September 19, 2018

Abstract

We present a detailed analysis of the Hamiltonian constraints of the d-dimensional tetrad-connection gravity where the non-dynamic part of the spatial connection is fixed to zero by an adequate gauge transformation. This new action leads to a coherent Hamiltonian formalism where the Lorentz, scalar and vectorial first-class constraints obeying a closed algebra in terms of Poisson brackets. This algebra closes with structure constants instead of structure functions resulting from the Hamiltonian formalisms based on the A.D.M. decomposition. The same algebra of the reduced first-class constraints, where the second-class constraints are eliminated as strong equalities, is obtained in terms of Dirac brackets. These first-class constraints lead to the same physical degrees of freedom of the general relativity.

1 Introduction

Any coherent canonical quantification of a theory requires a correct treatment of its classical Hamiltonian formalism. During the last half-century, canonical
quantization of general relativity has attracted much attention, especially these last few decades with the development of the loop quantum gravity [1], [2] and [3] (and references therein). Despite a lot of progress made in the different approaches of the canonical quantization of the gravity, these approaches are not complete in the sense that the algebra of the first-class constraints closes with structure functions both in the metrical [4] and the tetrad formulation of gravity [1]. The presence of structure functions can be a potential source of anomalies and reveals that the first-class constraints do not correspond to symmetries based on true Lie groups. This shows the special attention that must be paid to the construction of the Hamiltonian formalism of gravity.

Among these different approaches, we cite the one where the Hamiltonian formalism is derived from a generalized action [5] where the time gauge is fixed in order to reduce Lorentz’s manifest invariance of the action to \( SO(3) = SU(2)/Z_2 \). The interest in \( SO(3) \) came from the fact that \( SO(3) \) is compact allowing the construction of the Hilbert space in loop quantum gravity. The Holst action does not modify the classical Einstein equation in the vacuum but contains a new dimensionless parameter known as the Barbero-Immirzi parameter [6] which appears in the spectra of area and volume operators at the quantum level [7]. It also appears in the black hole entropy formula [8]. Note that even at the classical level, once gravity is coupled to fermionic matter, the Barbero-Immirzi parameter appears on-shell via the non-zero torsion [9].

The local Lorentz invariance of the canonical vierbein form of general relativity has been done in the second order formalism in [10]. The main complication of the covariant canonical formulation of the first order tetrad-connection gravity is the presence of the second-class constraints which require the Dirac brackets. The covariant Hamiltonian treatments of the generalized 4-dimensional action [5] have been developed either in terms of Dirac brackets in [13], where two copies of \( su(2) \) Barbero tetrad-connection gravity are combined to get a \( SO(4, C) \) covariant Hamiltonian, or in [14] where the resolution of second-class constraints leads to a reduced symplectic form where the phase space elements obey canonical Poisson’s brackets.

Almost at the same period, the enthusiasm aroused by the spin foam model of the BF-theory [11] and [12] has encouraged the investigation of the covariant Hamiltonian of the tetrad gravity formulated as a BF-theory with extra constraints on the 2-form \( B \). In [15] the extra constraints on the 2-form \( B \) are solved leading to similar results as the ones of [14].

For higher dimensions, the analysis of the covariant Hamiltonian formalism of the tetrad-connection action was performed in [16] by considering an extension of the A.D.M. phase space where the Lagrange multipliers, the
lapse and the shift, are considered as part of the phase space. After solving the second-class constraints, a canonical reduced symplectic form is obtained leading to an algebra of constraints which closes with structure functions.

Until now all the Hamiltonian formulations of gravity where one starts from the very beginning by the A.D.M. Decomposition of the tetrad components in terms of lapse and shift lead to an algebra of first-class constraints involving structure functions.

Rather than proceeding as in [16], we begin from the phase space resulting directly from the tetrad-connection action without using the A.D.M. formalism. We show that the connection splits in dynamic and non dynamic parts. By fixing the non dynamic part of the connection to zero we obtain a coherent Hamiltonian formalism where all the stages of the Dirac procedure [17] for constrained systems are scrupulously respected. Especially the second-class constraints are eliminated as strong equalities only after the Dirac brackets are established.

The paper is organized as follows:

In section II, we investigate and classify the different constraints according to Dirac terminology. The resolution of the equations involving the Lagrange multiplier leads to a problematic constraint which is difficult to check its consistency. In section III, we show that this problematic constraint is tied to the non-dynamic part of the spatial connection which can be fixed to zero by an adequate gauge fixing. The formalism derived from the new action where the non-dynamic part of the connection is fixed to zero leads to a consistent Hamiltonian treatment where the Lorentz, scalar and vectorial first-class constraints form a Poisson algebra that closes with structure constants. In section IV, we establish the Dirac brackets of the reduced phase space elements where the second-class constraints are eliminated as strong equalities. The reduced first-class constraints becomes polynomial and obey, in terms of Dirac brackets, to the same algebra as the one of the previous section and lead to the same physical degrees of freedom of the general relativity. We end this section by showing that the solutions of Hamiltonian’s equations of the reduced phase space elements lead to a zero torsion which is required to establish the equivalence between the tetrad-connection gravity and the general relativity.

2 Hamiltonian formalism of Tetrad-Gravity

In $d$—dimension space-time manifold $\mathcal{M}$, the functional action of the tetrad-connection gravity is:
\[
S(e, \omega) = \int_{\mathcal{M}} \frac{1}{(d-2)!} e_{I_0} \wedge ... e_{I_{d-3}} \wedge \Omega_{I_{d-2}I_{d-1}} e^{I_0...I_{d-1}} \tag{1}
\]

where the capital Latin letters \( I_0, ..., I_{d-1} \in [0, ..., d-1] \) denote internal indices of the tensor representation spaces of the Lorentz group, \( e_{I_0...I_{d-1}} \) are the components of the totally antisymmetric Levi-Cevita symbol, \( \epsilon_{I_0...I_{d-1}} = \epsilon_{I_0...I_{d-1}} = -\epsilon_{I_0...I_{d-1}} = 1 \), satisfying \( \epsilon_{I_0...I_{n}I_{n+1}...I_{d-1}} \epsilon^{I_0...I_{n}I_{n+1}...I_{d-1}} = -(d-n)! \delta^{[I_0...I_{n}} \delta_{I_{n+1}...I_{d-1}]} \).

Before starting the Hamiltonian analysis of the action (1), let us recall that in the Lagrangian formalism of fields theories the basic variables are fields \( \phi_i(x) \) and their time derivative \( \partial_t \phi_i(x) \) which, in our case, are the co-tetrad components \( e_{\mu I} \), the connection components \( \omega_{\mu IJ} \) and their time derivative \( \partial_t \phi_i(x) = (\partial_t e_{\mu I}, \partial_t \omega_{\mu IJ}) \). These variables and their time derivatives are considered as independent variables and constitute the configuration space. In this framework the dynamic is presupposed determined by evolution equations of second order with respect to time and the configuration space is nothing but a space isomorph to the set of initial conditions of the solutions of the evolution equations. It is not the case here where we are dealing with a first order theory where the equations of motion are of the first order, so they are only constraints in the configuration space. In addition, since the action (1) is given in terms of differential forms, it follows that the time derivative of the temporal components of the co-tetrad and the connection are absent from the evolution equations that govern the tetrad-connection gravity theory and therefore the evolution in time of these variables is undetermined. In the following, these points will be investigated in the Hamiltonian formalism which is more suitable for constrained systems.

To pass from the Lagrangian formalism to the Hamiltonian formalism, we will suppose that the manifold \( \mathcal{M} \) has topology \( R \times \Sigma \), where \( R \) represents the time which is an evolution parameter of \( d - 1 \) dimensional space-like
hypersurfaces $\Sigma_t$ into the $d-$dimensional manifold $\mathcal{M}$. In order to get the momenta conjugate to the configuration fields $e_{\mu I}$ and $\omega_{\mu IJ}$ we must develop the action (1) in terms of components of the co-tetrad and the connection

\[
S(e, \omega) = \int_{\mathcal{M}} \frac{1}{(d-2)!} e_{I_0} \wedge ... e_{I_{d-3}} \wedge \Omega_{I_{d-2}I_{d-1}} e^{I_0 ... I_{d-1}}
\]

\[
= \int_{\mathcal{M}} \frac{1}{2(d-2)!} e^{I_0 ... I_{d-2}} e_{\mu_0 I_0} ... e_{\mu_{d-3} I_{d-3}} \Omega_{\mu_{d-2} \mu_{d-1} I_{d-2} I_{d-1}} e^{\mu_0 ... \mu_{d-4}} d^d x
\]

\[
= - \int e A^\mu K \nu L \frac{\Omega_{\mu \nu KL}}{2} d^d x
\]

where

\[
\Omega_{IJ} = \frac{1}{2} \Omega_{\mu \nu IJ} dx^\mu \wedge dx^\nu = \frac{1}{2} (\partial_\mu \omega_{\nu IJ} - \partial_\nu \omega_{\mu IJ} + \omega_{\mu I} \gamma^N_{\nu J} - \omega_{\nu I} \gamma^N_{\mu J}) dx^\mu \wedge dx^\nu,
\]

\[
e A^\mu K \nu L = \frac{1}{(d-2)!} e^{I_0 ... I_{d-3} K L} e_{\mu_0 I_0} ... e_{\mu_{d-3} I_{d-3}} e^{\mu_0 ... \mu_{d-4}}
\]

\[
= e (e^\mu K e^\nu L - e^\nu K e^\mu L) = -A^\mu K L = -A^\mu L K L,
\]

$e = \det(e_{\mu I})$, and $e^\mu K$ is the inverse of $e_{\mu L}$, $e^\mu K e_{\mu L} = \delta^K_L$, $e^\mu K e^\nu K = \delta^\mu_\nu$.

To carry out the Legendre transformations, the time derivatives must appear explicitly in the action (2)

\[
S(e, \omega) = - \int_{\mathcal{M}} e A^a K KL (\partial_t \omega_{a KL} - D_a \omega_{t KL}) - e A^a K KL \frac{\Omega_{ab KL}}{2} d^d x
\]

from which we deduce the conjugate momenta $\pi^\beta N$ and $P^\beta KL$ of the co-tetrad $e_{\beta N}$ and the $so(1, d - 1)$ connection $\omega_{\beta KL}$

\[
\pi^\beta N(x) = \frac{\delta S(e, \omega)}{\delta \partial_t e_{\beta N}(x)} = 0, \quad P^a KL(x) = \frac{\delta S(e, \omega)}{\delta \partial_t \omega_{a KL}(x)} = e A^a K KL(x)
\]

and

\[
P^t KL(x) = \frac{\delta S(e, \omega)}{\delta \partial_t \omega_{t KL}(x)} = 0
\]

obeying the following non-zero Poisson brackets
where \( \vec{x} \) denotes the local coordinates \( x^a \) of \( \Sigma_t \).

