# GEOMETRIC CONFIGURATION OF RIEMANNIAN SUBMANIFOLDS OF ARBITRARY CODIMENSION 

MOHAMED ABDELMALEK, MOHAMMED BENALILI, AND KAMIL NIEDZIAEOMSKI

#### Abstract

In this paper we study a geometric configuration of submanifolds of arbitrary codimension in an ambient Riemannian space. We obtain relations between the geometry of a $q$-codimension submanifold $M^{n}$ along its boundary and the geometry of the boundary $\Sigma^{n-1}$ of $M^{n}$ as an hypersuface of a $q$-codimensional submanifold $P^{n}$ in an ambient space $\bar{M}^{n+q}$. As a consequence of these geometric ralations we get that the ellipticity of the generalized Newton transformations implies the tranversality of $M^{n}$ and $P^{n}$ in $P^{n}$ is totally geodesic in $\bar{M}^{n+q}$.

## 1. Introduction

Let $\bar{M}^{n+q}$ be $n+q$-dimensional connected and orientable Riemannian manifold with metric $\langle.,$.$\rangle and Levi-Civita connection \bar{\nabla}$. Denote by $P^{n}$ an oriented connected $n$ - submanifold of $\bar{M}^{n+q}$ and consider $\Sigma^{n-1}$ an $n-1$ compact hypersurface of $P^{n}$. If $\Psi: M^{n} \rightarrow \bar{M}^{n+q}$ is an oriented connected and compact submanifold of $\bar{M}^{n+q}$ with boundary $\partial M . M^{n}$ will be said submanifold of $\bar{M}^{n+q}$ with boundary $\Sigma^{n-1}$ if the restriction of $\Psi$ to $\partial M$ is a diffeomorphism onto $\Sigma^{n-1}$. A natural question would be: How can one describe the geometry of $M^{n}$ along its boundary $\partial M$ with respect to the geometry of the inclusion $P^{n} \subset \bar{M}^{n+q}$ ? A partial answer to this question is given by the following formula, obtained in this paper, which holds along the boundary $\partial M$ : for any multi-index $u=\left(u_{1}, \ldots, u_{q}\right)$ with length $|u| \leq n-1$,

$$
\begin{equation*}
\left\langle T_{u} \nu, \nu\right\rangle=\frac{1}{n-1-|u|} \sum_{l \leq u}\binom{n-1-|l|}{|u|-l} \rho^{l} \mu^{u-l} \sigma_{|l|}\left(A_{\Sigma}\right) . \tag{1.1}
\end{equation*}
$$

where $\left(T_{u}\right)_{u}$ stands for the family of the generalized Newton transformations introduced in [4] associated to the matrix $A=\left(A_{1}, \ldots, A_{q}\right) ;\left(A_{\alpha}\right)_{\alpha \in\{1, \ldots, q\}}$ is a system of matrices of the shape operators corresponding to a normal basis to the manifold $M^{n}$ and $\tilde{\sigma}_{u}=\tilde{\sigma}_{u}\left(\left.A_{1}\right|_{\Sigma}, \ldots,\left.A_{q}\right|_{\Sigma}\right)$ are the coefficients of the

[^0]Newton polynomial $P_{\widetilde{A}}: \mathbb{R}^{q} \longrightarrow \mathbb{R}$ defined by

$$
P_{\widetilde{A}}(t)=\sum_{|u| \leq n-1} \tilde{\sigma}_{u} t^{u}
$$

where $\widetilde{A}=\left(\left.A_{1}\right|_{\Sigma}, \ldots,\left.A_{q}\right|_{\Sigma}\right),\left.\quad A_{\alpha}\right|_{\Sigma}$ is the restriction of $A_{\alpha}$ to $\Sigma^{n-1}$ and $\sigma_{r}\left(A_{\Sigma}\right)$ is the symmetric function coefficient of $t^{r}$ in the characteristic polynomial of the matrix $A_{\Sigma}$.

In [2] Alías and Malacarne considered the above geometric configuration to the case of hypersurfaces where $\Sigma_{n-1}$ is an $(n-1)$-dimensional compact submanifold contained in an hyperplane $\Pi$ of $\mathbb{R}^{n+1}$ and $M^{n}$ stands for a smooth compact, connected and oriented manifold with boundary $\partial M^{n}$. Moreover $M^{n}$ is an hypersurface of $\mathbb{R}^{n+1}$ with boundary $\Sigma_{n-1}$ in the sense that there exists $\psi: M^{n} \rightarrow R^{n+1}$ an oriented hypersurface immersed in $\mathbb{R}^{n+1}$ such that the restriction of $\psi$ to the boundary $\partial M^{n}$ is a diffeomorphism onto $\Sigma_{n-1}$. They showed that along the boundary $\partial M^{n}$, for every $1 \leq r \leq n-1$ :

$$
\begin{equation*}
\left\langle T_{r} \nu, \nu\right\rangle=(-1)^{r} s_{r}\langle a, \nu\rangle^{r} \tag{1.2}
\end{equation*}
$$

where $\nu$ stands for the outward pointing unit conormal vector field along $\partial M^{n}$ while $T_{r}$ denotes the classical Newton transformation, $a \in R^{n+1}$ such that $\Pi=a^{\perp}$ and $s_{r}$ is the $r$-th symmetric function of the principal curvatures of $\Sigma_{n-1}$ with respect to $\nu$. In [3] Alías, de Lira and Malacarne studied the question in the context of an ( $n+1$ )-dimensional connected oriented ambient Riemannian manifold $\bar{M}^{n+1}$, they established that along the boundary $\partial M^{n}$, for every $1 \leq r \leq n-1$ :

$$
\begin{equation*}
\left\langle T_{r} \nu, \nu\right\rangle=(-1)^{r} s_{r}\langle\xi, \nu\rangle^{r} \tag{1.3}
\end{equation*}
$$

where $T_{r}, \nu, s_{r}$, are as in relation /(1.2) where $P^{n} \subset \bar{M}^{n+1}$ is an embedded totally geodesic submanifold instead of the hyperplane $\Pi$ and $\xi$ is a unitary normal vector field to $P^{n}$. Relation (1.3) shows that the ellipticity of the Newton transformation $T_{r}$, for some $1 \leq r \leq n-1$ on $M^{n}$, implies the transversality of the hypersurfaces $M^{n}$ and $P^{n}$ along their boundary. Formula (1.3) was also obtained, in [1], by the two first authors in context of pseudo-Riemannian spaces. Moreover we deduce from relation (1.1) that the ellipticity of the generalized Newton transformation $T_{u}$ implies the transversality of the $q$-codimension submanifolds $M^{n}$ and $P^{n}$ in case where $P^{n}$ is totally geodesic submanifold of $\bar{M}^{n+q}$.

## 2. Preliminaries

In this section, we will recall some properties of the generalized Newton transformations and we will show how our method works.
2.1. Generalized Newton Transformations. Let $E$ be an $n$-dimensional real vector space and $\operatorname{End}(E)$ be the vector space of endomorphisms of $E$. Denote by $\mathbb{N}$ the set of nonnegative integers and let $\mathbb{N}^{q}$ be the one of multi- index $u=\left(u_{1}, \ldots, u_{q}\right)$ with $u_{j} \in \mathbb{N}$. The length $|u|$ of $u$ is given by
$|u|=u_{1}+\ldots+u_{q} . E n d^{q}(E)$ stands for the vector space $\operatorname{End}(E) \times \ldots \times \operatorname{End}(E)$ q-times. For $A=\left(A_{1}, \ldots, A_{q}\right) \in E n d^{q}(E), t=\left(t_{1}, \ldots, t_{q}\right) \in R^{q}$ and $u \in \mathbb{N}^{q}$, we set

$$
\begin{aligned}
t A & =t_{1} A_{1}+\ldots+t_{q} A_{q} \\
t^{u} & =t_{1}^{u_{1}} \ldots t_{q}^{u_{q}} .
\end{aligned}
$$

For $\alpha \in\{1, \ldots, q\}$ we define ( see [4] ) the musical functions $\alpha_{b}: \mathbb{N}^{q} \longrightarrow \mathbb{N}^{q}$ and $\alpha^{\sharp}: \mathbb{N}^{q} \longrightarrow \mathbb{N}^{q}$ by

$$
\alpha_{b}\left(i_{1}, \ldots, i_{q}\right)=\left(i_{1}, \ldots, i_{\alpha-1}, i_{\alpha}-1, i_{\alpha+1}, \ldots, i_{q}\right)
$$

and

$$
\alpha^{\sharp}\left(i_{1}, \ldots, i_{q}\right)=\left(i_{1}, \ldots, i_{\alpha-1}, i_{\alpha}+1, i_{\alpha+1}, \ldots, i_{q}\right)
$$

