}
\]

Hence, introducing $\ell = 2r+1-s$ to (\star) and $\ell = r-j$ to (\circ), we get

\[
\sum_{k=0}^{n-1} k^r (n-k)^r = \frac{1}{(2r+1)(2^r)} n^{2r+1} + \sum_{\ell} \frac{(-1)^r}{2r+1-\ell} \binom{r}{\ell} B_{2r+1-\ell} n^\ell
\]

\[- \sum_{\ell} \binom{r}{\ell} \frac{(-1)^{\ell}}{2r+1-\ell} B_{2r+1-\ell} n^\ell
\]

\[
= \frac{1}{(2r+1)(2^r)} n^{2r+1} + 2 \sum_{\ell \text{ odd}} \frac{(-1)^r}{2r+1-\ell} \binom{r}{\ell} B_{2r+1-\ell} n^\ell
\]

Using the definition of $A_{m,r}$ coefficients, we obtain the following identity for polynomials in $n$

\[
(4.2) \quad \sum_r A_{m,r} \frac{1}{(2r+1)(2^r)} n^{2r+1} + 2 \sum_{r, \text{ odd}} A_{m,r} \frac{(-1)^r}{2r+1-\ell} \binom{r}{\ell} B_{2r+1-\ell} n^\ell \equiv n^{2m+1}
\]

Taking the coefficient of $n^{2m+1}$ in (4.2) we get $A_{m,m} = (2m+1)\binom{2m}{m}$ and taking the coefficient of $n^{2d+1}$ for an integer $d$ in the range $m/2 \leq d < m$, we get $A_{m,d} = 0$. Taking the coefficient of $n^{2d+1}$ for $d$ in the range $m/4 \leq d < m/2$, we get

\[
A_{m,d} \frac{1}{(2d+1)(2^d)} + 2(2m+1)\binom{2m}{m} \binom{m}{2d+1} \frac{(-1)^m}{2m-2d} B_{2m-2d} = 0,
\]

i.e.,

\[
A_{m,d} = (-1)^{m-1} \frac{(2m+1)!}{d! m! (m-2d-1)!} \frac{1}{m-d} B_{2m-2d}.
\]

Continue similarly, we can express $A_{m,d}$ for each integer $d$ in range $m/2^{s+1} \leq d < m/2^s$ (iterating consecutively $s = 1, 2, \ldots$) via previously determined values of $A_{m,j}$ as follows

\[
A_{m,d} = (2d+1)\binom{2d}{d} \sum_{j \geq 2d+1} A_{m,j} \binom{j}{2d+1} \frac{(-1)^{j-1}}{j-d} B_{2j-2d}.
\]

Thus, for every $(n,m) \in \mathbb{N}$ holds

\[
n^{2m+1} = \sum_{r=0}^{m} A_{m,r} \sum_{k=0}^{n-1} k^r (n-k)^r.
\]
5. Verification of the results and examples

To fulfill our study we provide an opportunity to verify its results by means of Wolfram Mathematica language. It is possible to verify the most important results of the manuscript using the Mathematica programs available at https://github.com/kolosovpetro/research_unit_tests. Also, we’d like to show why an odd-power identity (2.2) holds by a few examples. We arrange in tables the values of $L_m(n, k)$ to show that $P_m^m(n) = L_m(n, 0) + L_m(n, 1) + \cdots + L_m(n, n - 1) = n^{2m+1}$. For example, for $m = 1$ we have the following values of $L_1(n, k)$

<table>
<thead>
<tr>
<th>$n/k$</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>7</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>13</td>
<td>13</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>19</td>
<td>25</td>
<td>19</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>25</td>
<td>37</td>
<td>37</td>
<td>25</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>1</td>
<td>31</td>
<td>49</td>
<td>55</td>
<td>49</td>
<td>31</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>37</td>
<td>61</td>
<td>73</td>
<td>61</td>
<td>37</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

Table 1. Triangle generated by $L_1(n, k)$, $0 \leq k \leq n$.

From table 1 it is seen that

$P_1^1(0) = 0 = 0^3$
$P_1^1(1) = 1 = 1^3$
$P_2^1(2) = 1 + 7 = 2^3$
$P_3^1(3) = 1 + 13 + 13 = 3^3$
$P_4^1(4) = 1 + 19 + 25 + 19 = 4^3$
$P_5^1(5) = 1 + 25 + 37 + 37 + 25 = 5^3$.

Another case, if $m = 2$, we have the following values of $L_2(n, k)$

<table>
<thead>
<tr>
<th>$n/k$</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>31</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>121</td>
<td>121</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>271</td>
<td>481</td>
<td>271</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>481</td>
<td>1081</td>
<td>1081</td>
<td>481</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>1</td>
<td>751</td>
<td>1921</td>
<td>2431</td>
<td>1921</td>
<td>751</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>1081</td>
<td>3001</td>
<td>4321</td>
<td>4321</td>
<td>3001</td>
<td>1081</td>
<td>1</td>
</tr>
</tbody>
</table>

Table 2. Triangle generated by $L_2(n, k)$, $0 \leq k \leq n$. 

Again, an odd-power identity (2.2) holds
\[
P_0^2(0) = 0 = 0^5
\]
\[
P_1^2(1) = 1 = 1^5
\]
\[
P_2^2(2) = 1 + 31 = 2^5
\]
\[
P_3^2(3) = 1 + 121 + 121 = 3^5
\]
\[
P_4^2(4) = 1 + 271 + 481 + 271 = 4^5
\]
\[
P_5^2(5) = 1 + 481 + 1081 + 1081 + 481 = 5^5.
\]

Tables (1), (2) are entries A287326, A300656 in [Slo64].

6. Acknowledgements

We would like to thank to Dr. Max Alekseyev (Department of Mathematics and Computational Biology, George Washington University) for sufficient help in the derivation of \( A_{m,r} \) coefficients. Also, we’d like to thank to OEIS editors Michel Marcus, Peter Luschny, Jon E. Schoenfield and others for their patient, faithful volunteer work and for their useful comments and suggestions during the editing of the sequences connected with this manuscript.

7. Conclusion

In this manuscript a relation between Binomial theorem and discrete convolution of piecewise defined power function is established. It is shown that Binomial expansion of \( s \)-powered sum \((a + b)^s\), \( s \geq 1 \) is equivalent to the sum of consequent convolutions of piecewise defined power function multiplied by the certain real coefficients. In addition, the relation between Binomial theorem and convolution of piecewise defined power function is generalised to Multinomial case.