The expressions of the conjugate momenta lead to the following primary constraints

\[
\pi^{tN} = 0, \quad \mathcal{P}^{tKL} = 0, \quad \pi^{bN} = 0 \quad \text{and} \quad C^{aKL} = \mathcal{P}^{aKL} - eA^{aKtL} = 0
\]

which satisfy the following non-zero Poisson brackets

\[
\{ \pi^{aN}(\vec{x}), C^{bKL}(\vec{y}) \} = -eB^{aNtKbL} \delta(\vec{x} - \vec{y})
\]

where \( B^{\alpha\beta\mu\nu} \) is defined as

\[
e^{\beta N} = \frac{1}{(d-3)!} \epsilon^{I_0 \ldots I_{d-4} N K L} e_{\mu_0 \ldots \mu_{d-4} I_{d-4}} e^{\mu_0 \ldots \mu_{d-4} \beta \nu} = e(\mathcal{E}^{\beta N} A^{aKL} + e^{\beta K} A^{\mu L N} + e^{\beta L} A^{a N K}) = e(\mathcal{E}^{\beta N} A^{aKL} + e^{\mu N} A^{\nu K} + e^{\nu N} A^{\beta K} L) = \frac{\delta}{\delta \epsilon^{\beta N}} eA^{\mu K\nu L}. (8)
\]

The total Hamiltonian is defined by

\[
\mathcal{H}_T = \int_{\Sigma} (\pi^{tN} \Lambda_{tN} + \mathcal{P}^{tKL} \frac{A_{tKL}}{2} + \pi^{bN} \Lambda_{bN} + C^{aKL} \frac{A_{aKL}}{2}) + H_0
\]

where \( \Lambda_{tN}, A_{tKL}, \Lambda_{bN} \) and \( A_{bKL} \) are the Lagrange multipliers for primary constraints (6) and

\[
H_0 = \int_{\Sigma} (eA^{aKbL} \Omega_{abKL} \frac{1}{2} + eA^{aKtL} D_{a} \omega_{tKL}).
\]

The consistency of the Hamiltonian formalism requires that these constraints must be preserved under the time evolution given in term of total Hamiltonian (9) in the standard form:

\[
\{ \pi^{tN}, \mathcal{H}_T \} = -eB^{tN aKbL} \frac{\Omega_{abKL}}{2} = P^N = 0, \quad (10)
\]
\{P^{tNM}, \mathcal{H}_T\} = D_a e A^{aNM} = e B^{cKaNLM} D_a e_c = M^{NM} = 0, \quad (11)

\{\pi^{bN}, \mathcal{H}_T\} = -e B^{bNtKL} \left( \frac{A_{aKL}}{2} - D_a \omega_{tKL} \right) - e B^{bNaKcL} \frac{\Omega_{acKL}}{2} = 0, \quad (12)

and

\{C^{aKL}, \mathcal{H}_T\} = e B^{bNtKL} \left( A_{bN} + \omega_{tNM} M_{bM} \right) + D_c (e A^{cKbL})

= e B^{bNtKL} \left( A_{bN} + \omega_{tNM} M_{bM} - D_b \epsilon_{tN} \right) + e B^{bNCaKL} D_c \epsilon_{bN} \quad (13)

where we have used (7) and \{\pi^{TN}, e A^{aKuL} \} = -\delta^{TN}_{a} e A^{aKuL} = -e B^{aN\mu K\nu L}.

These consistency conditions show that the evolution of the constraint \pi^{TN} and \mathcal{P}^{tNM} leads to the secondary constraints \pi^{bN} and \mathcal{C}^{aKL} respectively, while the evolution of the constraints \pi^{N} and \mathcal{C}^{aKL} leads to the equations for the Lagrange multipliers \Lambda_{aKL} and \Lambda_{aN}.

Now we have to check the consistency of the secondary constraints. For the constraint (11) we get

\{M^{KL}, \mathcal{H}_T\} = D_a (e B^{bNaKtL} A_{bN}) + \frac{1}{2} A^K_a N \epsilon A^{aNTL} + \frac{1}{2} A^L_a N \epsilon A^{aKTN} \quad (14)

Using (13) we obtain

\[ D_a \left( e B^{bNaKtL} A_{bN} \right) = -D_a \left( e B^{bNtKL} A_{bN} \right) \]

\[ = D_a \left( e B^{bNtKL} \omega_{tNM} e^M_b \right) + D_a \left( e B^{\mu N K} b L D_b \epsilon_{\mu N} \right) \]

where the second term of the right hand side of the equality above is written as

\[ D_a \left( e B^{\mu N K} b L D_b \epsilon_{\mu N} \right) = D_a D_b e A^{bKbL} = -\frac{1}{2} \left( D_a D_b - D_b D_a \right) e A^{aKbL} \]

\[ = -\frac{1}{2} \left( \Omega_{ab}^K \epsilon A^{aKbL} + \Omega_{ab}^L \epsilon A^{bKbL} \right) \]

From the properties (8) of the B-matrix, an explicit computation leads, for any antisymmetric tensor \mathcal{D}_{NM} = -\mathcal{D}_{MN}, to the identity

\[ D^K_N e A^{aN\rho L} + D^L_N e A^{a\nu K\rho} = \frac{1}{2} \left( \epsilon^{K}_{\beta} e B^{a\beta L \nu \rho M} - \epsilon^{L}_{\beta} e B^{a\beta K \nu \rho M} \right) \mathcal{D}_{NM} \]

\[ = \frac{1}{2} \left( \epsilon^{M}_{\beta} e B^{a\beta N \nu \rho L} - \epsilon^{N}_{\beta} e B^{a\beta M \nu K \rho L} \right) \mathcal{D}_{NM} \]
leading to

\[ D_a(e^{b^{Nt}Ka^L} \omega_{tNM} e^M_b) = D_a(\omega_{tN}^K e^{t^{Na}L} + \omega_{tN}^L e^{t^{A}KaN}) \]

\[ = -e^{A^{nt}L} D_a \omega_{tN}^K - e^{A^{aKn}L} D_a \omega_{tN}^L \]

\[ - (\omega_{tN}^K M_{tNL} + \omega_{tN}^L M_{tKN}) \]

from which we get

\[ \{ M_{tL}, H_T \} = - (\omega_{tN}^K M_{tNL} + \omega_{tN}^L M_{tKN}) \]

\[ - (\frac{A_{tN}}{2} - D_a \omega_{tN}^K) e^{t^{Na}L} - (\frac{A_{tN}}{2} - D_a \omega_{tN}^L) e^{t^{A}KaN} \]

\[ - \frac{1}{2} (\Omega_{ab}^K e^{A^{ahn}L} + \Omega_{ab}^L e^{A^{akh}N}) \] . \quad (16)

As a consequence of (15), (16) is written in the form

\[ \{ M_{tL}, H_T \} = - \frac{1}{2} (e^K e^{b^{L}tNa} M_{tNM} - D_a \omega_{tNM}) + \frac{1}{2} e^{b^{L}aNa} M_{tNM} \Omega_{acNM} \]

\[ + (K \leftrightarrow L) \]

\[ + \frac{1}{2} (e^K e^{P^L} - e^L e^{P^K}) - (\omega_{tN}^K M_{tNL} + \omega_{tN}^L M_{tKN}) \]

which, when (12) and (13) are satisfied, reduces to

\[ \{ M_{tL}, H_T \} = \frac{1}{2} (e^K e^{P^L} - e^L e^{P^K}) - (\omega_{tN}^K M_{tNL} + \omega_{tN}^L M_{tKN}) \approx 0 \] \quad (17)

ensuring the consistency of the constraint $M_{tL}$. Here ”\(\approx\)” denotes weak equality which means equality modulo the constraints.

The evolution of the constraint $P^{N}$ is given by

\[ \{ P^{N}, H_T \} = - e^{C^{aM}tNbKcL} \frac{\Omega_{BCKL}}{2} \Lambda_{aM} - e^{b^{L}nKb^L} D_a \frac{A_{aKL}}{2} \]

where

\[ e^{C^{\mu}M^{\nu}N^{\alpha}K^{\beta}L} = \frac{1}{(d - 4)!} e_{\mu_0} e_{\mu_2} \cdots e_{\mu_{d-5}} e_{\mu_{d-5}} e_{\mu_{d-5}} e_{\mu_{d-5}} e_{\mu_{d-5}} \]

\[ = e^{\mu^M} e^{B^{\nu}NaK^L} - e^{\beta^M} e^{B^{\nu}NaK^L} + e^{\alpha^M} e^{B^{\nu}NaK^L} - e^{\nu^M} e^{B^{\nu}NaK^L} \]

\[ = e^{\mu^M} e^{B^{\nu}NaK^L} - e^{\nu^L} e^{B^{\nu}Ma\beta K} + e^{\mu^K} e^{B^{\nu}LaM\beta N} - e^{\nu^N} e^{B^{\nu}KaL\beta M} \]

\[ = \frac{\delta e^{B^{\nu}NaK^L}}{\delta e_{\mu^M}} . \] \quad (19)
By using (12), (13) and the properties of the C-matrix (19) we get, after lengthy computation, the evolution of the constraint $P^N$ under the form of combination of constraints 

$$\{P^N, \mathcal{H}_T\} = -\omega^N_{\ t\ M}P^M$$

$$-e^{cN}\left(P^M(\Lambda_{cM} + \omega_{tMK}e^K_c - D_ce_{tM}) + M^{KL}\left(\frac{A_{cKL}}{2} - D_c\omega_{tKL}\right)\right) \simeq (20)$$

Note that the second term of the right hand side of (20) is orthogonal to $e_{tN}$, therefore the evolution of $e_{tN}P^N$ gives

$$\{e_{tN}P^N, \mathcal{H}_T\} = (\Lambda_{tN} + \omega_{tN}^M e_{tM}) P^N \simeq 0 \quad (21)$$

while the part of (20) proportional to $e^{cN}$ shows, by using the consistency of the constraint $M^{KL}$ (17), that the evolution of the linear combination of the constraints $P^N$ and $M^{KL}$, $\mathcal{D}_{spa} = e_{aN}P^N + \omega_{aKL}M^{KL}$ is given by

$$\{e_{aN}P^N + \omega_{aKL}M^{KL}, \mathcal{H}_T\} = P^N\partial_a e_{tN} + M^{KL}\partial_a \omega_{tKL} \simeq 0. \quad (22)$$

The consistency conditions (21) and (22) show that contrary to the constraint $P^N$ the evolution of its projections $P^N e_{tN}$ and $\mathcal{D}_{spa} = e_{aN}P^N + \omega_{aKL}M^{KL}$ are simple and independent of the Lagrange multipliers $\Lambda_{aN}$ and $A_{aKL}$.

In what follows, instead of the constraint $P^N$ we consider its temporal projection

$$\mathcal{D}_t = P^N e_{tN} = -eA^{kbl}\Omega_{abkl}^N \quad (23)$$

and its smeared spatial projection

$$\mathcal{D}_{sp}(\vec{N}) = -\int_{\Sigma} N^a(e_{aN}P^N + \omega_{aKL}M^{KL}) = \int_{\Sigma} eA^{aKl}\mathcal{L}_{\vec{N}}(\omega_{aKL}) \quad (24)$$

where we have used $eB^{lNaKb}e_{tN} = eA^{aKbl}$ to obtain (23) and

$$-N^c e_{cN}P^N = N^c e_{cN}eB^{lNaKb}\Omega_{abKL}^N = eA^{aKl}(\mathcal{L}_{\vec{N}}(\omega_{aKL}) - D_a(N^c\omega_{aKL})) \quad (25)$$

to obtain (24). $\mathcal{L}_{\vec{N}}(\omega_{aKL}) = N^b\partial_b\omega_{aKL} + \partial_a(N^b)\omega_{bKL}$ is the Lie derivative along the arbitrary vector field $\vec{N}$ tangent to $\Sigma_t$. This Lie derivative does not affect the Lorentz indices.