It is clear that $\alpha_{b}$ is the inverse map of $\alpha^{\sharp}$.
The generalized Newton transformation (GNT in brief) is a system of endomorphisms $T_{u}=T_{u}(A), u \in \mathbb{N}^{q}$, that satisfies the following recursive relations

$$
\begin{array}{rlr}
T_{0} & =I & \quad \text { where } 0=(0, \ldots, 0), \\
T_{u} & =\sigma_{u} I-\sum_{\alpha} A_{\alpha} T_{\alpha_{b}(u)} & \text { where }|u|>1 \\
& =\sigma_{u} I-\sum_{\alpha} T_{\alpha_{b}(u)} A_{\alpha} &
\end{array}
$$

where $\sigma_{u}$ are the coefficients of the Newton polynomial $P_{A}: \mathbb{R}^{q} \longrightarrow \mathbb{R}$ of $A$, given by

$$
P_{A}(t)=\operatorname{det}(I+t A)=\sum_{|u| \leq n} \sigma_{u} t^{u}
$$

$\sigma_{u}=\sigma_{u}\left(A_{1}, \ldots, A_{q}\right)$ depends only on $A=\left(A_{1}, \ldots, A_{q}\right)$ and $I$ is the identity map on $E$.
2.2. The method. We will describe how our method works.
2.2.1. Hypersurfaces' case. Let $M^{n}$ be a $n$-submanifold of codimension one in $\bar{M}^{n+1}$ of boundary $\partial M$. Assume the boundary $\Sigma^{n-1}=\partial M$ is a codimension one in $P^{n} \subset \bar{M}^{n+1}$. Then we have the inclusions

$$
\Sigma^{n-1} \subset M^{n} \subset \bar{M}^{n+1}, \Sigma^{n-1} \subset P^{n} \subset \bar{M}^{n+1}
$$

Denote the corresponding shape operators, respectively, by

$$
A_{\Sigma}, A_{P}, A_{\Sigma, P}, A
$$

In our consideration we will need only $A_{\Sigma}, A_{P}, A$. More precisely we will use

$$
A_{\Sigma},\left.\quad A_{P}\right|_{\Sigma}, \quad A
$$

First two are represented by square matrices of dimension $n-1$ whereas the last one by a square matrix of dimension $n$. The intrinsic geometry of $\Sigma^{n-1}$
in $M^{n}$ is coded in the pair $\left(A_{\Sigma},\left.A_{P}\right|_{\Sigma}\right)$ and the geometry of $M^{n} \subset \bar{M}^{n+1}$ is given by $A$. Therefore we will use the following Newton Transformation and the generalized Newton Transformations

$$
T_{(k, l)}=T_{(k, l)}\left(A_{\Sigma},\left.A_{P}\right|_{\Sigma}\right) \text { and } T_{r}=T_{r}(A)
$$

and corresponding symmetric functions

$$
\sigma_{(k, l)}=\sigma_{(k, l)}\left(A_{\Sigma},\left.A_{P}\right|_{\Sigma}\right) \text { and } \sigma_{r}=\sigma_{r}(A)
$$

The goal is to show that

$$
\begin{equation*}
\left\langle T_{r} \nu, \nu\right\rangle=\sum_{k+l=r} \sigma_{(k, l)} \tag{2.1}
\end{equation*}
$$

where $\nu$ is the unit normal vector to $\Sigma^{n-1}$ in $M^{n}$.
The only geometric considerations involved are the ones which lead to the formulas

$$
\langle N, \nu\rangle=\langle\xi, N\rangle,\langle\eta, N\rangle=-\langle\xi, \nu\rangle
$$

and

$$
\left\langle A e_{i}, e_{j}\right\rangle=-\left\langle A_{\Sigma} e_{i}, e_{j}\right\rangle\langle\xi, \nu\rangle+\left\langle A_{P} e_{i}, e_{j}\right\rangle\langle\xi, N\rangle
$$

where $N$ is unit normal vector with the respect to inclusion $M^{n} \subset \bar{M}^{n+1}$, $\xi$ unit normal vector with respect to $P^{n} \subset \bar{M}^{n+1}$ and $\eta$ is the unit normal vector of $\Sigma^{n-1} \subset P^{n}$ and $\left(e_{1}, \ldots, e_{n-1}\right)$ is a local orthonormal basis of $T \Sigma^{n-1}$, we may assume that this basis consists of eigenvectors of $A_{\Sigma}$ i.e. $A_{\Sigma} e_{i}=\tau_{i} e_{i}$. In other words

$$
\left.A\right|_{\Sigma}=-\langle\xi, \nu\rangle A_{\Sigma}+\left.\langle\xi, N\rangle A_{P}\right|_{\Sigma} .
$$

Assuming $P$ is totally umbilical in $\bar{M}^{n+1}$, we have $\left.A_{P}\right|_{\Sigma}=\lambda I_{T \Sigma^{n-1}}$. Hence

$$
\begin{equation*}
\left.A\right|_{\Sigma}=-\langle\xi, \nu\rangle A_{\Sigma}+\lambda\langle\xi, N\rangle I_{T \Sigma^{n-1}} . \tag{2.2}
\end{equation*}
$$

Denote by $\tilde{A}$ the matrix of $A$ with the respect of the basis $\left(e_{1}, \ldots, e_{n-1}, \nu\right)$ and by $A$ the matrix of $\left.A\right|_{\Sigma}$. Then

$$
\widetilde{A}=\left(\begin{array}{cc}
A & B \\
B^{\top} & c
\end{array}\right), \text { where } B=\left(\begin{array}{c}
\left\langle A \nu, e_{1}\right\rangle \\
\vdots \\
\left\langle A \nu, e_{n-1}\right\rangle
\end{array}\right) \text { and } c=\langle A \nu, \nu\rangle .
$$

Let us compare symmetric functions of $\widehat{A}$ with symmetric functions of $A$. We have

$$
\begin{aligned}
P_{\widetilde{A}}(t) & =\operatorname{det}\left(\begin{array}{cc}
I_{n-1}+t A & t B \\
t B^{\top} & 1+t c
\end{array}\right)=\left(1+t c-t^{2} B^{\top}\left(I_{n-1}+t A\right)^{-1} B\right) \operatorname{det}\left(I_{n-1}+t A\right) \\
& =f(t) P_{A}(t),
\end{aligned}
$$

where $f(t)=1+t c-t^{2} B^{\top}\left(I_{n-1}+t A\right)^{-1} B$. Recall that

$$
P_{\widetilde{A}}(t)=\sum_{j=0}^{n}(-1)^{j} \sigma_{j}(\widetilde{A}) t^{j}
$$

Hence

$$
\begin{aligned}
(-1)^{r} r!\sigma_{r}(\widetilde{A}) & =\frac{d^{r}}{d t^{r}} P_{\widetilde{A}}(0)=\sum_{j=0}^{r}\binom{r}{j} \frac{d^{r-j}}{d t^{r-j}} P_{A}^{(r-j)}(0) f^{(j)}(0) \\
& =\sum_{j=0}^{r}\binom{r}{j}(-1)^{r-j}(r-j)!\sigma_{r-j}(A) f^{(j)}(0)
\end{aligned}
$$

It is not hard to see that

$$
f(0)=1, f^{\prime}(0)=-c \text { and } f^{(j)}(0)=-j!B^{\top} A^{j-2} B \text { for } j \geq 2
$$

Therefore

$$
\begin{equation*}
\sigma_{r}(\widetilde{A})=\sigma_{r}(A)+c \sigma_{r-1}(A)-\sum_{j=2}^{r}(-1)^{j}\left(B^{\top} A^{j-2} B\right) \sigma_{r-j}(A) \tag{2.3}
\end{equation*}
$$

Let us now move to symmetric functions of two matrices. Notice first that

$$
\sigma_{r}\left(\widetilde{A}+\lambda I_{n}\right)=\sum_{j=0}^{r}\binom{n-j}{r-j} \lambda^{r-j} \sigma_{j}(\widetilde{A})
$$

Indeed, $P_{\widetilde{A}+\lambda I_{n}}(t)=\left(1+t\left(a_{1}+\lambda\right) \ldots\left(1+t\left(a_{n}+\lambda\right)\right.\right.$ if $a_{1}, \ldots, a_{n}$ are the eigenvalues of $\widetilde{A}$. Notice moreover that

$$
\begin{aligned}
P_{\widetilde{A}, \lambda I_{n}}(t) & =\operatorname{det}\left(I_{n}+t \widetilde{A}+s \lambda I_{n}\right) \\
& =\left(1+t a_{1}+s \lambda\right) \ldots\left(1+t a_{n}+s \lambda\right)
\end{aligned}
$$

