#### Abstract

A small improvement in the structure of the material could save the manufactory a lot of money. The free material design can be formulated as an optimization problem. However, due to its large scale, secondorder methods cannot solve the free material design problem in reasonable size. We formulate the free material optimization (FMO) problem into a saddle-point form in which the inverse of the stiffness matrix $A(E)$ in the constraint is eliminated. The size of $A(E)$ is generally large, denoted as $N \times N$. This is the first formulation of FMO without $A(E)^{-1}$. We apply the primal-dual subgradient method [17] to solve the restricted saddle-point formula. This is the first gradient-type method for FMO. Each iteration of our algorithm takes a total of $\mathcal{O}\left(N^{2}\right)$ floating-point operations and an auxiliary vector storage of size $\mathcal{O}(N)$, compared with formulations having the inverse of $A(E)$ which requires $\mathcal{O}\left(N^{3}\right)$ arithmetic operations and an auxiliary vector storage of size $\mathcal{O}\left(N^{2}\right)$. To solve the problem, we developed a closed-form solution to a semidefinite least squares problem and an efficient parameter update scheme for the gradient method, which are included in the appendix. We also approximate a solution to the bounded Lagrangian dual problem. The problem is decomposed into small problems each only having an unknown of $k \times k$ ( $k=3$ or 6) matrix, and can be solved in parallel. The iteration bound of our algorithm is optimal for general subgradient scheme. Finally we present promising numerical results.

## 1 Introduction

The approach of Free Material Optimization (FMO) optimizes the material structure while the distribution of material and the material itself can be freely varied. FMO has been used to improve the overall material arrangement in air frame design (wWW.plato-n.org). The fundamentals of FMO were introduced in 3, 19 . And the model was further developed in [2, 24] etc. In the model, the elastic body of the material under consideration is represented as a bounded domain with a Lipschitzian boundary in a two- or three-dimensional Euclidean space depending on the design requirement. For computational purpose, the domain is discretized into $m$ finite elements: $\Omega=\left(\Omega_{1}, \ldots, \Omega_{m}\right)$ so that all the points in the same element are considered to have the same property.

Let $u(x)$ denote the displacement vector of the body at point $x$ under load. Denote the (small-)strain tensor as:

$$
e_{i j}(u(x)) \stackrel{\text { def }}{=} \frac{1}{2}\left(\frac{\partial u(x)_{i}}{\partial x_{j}}+\frac{\partial u(x)_{j}}{\partial x_{i}}\right) .
$$

Let $\sigma_{i j}(x)(i, j=1, \ldots, 3)$ denote the stress tensor. The system is assumed to follow the Hooke's law-the stress is a linear function of the strain:

$$
\sigma_{i j}(x)=E_{i j k l}(x) e_{k l}(u(x)) \quad(\text { in tensor notation })
$$

[^0]where $E$ is the (plain-stress) elasticity tensor of order 4 , which maps the strain to the stress tensor. The matrix $E$ measures the degree of deformation of a material under external loads and is a symmetric positive semidefinite matrix of order 3 for the 2-dimensional and of order 6 for the 3 -dimensional material design problem. The diagonal elements of $E(x)$ measure the stiffness of the material at $x$ in the coordinate directions. Hence the trace of $E$ is used to measure the cost (resource used) of a material in the model.

Denote by $I_{k}$ the identity matrix of order $k$ and $S_{k}^{+m}$ the direct product of $m$ cones of symmetric positive semidefinite $k \times k$-matrices:

$$
S_{k}^{+m}=\underbrace{S_{k}^{+} \times \cdots \times S_{k}^{+}}_{m \text { times }}
$$

For a $k \times k$ symmetric matrix $M$, let $M \succeq 0$ denote $M \in S_{k}^{+}$.
Let $E_{i}$ denote the elasticity tensor of order 4 for the $i$ th element $\Omega_{i}$ : The $E_{i}$ 's are considered to be constant on each $\Omega_{i}$ but can be different for different $\Omega_{i}$ 's and are the design variables of the FMO model:

$$
E=\left(E_{1}, \ldots, E_{m}\right), \quad E_{i} \succeq 0, i=1, \ldots, m
$$

The design problem is to find a structure that is low 'cost' (the tensor $E$ having small trace) and is stable under given multiple independent loads (forces). There are some different formulas of the FMO problem depending on the design needs. This paper focuses on the minimum-cost FMO problem which is to design a material structure that can withstand a whole given set of loads in the worst-case scenario and the trace of $E$ is minimal. Below we describe the model based on [11].