The relation (22) exhibits the consistency of the constraint $\mathcal{D}_{sp}(\vec{N})$ as
\[ \left\{ D_{sp}(\vec{N}), \mathcal{H}_T \right\} = \int \Sigma (P^N \mathcal{L}_{\vec{N}}(e_{1N}) + M^{KL} \mathcal{L}_{\vec{N}}(\omega_{1KL})) \simeq 0 \]

which shows, by comparing to (22), that \( \mathcal{L}_{\vec{N}}(e_{1N}) = N^a \partial_a e_{1N} \) and \( \mathcal{L}_{\vec{N}}(\omega_{1KL}) = N^a \partial_a \omega_{1KL} \) from which we see that the Lie derivative \( \mathcal{L}_{\vec{N}} \) treats the temporal components \( e_{1N} \) and \( \omega_{1KL} \) as scalars.

This analysis of the primary constraints \( \pi^{tN}, \pi^{tKL}, \pi^{aN} \) and \( C^{aKL} \) and the secondary constraints \( D_t, D_{sp} \) and \( M^{KL} \) shows that the set of constraints is complete meaning that the total Hamiltonian \( \mathcal{H}_T \) is coherent provided that (12) and (13) are satisfied.

To complete this analysis, we have to solve the equations (12) and (13). We can check that

\[ B_{\mu N\nu K\alpha L} = \frac{1}{2} \left( \frac{e_{\mu N} A_{\nu K\alpha L}}{d-2} + \frac{e_{\nu N} A_{\alpha K\mu L}}{d-2} + e_{\alpha N} A_{\mu K\nu L} \right) \]

is the inverse of \( B^{\beta N\mu K\nu L} \) in the sense that

\[ B_{\mu N\nu K\alpha L} B^{\mu N\nu P\beta Q} = \frac{1}{2} \frac{1}{2} \delta^\beta_{\mu} \delta^Q_{\nu} \delta^K_{\alpha} \]

(27)

and

\[ B_{\mu N\nu K\alpha L} B^{\rho M\sigma K\alpha L} = \delta^M_{N} \left( \delta^\rho_{\mu} \delta^\sigma_{\nu} - \delta^\rho_{\nu} \delta^\sigma_{\mu} \right). \]

(28)

We see from (26) that, contrary to \( B^{\mu N\nu K\alpha L} \) which is antisymmetric with respect of the indices \( \mu, \nu \) and \( \alpha \) and of the indices \( N, K \) and \( L \), \( B_{\mu N\nu K\alpha L} \) is antisymmetric with respect of the indices \( \mu \) and \( \nu \) and of the indices \( K \) and \( L \) only.

For \( \beta = b \) and \( \alpha = a \), (27) gives

\[ B_{c N t K a L} B^{c N t P Q} + \frac{1}{2} B_{c N d K a L} B^{c N d P Q} = \frac{1}{2} \frac{1}{2} \delta^b_{\mu} \delta^Q_{\nu} \delta^K_{\alpha} \]

(29)

As a consequence of the antisymmetric of the indices \( \mu, \nu \) and \( \alpha \) of \( B^{\mu N\nu K\alpha L} \), (28) gives for \( \sigma = \nu = t \)

\[ B_{c N t K a L} B^{b M t K a L} = \delta^M_{N} \delta^K_{c} \]

(30)

and for \( \sigma = t \) and \( \nu = d \)

\[ B_{c N d K a L} B^{b M t K a L} = 0. \]

(31)

Using (30) and (31) we get the solution of (12) as
\[
\frac{1}{2} A_{aKL} = D_a \omega_{tKL} - \frac{1}{2} B_{bNtKL} B^{bNcPdQ} \Omega_{cdPQ} + B_{bNcKL} \Lambda^{bNc} \tag{32}
\]
with arbitrary \( \Lambda^{bNc} \). The third term of the right hand side of (32) is the part of solution of the homogeneous equation associated with (12).

The determination of the lagrange multipliers \( \Lambda_{bN} \) is obtained by multiplying (13) by \( B_{bNtKaL} \) and using (30) to get

\[
\Lambda_{bN} = -\omega_{tN}^M e_{bM} + D_b e_{tN} - B_{bNtKL} B^{cMdKaL} D_d e_{cM} = -\omega_{tN}^M e_{bM} + D_b e_{tN}\tag{33}
\]

By multiplying (13) by \( B_{dMaKeL} B^{bNcKeL} D^c e_{bN} = 0 = (\delta^N_M (\delta^b_d \delta^c_a - \delta^b_a \delta^c_d) - B_{dMaKL} B^{bNcKL}) D^c e_{bN} = D_a e_{dM} - D_d e_{aM} - e^{-1} B_{dMaKL} M^{KL} = 0. \tag{34}
\]

The above condition is not a solution of the homogeneous equation associated with (13). It result neither from the Legendre transform nor from the consistency of the constraints. This condition shows that the spatial components of the torsion \( \Theta_{Med} = \frac{1}{2} (D_a e_{dM} - D_d e_{aM}) \) are a combination of constraints \( M^{KL} \). It is a condition to have the general solution of (13). In fact if we multiply (33) by \( B_{bNfPdeQ} \) and use (29) we get

\[
B_{bNfPdeQ} \left( \Lambda_{bN} + \omega_{tN}^M e_{bM} - D_b e_{tN} \right) + B_{bNfPdeQ} \left( B_{bNtKaL} B^{cMdKaL} D_d e_{cM} \right) = 0 = \frac{1}{2} B_{bNfPdeQ} B_{bNfKL} B^{cMdKaL} D_d e_{cM} \tag{35}
\]

implying, by virtue of (13),

\[
\frac{1}{2} B_{bNfPdeQ} \left( B_{bNfKL} B^{cMdKaL} D_d e_{cM} \right) = 0
\]

which is equivalent to the condition (31).

By substituting (32) and (33) in \( H_T \), we get

\[
H'_T = \int_\Sigma \left( \pi^{KL} A_{aKL} - \pi^{tN} \Lambda_{tN} \right)
- \int_\Sigma \left( (\pi^a_K e_a - \pi^a_L e_K) + 2 D_a (C^{aKL} + e A^{aKL}) \right) \omega_{tKL}
+ \int_\Sigma \left( e A^{abKL} \Omega_{aKL} - \pi^{aN} D_a e_{tN} - C^{aKL} B_{bNtKaL} B^{bNcPdQ} \Omega_{cdPQ} \right)
+ \int_\Sigma C^{aKL} B_{bNcKL} \Lambda^{bNc}. \tag{35}
\]
Now we check the consistency of constraints with the Hamiltonian $H'_T$. The evolution of the primary constraint $\pi^{aN}$ is consistent in the sense that its Poisson brackets with the Hamiltonian $H'_T$ give combinations of $\pi^{aN}$ and $C^{aNM}$ as

$$\{\pi^{cN}, H'_T\} = -\omega_i^N K^cK = \frac{1}{2} \frac{C^{aKL}}{\delta \epsilon cN} (B_{bMlKAL} B_{bMcPdQ} \Omega_{cdPQ} \frac{1}{2})$$

$$- \frac{1}{2} C^{aKL} \frac{\delta}{\delta \epsilon cN} (B_{bMlKAL}) A^{bMl} \simeq 0. \tag{36}$$

For the constraint $C^{aNM}$, we obtain

$$\{C^{aNM}, H'_T\} = -\omega_i^N K^{aKM} = \omega_i^M C^{aNK} - \frac{1}{2} (\pi^{aN} e^M_t - \pi^a M e^N_t) + D_b(e^{bNaM}) + e^{B^{bQN}aM} D_b e^Q_t - D_c(C^{dKL} B_{bNlKdL} B^{bNcNaM}) \tag{37}$$

which vanishes weakly if we use (34) to get

$$D_b(e^{bNaM}) + e^{B^{bQN}aM} D_b e^Q_t = \frac{1}{2} e^{B^{cQbNaM}} (D_b e^c_t - D_c e^b_t) = \frac{1}{2} e^{B^{cQbNaM}} e^{-1} B_{cQbKtLM} M^{KL} \simeq 0$$

showing that the evolution of the constraint $C^{aNM}$ is consistent only when (34) is satisfied. This is due to the fact that (34) is a condition to solve the equation (13) which result from the consistency of the constraint $C^{aNM}$. From that, we expect that the consistency of the constraints $M^{KL}$, $D_t$ and $D_{sp}(\vec{N})$ depends on (34) also. In fact a direct computation gives

$$\{M^{KL}, H'_T\} = -\omega_i^N M^{NL} - \omega_i^N M^{KN} + \frac{1}{2} (e^K_t P^L - e^K_t P^K)$$

$$- \frac{1}{2} D_a(e^{B^{dNbKaL}}(D_b e^c_t - D_c e^b_t)),$$

$$\{D_t, H'_T\} = -\Lambda_N + \omega_{tNM} e^M_t \Lambda^P + B_{dNeKbL} D_a(e^{aKbL}) \Lambda^{dNe}$$

and

$$\{D_{sp}(\vec{N}), H'_T\} = - \int_{\Sigma} (P^N \mathcal{L}_{\vec{N}} e^c_t N + M^{KL} \mathcal{L}_{\vec{N}} \omega_{tKL})$$

$$- \int_{\Sigma} \frac{1}{2} e^{B^{dNbKaL}}(D_b e^c_t - D_c e^b_t) \mathcal{L}_{\vec{N}} \omega_{aKL}$$

and

$$- \int_{\Sigma} \frac{1}{2} e^{B^{dNbKaL}}(D_b e^c_t - D_c e^b_t) \mathcal{L}_{\vec{N}} \omega_{aKL}.$$
which show that the secondary constraints $M^{KL}$, $D_t$, and $D_{sp}(\hat{N})$ are consistent only when (34) is satisfied.

The consistency of the constraint $\pi^{tN}$ gives

$$\{\pi^{tN}, \mathcal{H}_T'\} = -eBtN\cdot \Omega_{abKL} + D_a\pi^{aN} + C^{aKL}(-e^{-1}e^{tN}B_{bM Kl}eB^{bMdPeQ} + e^{-1}e^{tN}B_{bM Kl}eB^{bMdPeQ} + e^{-1}B_{bM Kl}eC^{tNbM PeQ})\Omega_{dePQ}/2 = P'N \simeq 0 \quad (38)$$

where we have used $\frac{\delta e^{-1}e^{tN}}{\delta e^{tN}} = -e^{-1}e^{tN}$ and (19).

From the relation $e_{tN}^{AN}B_{bM Kl}eB_{bM Kl} = B_{bM Kl}$, the projection of the constraint $P^{tN}$, $D'_t = P^{tN}e_{tN}$, is written in a combination of constraints

$$D'_t = D_t - \pi^{aN}D_a\pi^{aN} + C^{aKL}B_{bN Kl}eB^{bN ePQ}\Omega_{dePQ}/2 \simeq 0 \quad (39)$$

where we have used $eC^{tNbMPeQ}e_{tN} = eB^{bMPeQ}$ obtained from the properties of the C-matrix (19).