Thus

$$
\begin{equation*}
\sigma_{(k, l)}\left(\widetilde{A}, \lambda I_{n}\right)=\binom{n-k}{l} \lambda^{l} \sigma_{k}(\widetilde{A}) \tag{2.4}
\end{equation*}
$$

Hence

$$
\begin{equation*}
\sigma_{r}\left(\widetilde{A}+\lambda I_{n}\right)=\sum_{j=0}^{r} \sigma_{(j, r-j)}\left(\widetilde{A}, \lambda I_{n}\right) \tag{2.5}
\end{equation*}
$$

We need to show, by (2.5) and (2.1), that

$$
\begin{equation*}
\left\langle T_{r} \nu, \nu\right\rangle=\tilde{\sigma}_{r}(A) \tag{2.6}
\end{equation*}
$$

By the recurrence formula for $T_{r}$ we have

$$
\begin{aligned}
\left\langle T_{r} \nu, \nu\right\rangle & =\sigma_{r}(\widetilde{A})-\left\langle T_{r-1} \nu, \widetilde{A} \nu\right\rangle \\
& =\sigma_{r}(\widetilde{A})-c\left\langle T_{r-1} \nu, \nu\right\rangle-\sum_{i=1}^{n-1}\left\langle T_{r-1} \nu, e_{i}\right\rangle\left\langle\widetilde{A} \nu, e_{i}\right\rangle
\end{aligned}
$$

We will show that

$$
\begin{equation*}
\sum_{i=1}^{n-1}\left\langle T_{k} \nu, e_{i}\right\rangle\left\langle\widetilde{A} \nu, e_{i}\right\rangle=-\sum_{j=2}^{k}(-1)^{j}\left(B^{\top} A^{j-2} B\right) \sigma_{k-j}(A) \tag{2.7}
\end{equation*}
$$

Indeed, assuming $\left(e_{i}\right)$ is a basis consisting of eigenvectors with eigenvalues $\left(\tau_{i}\right)_{i}$ by induction we have

$$
\begin{aligned}
\sum_{i=1}^{n-1}\left\langle T_{k} \nu, e_{i}\right\rangle\left\langle\widetilde{A} \nu, e_{i}\right\rangle & =-b_{i}^{2} \sum_{j=2}^{k}(-j) \sigma_{k-j}(A) \tau_{i}^{j-2} \\
& =\sum_{j=2}^{k}(-1)^{j}\left(b_{i} \tau_{i}^{j-2} b_{i}\right) \sigma_{k-j}(A)
\end{aligned}
$$

where $B^{\top}=\left(b_{i}\right)_{i}$, which proves (2.7). Thus by induction and (2.3), we get

$$
\left\langle T_{r} \nu, \nu\right\rangle=\sigma_{r}(\widetilde{A})-c \sigma_{r-1}(A)+\sum_{j=2}^{r}(-1)^{j}\left(B^{\top} A^{j-2} B\right) \sigma_{r-j}(A)=\widetilde{\sigma}_{r}(A)
$$

2.2.2. General case. We generalize considerations to any codimension $q$. We generalize equations (2.1) and (2.6). Let $P^{n}$ and $M^{n}$ be of codimension $q$ in $\bar{M}^{n+q}$. We assume that $P^{n}$ is totally umbilical in $\bar{M}^{n+1}$. As before $\Sigma^{n-1} \subset$ $P^{n}$ is a boundary of $M^{n}$. Then we have the following shape operators

$$
A_{\Sigma}, \quad A_{P}^{\xi_{1}}, \ldots, A_{P}^{\xi_{p}}, A^{N_{1}}, \ldots, A^{N_{q}}
$$

corresponding to inclusions $\Sigma^{n-1} \subset P^{n}, P^{n} \subset \bar{M}^{n+q}$, and $M^{n} \subset \bar{M}^{n+q}$, where $\left(\xi_{1}, \ldots, \xi_{q}\right)$ are orthogonal to $P^{n}$ and $\left(N_{1}, \ldots, N_{q}\right)$ are orthogonal to $M^{n}$. Let

$$
T_{u}=T_{u}\left(A^{N_{1}}, \ldots, A^{N_{q}}\right), \quad T_{v}=T_{v}\left(A_{\Sigma},\left.A^{\xi_{1}}\right|_{\Sigma}, \ldots,\left.A^{\xi_{q}}\right|_{\Sigma}\right)
$$

and

$$
\widetilde{T_{u}}=\widetilde{T}_{u}\left(\left.A^{N_{1}}\right|_{\Sigma}, \ldots,\left.A^{N_{q}}\right|_{\Sigma}\right)
$$

where $u$ is of length $q$ and $v$ of length $q+1$. We hope that the following relations hold

$$
\begin{equation*}
\left\langle T_{u} \nu ; \nu\right\rangle=\widetilde{\sigma}_{u} \tag{2.8}
\end{equation*}
$$

and

$$
\tilde{\sigma}_{u}=\sum_{|v|=|u|, v} c_{v} \sigma_{v}
$$

where $c_{v}$ is a coefficient independent of $\left(\left.A^{N_{1}}\right|_{\Sigma}, \ldots,\left.A^{N_{q}}\right|_{\Sigma}\right)$. Both of them imply

$$
\left\langle T_{u} \nu ; \nu\right\rangle=\sum_{|v|=|u|, v \text { not increasing }} c_{v} \sigma_{v}
$$

The first equality is a generalization of (2.6), whereas the second one of (2.5). Moreover, the first one is purely algebraic and the second one uses correspondence between $A_{\Sigma},\left.A^{\xi_{1}}\right|_{\Sigma}, \ldots,\left.A^{\xi_{q}}\right|_{\Sigma}$ and $\left.A^{N_{1}}\right|_{\Sigma}, \ldots,\left.A^{N_{q}}\right|_{\Sigma}$ analogous to the relation (2.2) in the codimension one case.

Let us be more precise. First notice that

$$
\begin{aligned}
\bar{\nabla}_{e_{i}} e_{j} & =\sum_{k=1}^{n-1}\left\langle\bar{\nabla}_{e_{i}} e_{j}, e_{k}\right\rangle e_{k}+\left\langle\bar{\nabla}_{e_{i}} e_{j}, \nu\right\rangle \nu+\sum_{\alpha=1}^{q}\left\langle\bar{\nabla}_{e_{i}} e_{j}, N_{\alpha}\right\rangle N_{\alpha} \\
& =\sum_{k=1}^{n-1}\left\langle\bar{\nabla}_{e_{i}} e_{j}, e_{k}\right\rangle e_{k}+\left\langle\bar{\nabla}_{e_{i}} e_{j}, \nu\right\rangle \nu+\sum_{\alpha=1}^{q}\left\langle A^{N_{\alpha}} e_{i}, e_{j}\right\rangle N_{\alpha}
\end{aligned}
$$

and

$$
\begin{aligned}
\bar{\nabla}_{e_{i}} e_{j} & =\sum_{k=1}^{n-1}\left\langle\bar{\nabla}_{e_{i}} e_{j}, e_{k}\right\rangle e_{k}+\left\langle\bar{\nabla}_{e_{i}} e_{j}, \eta\right\rangle \eta+\sum_{\alpha=1}^{q}\left\langle\bar{\nabla}_{e_{i}} e_{j}, \xi_{\alpha}\right\rangle \xi_{\alpha} \\
& =\sum_{k=1}^{n-1}\left\langle\bar{\nabla}_{e_{i}} e_{j}, e_{k}\right\rangle e_{k}+\left\langle A_{\Sigma} e_{i}, e_{j}\right\rangle \eta+\sum_{\alpha=1}^{q}\left\langle A^{\xi_{\alpha}} e_{i}, e_{j}\right\rangle \xi_{\alpha}
\end{aligned}
$$

Thus

$$
\left\langle\bar{\nabla}_{e_{i}} e_{j}, \nu\right\rangle \nu+\sum_{\alpha=1}^{q}\left\langle A^{N_{\alpha}} e_{i}, e_{j}\right\rangle N_{\alpha}=\left\langle A_{\Sigma} e_{i}, e_{j}\right\rangle \eta+\sum_{\alpha=1}^{q}\left\langle A^{\xi_{\alpha}} e_{i}, e_{j}\right\rangle \xi_{\alpha}
$$