The "cost"-stiffness of the material-is measured by the trace of $E: \operatorname{tr}(E)=\sum_{i=1}^{m} \operatorname{tr}\left(E_{i}\right)=\left\langle I_{k}, E\right\rangle$. For each $i \in\{1, \ldots, m\}, \operatorname{tr}\left(E_{i}\right)$ is lower bounded to avoid singularity in the FMO model. The constraints for the point-wise stiffness upper and lower bounds are:

$$
\operatorname{tr} E_{i} \leq \rho_{u}^{(i)}, \quad \operatorname{tr} E \geq \rho_{L}^{(i)}
$$

From the engineering literature the dynamic stiffness of a structure can be improved by raising its fundamental eigenfrequency. Thus we have a lower bound on its eigen values:

$$
\lambda_{\min }(E) \geq r
$$

Let $n$ be the number of nodes (vertices of the elements). Let nig denote the number of Gauss integration points in each element. In every element, the displacement vector $u(x)$ is approximated as a continuous function which is linear in every coordinate:

$$
u(x)=\sum_{i=1}^{n} u_{i} \vartheta_{i}(x)
$$

where $u_{i}$ is the value of $u$ at the $i$ th node, and $\vartheta_{i}$ is the basis function associated with the $i$ th node. For $\vartheta_{j}$, define matrices

$$
\hat{B}_{j} \stackrel{\text { def }}{=}\left(\begin{array}{cc}
\frac{\partial \vartheta_{j}}{\partial x_{1}} & 0 \\
0 & \frac{\partial \vartheta_{j}}{\partial x_{2}} \\
\frac{1}{2} \frac{\partial \vartheta_{j}}{\partial x_{2}} & \frac{1}{2} \frac{\partial \vartheta_{j}}{\partial x_{1}}
\end{array}\right) \text { (for 2-dimension), } \quad \hat{B}_{j} \stackrel{\text { def }}{=}\left(\begin{array}{ccc}
\frac{\partial \vartheta_{j}}{\partial x_{1}} & 0 & 0 \\
0 & \frac{\partial \vartheta_{j}}{\partial x_{2}} & 0 \\
0 & 0 & \frac{\partial \vartheta_{j}}{\partial x_{3}} \\
\frac{1}{2} \frac{\partial \vartheta_{j}}{\partial x_{2}} & \frac{1}{2} \frac{\partial \vartheta_{j}}{\partial x_{1}} & 0 \\
0 & \frac{1}{2} \frac{\partial \vartheta_{j}}{\partial x_{3}} & \frac{1}{2} \frac{\partial \vartheta_{j}}{\partial x_{2}} \\
\frac{1}{2} \frac{\partial \vartheta_{j}}{\partial x_{3}} & 0 & \frac{1}{2} \frac{\partial \vartheta_{j}}{\partial x_{1}}
\end{array}\right) \text { (for 3-dimension). }
$$

For $\Omega_{i}$, let $B_{i, k}$ be the block matrix whose $j$ th block is $\hat{B}_{j}$ evaluated at the $k$ th integration point and zero otherwise. The full dimension of $B_{i, k}$ is $3 \times 2 n$ for the 2 -dimensional case and $6 \times 3 n$ for the 3 -dimensional case.

Let $A(E)$ denote the stiffness matrix relating the forces to the displacements; Let $A_{i} \in \mathbb{R}^{N \times N}$ denote the element stiffness matrices:

$$
A(E) \stackrel{\text { def }}{=} \sum_{i=1}^{m} A_{i}(E), \quad A_{i}(E)=\sum_{k=1}^{n i g} B_{i, k}^{\top} E_{i} B_{i, k}
$$

Since the material obeys Hooke's law, forces (loads) on each element, denoted as $f_{j}(j=1, \ldots L)$, are linearly related to the displacement vector:

$$
\begin{equation*}
f_{j}=A(E) u \quad j=1, \ldots L \tag{1}
\end{equation*}
$$

The system is in equilibrium for $u$ if outer and inner forces balance each other. The equilibrium is measured by the compliances of the system: the less the compliance, the more rigid the structure with respect to the loads. The compliance can be represented as:

$$
f_{j}^{\top} u
$$

In the minimum-cost FMO model, an upper bound $\gamma>0$ is imposed on the compliances. Further in view of equation (1), we have

$$
\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle \leq \gamma, \quad j=1, \ldots L
$$

In summary, with given loads $f_{j},(j=1, \ldots L)$, imposed upper and lower bounds $\rho_{l}^{(i)}$ and $\rho_{u}^{(i)}(i=1, \ldots m)$, $r$, and compliance upper bound $\gamma$, the minimum-cost multiple-load material design problem is the following:

$$
\begin{align*}
\min _{E \in S_{k}^{+m}} & \sum_{i=1}^{m}\left\langle I_{k}, E_{i}\right\rangle \\
\text { s.t. } & \rho_{l}^{(i)} \leq\left\langle I_{k}, E_{i}\right\rangle \leq \rho_{u}^{(i)}, i=1, \ldots, m  \tag{2}\\
& \left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle \leq \gamma, j=1, \ldots, L \\
& \lambda_{\min }(E) \geq r .
\end{align*}
$$