For the projection on the spatial component of the co-tetrad we use the relation $e_{tN}^{cN}B_{bM Kl}eB_{bM Kl} = B_{bM eK}e_{tN}$ and

$$e_{tN}^{cN}C^{tNbMPeQ}\frac{\Omega_{dePQ}}{2} = -B^{bMPeQ}\Omega_{cePQ} + \delta^{b}_{e}P^{M},$$

obtained from the properties of the C-matrix (19), to get

$$C^{aKL}B_{bM Kl}e_{tN}^{cN}C^{tNbMPeQ}\frac{\Omega_{dePQ}}{2} = -C^{aKL}\Omega_{caKL} + \frac{1}{2}C^{aKL}B_{bM Kl}eB^{bMPeQ}\Omega_{cePQ} + C^{aKL}B_{cM Kl}P^{M}$$

from which we obtain

$$e_{tN}^{cN}P^{tN} = -(C^{aKL} + eA^{aKL})\Omega_{caKL} + e_{tN}^{cN}D_a\pi^{aN} + C^{aKL}e^{-1}B_{cM Kl}P^{M} + C^{aKL}(B_{bM K}eB^{bM PeQ}\frac{\Omega_{dePQ}}{2} + B_{bM Kl}eB^{bM PeQ}\frac{\Omega_{cePQ}}{2})$$

leading to a linear combination of smeared constraints as
\[
\int \Sigma N^c (e_{cN} P^{tN} + \frac{\omega_{cKL}}{2} M^{tKL} + \pi^{aN} (D_a e_{cN} - D_c e_{aN}))
- \int \Sigma N^c C^{aKL} (B_{bNcKaL} B^{bNdPeQ} \frac{\Omega_{dePQ}}{2} + B_{bNkdKaL} B^{bNdPeQ} \frac{\Omega_{cePQ}}{2})
- \int \Sigma N^c C^{aKL} B_{cMtlKaL} P^M
= - \int \Sigma (\pi^{aM} \mathcal{L}_{\xi} (e_{aM}) + (C^{aKL} + e_{aKtl}) \mathcal{L}_{\xi} (\omega_{aKL})). \tag{40}
\]

Here the new secondary constraint \(M^{tKL}\) is deduced from the consistency of the primary constraint \(P^{tN}\)

\[
\{P^{tKL}, \mathcal{H}_T\} = (D_a (C^{aKL} + e_{aKtl}) + \frac{1}{2} (\pi^{aK} e_{aL} - \pi^{aL} e_{aK}))
= \frac{1}{2} M^{tKL} \simeq 0. \tag{41}
\]

From the expressions (39) and (41), the total Hamiltonian takes the compact form

\[
\mathcal{H}_T = \int \Sigma (\frac{1}{2} P^{tKL} A_{tKL} + \pi^{tN} \Lambda_{tN} - D' - M^{tKL} \omega_{tKL})
+ \int \Sigma C^{aKL} B_{bNcKaL} \Lambda^{bNc}.
\]

The constraint (41) can be completed by adding the constraint \(\pi^{tN} \mathcal{L}_{\xi} (e_{tN})\), where \(\mathcal{L}_{\xi} (e_{tN}) = N^a \partial_a (e_{tN})\), to get

\[
D'_{sp}(\vec{N}) = \int \Sigma (\pi^{\muM} \mathcal{L}_{\xi} (e_{\muN}) + (C^{aKL} + e_{aKtl}) \mathcal{L}_{\xi} (\omega_{aKL})),
\]

which satisfy

\[
\{D'_{sp}(\vec{N}), D'_{sp}(\vec{N}')\} = D'_{sp}(\left[\vec{N}, \vec{N}'\right])
\]

where \(\left[\vec{N}, \vec{N}'\right]\) is the Lie bracket. \(D'_{sp}(\vec{N})\) acts on the co-tetrad components \(e_{\muN}\) and on the connection \(\omega_{aNM}\) as diffeomorphisms of the hypersurface \(\Sigma_t\)

\[
\{e_{\muN}, D'_{sp}(\vec{N})\} = \mathcal{L}_{\xi} (e_{\muN}), \{\omega_{aNM}, D'_{sp}(\vec{N})\} = \mathcal{L}_{\xi} (\omega_{aNM}). \tag{42}
\]
The primary constraints $\pi^{\mu N}$ and $C^{aNM}$ transform as

$$\{\pi^{\mu N}, D'_{sp}(\vec{N})\} = \mathcal{L}_N(\pi^{\mu N}), \quad \{C^{aNM}, D'_{sp}(\vec{N})\} = \mathcal{L}_N(C^{aNM})$$ (43)

which show that, contrary to the constraint $D'_{sp}(\vec{N})$, the Poisson brackets of $D'_{sp}(\vec{N})$ with the primary constraints $\pi^{\mu N}$ and $C^{aNM}$ vanish weakly. On the other hand, the above transformations imply that the constraints $D'_t$ and $M'_{KL}$ are treated by the spatial diffeomorphism constraint $D'_t$ as scalar densities of weight one

$$\{D'_t, D'_t(M)\} = \mathcal{L}_N(M'_t)$$

and

$$\{D'_t, M'_{KL}(\vec{x})\} = -\partial_a(N^aD'_t) = -\partial_a(N^aM'_{KL}(\vec{x}))$$

which can be verified by a direct computation. Here $D'_t(M) = \int_{\Sigma} M D'_t$ is the smeared scalar constraint where $M$ is an arbitrary function and $M'(\theta) = \int_{\Sigma} M'_{KL}\frac{\theta_{KL}}{2}$ where $\theta_{KL}$ may be identified to the dimensionless infinitesimal arbitrary parameters $\theta_{KL} = \delta t\omega_{KL}$.

From (42) and (43), we deduce

$$\{D'_{sp}(\vec{N}), \int_{\Sigma} C^{aKL}B_{bNcKaL}A^{bNc}\} = \int_{\Sigma} C^{aKL}B_{bNcKaL}\mathcal{L}_N(A^{bNc}) \simeq 0$$

showing that the constraint $D'_{sp}(\vec{N})$ is preserved in the time evolution. In addition, the Poisson bracket of $D'_{sp}(\vec{N})$ with the condition (34) gives

$$\{D'_{sp}(\vec{N}), B_{dMakelaLB^{bNcKeL}D_c\epsilon_{bN}}\} = \mathcal{L}_N(B_{dMakelaLB^{bNcKeL}D_c\epsilon_{bN}}) \simeq 0$$

which shows that $D'_{sp}(\vec{N})$ is a first-class constraint.

We may also complete the Lorentz constraint $M'_{KL}$ by adding the constraint $\pi^{tN}$ as

$$\frac{M'_{KL}}{2} = (D_a(C^{aKL} + e^a_{KL}) + \frac{1}{2}(\pi^{aKL}e^L_{\mu} - \pi^{aL}e^K_\mu))$$

which acts on the co-tetrad components $\epsilon_{\mu N}$ and on the connection $\omega_{aNM}$ like local infinitesimal transformations of gauge.
\{\epsilon_{\mu N}, \mathcal{M}'(\theta)\} = \theta_N^L \epsilon_{\mu L}, \quad \{\omega_{aNM}, \mathcal{M}'(\theta)\} = -D_a \theta_{NM}.

(44)

The primary constraints $\pi^{\mu N}$ and $C^{aNM}$ transform like the contravariant tensors

$$\{\pi^{\mu N}, \mathcal{M}'(\theta)\} = \theta_N^L \pi^{\mu L}, \quad \{C^{aNM}, \mathcal{M}'(\theta)\} = \theta_N^L C^{aLM} + \theta_M^L C^{aN L}

(45)$$

from which we deduce that the Poisson brackets of $\mathcal{M}'(\theta)$ with the primary constraints $\pi^{aN}$ and $C^{aN M}$ vanish weakly. The fact that the space-time indices do not transform facilitate the calculation of transformations that $\mathcal{M}'(\theta)$ generates.

The constraint $D_t$ is a scalar under Lorentz transformations

$$\{D_t(\vec{x}), \mathcal{M}'(\theta)\} = 0 \implies \{D_t(\vec{x}), \mathcal{M}'(\theta)\} = 0$$

and $M'^{KL}$ is a contravariant tensor

$$\{M'^{KL}, \mathcal{M}'(\theta)\} = \theta^K_N M'^{NL} + \theta^L_N M'^{KN}$$

leading to the so$(1,d-1)$ Lie algebra

$$\{M'^{NM}(\vec{x}), M'^{KL}(\vec{y})\} = (\eta^{NL} M'^{MK}(\vec{x}) + \eta^{MK} M'^{NL}(\vec{x}) - \eta^{NK} M'^{ML}(\vec{x}) - \eta^{ML} M'^{NK}(\vec{x})) \delta(\vec{x} - \vec{y}).$$

The transformations rules (44) and (45) lead to

$$\left\{\mathcal{M}'(\theta), \int \Sigma C^{aKL} B_{bNcKaL} A^{bNc}\right\} = \int \Sigma \theta^M_N C^{aKL} B_{bMcKaL} A^{bNc}$$

and

$$\left\{\mathcal{M}'(\theta), B_{dMaKеЬL} B^{bNcKeL} D_c e_{bN}\right\} = \theta^Q_M B_{dQaKeL} B^{bNcKeL} D_c e_{bN}$$

showing that $M'^{KL}$ is first-class constraint.

Finally, a straightforward computation gives

$$\{D_t'(M), D_t'(M')\} = 0.$$

But (37) shows that the Poisson brackets of $D_t'(M)$ with the primary constraints $C^{aN M}$ and with $\int \Sigma C^{aKL} B_{bNcKaL} A^{bNc}$ vanish modulo the constraint (34). Therefore, the scalar constraint $D'_t$ is preserved under the time evolution and can be considered as a first-class constraint only if the condition (34) is satisfied.
In conclusion, we are in presence of a Hamiltonian formalism of the tetrad-connection gravity composed of first-class constraints, $\pi^{tN}$, $\mathcal{P}^{tNM}$, the Lorentz constraint $\mathcal{M}'(\theta)$ and the spatial diffeomorphism constraint $\mathcal{D}'_{sp}(\vec{N})$. Although the scalar constraint $\mathcal{D}'_{sp}(M)$ forms with $\mathcal{M}'(\theta)$ and $\mathcal{D}'_{sp}(\vec{N})$ a closed algebra with structure constants, its Poisson bracket with the primary constraint $C^{aNLM}$ vanishes weakly only if the condition (34) is resolved.

3 The fixing of the non-dynamical connection

In spite of the fact that we have obtained a closed algebra in terms of structure constants, the constraint (34) is problematic because of the difficulties to check its consistency. To avoid this problem, we decompose the spatial connection as

$$\omega_{aKL} = \omega_{1aKL} + \omega_{2aKL}$$

where

$$\omega_{1aKL} = P_{1KaL}^dP_dQ_{aKL} = B_{bNtKaL}B_b^{bNt}P_dQ_{\omega_dPQ}$$

and

$$\omega_{2aKL} = P_{2KaL}^dP_dQ_{\omega_dPQ} = \frac{1}{2}B_{bNcKaL}B_b^{bNc}P_dQ_{\omega_dPQ}.$$  

It is easy to check from (29), (30) and (31) that

$$P_{1KaL}P_dQ_{1aKL} + P_{2KaL}P_dQ_{2aKL} = \frac{1}{2}\delta_a^{d} \left( \delta_K^{P} \delta_L^{Q} - \delta_L^{P} \delta_K^{Q} \right),$$

$$P_{1KaL}^{NbM}P_{1NbM}^dP_dQ_{2aKL} = P_{1KaL}P_dQ_{1aKL},$$

and

$$P_{1KaL}^{NbM}P_{2NbM}^dP_dQ_{2aKL} = 0$$

which show that $P_{1KaL}P_dQ_{2aKL}$ and $P_{2KaL}P_dQ_{2aKL}$ are projectors.