Hence

$$
\begin{aligned}
\left\langle A^{N_{\alpha}} e_{i}, e_{j}\right\rangle & =\left\langle\eta, N_{\alpha}\right\rangle\left\langle A_{\Sigma}\left(e_{i}\right), e_{j}\right\rangle+\sum_{\beta=1}^{q}\left\langle\xi_{\beta}, N_{\alpha}\right\rangle\left\langle\left(A^{\xi_{\beta}}\right) e_{i}, e_{j}\right\rangle \\
& =\left\langle\eta, N_{\alpha}\right\rangle\left\langle A_{\Sigma}\left(e_{i}\right), e_{j}\right\rangle+\sum_{\beta=1}^{q}\left\langle\xi_{\beta}, N_{\alpha}\right\rangle\left\langle A^{\xi_{\beta}} e_{i}, e_{j}\right\rangle
\end{aligned}
$$

Assuming that $P^{n}$ is totally umbilical, i.e. $A^{\xi_{\alpha}}=\lambda_{\alpha} I_{n}$, where $I_{n}$ denotes the identity map of the tangent space $T_{p} P^{n}$, we get

$$
\left.A^{N_{\alpha}}\right|_{\Sigma}=\left\langle\eta, N_{\alpha}\right\rangle A_{\Sigma}+\sum_{\beta=1}^{q}\left\langle\xi_{\beta}, N_{\alpha}\right\rangle \lambda_{\beta} I_{n-1}
$$

Notice that it can be written in the form

$$
\begin{equation*}
\left.A^{N_{\alpha}}\right|_{\Sigma}=\left\langle\eta, N_{\alpha}\right\rangle A_{\Sigma}+\left\langle V, N_{\alpha}\right\rangle I_{n-1}, \quad \text { where } V=\sum_{\beta=1}^{q} \lambda_{\beta} \xi_{\beta} . \tag{2.9}
\end{equation*}
$$

Moreover one can show that

$$
\langle\eta, V\rangle=\operatorname{det}\left(\left\langle\xi_{\alpha}, N_{\beta}\right\rangle\right)_{\alpha, \beta} \text { and }\left\langle\eta, N_{\alpha}\right\rangle=-\operatorname{det} C_{\alpha}
$$

where $C_{\alpha}$ is a matrix obtained from $C=\left(\left\langle\xi_{\alpha}, N_{\beta}\right\rangle\right)_{\alpha, \beta}$ by replacing the $\alpha$-th column by $\left\langle\xi_{\alpha}, \nu\right\rangle$.

Hence we have

$$
\widetilde{T}_{u}=\widetilde{T}_{u}\left(\rho_{1} A_{\Sigma}+\mu_{1} I_{n-1}, \ldots, \rho_{q} A_{\Sigma}+\mu_{q} I_{n-1}\right), \text { where } \rho_{\alpha}=\left\langle\eta, N_{\alpha}\right\rangle, \mu_{\alpha}=\left\langle V, N_{\alpha}\right\rangle .
$$

Now if $\left\{e_{1}, \ldots, e_{n-1}\right\}$ is a basis of eigenvectors of the shape operator $A_{\Sigma}$ then, for every $i \in\{1, \ldots, n-1\}$,

$$
A_{\Sigma}\left(e_{i}\right)=\tau_{i} e_{i}
$$

where $\tau_{i}$ are the corresponding eigenvalues.
By relation (2.9) we get

$$
\begin{aligned}
\left\langle A_{\alpha}\left(e_{i}\right), e_{j}\right\rangle & =\left(\left\langle\eta, N_{\alpha}\right\rangle \tau_{i}+\left\langle V, N_{\alpha}\right\rangle\right) \delta_{i}^{j} \\
& =\gamma_{i, \alpha} \delta_{i}^{j}
\end{aligned}
$$

where

$$
\gamma_{i, \alpha}=\left\langle\eta, N_{\alpha}\right\rangle \tau_{i}+\left\langle V, N_{\alpha}\right\rangle
$$

Thus the matrix associated to the shape operator $A_{\alpha}$ with respect to the basis $\left\{e_{1}, \ldots, e_{n-1}, \nu\right\}$ is given by

$$
A_{\alpha}=\left(\begin{array}{ccccc}
\gamma_{1, \alpha} & 0 & \ldots & 0 & \left\langle A_{\alpha} \nu, e_{1}\right\rangle \\
0 & \gamma_{2, \alpha} & \ldots & 0 & \vdots \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & \ldots & \cdots & \gamma_{n-1, \alpha} & \left\langle A_{\alpha} \nu, e_{n-1}\right\rangle \\
\left\langle A_{\alpha} \nu, e_{1}\right\rangle & \ldots & \ldots & \left\langle A_{\alpha} \nu, e_{n-1}\right\rangle & \left\langle A_{\alpha} \nu, \nu\right\rangle
\end{array}\right)
$$

## 3. Algebraic Formulas

Let us prove the algebraic relation (2.8), to do so, we put

$$
\rho_{\alpha}=\left\langle\eta, N_{\alpha}\right\rangle, \quad \mu_{\alpha}=\left\langle V, N_{\alpha}\right\rangle
$$

Moreover, we will write $v \leq u$ for multi-indices $v, u \in \mathbb{N}^{q}$ if the difference $u-v \in \mathbb{N}^{q}$. For a multi-index $u=\left(u_{1}, \ldots, u_{q}\right) \in \mathbb{N}^{q}$ of length $|u|=n$, we set

$$
\binom{n}{u}=\frac{n!}{u!}=\frac{n!}{u_{1}!\ldots u_{q}!}
$$

Proposition 1. Let $\tilde{A}=\left(\left.A_{1}\right|_{\Sigma}, \ldots,\left.A_{q}\right|_{\Sigma}\right)=\left(\rho_{1} A_{\Sigma}+\mu_{1} I, \ldots, \rho_{q} A_{\Sigma}+\mu_{q} I\right)$. Put $\tilde{\sigma}_{u}=\sigma_{u}(\tilde{A})$. Then for every multi-index $u \in \mathbb{N}^{q}$ we have

$$
\begin{equation*}
\tilde{\sigma}_{u}=\frac{1}{(n-1-|u|)!} \sum_{l \leq u}\binom{|l|}{l} \rho^{l} \mu^{u-l}\binom{n-1-|l|}{u-l} \sigma_{|l|}\left(A_{\Sigma}\right) \tag{3.1}
\end{equation*}
$$

Proof. First, by applying the following relation (see [6])

$$
\sigma_{u}\left(a A_{1}, \ldots, A_{q}\right)=a^{u_{1}} \sigma_{u}\left(A_{1}, \ldots, A_{q}\right)
$$

we obtain

$$
\begin{equation*}
\tilde{\sigma}_{u}\left(\rho_{1} A_{\Sigma}+\mu_{1} I, \ldots, \rho_{q} A_{\Sigma}+\mu_{q} I\right)=\rho^{u} \hat{\sigma}_{u}\left(A_{\Sigma}+\theta_{1} I, \ldots, A_{\Sigma}+\theta_{q} I\right) \tag{3.2}
\end{equation*}
$$

where

$$
\theta_{\alpha}=\frac{\mu_{\alpha}}{\rho_{\alpha}} \text { and } \rho^{u}=\rho_{1}^{u_{1}} \ldots \rho_{q}^{u_{q}}
$$

Consider the GNT $T_{u}=T_{u}(\hat{A})$, with

$$
\hat{A}=\left(A_{\Sigma}+\theta_{1} I, \ldots, A_{\Sigma}+\theta_{q} I\right)
$$

The characteristic polynomial associate to $\hat{A}$ is then

$$
P_{\hat{A}}(t)=\sum_{|u| \leq n-1} \hat{\sigma}_{u} t^{u}
$$

Moreover, we have

$$
\begin{align*}
P_{\hat{A}}(t) & =\operatorname{det}\left(I+\sum_{\alpha=1}^{q} t_{\alpha}\left(A_{\Sigma}+\theta_{\alpha}\right) I\right)  \tag{3.3}\\
& =\prod_{j=1}^{n-1}\left(1+\tau_{j}\left(t_{1}+. .+t_{q}\right)+t_{1} \theta_{1}+\ldots+t_{q} \theta_{q}\right) . \tag{3.4}
\end{align*}
$$

By expanding the linear factorization of a monic polynomial we obtain

$$
P_{\hat{A}}(t)=\sum_{j=0}^{n-1}\left(1+t_{1} \theta_{1}+\ldots+t_{q} \theta_{q}\right)^{n-1-j}\left(t_{1}+\ldots+t_{q}\right)^{j} \sigma_{j}\left(A_{\Sigma}\right)
$$

and by the multinomial theorem we get

$$
P_{\hat{A}}(t)=\sum_{j=0}^{n-1} \sum_{k=0}^{n-1-j} \sum_{|v|=k} \sum_{||l|=j} \frac{1}{(n-1-j-k)!}\binom{j}{l}\binom{n-1-j}{v} \sigma_{j}\left(A_{\Sigma}\right) \theta^{v} t^{v+l} .
$$

where $l=\left(l_{1}, \ldots, l_{q}\right), v=\left(v_{1}, \ldots, v_{q}\right), \theta=\left(\theta_{1}, \ldots, \theta_{q}\right)$ and $t=\left(t_{1}, \ldots, t_{q}\right)$. Let $u=v+l$ so $j=|u|-|v|$ and

$$
P_{\hat{A}}(t)=\sum_{|u| \leq n-1} \sum_{l \leq u} \frac{1}{(n-1-|u|)!}\binom{|l|}{l}\binom{n-1-|l|}{u-l} \theta^{u-l} \sigma_{|l|}\left(A_{\Sigma}\right) t^{u} .
$$