These projections of the connection is motivated by the fact that the time derivative of $\omega_{2aKL}$ does not contribute to the kinematic part of the action (34). In fact, from the identities

$$B_{bNcKaL}e^{aL} = B_{bNcKaLe^{aK} = B_{bNcKaL}e^{1L} = B_{bNcKaL}e^{1K} = 0$$

we deduce the relations

$$eA^{aKtL}P_{2KaL}^dP_dQ = 0$$

and

$$eA^{aKtL}P_{1KaL}^dP_dQ = eA^{dPtQ}.$$
from which we get
\begin{align*}
e A^{aKtl} \partial_t \omega_{2aKL} &= \partial_t (e A^{aKtl} \omega_{2aKL}) - \partial_t (e A^{aKtl}) \omega_{2aKL} \\
&= -e B^{bNtK} (\partial_t \epsilon_{bN}) \omega_{2aKL} = 0
\end{align*}
as a consequence of (31). Therefore, like for the temporal component of the
co-tetrad and of the connection, the projected spatial connection \( \omega_{2aKL} \) is
non-dynamic.

We also have
\begin{align*}
e A^{aKtL} D^a_2 \omega_{tKL} &= e A^{aKtL} P^i e P_d Q_2 KaL D^i d \omega_{tPQ} = 0
\end{align*}
implying
\begin{align*}
e A^{aKtL} D_a \omega_{tKL} &= e A^{aKtL} P^i e P_d Q_1 KaL D^i d \omega_{tPQ} = e A^{aKtL} D_{a1} \omega_{tKL}
\end{align*}
which shows that only the projected part \( P_{1KaL} \) of the
covariant derivative of \( \omega_{tKL} \) given in terms of the connection \( \omega_{1aKL} \)
contributes to the action. So, the action (4) can be rewritten under the form
\begin{equation}
S(e, \omega) = \int_M \left( e A^{aKtL} (\partial_t \omega_{1aKL} - D^i_{1a} \omega_{tKL}) - e A^{aKtL} \frac{\Omega_{abKL}}{2} \right) \tag{46}
\end{equation}
showing that the two parts of the spatial connection do not play the same
role. The non-dynamic spatial connection \( \omega_{2aKL} \) contributes only to the
third term. The above section showed us that the temporal components of the
connection are Lagrange multipliers and \( \delta t \omega_{tKL} = \theta_{KL} \) play the role of
infinitesimal dimensionless parameters of local transformations of the Lorentz
group under which the spatial connection transforms as \( \delta \omega_{aKL} = -D_a \theta_{KL} =
D_a \delta t \omega_{tKL} \). Since the projected part \( D_a \omega_{tKL} \) does not contribute to the
action, we can fix it to zero without modifying the action (4). We will show
that this gauge fixing results from the fixing of the non-dynamic connection
\( \omega_{2aKL} = 0 \).

Before showing how the gauge transformations of the connection allow us
to fix the non-dynamic connection \( \omega_{2aKL} \) to zero, let us note that the ranks
of the propagators \( P_{1KaL} \) and \( P_{2KaL} \), given by their trace,
\begin{align*}
\frac{1}{2} \delta_d^a (\delta^K_P \delta_L^Q - \delta^K_P \delta_P^L) P_{1KaL}^{PdQ} &= d(d - 1) \\
\frac{1}{2} \delta_d^a (\delta^K_P \delta_L^Q - \delta^K_P \delta_P^L) P_{2KaL}^{PdQ} &= \frac{1}{2} d(d - 1)(d - 3)
\end{align*}
are equal exactly to the number of independent components $\omega_{1aKL}$ and $\omega_{2aKL}$ respectively. On the other side the number $\frac{1}{2}d(d-1)(d-3)$ of independent relations (34) which is equal to $\frac{1}{2}d(d-1)(d-2)$ relations in (33) minus $\frac{1}{2}d(d-1)$ identities

$$eB^{dNcPdQ}(D_{c}e_{dN} - D_{d}e_{cN} - e^{-1}B_{dNcKLMK^L}) = 2M^{PQ} - 2M^{PQ} = 0$$

corresponds exactly to the number of components $\omega_{2aKL}$. Since the equation which results from the functional derivative of the action (46) with respect to $\omega_{2aKL}$ is (34), an action which does not contain explicitly this projected spacial connection does not lead to (34).

Now, let us see how to fix the non-dynamic spatial connection. From the Lorentz infinitesimal transformations $\delta e_{\mu K} = \theta_{N}^{K} e_{\mu N}$ and $\delta \omega_{aKL} = -D_{a}\theta_{KL}$ we deduce

$$\delta \omega_{1aKL} = \theta_{K}^{N} \omega_{1aNL} + \theta_{L}^{N} \omega_{1aKN} - P_{1KaL} P^{dQ} \partial_{d} \theta_{PQ}$$

and

$$\delta \omega_{2aKL} = \theta_{K}^{N} \omega_{2aNL} + \theta_{L}^{N} \omega_{2aKN} - P_{2KaL} P^{dQ} \partial_{d} \theta_{PQ}$$

which show that each part of the projected spatial connection transforms independently of the other. This allows us to fix the non-dynamic part of the connection to zero

$$\omega'_{2aK1} = \omega_{2aKL} + \theta_{K}^{N} \omega_{2aNL} + \theta_{L}^{N} \omega_{2aKN} - P_{2KaL} P^{dQ} \partial_{d} \theta_{PQ} = 0.$$  

A transformation of $\omega'_{2aK1}$ gives

$$\omega''_{2aK1} = \omega'_{2aKL} + \theta'_{K}^{N} \omega'_{2aNL} + \theta'_{L}^{N} \omega'_{2aKN} - P_{2KaL} P^{dQ} \partial_{d} \theta'_{PQ}$$

$$= -P_{2KaL} P^{dQ} \partial_{d} \theta'_{PQ}$$

showing that this fixing of the non-dynamic part of the connection remains invariant if

$$P_{2KaL} P^{dQ} \partial_{d} \theta'_{PQ} = \partial_{2a} \theta_{K1L} = 0 \implies \partial_{a} \theta_{KL} = P_{1KaL} P^{dQ} \partial_{d} \theta_{PQ}. \quad (47)$$

On the other hand, in order to keep the same degrees of freedom during gauge transformations of $\omega_{1aKL}$, we impose

$$\delta_{2} \omega_{1aKL} = P_{2KaL} P^{dQ} \delta \omega_{1dPQ} = -P_{2KaL} P^{dQ} (\theta_{P}^{N} \omega_{1aNQ} + \theta_{Q}^{N} \omega_{1aPN}) = 0$$

implying

$$\theta_{K}^{N} \omega_{1aNL} + \theta_{L}^{N} \omega_{1aKN} = P_{1KaL} P^{dQ} (\theta_{P}^{N} \omega_{1aNQ} + \theta_{Q}^{N} \omega_{1aPN}) = 0.$$  

19
The relations (47) and (48) show that the fixing of the non-dynamic connection to zero does not restrict the gauge parameters but only the gauge transformations of the dynamic part of the spatial connection to

\[ \delta e_{\mu K} = \theta^K_N e_{\mu N} \quad, \quad \delta \omega_{1NM} = -D_t \theta_{NM} \quad \text{and} \quad \delta \omega_{1aKL} = -D_{1a} \theta_{KL} \]  

subject to the condition

\[ D_{2a} \theta_{KL} = 0 \quad \text{and} \quad \partial_{2a} \theta_{KL} = 0. \]  

Since the first and the second term of (46) do not depend on \( \omega_{2aKL} \), to verify that the Lagrangian density (46), where \( \omega_{2aKL} = 0 \), is invariant under the infinitesimal gauge transformations (49) subject to the conditions (50), it suffices to check the invariance of the third term

\[ \delta \left( e^{A}a_{KbL} \Omega(\omega_{1})_{abKL} \right) = \left( \theta^K_N e^{A}a_{Nbl} + \theta^L_N e^{A}a_{KbN} \right) \Omega(\omega_{1})_{abKL} \]

\[ -e^{A}a_{KbL} D_{a}^{\omega_{1}} D_{b}^{\omega_{1}} \theta_{KL} \]

\[ = \left( \theta^K_N e^{A}a_{Nbl} + \theta^L_N e^{A}a_{KbN} \right) \Omega(\omega_{1})_{abKL} - e^{A}a_{KbL} D_{a}^{\omega_{1}} D_{b}^{\omega_{1}} \theta_{KL} \]

\[ = \left( \theta^K_N e^{A}a_{Nbl} + \theta^L_N e^{A}a_{KbN} \right) \Omega(\omega_{1})_{abKL} \]

\[ -e^{A}a_{KbL} \left( \Omega(\omega_{1})_{abKN} \theta^{N}_{L} + \Omega(\omega_{1})_{abLN} \theta^{N}_{K} \right) = 0. \]

In what follows, we consider the action (4) where we fix \( \omega_{2aKL} \) to zero:

\[ S^f(e, \omega_1) = \int_{\mathcal{M}} \left( e^{A}a_{KtL} \left( \partial_{t} \omega_{1aKL} - D^{\omega_{1}}_{1a} \omega_{tKL} \right) - e^{A}a_{KbL} \Omega(\omega_{1})_{abKL} \right). \]

The fixed phase space, \( e_{tN}, e_{aN}, \omega_{tKL}, \omega_{1aKL} \) and their conjugate momenta \( \pi^{tN}, \pi^{aN}, \mathcal{P}^{tKL} \) and \( \mathcal{P}^{1aKL} = P_{PbQ}^{K}aL \mathcal{P}^{bKQ} \), is equipped by the following non zero Poisson brackets

\[ \{ e_{\alpha I}(\vec{x}), \pi^{\beta N}(\vec{y}) \} = \delta^{\beta}_{\alpha} \delta^{I}_{N} \delta(\vec{x} - \vec{y}), \]

\[ \{ \omega_{IJ}(\vec{x}), \mathcal{P}^{tKL}(\vec{y}) \} = \frac{1}{2} \left( \delta^{K}_{I} \delta^{L}_{J} - \delta^{I}_{L} \delta^{K}_{J} \right) \delta(\vec{x} - \vec{y}), \]

\[ \{ \omega_{1aIJ}(\vec{x}), \mathcal{P}^{bKL}(\vec{y}) \} = P_{1aJ}^{K}bL \delta(\vec{x} - \vec{y}). \]

The primary constraints are

\[ \pi^{tN} = 0, \quad \mathcal{P}^{tKL} = 0, \quad \pi^{bN} = 0, \quad \mathcal{C}^{aKL} = \mathcal{P}^{aKL} - e^{A}a_{KtL} = 0 \]
and the total fixed Hamiltonian is
\[ H_T^f = \int_\Sigma \left( \pi^t N A_N + \mathcal{P}^{tKL} \frac{A_{tKL}}{2} + \pi^b N A_{bN} + C_{1aKL}^a \frac{A_{1aKL}}{2} \right) + H_0^f \] (53)

where
\[ H_0^f = \int_\Sigma \left( e A^aKbl \frac{\Omega(\omega_1)_{abKL}}{2} + e A^aKtl D_{1a}^a \omega_{tKL} \right). \]