Thus the coefficient before $t^{u}$ is given by
$\hat{\sigma}_{u}\left(A_{\Sigma}+\theta_{1} I, \ldots, A_{\Sigma}+\theta_{q} I\right)=\frac{1}{(n-1-|u|)!} \sum_{l \leq u}\binom{|l|}{l} \theta^{u-l}\binom{n-1-|l|}{u-l} \sigma_{|l|}\left(A_{\Sigma}\right)$.
Consequently

$$
\begin{gather*}
\tilde{\sigma}_{u}\left(\rho_{1} A_{\Sigma}+\mu_{1} I, \ldots, \rho_{q} A_{\Sigma}+\mu_{q} I\right)= \\
\frac{1}{(n-1-|u|)!} \sum_{l \leq u}\binom{|l|}{l} \rho^{l} \mu^{u-l}\binom{n-1-|l|}{u-l} \sigma_{|l|}\left(A_{\Sigma}\right) \tag{3.5}
\end{gather*}
$$

On the other hand
Denote by $\bar{A}=\left(A_{\Sigma}, \mu_{1} I, \ldots, \mu_{q} I\right)$ and $\bar{\sigma}_{(k, v)}=\sigma_{(k, v)}(\bar{A})$. We have

$$
\sigma_{(k, v)}(\bar{A})=\mu^{v} \sigma_{(k, v)}\left(A_{\Sigma}, I, \ldots, I\right)
$$

Now, we use the following formula ( see [6] )

$$
\left.\sigma_{( } v, k\right)\left(B_{1}, \ldots, B_{q}, I\right)=\binom{n-1-|v|}{k} \sigma_{v}\left(B_{1}, \ldots, B_{q}\right)
$$

consecutively $q$-times and we get

$$
\begin{aligned}
\sigma_{(j, v)}\left(A_{\Sigma}, I, \ldots, I\right) & =\binom{n-1-|v|+v_{1}}{v_{1}} \ldots\binom{n-1-|v|+|v|}{v_{q}} \sigma_{j}\left(A_{\Sigma}\right) \\
& =\frac{1}{(n-1-|v|-j)!}\binom{n-1-j}{v} \sigma_{j}\left(A_{\Sigma}\right) .
\end{aligned}
$$

Taking $j=|u|-|v|$, we obtain

$$
=\frac{1}{(n-1-|u|)!}\binom{n-1-|u|+|v|}{v} \sigma_{|u|-|v|}\left(A_{\Sigma}\right)
$$

and if we let $l=u-v$, we have

$$
\begin{equation*}
\sigma_{(|l|, u-l)}\left(A_{\Sigma}, I, \ldots, I\right)=\frac{1}{(n-1-|u|)!}\binom{n-1-|l|}{u-l} \sigma_{|l|}\left(A_{\Sigma}\right) \tag{3.6}
\end{equation*}
$$

So by relations (3.2) and (3.6), we get

$$
\begin{equation*}
\tilde{\sigma}_{u}=\frac{1}{(n-1-|u|)!} \sum_{l \leq u}\binom{|l|}{l} \rho^{l} \mu^{u-l}\binom{n-1-|l|}{u-l} \sigma_{|l|}\left(A_{\Sigma}\right) \tag{3.7}
\end{equation*}
$$

Notice, that in the proof of the above Proposition, we assumed $\rho_{\alpha} \neq 0$ for all $\alpha$, this allowed us to defined the constants $\theta_{\alpha}$. The assumption $\rho_{\alpha} \neq 0$ is not necessary. Since if there exists $\alpha \in\{1, . ., q\}$ such that $\rho_{\alpha}=0$. then (see [6])

$$
\begin{aligned}
\tilde{\sigma}_{u} & =\tilde{\sigma}_{u}\left(\rho_{1} A_{\Sigma}+\mu_{1} I, \ldots, \rho_{q} A_{\Sigma}+\mu_{q} I\right) \\
& =\tilde{\sigma}_{u}\left(\rho_{1} A_{\Sigma}+\mu_{1} I, \ldots, \rho_{i-1} A_{\Sigma}+\mu_{i-i} I, \mu_{i} I, \rho_{i+1} A_{\Sigma}+\mu_{i+1} I, \ldots, \rho_{q} A_{\Sigma}+\mu_{q} I\right) \\
& =\mu_{i}^{u_{i}} \tilde{\sigma}_{\tilde{u}}\left(\rho_{1} A_{\Sigma}+\mu_{1} I, \ldots, \rho_{i-1} A_{\Sigma}+\mu_{i-i} I, \rho_{i+1} A_{\Sigma}+\mu_{i+1} I, \ldots, \rho_{q} A_{\Sigma}+\mu_{q} I\right),
\end{aligned}
$$

where

$$
\tilde{u}=\left(u_{1}, \ldots, u_{i-1}, u_{i+1}, \ldots, u_{q}\right)
$$

and we may apply the above Proposition to $\tilde{\sigma}_{\tilde{u}}$.
Proposition 2. Let $\tilde{A}=\left(\left.A_{1}\right|_{\Sigma}, \ldots,\left.A_{q}\right|_{\Sigma}\right)$, where $\left.A_{\alpha}\right|_{\Sigma}=\left(\rho_{\alpha} A_{\Sigma}+\mu_{\alpha} I\right.$, and $\bar{A}=\left(A_{\Sigma}, \mu_{1} I, \ldots, \mu_{q} I\right)$. For any multi-index $u \in \mathbb{N}^{q}$, put $\tilde{\sigma}_{u}=\sigma_{u}(\tilde{A})$ and $\bar{\sigma}_{u}=\sigma_{u}(\bar{A})$. Then we have

$$
\begin{equation*}
\tilde{\sigma}_{u}=\sum_{l \leq u}\binom{|l|}{l} \rho^{l} \bar{\sigma}_{(|l|, u-l)} . \tag{3.8}
\end{equation*}
$$

Proof. First notice that

$$
\bar{\sigma}_{(j, v)}=\sigma_{(j, v)}(\bar{A})=\mu^{v} \sigma_{(j, v)}\left(A_{\Sigma}, I, \ldots, I\right)
$$

Using the following formula (see [6])

$$
\sigma_{(v, j)\left(B_{1}, \ldots, B_{q}, I\right)}=\binom{n-1-|v|}{j} \sigma_{v}\left(B_{1}, \ldots, B_{q}\right)
$$

consecutively $q$-times, we obtain

$$
\begin{aligned}
\sigma_{(j, v)}\left(A_{\Sigma}, I, \ldots, I\right) & =\binom{n-1-|v|+v_{1}}{v_{1}} \ldots\binom{n-1-|v|+|v|}{v_{q}} \sigma_{j}\left(A_{\Sigma}\right) \\
& =\frac{1}{(n-1-|v|-j)!}\binom{n-1-j}{v} \sigma_{j}\left(A_{\Sigma}\right)
\end{aligned}
$$

or by putting $l=u-v$

$$
\sigma_{(|l|, u-l)}=\frac{1}{(n-1-|u|)!}\binom{n-1-|l|}{u-l} \sigma_{|l|}\left(A_{\Sigma}\right)
$$

so

$$
\bar{\sigma}_{(l l \mid, u-l)}=\frac{\mu^{u-l}}{(n-1-|u|)!}\binom{n-1-|l|}{u-l} \sigma_{|l|}\left(A_{\Sigma}\right)
$$