Before we start the analysis of this Hamiltonian, which will be performed step by step in complete analogy with the treatment of the previous section, let us precise some remarks concerning the Poisson brackets between the elements of the fixed phase space. Like for the gauge transformations of \( \omega_{1aKL} \) [19], to keep the same degrees of freedom, we project the Poisson brackets acting on the projected elements of the phase space as
\[ \{., \omega_{1aKL} \}_1 = P_{1Kal} P_{dQ} \{., \omega_{1dPQ} \} \]
leading to
\[ \{\pi^\alpha N, \omega_{1aKL} \}_1 = P_{1Kal} P_{dQ} \{\pi^\alpha N, \omega_{1dPQ} \} = P_{1Kal} P_{dQ} \{\pi^\alpha N, P_{1Pbq} \omega_{dRS} \} \]
\[ = P_{1Kal} P_{dQ} \{\pi^\alpha N, P_{1Pbq} \omega_{dRS} \} = 0 \]
(54)
where we have used \( \omega_{2dRS} = 0 \) and \( P(\delta P)P = 0 \) true for any projector \( P \). The same computation gives
\[ \{\pi^\alpha N(\vec{x}), \mathcal{P}_1^{aKL}(\vec{y}) \}_1 = 0 \]
(55)
from which we deduce
\[ \{\pi^\alpha N(\vec{x}), C_1^{bKL}(\vec{y}) \}_1 = -e B_{aNTKbl} \delta(\vec{x} - \vec{y}). \]

With these projected Poisson brackets the Jacobi identities are satisfied. For example
\[ \{\pi^\alpha N, \{\omega_{1aIJ}, \mathcal{P}_1^{bKL} \}_1 \}_1 + \{\mathcal{P}_1^{bKL}, \{\pi^\alpha N, \omega_{1aIJ} \}_1 \}_1 + \{\omega_{1aIJ}, \{\mathcal{P}_1^{bKL}, \pi^\alpha N \}_1 \}_1 = 0 \]
as a consequence of (54), (55) and
\[ \{\pi^\alpha N, \{\omega_{1aIJ}, \mathcal{P}_1^{bKL} \}_1 \}_1 = P_{1Kal} P_{dQ} \{\pi^\alpha N, \omega_{1dPQ}, \mathcal{P}_1^{cNM} \}_1 P_{1NcM}^{Kbl} \]
\[ = P_{1Kal} P_{dQ} \{\pi^\alpha N, P_{1PdQ}^{cNM} \}_1 P_{1NcM}^{Kbl} = 0. \]

Now we are ready to perform the treatment of the Hamiltonian (53) by using the projected Poisson brackets. The consistency of the constraint \( \pi^b N \) is
given by the equation (12) expressed in term of $\omega_{1aKL}$ where $A_{aKL}$ is replaced by $A_{1aKL}$ and whose solution is (32) without the term containing $\Lambda_{bNC}$. The consistency of the constraint $C_{aKL}^f$ is given by the same equation (13) where $D_{f}eA^{cKaN}$ is replaced by its projection $D_{1f}eA^{cKaN}$ and whose solution is (33) independently of the condition (34). The substitution of $D_{1f}eA^{cKaN}$ in (13) results from the Poisson bracket of the fixed phase space.

With the new expressions of $\Lambda_{bN}$ and $A_{1aKL}$ the Hamiltonian takes the compact form

$$\mathcal{H}_{T}^{f} = \int_{\Sigma} (\pi^{LN}A_{tN} + P_{tKL}A_{tKL}^f - D_{t}^{f} - M_{fKL}^{f}\omega_{tKL})$$

where

$$D_{t}^{f} = -eA^{aKbL}\frac{\Omega(\omega_{1})}{2} - aN D_{a}^{t}\epsilon_{tN} + C_{1}^{KNL}B_{bkNtkaL}B_{bNcPdQ}^{tKL}\frac{\Omega(\omega_{1})}{2} \simeq 0$$

and

$$\frac{1}{2}M_{fNM}^{f} = (D_{a}^{t}\{C_{1}^{aNM} + eA^{aNtM}\} + \frac{1}{2} (\pi^{tN}e_{tN}^{M} - \pi^{tM}e_{tN}^{M})) \simeq 0.$$

The fixed diffeomorphism constraint is

$$D_{sp}^{f}(\vec{N}) = \int_{\Sigma} (\pi^{tN}A_{tN} + P_{tKL}A_{tKL}^f - D_{t}^{f} - M_{fKL}^{f}\omega_{tKL}) = \mathcal{L}_{\vec{N}}^{f}.$$  

A direct computation shows that $D_{sp}^{f}(\vec{N})$ satisfies the algebra

$$\{D_{sp}^{f}(\vec{N}), D_{sp}^{f}(\vec{N}')\} = D_{sp}^{f}[\vec{N}, \vec{N}'].$$

(56)

The transformations induced by $D_{sp}^{f}(\vec{N})$ on the primary constraints are given by

$$\{\pi^{tN}, D_{sp}^{f}(\vec{N})\} = \mathcal{L}_{\vec{N}}^{f}(\pi^{tN}), \{C_{1}^{aNM}, D_{sp}^{f}(\vec{N})\} = \mathcal{L}_{1\vec{N}}^{f}(C_{1}^{aNM})$$

and on the co-tetrad and the spatial components of the dynamic connection by

$$\{e_{tN}, D_{sp}^{f}(\vec{N})\} = \mathcal{L}_{\vec{N}}^{f}(\epsilon_{tN}), \{\omega_{1aNM}, D_{sp}^{f}(\vec{N})\} = \mathcal{L}_{1\vec{N}}^{f}(\omega_{1aNM}).$$

The transformations induced by $\mathcal{M}^{f}(\theta)$ on the primary constraints are given by

$$\{\pi^{tN}, \mathcal{M}^{f}(\theta)\} = \theta_{tN}^{L}\pi^{tL}, \{C_{1}^{aNM}, \mathcal{M}^{f}(\theta)\} = \theta_{1L}^{N}C_{1}^{aLM} + \theta_{1L}^{M}C_{1}^{aNL}.$$
and on the co-tetrad and the spatial components of the dynamic connection by

\[ \{ e_{\mu N}, \mathcal{M}^I(\theta) \} = \theta_{N}^L e_{\mu L}, \quad \{ \omega_{1aNM}, \mathcal{M}^I(\theta) \} = -D_{1a} \theta_{NM} \]

where \( \theta_{KL} \) are subject to the condition (50).

The above transformations show that the Poisson brackets of \( \mathcal{D}^f_{sp}(\vec{N}) \) and \( \mathcal{M}^f(\theta) \) with the primary constraints vanish weakly. Like in the previous section, \( D^f_t \) and \( M^f_{NM} \) are transformed as scalar densities of weight one by the diffeomorphisms

\[ \{ D^f_{sp}(\vec{N}), D^f_t(M) \} = D^f_t(L_{\vec{N}}^L M), \quad \{ \mathcal{D}^f_{sp}(\vec{N}), \mathcal{M}(\theta) \} = \mathcal{M}^f(L_{\vec{N}}^L (\theta)). \]  

(57)

\( D^f_t \) is transformed under \( M^f_{NM} \) as a scalar

\[ \{ \mathcal{M}^f(\theta), D^f_t(M) \} = 0 \]  

(58)

and \( M^f_{NM} \) as a tensor

\[ \{ M_{KL}^f, M^f(\theta) \} = \theta^K_N M^L^{IN} + \theta^L_N M^K^{KN} \]

from which we deduce the \( so(1, d-1) \) Lie algebra for the generators \( M_{KL}^f \).

The Poisson bracket of \( D^f_t \) with \( \pi^a_N(\vec{x}) \) gives

\[ \left\{ \pi^a_N(\vec{x}), D^f_t(\vec{y}) \right\} = -\frac{1}{2} C^a_{KL}(\vec{y}) \frac{\delta}{\delta e_{aNM}(\vec{x})} (B_b M_{KeL} M_{bMcPdQ}(\vec{y})) \frac{\Omega_{edPQ}(\vec{y})}{2} \approx 0 \]

and with \( C^a_{NM}(\vec{x}) \) gives

\[ \left\{ C^a_{NM}(\vec{x}), D^f_t(\vec{y}) \right\} = \begin{align*} D^a_{1b}(e A^{bNaM}) + e B^{bNQaM} D^a_{bQ} e_{Q} &+ D^a_{1c}(C^d_{KL} B_{bN1KdL} M_{bNcNaM}) \\ &= P^a_{1KdL N} (e B^{cNQ} M_{dL} D^a_{bQ} e_{Q}) &+ D^a_{1c}(C^d_{KL} B_{bN1KdL} M_{bNcNaM}) \\ &- B_{eP1KdL} B^{eN1NaM} M^{KL} \end{align*} \]

which show that the constraint \( D^f_t \) commutes weakly, in terms of Poisson brackets, with the primary constraints \( \pi^a_N \) and \( C^a_{KL} \). Finally, from a direct calculation we get
\[ \{ D_f^I(M), D_f^I(M') \} = 0 \] (59)

which shows that the Hamiltonian treatment is coherent and the algebra of the first-class constraints \( M_f(\theta), D_f sp(-\vec{N}) \) and \( D_f^I(M) \) closes with structure constants. The function \( M \) and the vector field \( -\vec{N} \) may be identified with the usual lapse and shift respectively although they do not result from the A.D.M. formalism.

In addition of the first-class constraints \( M_f(\theta), D_f^I(-\vec{N}) \) and \( D_f^I(M) \), we have the first-class constraints \( \pi^{tN} \) and \( P^{tKL} \) and the second-class constraints \( \pi^{aN} \) and \( C^{aNM}_1 \). The physical degrees of freedom per point in space-time are obtained by subtracting from the \( d(5d-3) \) degrees of freedom of the fixed phase space the number \( 2d(d-1) \) of the second-class constraints and twice the number \( d(d+1) \) of the first-class constraints to get \( d(d-3) \) which is exactly the number of the degrees of freedom of the physical phase space of the d-dimensional general relativity.

Remark: in order to avoid the constraint (34), one might wonder what happen if instead of fixing the non dynamic part of the connection to zero one solve its equation of motion and then put the solution back into the action as in [18]. Since the decomposition of the connection in dynamic and non-dynamic part is unique, the part of solution of the zero-torsion [19] which corresponds to \( \omega^{2aKL} \) must be of the form

\[ \omega^{2aKL} = P_{2aKL}^{bPQ} \epsilon^{\mu P} \nabla_{\mu} e_{Q}^{\nu} = P_{2aKL}^{bPQ} \epsilon^{\mu P}(\partial_{b} e^{\mu}_{Q} + \Gamma^{\mu}_{b\nu} e^{\nu}_{Q}) \]

where \( \nabla_{a} e^{\mu}_{M} = \partial_{a} e^{\mu}_{M} + \Gamma^{\mu}_{a\nu} e^{\nu}_{M} \) is the covariant derivative with respect to Christoffel's symbol \( \Gamma^{\mu}_{a\nu} \) whose expression contains linearly the derivatives of the components of the co-tetrad. an explicit computation shows that \( \omega^{2aKL} \) contains linearly only the time derivatives of the spatial components of the co-tetrad. This leaves \( \pi^{tN} \) as a primary constraint but not \( \pi^{aN} \) which takes the form

\[ \pi^{aN} = (D_{b}^{\omega_{a}}e^{bKaN} + \omega_{2b}^{K}e^{bMaL} + \omega_{2b}^{L}e^{bMaK}) \frac{\delta \omega^{2aKL}}{\delta \partial_{t} e_{aN}} \]

where \( \frac{\delta \omega^{2aKL}}{\delta \partial_{t} e_{aN}} = (P_{2aKL}^{bPQ} \epsilon^{P}_{\mu} \frac{\delta}{\delta \partial_{t} e^{\mu}_{Q}}(\Gamma^{\mu}_{a\nu}) e_{Q}^{\nu}) \) is not null. The linear dependence of \( \pi^{aN} \) with respect to the time derivative of the spatial components of the co-tetrad leads to a second order formalism.

4 The algebra of constraints in terms of Dirac
In the previous section we have showed that the set of constraints is complete and closed meaning that the total Hamiltonian $H_T^f$ is consistent. In this section we consider the second-class constraints $\pi^{aN}$ and $C_{1}^{aKL}$ as strong equalities by eliminating them. In this case the algebra of the first-class constraints must be computed with the projected Dirac brackets defined in terms of the Poisson brackets of the previous section as

$$\{A, B\}_D = \{A, B\}_1 - \{A, C_i\}_1 \{C_i, C_j\}_1^{-1} \{C_j, B\}_1$$

where $C_i = (\pi^{aN}, C_{1}^{aKL})$. The inverse of the Poisson bracket

$$\left\{\pi^{bN}(\vec{x}), C_{1}^{aKL}(\vec{y})\right\}_1 \simeq eB^{bNaKl}\delta(\vec{x} - \vec{y})$$

is given by $\left\{\pi^{bN}, C_{1}^{aKL}\right\}_1^{-1} = e^{-1} B_{bNaKl}$ satisfying

$$\left\{\pi^{bN}, C_{1}^{aKL}\right\}_1^{-1} \left\{C_{1}^{aKL}, \pi^{cM}\right\}_1 = \delta_{b}^{c} \delta_{M}^{N}$$

and

$$\left\{C_{1}^{aKL}, \pi^{bN}\right\}_1^{-1} \left\{\pi^{bN}, C_{1}^{dPQ}\right\}_1 = P_{1Kl} P_{dQ}.$$

Now we can consider the constraints of second-class $\pi^{bN}$ and $C_{1}^{aKL}$ as strong equalities by eliminating them from the total Hamiltonian $H_T'$ to get the reduced Hamiltonian

$$H_T' = \int_{\Sigma} \left( \pi^{tN} \Lambda_{tN} + \mathcal{P}_{tKL} \mathcal{A}_{tKL} - D_{t}^{r} - \frac{M_{rKL}}{2} \frac{\omega_{1KL}}{2} \right)$$

where

$$M_{rKL} = (\pi^{tK} \epsilon_{tL} - \pi^{tL} \epsilon_{tK}) + 2 D_{a}^{\omega_{1}} (eA_{aKL})$$

and

$$D_{t}^{r} = -eA_{aKl} \Omega_{(\omega_{1})abKL}. \ (61)$$

The diffeomorphism constraint reduces to

$$D_{sp}(\vec{N}) = \int_{\Sigma} \left( \pi^{tN} \mathcal{L}_{\vec{N}}(\epsilon_{tN}) + eA^{aKl} \mathcal{L}_{\vec{N}}(\omega_{1aKL}) \right).$$

The Hamiltonian (60) is defined on the reduced phase space $e_{aN}$, $\omega_{1aKL}$, $\epsilon_{tN}$, $\pi^{tK}$, $\omega_{tKL}$, and $\mathcal{P}_{tKL}$ equipped with the following non zero Dirac brackets:
\{e_{tN}(\vec{x}), \pi^M(\vec{y})\}_D = \delta^M_N \delta(\vec{x} - \vec{y}),
\{\omega_{tJ}(\vec{x}), \mathcal{P}^{tKL}(\vec{y})\}_D = \frac{1}{2}(\delta^K_J \delta^L_I - \delta^K_I \delta^L_J)\delta(\vec{x} - \vec{y})

and
\{e_{aN}(\vec{x}), \omega_{1bKL}(\vec{y})\}_D = e^{-1}B_{aNtKbL}\delta(\vec{x} - \vec{y}). \quad (62)

Note that as opposite to the results obtained in [13], the dynamic connection is Dirac self commuting as a consequence of (54).

These projected Dirac brackets guarantee the Jacobi identities. In fact for the non trivial example
\{e_{cN}, \{\omega_{1aKL}, \omega_{1bPQ}\}\}_D + \{\omega_{1bPQ}, \{e_{cN}, \omega_{1aKL}\}\}_D + \{\omega_{1aKL}, \{\omega_{1bPQ}, e_{cN}\}\}_D
the first term vanishes and the second and third term give

\[-P_{1Ka}^{Rds} \frac{\delta}{\delta e_{hI}}(e^{-1}B_{cNtRds}) e^{-1}B_{hItpQ} - P_{1PbQ}^{Rds} \frac{\delta}{\delta e_{hI}}(e^{-1}B_{cNtRds}) e^{-1}B_{hItpQ} + e^{-1}P_{1PbQ}^{Rds} \frac{\delta}{\delta e_{hI}}(B_{cNtRds}) e^{-1}B_{hItpQ}\]

where we have used
\{\omega_{1aKL}, e^{-1}B_{cNtPQ}\}_D = P_{1PbQ}^{Rds} \frac{\delta}{\delta e_{hI}}(e^{-1}B_{cNtRds}) \{\omega_{1aKL}, e_{hI}\}_D

\[= -P_{1PbQ}^{Rds} \frac{\delta}{\delta e_{hI}}(e^{-1}B_{cNtRds}) e^{-1}B_{hItpQ} \]

and \(\frac{\delta}{\delta e_{hI}} e^{-1} = -e^{-1}e^{hI}\). A direct computation leads to

\[+ e^{-1}P_{1PbQ}^{Rds} \frac{\delta}{\delta e_{hI}}(B_{cNtRds}) e^{-1}B_{hItpQ} - P_{1Ka}^{Rds} \frac{\delta}{\delta e_{hI}}(B_{cNtRds}) e^{-1}B_{hItpQ}\]

\[= -e^{hI}e^{-1}B_{cNtKaL} e^{-1}B_{hItpQ} + e^{hI}e^{-1}B_{cNtPbQ} e^{-1}B_{hItpQ}\]

showing that the Jacobi identities are satisfied.

Now we are ready to calculate the algebra of constraints in terms of the projected Dirac brackets. The smeared Lorentz Constraint

\[\mathcal{M}^r(\theta) = \int_\Sigma \left( \left( \pi^L_1 e^L_1 - \pi^L_1 e^K_1 \right) + 2D_\omega \omega e^a_{KL} \right) \frac{\theta_{KL}}{2} = \int_\Sigma M^{rKL} \frac{\theta_{KL}}{2}\]
acts on $e_{\mu N}$ and $\omega_{1aKL}$ like local infinitesimal transformations of gauge

\[
\{e_{\mu N}, \mathcal{M}'(\theta)\}_D = \theta^M_N e_{\mu M}, \quad \{\omega_{1aKL}, \mathcal{M}'(\theta)\}_D = -D_{1a} \theta_{KL}
\]

leading to

\[
\{\mathcal{M}'(\theta), \mathcal{D}_i(M)\}_D = 0
\]

as a consequence of (51) and to

\[
\{M^{rKL}, \mathcal{M}'(\theta)\}_D = \theta^K_M M^{rNL} + \theta^K_N M^{rKN}
\]

from which we get the $\mathfrak{so}(1, d - 1)$ Lie algebra for the generators $M^{rKL}$.

From a direct computation we get for the spatial diffeomorphism constraint

\[
\{\mathcal{D}^r_{sp}\left(\vec{N}\right), \mathcal{D}^r_{sp}\left(\vec{N}'\right)\}_D = \mathcal{D}^r_{sp}\left(\left[\vec{N}, \vec{N}'\right]\right).
\]

The transformations induced by $\mathcal{D}^r_{sp}\left(\vec{N}\right)$ on $e_{\mu N}$ and $\omega_{1aKL}$ are given by

\[
\{e_{\mu N}, \mathcal{D}^r_{sp}\left(\vec{N}\right)\}_D = \mathcal{L}_{\vec{N}}(e_{\mu N}), \quad \{\omega_{1aKL}, \mathcal{D}^r_{sp}\left(\vec{N}\right)\}_D = \mathcal{L}_{\vec{N}}(\omega_{1aKL}).
\]

In view of these transformations we then deduce that $\mathcal{D}^r_i$ and $M^{rKL}$ transform under the spatial diffeomorphisms as scalar densities of weight one leading to

\[
\{\mathcal{D}^r_{sp}\left(\vec{N}\right), \mathcal{D}^r_i(M)\}_D = \mathcal{D}^r_i(\mathcal{L}_{\vec{N}}(M)), \quad \{\mathcal{D}^r_{sp}\left(\vec{N}\right), \mathcal{M}'(\theta)\}_D = \mathcal{M}'(\mathcal{L}_{\vec{N}}(\theta)).
\]

Finally, a direct calculation gives for the smeared scalar constraint

\[
\{\mathcal{D}^r_i(M), \mathcal{D}^r_i(M')\}_D = \left\{\int_\Sigma M e^A e^{aKbL} \frac{\Omega(\omega_1)_{aKL}}{2}, \int_\Sigma M' e^A e^{cNdM} \frac{\Omega(\omega_1)_{cdNM}}{2}\right\}_D
\]

\[
= \int_\Sigma D_a(M e^A e^{aKbL}) M' e^B e^{bQcNdM} e^{-1} B_{h_{KL}} \frac{\Omega(\omega_1)_{cdNM}}{2}
\]

\[
- \int_\Sigma D_c(M' e^A e^{cNdM}) M e^B e^{bQaKbL} e^{-1} B_{h_{KL}} \frac{\Omega(\omega_1)_{abKL}}{2}
\]

\[
= \int_\Sigma M M' D_a(e^{aKbL}) e^B e^{bQcNdM} e^{-1} B_{h_{KL}} \frac{\Omega(\omega_1)_{cdNM}}{2}
\]

\[
- \int_\Sigma M M' D_c(e^{cNdM}) e^B e^{bQaKbL} e^{-1} B_{h_{KL}} \frac{\Omega(\omega_1)_{abKL}}{2}
\]

\[
= 0
\]
where we have used
\[
\int_S \partial_a (M) e^{A^aKbL} B^{bQcNdM} B_{bQKbL} \frac{\Omega(\omega_1)_{cdNM}}{2} = 0
\]
due to \(A^{aKbL} A_{aKcL} = 0\) and \(e_{tQ} B^{bQcNdM} = 0\). The above Dirac brackets between \(D^- sp(N)\), \(M^r(\theta)\) and \(D^r_t(M)\) show that the algebra of the reduced first-class constraints closes with structure constants.

As in the previous section, the degrees of freedom of the physical phase space is \(d(d-3)\) which is exactly the number of the degrees of freedom of the physical phase space of the \(d\)-dimensional general relativity.