Thus by (3.1) we get (3.8).
Let us now state the relation between symmetric functions corresponding to the families $\left(A_{\alpha}\right)$ and $\left(A_{\alpha} \mid \Sigma\right)$. Notice that there are of different sizes.
Proposition 3. Let $A=\left(A_{1}, \ldots, A_{q}\right)$ and $\tilde{A}=\left(A_{1}\left|\Sigma, \ldots, A_{q}\right| \Sigma\right)$. Put $\sigma_{u}=$ $\sigma_{u}(A)$ and $\tilde{\sigma}_{u}=\sigma_{u}(\tilde{A})$. Then

$$
\begin{aligned}
\sigma_{u}=\tilde{\sigma}_{u}+ & \sum_{\alpha} C_{\alpha} \tilde{\sigma}_{\alpha_{b}(v)} \\
& +\sum_{\alpha^{\sharp} \beta^{\sharp}(0) \leq w \leq u} \sum_{\alpha, \beta}(-1)^{|w|-|v|+1}\binom{|u|-|w|}{u-w} B_{\alpha}^{\top} \tilde{A}^{u-w} B_{\beta} \tilde{\sigma}_{\alpha_{b} \beta_{b}(w)}
\end{aligned}
$$

where $B_{\alpha}^{\top}=\left(\left\langle A_{\alpha} v, e_{1}\right\rangle, \ldots,\left\langle A_{\alpha} v, e_{n-1}\right\rangle\right)$ and $C_{\alpha}=\left\langle A_{\alpha} v, v\right\rangle$.
Proof. First calculate the characteristic polynomial $P_{A}(t)$ of $A=\left(A_{1}, \ldots, A_{q}\right)$. By definition, we have

$$
\begin{aligned}
P_{A}(t) & =\operatorname{det}\left(I+\sum_{\alpha} t_{\alpha} A_{\alpha}\right) \\
& =\operatorname{det}\left(I_{n-1}+\left.\sum_{\alpha} t_{\alpha} A_{\alpha}\right|_{\Sigma}\right) \operatorname{det}\left(C-B^{\top}\left(I_{n-1}+\left.\sum_{\alpha} t_{\alpha} A_{\alpha}\right|_{\Sigma}\right)^{-1} B\right)
\end{aligned}
$$

where $B^{\top}$ and $C$ are respectively given by

$$
B^{\top}=\left(\sum_{\alpha} t_{\alpha}\left\langle A_{\alpha} v, e_{1}\right\rangle, \ldots, \sum_{\alpha} t_{\alpha}\left\langle A_{\alpha} v, e_{n-1}\right\rangle\right)=\sum_{\alpha} t_{\alpha} B_{\alpha}^{\top}
$$

and

$$
C=1+\sum_{\alpha} t_{\alpha}\left\langle A_{\alpha} v, v\right\rangle .
$$

To simplify the expressions, we put

$$
M=\left(I_{n-1}+\sum_{\alpha} t_{\alpha} A_{\alpha} \mid \Sigma\right) .
$$

and

$$
f(t)=\operatorname{det}\left(C-B^{\top} M^{-1} B\right)
$$

Moreover it is clear that

$$
B^{\top} M^{-1} B=\sum_{\alpha, \beta} t_{\alpha} t_{\beta} B_{\alpha}^{\top} M^{-1} B_{\beta},
$$

therefore we get

$$
f(t)=\left(1+\sum_{\alpha} t_{\alpha} C_{\alpha}-\sum_{\alpha, \beta} t_{\alpha} t_{\beta} B_{\alpha}^{\top} M^{-1} B_{\beta}\right) .
$$

As it is easily seen that

$$
P_{A}(t)=f(t) P_{\tilde{A}}(t) .
$$

where $P_{A}(t)$ and $P_{\tilde{A}}(t)$ are defined by

$$
P_{A}(t)=\sum_{|u| \leq n} \sigma_{u} t^{u}
$$

and

$$
P_{\tilde{A}}(t)=\sum_{|u| \leq n-1} \tilde{\sigma}_{u} t^{u} .
$$

Thus we get

$$
\left.\frac{\partial^{u}}{\partial t^{u}} P_{A}(t)\right|_{t=0}=u!\sigma_{u},\left.\quad \frac{\partial^{u}}{\partial t^{u}} P_{\tilde{A}}(t)\right|_{t=0}=u!\tilde{\sigma}_{u} .
$$

Similarly we obtain

$$
\left.\frac{\partial^{u}}{\partial t^{u}}\left(P_{\tilde{A}}(t) \cdot f(t)\right)\right|_{t=0}=\left.\sum_{v \leq u}\binom{u}{v}\left(\frac{\partial^{v}}{\partial t^{v}} P_{\tilde{A}}(t) \cdot \frac{\partial^{u-v}}{\partial t^{u-v}} f(t)\right)\right|_{t=0},
$$

where

$$
\binom{u}{v}=\frac{u!}{v!}=\frac{u_{1}!\ldots u_{1}!}{v_{1}!\ldots v_{q}!} .
$$

Now we will compute $\frac{\partial^{u-v}}{\partial t^{u-v}} f(t)$. For $v=u$, it is checked

$$
\left.\frac{\partial^{u-v}}{\partial t^{u-v}} f(t)\right|_{t=0}=f(0, \ldots, 0)=1
$$

If $v=\alpha_{b}(u)$, we have

$$
\left.\frac{\partial^{u-v}}{\partial t^{u-v}} f(t)\right|_{t=0}=\left.\frac{\partial}{\partial t_{\alpha}} f(t)\right|_{t=0}=C_{\alpha}
$$

and for any $v \leq \alpha_{b} \beta_{b}(u)$, we obtain

$$
\left.\frac{\partial^{u-v}}{\partial t^{u-v}} f(t)\right|_{t=0}=\left.\frac{\partial^{u-v}}{\partial t^{u-v}}\left(1+\sum_{\alpha} t_{\alpha} C_{\alpha}-\sum_{\alpha, \beta} t_{\alpha} t_{\beta} B_{\alpha}^{\top}\left(I_{n-1}+\left.\sum_{\alpha} t_{\alpha} A_{\alpha}\right|_{\Sigma}\right)^{-1} B_{\beta}\right)\right|_{t=0} .
$$

Taking $|t|<\varepsilon$ for some small enough $\varepsilon$ we get

$$
\left\|\sum_{\alpha} t_{\alpha} A_{\alpha} \mid \Sigma\right\| \leq 1 .
$$

Thus

$$
\left(I_{n-1}+\left.\sum_{\alpha} t_{\alpha} A_{\alpha}\right|_{\Sigma}\right)^{-1}=\sum_{k=0}^{\infty}(-1)^{k}\left(\sum_{\alpha} t_{\alpha} A_{\alpha} \mid \Sigma\right)^{k}
$$

Since the matrices $\left.A_{\alpha}\right|_{\Sigma}$ are diagonal, then they commute. Therefore, we may write

$$
\left(\sum_{\alpha} t_{\alpha} A_{\alpha} \mid \Sigma\right)^{k}=\sum_{w_{1}+\ldots+w_{q}=k}\binom{k}{w} t^{w} \tilde{A}^{w}
$$

Hence

$$
\left(I_{n-1}+\sum_{\alpha} t_{\alpha} A_{\alpha} \mid \Sigma\right)^{-1}=\sum_{k=0}^{\infty}(-1)^{k}\left(\sum_{w_{1}+\ldots+w_{q}=k}\binom{k}{w} t^{w} \tilde{A}^{w}\right)
$$

Which gives

$$
\begin{aligned}
&\left.\frac{\partial^{u-v}}{\partial t^{u-v}} f(t)\right|_{t=0}=\left.\frac{\partial^{u-v}}{\partial t^{u-v}}\left(-\sum_{\alpha, \beta} t_{\alpha} t_{\beta} B_{\alpha}^{\top} \sum_{k=0}^{\infty}(-1)^{k}\left(\sum_{w_{1}+\ldots+w_{q}=|w|=k}\binom{|w|}{w} t^{w} \tilde{A}^{w}\right) B_{\beta}\right)\right|_{t=0} \\
&=\left.\frac{\partial^{u-v}}{\partial t^{u-v}}\left(-\sum_{\alpha, \beta} B_{\alpha}^{\top} \sum_{k=0}^{\infty}(-1)^{k}\left(\sum_{w_{1}+\ldots+w_{q}=|w|=k}\binom{|w|}{w} t^{w+\alpha^{\sharp} \beta^{\sharp}(0)} \tilde{A}^{w}\right) B_{\beta}\right)\right|_{t=0} \\
&=-\sum_{\alpha, \beta} \sum_{v \leq \alpha_{b} \beta_{b}(u)} B_{\alpha}^{\top}(-1)^{|u|-|v|-2}(u-v)!\binom{|u|-|v|-2}{u-\alpha^{\sharp} \beta^{\sharp}(v)} \tilde{A}^{u-\alpha^{\sharp} \beta^{\sharp}(v)} B_{\beta} \\
&=\sum_{\alpha, \beta} \sum_{v \leq \alpha_{b} \beta_{b}(u)} B_{\alpha}^{\top}(-1)^{|u|-|v|-1}(u-v)!\binom{|u|-|v|-2}{u-\alpha^{\sharp} \beta^{\sharp}(v)} \tilde{A}^{u-\alpha^{\sharp} \beta^{\sharp}(v)} B_{\beta} .
\end{aligned}
$$

Finally we obtain

$$
\begin{aligned}
u!\sigma_{u} & =u!\tilde{\sigma}_{u}+\sum_{\alpha}\left(\alpha_{b}(u)\right)!\binom{u}{\alpha_{b}(u)} C_{\alpha} \tilde{\sigma}_{\alpha_{b}(u)} \\
& +\sum_{\alpha, \beta v \leq u} \sum_{v \leq}\binom{u}{v}(-1)^{|u|-|v|-1}(u-v)!v!\binom{|u|-|v|-2}{u-\alpha_{b} \beta_{b}(v)} B_{\alpha}^{\top} \tilde{A}^{u-\alpha_{b} \beta_{b}(v)} B_{\beta} \tilde{\sigma}_{v}
\end{aligned}
$$

or equivalently,

$$
\sigma_{u}=\tilde{\sigma}_{u}+\sum_{\alpha} C_{\alpha} \tilde{\sigma}_{\alpha_{b}(u)}+\sum_{\alpha, \beta} \sum_{0 \leq v \leq \alpha_{b} \beta_{b}(u)}(-1)^{|u|-|v|-1}\binom{|u|-|v|-2}{u-\alpha^{\sharp} \beta^{\sharp}(v)} B_{\alpha}^{\top} \tilde{A}^{u-\alpha^{\sharp} \beta^{\sharp}(v)} B_{\beta} \tilde{\sigma}_{v} .
$$

Hence
$\sigma_{u}=\tilde{\sigma}_{u}+\sum_{\alpha} C_{\alpha} \tilde{\sigma}_{\alpha_{b}(u)}+\sum_{\alpha^{\sharp} \beta^{\sharp}(0) \leq w \leq u \alpha, \beta} \sum(-1)^{|w|-|v|+1}\binom{|u|-|w|}{u-w} B_{\alpha}^{\top} \tilde{A}^{u-w} B_{\beta} \tilde{\sigma}_{\alpha_{b} \beta_{b}(w)}$.

## 4. Generalized Newton transformation on the boundary

We use the same notations as in previous sections. In this section we give the expression of the GNT $T_{u}=T_{u}(\tilde{A})$, where $\tilde{A}=\left(A_{1}\left|\Sigma, \ldots, A_{q}\right| \Sigma\right)$, on the boundary $\Sigma^{n-1}$ of $M^{n}$. Recall that

$$
\left.A_{\alpha}\right|_{\Sigma}=\rho_{\alpha} A_{\Sigma}+\mu_{\alpha} I,
$$

where

$$
\rho_{\alpha}=\left\langle\eta, N_{\alpha}\right\rangle, \quad \mu_{\alpha}=\left\langle V, N_{\alpha}\right\rangle, \quad V=\sum_{\alpha=1}^{q} \lambda_{\alpha} \xi_{\alpha} .
$$

Proposition 4. Let $\bar{M}^{n+q}$ be an $(n+q)$-Riemannian manifold and $P^{n} \subset$ $\bar{M}^{n+q}$ an oriented totally umbilical n-submanifold of $\bar{M}^{n+q}$. Denote by $\Sigma^{n-1} \subset P^{n}$ an $(n-1)$-compact hypersurface of $P^{n}$. Let $\Psi: M^{n} \longrightarrow \bar{M}^{n+q}$ be an oriented connected and compact submanifold of $\bar{M}^{n+q}$ with boundary $\Sigma^{n-1}=\Psi(\partial M)$. Then along the boundary $\partial M$, we have

$$
\begin{equation*}
\left\langle T_{u} \nu, \nu\right\rangle=\tilde{\sigma}_{u}\left(A_{1}\left|\Sigma, \ldots, A_{q}\right| \Sigma\right) . \tag{4.1}
\end{equation*}
$$

Proof. We make a recursive proof. Assume that (4.1) holds for any multiindex $v<u$. We have by the recurrence definition of $T_{u}$

$$
\begin{aligned}
\left\langle T_{u} \nu, \nu\right\rangle & =\sigma_{u}\langle\nu, \nu\rangle-\sum_{\alpha}\left\langle A_{\alpha} T_{\alpha_{b}(u)} \nu, \nu\right\rangle \\
& =\sigma_{u}-\sum_{\alpha}\left\langle T_{\alpha_{b}(u)} \nu, A_{\alpha} \nu\right\rangle \\
& =\sigma_{u}-\sum_{\alpha}\left\langle T_{\alpha_{b}(u)} \nu, \nu\right\rangle\left\langle A_{\alpha} \nu, \nu\right\rangle-\sum_{\alpha, i}\left\langle T_{\alpha_{b}(u)} \nu, e_{i}\right\rangle\left\langle A_{\alpha} e_{i}, \nu\right\rangle .
\end{aligned}
$$

Put

$$
C_{\alpha}=\left\langle A_{\alpha} \nu, \nu\right\rangle, b_{i, \alpha}=\left\langle A_{\alpha} e_{i}, \nu\right\rangle
$$

then

$$
\left\langle T_{u} \nu, \nu\right\rangle=\sigma_{u}-\sum_{\alpha} C_{\alpha} \tilde{\sigma}_{\alpha_{b}(u)}-\sum_{\alpha, i} b_{i, \alpha}\left\langle T_{\alpha_{b}(u)} \nu, e_{i}\right\rangle .
$$

Let us compute $\left\langle T_{u} \nu, e_{i}\right\rangle$ for any multi-index $u \in \mathbb{N}^{q}$. Notice that

$$
A_{\alpha} e_{i}=\rho_{\alpha} A_{\Sigma} e_{i}+\mu_{\alpha} e_{i}+b_{i, \alpha} \nu
$$

assuming that $\left\{e_{1}, \ldots, e_{n-1}\right\}$ is an orthonormal basis of $T_{p} \Sigma^{n-1}$ consisting of eigenvectors of $A_{\Sigma}$ (with eigenvalues $\tau_{i}$ ). Thus

$$
A_{\alpha} e_{i}=\gamma_{i, \alpha} e_{i}+b_{i, \alpha} \nu
$$

where

$$
\gamma_{i, \alpha}=\rho_{\alpha} \tau_{i}+\mu_{\alpha}
$$

We will show inductively that

$$
\begin{equation*}
\left\langle T_{u} \nu, e_{i}\right\rangle=\sum_{\alpha} \sum_{\alpha^{\sharp}(0) \leq w \leq u}(-1)^{|u|-|w|+1}\binom{|u|-|w|}{u-w} b_{i, \alpha} \gamma_{i}^{u-w} \tilde{\sigma}_{\alpha_{b}(w)} \tag{4.2}
\end{equation*}
$$

where

$$
\gamma_{i}=\left(\gamma_{i, 1}, \ldots, \gamma_{i, q}\right)
$$

Indeed, for $u=\beta^{\sharp}(0)$ we have,

$$
\begin{aligned}
\left\langle T_{u} \nu, e_{i}\right\rangle & =\sigma_{\beta^{\sharp}(0)}\left\langle\nu, e_{i}\right\rangle-\sum_{\alpha}\left\langle A_{\alpha} T_{\alpha_{b}\left(\beta^{\sharp}(0)\right)} \nu, \nu\right\rangle \\
& =-\sum_{\alpha}\left\langle A_{\alpha} \nu, \nu\right\rangle \\
& =-b_{i, \beta} \\
& =\sum_{\alpha} \sum_{\alpha^{\sharp}(0) \leq w \leq \beta^{\sharp}(0)}(-1)^{\left|\beta^{\sharp}(0)\right|-|w|+1}\binom{\left|\beta^{\sharp}(0)\right|-|w|}{\beta^{\sharp}(0)-w} b_{i, \alpha} \gamma_{i}^{\beta^{\sharp}(0)-w} \tilde{\sigma}_{\alpha_{b}(w)},
\end{aligned}
$$

since the sum reduces to one element for $\alpha=\beta$.
Assume that (4.2) holds for all multi index $v<u$. Then again by the recursive definition of $T_{u}$ we get

$$
\begin{aligned}
\left\langle T_{u} \nu, e_{i}\right\rangle & =\sigma_{u}\left\langle\nu, e_{i}\right\rangle-\sum_{\alpha}\left\langle A_{\alpha} T_{\alpha_{b}(u)} \nu, e_{i}\right\rangle \\
& =-\sum_{\alpha}\left\langle T_{\alpha_{b}(u)} \nu, A_{\alpha} e_{i}\right\rangle \\
& =-\sum_{\alpha}\left\langle T_{\alpha_{b}(u)} \nu, \nu\right\rangle\left\langle A_{\alpha} e_{i}, \nu\right\rangle-\sum_{\alpha, j}\left\langle T_{\alpha_{b}(u)} \nu, e_{i}\right\rangle\left\langle A_{\alpha} e_{i}, e_{j}\right\rangle \\
& =-\sum_{\alpha}\left\langle T_{\alpha_{b}(u)} \nu, e_{i}\right\rangle \gamma_{i, \alpha}-\sum_{\alpha} b_{i, \alpha} \tilde{\sigma}_{\alpha_{b}(u)} \\
& =-\sum_{\alpha} \gamma_{i, \alpha}\left(\sum_{\beta} \sum_{\beta^{\sharp}(0) \leq w \leq \alpha_{b}(u)}(-1)^{|u|-|w|}\binom{|u|-|w|-1}{\alpha_{b}(u)-w} b_{i, \beta} \gamma_{i}^{\alpha_{b}(u)-w} \tilde{\sigma}_{\beta_{b}(w)}\right) \\
& -\sum_{\alpha} b_{i, \alpha} \tilde{\sigma}_{\alpha_{b}(u)} .
\end{aligned}
$$