In terms of Dirac brackets, the Hamiltonian (60) propagates the phase space variable from an initial hypersurface \(\Sigma_{t_0}\) to the hypersurface \(\Sigma_{t_0 + \delta t}\). In this sense, we can interpret geometrically that the Hamiltonian (60) propagates the hypersurface \(\Sigma_{t_0}\) in the space-time. This propagation is done along the infinitesimal time \(\delta t\) or \(M \delta t\) depending on whether we consider the scalar density \(D^r_t\) or \(D^r_t(M)\) in the Hamilton equation while the Lorentz constraint induces, during this propagation, a gauge transformation of infinitesimal parameter \(\theta_{KL} = \delta t \omega_{tKL}\). The constraint (61) acts independently of (60) and induces diffeomorphisms on each hypersurfaces.

We end this section by solving Hamilton’s equations in terms of Dirac brackets. For the co-tetrad components \(e_{cN}\), we get

\[
\partial_t e_{cN}(x) = \{e_{cN}(x), H_T\}_D = -D^a e^{A^aKbL} e^{-1} B_{cNtKbL} \\
+ e^{A^aKtL} (e^{-1} B_{cNtKaM} \omega^M_{t L} + e^{-1} B_{cNtLaM} \omega^M_{t K}).
\]

The first term of the right hand side gives

\[
-D^a e^{A^aKbL} e^{-1} B_{cNtKbL} = -e^{-1} B_{cNtKbL} e^{B^aMaKbL} D^a e_{\mu M} \\
= D^c e_t e_{\mu M} - e B_{cNtKbL} e^{-1} B^{bMaKbL} D^a e_{\mu M} \\
= D^c e_t e_{\mu M} + e^{-1} B_{cNtKtL} M_{KL}
\]

and a direct computation gives for the second term of the right hand side

\[
e^{A^aKtL} (e^{-1} B_{cNtKaM} \omega^M_{t L} + e^{-1} B_{cNtLaM} \omega^M_{t K}) = -\omega^M_{t N} e_{cM}
\]

leading to

\[
D_t e_{aN} - D^a e_{tN} = B_{cNtKtL} M_{KL}.
\]
Since $\omega_{IKL}$ can be considered as Lagrange multiplier, in addition to the above equation we have

$$B^{dM}a^{KL}D_a\epsilon_dM = D^a\left(e^{A_KL}\right) = M^{KL} = 0$$

leading

$$D_t\epsilon_{aN} - D^a\left(e^{A_KL}\right) = 0.$$

The solutions of $D^a\left(e^{A_KL}\right) = M^{KL} = 0$ are $\omega_{aN} = e_{MN}\nabla_d\epsilon^M = e_{MN}\left(\partial_d\epsilon^M + \Gamma_{MN}^{d}\epsilon^M\right)$. The solution $\omega_{aN}$ is injected in the second equation to get

$$D_t\epsilon_{aN} - D^a\epsilon_{tN} = \partial_t\epsilon_{aN} + \omega_{tNM}\epsilon^M - \partial_a\epsilon_{tN} - \omega_{aNM}\epsilon^M$$

$$= \partial_t\epsilon_{aN} + \omega_{tNM}\epsilon^M - \partial_a\epsilon_{tN} + \nabla_a\epsilon_{MN}\epsilon^M$$

leading to $\omega_{tNM} = e_{MN}\nabla_d\epsilon^M = e_{MN}\left(\partial_d\epsilon^M + \Gamma_{MN}^{d}\epsilon^M\right)$ [19] which exhibits solutions of the zero torsion, condition to have an equivalence between the tetrad-connection gravity and the general relativity.

5 Conclusion

The results presented in this paper show that a modified action of the tetrad-gravity where the non-dynamic connection $\omega_{2aKL}$ is fixed to zero makes possible the construction of a consistent Hamiltonian formulation for any dimension $d \geq 3$ without Barbero-Immirzi’s parameter neither the A.D.M. decomposition of the action.

Unlike the works where the ADM decomposition of action is taken as starting point leading to a Hamiltonian system where the algebra of the first-class constraints closes with structure functions we have showed that, by starting from a phase space without using the A.D.M. decomposition, we get a coherent Hamiltonian formalism with an algebra of the first-class constraints which closes with structure constants. This algebra expresses the invariance of the action under a true Lie group whose generators are the first class constraints.

The absence of structure functions is due to the fact that the scalar function $M$ and the spatial vector field $\vec{N}$ are introduced as test functions independently of the co-tetrad not as objects which result from the A.D.M. decomposition of the tangent space where the pure deformation of the space-like hypersurface, expressed in term of the lapse, requires for its definition the metric of space-time which appears in the structure functions [20]. It was
shown in [21] that it is possible to obtain an algebra of the diffeomorphism constraints which closes with structure constants by considering the general transformations of the coordinates which depend on the metric.

In [16] the simplicity constraint, which corresponds to the primary constraint $C_{aKL}$ of the section 2, is split into boost and non-boost part while in our case the decomposed is done by the projectors like $C_{aKL} = C_{aKL}^1 + C_{aKL}^2$ where $C_{aKL}^1$ is the primary constraint of the section 3 and $C_{aKL}^2 = P_{aKL}$ is the conjugate momenta of the non-dynamic part of the connection which is a primary constraint whose the consistency condition is (34). The fixing in the action of the non-dynamic part of connection to zero allowed us to eliminate the constraint (34) to get a coherent Hamiltonian formalism.

Note that all reduced first-class constraints are polynomial but the phase space variables obey a non polynomial Dirac bracket because of the presence of $e^{-1}$ (62). Since the rank of the projector $P_{1NcM}^K = d(d-1)$, the number of the independents components of the dynamic connection is equal to the ones of the co-tetrad $e_{aK}$. This allows us to perform an invertible transformation

$$\omega_{1aKL} \longrightarrow P^{bN} = eB^{bNtKL} \omega_{1aKL} \Longleftrightarrow \omega_{1aKL} = P^{bN} e^{-1} B_{bNtKL}$$

to get a reduced phase space obeying the following canonical commutation relations in terms of Dirac brackets

$$\{e_{aN}(\vec{x}), P^{bM}(\vec{y})\}_{D} = \delta_{a}^{b} \delta_{N}^{M} \delta(\vec{x} - \vec{y}),$$

$$\{e_{aN}(\vec{x}), e_{bM}(\vec{y})\}_{D} = 0 \text{ and } \{P^{aN}(\vec{x}), P^{bM}(\vec{y})\}_{D} = 0. \quad (63)$$

Substituting $\omega_{1aKL}$ by $P^{bN} e^{-1} B_{bNtKL}$, we get polynomial constraints for

$$M_{rKL} = \partial_{a} eA_{aKL} + \frac{1}{2}(P^{aK} e_{a}^{L} - P^{aL} e_{a}^{K})$$

and

$$D_{r}^{p} (\vec{N}) = \int_{\Sigma} (\pi^{tN} L_{N}^{N}(e_{tN}) + P^{aN} L_{N}^{N}(e_{aN}))$$

whereas the scalar constraint becomes non-polynomial because of the quadratic term of the dynamic connection $\omega_{1aKL}(e, P) = P^{bN} e^{-1} B_{bNtKL}$ in the curvature $\Omega(\omega_{1})_{abKL}$. From the same calculation done in section 4 to check the Jacobi identities we deduce

$$\{\omega_{1aKL}, \omega_{1dPQ}\}_{D} = \{P^{bN} e^{-1} B_{bNtKL}, P^{cM} e^{-1} B_{cMtPdQ}\}_{D} = 0$$

conducting, with the use of (63), to the same algebra of first class constraints of the previous section. A similar approach with the same phase space was
adopted in [18] where the connection is decomposed in dynamic and non-dynamic part and where the latter is replaced by the solution of its equation of motion. If the algebra of the Lorentz constraints is explicitly computed, because they depend only on the dynamic part of the connection, the computation of the bracket between the translation constraints raises problems because of the reasons given in the remark of the section 3.

In three dimension $eB^{bNaKcL}$ vanishes, as a result of the antisymmetry of the spacial indices $b, a$ and $c$, implying that the projected connection $\omega_{2aKL}$ disappears in the same way. All the previous results are valid in the three dimensional case. In addition, the first class constraint $P^N$ can be retained instead of $D_t(M)$ and $D_{sp}(\vec{N})$. $P^N$ and $M^{KL}$ obey the following Dirac bracket

$$\{M^{NM}(\vec{x}), M^{KL}(\vec{y})\}_D = (\eta^{NL} M^{MK}(\vec{x}) + \eta^{MK} M^{NL}(\vec{x}) - \eta^{NK} M^{ML}(\vec{x}) - \eta^{ML} M^{NK}(\vec{x})) \delta(\vec{x} - \vec{y})$$

and

$$\{P^N(\vec{x}), M^{KL}(\vec{y})\}_D = (\eta^{NL} P^K(\vec{x}) - \eta^{NK} P^L(\vec{y})) \delta(\vec{x} - \vec{y})$$

which exhibit the Lie algebra of the Poincaré group, where $\delta t e^l_N$ plays the role of the infinitesimal local translation. This shows that, in the three dimensional case, we can either consider the Poincaré group or the Lorentz and diffeomorphism group. The physical degrees of freedom vanish, expressing the topological character of the $d = 3$ gravity.

We end this paper by noticing that, as opposed to [22] where it is claimed that diffeomorphism invariance is not a gauge symmetry derived from the first-class constraints of the tetrad-gravity or in [23] where the equivalence between the translation transformations of Poincaré group and the diffeomorphism can only be established on-shell. In this paper, we have shown that the symmetries of the Hamiltonian formalism of three dimensional tetrad-connection gravity are obtained either through the first-class constraints of Poincaré group or the ones of Lorentz and diffeomorphisms which show that this equivalence is established off-shell.

For $d \geq 4$, the smeared first-class constraint $P^N$ can be written as a sum of first-class constraints

$$P(N) = \int N_N e^{BtNaKbL} \frac{\Omega_{abKL}}{2} = -D_t(N) + D_{sp}(\vec{N}) + M^r(\theta)$$
where \( D_{sp}(\vec{N}) = \int_{\Sigma} e^{AaKtL} \mathcal{L}_{\vec{N}}(\omega_{1aKL}), \mathcal{M}(\theta) = \int_{\Sigma} D_{a}^{\omega_1} e^{AaKtL} \theta_{KL} \), \( N \) is a Lorentzian vector, \( N = N_{N}e^{tN} \), \( \theta_{KL} = N_{N}e^{aN} \omega_{aKL} \) and \( N_{N}e^{aN} \) are the \( d-1 \) components of the vector \( \vec{N} \) tangent to \( \Sigma \). The Dirac bracket between the smeared translation constraints does not vanish but gives a sum of which a part is linear in the first-class constraints with structure functions and the other quadratic. The quadratic part results from the fact that the functions \( N, \vec{N} \) and \( \theta_{KL} \) depend on the components of the tetrad and thus contribute to the results of Dirac’s bracket. This shows that \( P^{N} \) does not satisfy (66) and therefore does not correspond to the translational part of the Lie algebra of the Poincaré group. Only the Lorentz group and the diffeomorphisms are symmetries, not the translation part of the Poincaré group, contrary to what is claimed in [24].