Clearly

$$
\gamma_{i, \alpha} \cdot \gamma_{i}^{\alpha_{b}(u)-w}=\gamma_{i}^{u-w}
$$

16MOHAMED ABDELMALEK, MOHAMMED BENALILI, AND KAMIL NIEDZIAŁOMSKI
Notice that taking $w=u$ we get the last sum. Thus we obtain

$$
\left\langle T_{u} \nu, e_{i}\right\rangle=\sum_{\alpha, \beta}\left(\sum_{\beta^{\sharp}(0) \leq w \leq u}(-1)^{|u|-|w|+1}\binom{|u|-|w|-1}{\alpha_{b}(u)-w} b_{i, \beta} \gamma_{i}^{u-w} \tilde{\sigma}_{\beta_{b}(w)}\right)
$$

Since

$$
\sum_{\alpha}\binom{|u|-|w|-1}{\alpha_{b}(u)-w}=\binom{|u|-|w|}{u-w}
$$

we deduce

$$
\left\langle T_{u} \nu, e_{i}\right\rangle=\sum_{\beta}\left(\sum_{\beta^{\sharp}(0) \leq w \leq u}(-1)^{|u|-|w|+1}\binom{|u|-|w|}{u-w} b_{i, \beta} \gamma_{i}^{u-w} \tilde{\sigma}_{\beta_{b}(w)}\right)
$$

which end the proof of (4.2).
Now, we may prove (4.1). First, we have
$\sum_{\alpha, i}\left\langle T_{\alpha_{b}(u)} \nu, e_{i}\right\rangle b_{i, \alpha}=\sum_{\alpha, \beta, i}\left(\sum_{\beta^{\sharp}(0) \leq w \leq \alpha_{b}(u)}(-1)^{|u|-|w|}\binom{|u|-|w|-1}{\alpha_{b}(u)-w} b_{i, \beta} \gamma_{i}^{\alpha_{b}(u)-w} \tilde{\sigma}_{\beta_{b}(w)}\right)$
Replacing $w$ by $\alpha_{b} \beta_{b}(w)$, we obtain
$\sum_{\alpha, i}\left\langle T_{\alpha_{b}(u)} \nu, e_{i}\right\rangle b_{i, \alpha}=\sum_{\alpha, \beta, i}\left(\sum_{\alpha^{\sharp} \beta^{\sharp}(0) \leq w \leq u}(-1)^{|u|-|w|+1}\binom{|u|-|w|}{u-w} b_{i, \alpha} \gamma_{i}^{u-w} b_{i, \beta} \tilde{\sigma}_{\alpha_{b} \beta_{b}(w)}\right)$
Noticing that

$$
\sum_{i} b_{i, \alpha} \gamma_{i}^{u-w} b_{i, \beta}=B_{\alpha}^{\top} \tilde{A}^{u-w} B_{\beta}
$$

we infer
$\sum_{\alpha, i}\left\langle T_{\alpha_{b}(v)} \nu, e_{i}\right\rangle b_{i, \alpha}=\sum_{\alpha, \beta} \sum_{\alpha^{\sharp} \beta^{\sharp}(0) \leq w \leq u}(-1)^{|u|-|w|+1}\binom{|u|-|w|}{u-w} B_{\alpha}^{\top} \tilde{A}^{u-w} B_{\beta} \cdot \tilde{\sigma}_{\alpha_{b} \beta_{b}(w)}$
Summing up all the above considerations we get

$$
\begin{aligned}
\left\langle T_{u} \nu, \nu\right\rangle & =\sigma_{u}-\sum_{\alpha}\left\langle T_{\alpha_{b}(u)} \nu, \nu\right\rangle\left\langle A_{\alpha} \nu, \nu\right\rangle-\sum_{\alpha, i}\left\langle T_{\alpha_{b}(u)} \nu, e_{i}\right\rangle\left\langle A_{\alpha} e_{i}, \nu\right\rangle \\
& =\sigma_{u}-\sum C_{\alpha} \tilde{\sigma}_{\alpha_{b}(u)}-\sum_{\alpha, \beta} \sum_{\alpha^{\sharp} \beta^{\sharp}(0) \leq w \leq u}(-1)^{|u|-|w|+1}\binom{|u|-|w|}{u-w} B_{\alpha}^{\top} \tilde{A}^{u-w} B_{\beta} \cdot \tilde{\sigma}_{\alpha_{b} \beta_{b}(w)}
\end{aligned}
$$

or, equivalently,

$$
\sigma_{u}=\tilde{\sigma}_{u}+\sum_{\alpha} C_{\alpha} \tilde{\sigma}_{\alpha_{b}(u)}+\sum_{\alpha, \beta} \sum_{\alpha^{\sharp} \beta^{\sharp}(0) \leq w \leq u}(-1)^{|u|-|w|+1}\binom{|u|-|w|}{u-w} B_{\alpha}^{\top} \tilde{A}^{u-w} B_{\beta} \cdot \tilde{\sigma}_{\alpha_{b} \beta_{b}(w)}
$$

Applying Proposition (3), we obtain

$$
\left\langle T_{u} \nu, \nu\right\rangle=\tilde{\sigma}_{u}
$$

By Proposition (1) we obtain the following expression of $\left\langle T_{u} \nu, \nu\right\rangle$ in terms of symmetric functions of the shape operator $A_{\Sigma}$.

Corollary 1. With the conditions of Proposition (4), we have

$$
\begin{equation*}
\left\langle T_{u} \nu, \nu\right\rangle=\frac{1}{n-1-|u|} \sum_{l \leq u}\binom{n-1-|l|}{|u|-l} \rho^{l} \mu^{u-l} \sigma_{|l|}\left(A_{\Sigma}\right) . \tag{4.3}
\end{equation*}
$$

The relation (4.3) will be more simple if we suppose that the embedding $P^{n} \subset \bar{M}^{n+q}$ is totally geodesic.

Corollary 2. With the conditions of Proposition (4) and assuming that $P^{n} \subset \bar{M}^{n+q}$ is totally geosedic, then for every multi-index $u$ with length $|u| \leq n-1$, we have

$$
\left\langle T_{u} \nu, \nu\right\rangle=\rho^{u} \sigma_{|u|}\left(A_{\Sigma}\right)
$$

Proof. It suffices to use (4.3) with $\mu_{\alpha}=0$.

## 5. Transversality of submanifolds

The formula for the generalized Newton transformation implies the relation between transversality of $M^{n}$ and $P^{n}$ and ellipticity of $T_{u}$ provided that $P^{n}$ is totally geodesic in $\bar{M}^{n+1}$. This generalizes the result in ([2]) to any arbitrary codimension.

Theorem 1. With the conditions in Corollary (2) the submanifolds $M^{n}$ and $P^{n}$ are transversal along $\partial M$ provided that for some multi-index $u$ of length $1 \leq|u| \leq n-1$, the generalized Newton transformation $T_{u}$ is positive definite on $M^{n}$.

Proof. Saying that $M^{n}$ and $P^{n}$ are not transversal means that there exist $p \in \partial M$ such that for every $\alpha \in\{1, \ldots, q\}$ we have

$$
\rho_{u}=\left\langle\eta, N_{\alpha}\right\rangle=0 \quad \text { at } p .
$$

Therefore, if we suppose that for all $p \in \bar{M}^{n+q}, T_{u}$ is positive definite, then by Corollary $7, \rho^{u}(p) \neq 0$. Thus

$$
\left\langle\eta, N_{\alpha}\right\rangle \neq 0
$$

hence $M^{n}$ and $P^{n}$ are transversal.