Some optimization approaches have been applied to FMO; for instance, Zowe et al. [24] formulate the multipleload FOM as a max-min convex program. They propose penalty/barrier multiplier methods and interior-point methods for the problem. Ben-Tal et al. [2] consider bounded trace minimum compliance multiple-load FMO problem. They formulate the problem as a semidefinite program and solve the problem by an interiorpoint method. Stingl et al. [21] solve the minimum compliance multiple-load FMO problem by a sequential semidefinite programming algorithm. Weldeyesus and Stolpe [22] propose a primal-dual interior point method to several equivalent FMO formulations. Stingl et al. [20] study minimum compliance single-load FMO problem with vibration constraint and propose an approach to the problem based on nonlinear semidefinite low-rank approximation of the semidefinite dual. Haslinger et al. [8] extend the original problem statement by a class of generic constraints. Czarnecki and Lewinski [5] deal with minimization of the weighted sum of compliances related to the non-simultaneously applied load cases. All of them are second-order methods. To our knowledge, no first-order methods have been employed to FMO.

Second-order methods exploit the information of Hessians in addition to gradients and function values. Thus, compared with first-order methods, second-order methods generally converge faster and are more accurate; on the other hand, first-order methods don't require formulation, storage, and inverse of Hessian and thus can be applied to large-scale problems. For certain structured problems with bounded simple feasible sets, Nesterov [13] showed that the complexity of fast gradient methods is one magnitude lower than the theoretical lower complexity bound of the gradient-type method for the black-box oracle model. After that work, there appears quite a lot of papers on fast gradient-type methods, such as [12, 17, 16, 18, 14, 6, 4, 15, 23,

However, not every real-world problem is suitable for second-order methods or fast gradient-type methods; for instance, when the structure of the problem is too complex to apply the interior-point method or the smoothing technique to. The minimum weight FMO model (2) is such a case. For the model, although the matrices $B_{i, l}$ are sparse, $A(E)$ is generally not. The number $m$ is at least thousands; and $n$ is smaller than $m$ only by a constant factor. To roughly measure the amount of work per iteration, we use flops, i.e. floating point operations, such as arithmetic operations $\left(+,-, *, /, \sqrt{\cdot}, \frac{1}{4}\right)$, comparisons and exchanges. It takes a vector of length $\frac{N(N+1)}{2}$ to store the matrix $A(E)$ or its Cholesky factor in the memory, and about $\left[\left(k+\frac{1}{2}\right) n i g \cdot m N^{2}+\frac{1}{2} N^{3}\right]$ flops to evaluate $\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle$. Hence, it is difficult to manage model (2)) of reasonable size by second-order methods, since second-order methods work on the Hessian of the problem whose size is at least the square of total variables. And the variables of model (2) are $m$ matrices of size $k \times k$. In addition, the constraints of model (2) are not simple, which prevents us from applying usual gradient-project type methods to it, because it is not easy to project onto its feasible set.

In this paper, we reformulate model (2) into a saddle-point problem and apply the primal-dual subgradient method [17] to the saddle-point problem. The advantage of our formulation is that the inverse or the Cholesky factorization of $A(E)$ doesn't need to be calculated; thus reduce the computational cost of each iteration to just $\mathcal{O}\left(N^{2}\right)$.

The traditional subgradient method for minimizing a nonsmooth convex function $F$ over the Euclidean space employs a pre-chosen sequence of steps $\left\{\lambda_{k}\right\}_{k=0}^{\infty}$ which satisfies the divergent-series rule:

$$
\lambda_{k}>0, \quad \lambda_{k} \rightarrow 0, \quad \sum_{k=0}^{\infty} \lambda_{k}=\infty .
$$

The iterates are generated as follows:

$$
g_{k} \in \partial F\left(x_{k}\right), \quad x_{k+1}=x_{k}-\lambda_{k} g_{k}, \quad k \geq 0 .
$$

In the traditional subgradient method, new subgradients enter the model with decreasing weights, which contradicts to the general principle of iterative scheme - new information is more important than the old one. But the vanishing of steps is necessary for the convergence of the iterates $\left\{x_{k}\right\}_{k=0}^{\infty}$.

The primal-dual subgradient method 17 associates the primal minimization sequence with a master process in the dual space; it doesn't have the drawback of diminishing step sizes in the dual space; the method is proven to be optimal for saddle-point problems, nonsmooth convex minimization, minimax problems, variational inequalities, and stochastic optimization. Let $\mathcal{E}$ be a finite dimensional real vector space equipped with a norm $\|\cdot\|$. Let $\mathcal{E}^{*}$ be its dual. Let $Q \in \mathcal{E}$ be a closed convex set. Let $d(x)$ be a prox-function of $Q$ with convexity parameter $\sigma \geq 0: \forall x, y \in Q, \forall \alpha \in[0,1]$ :

$$
d(\alpha x+(1-\alpha) y) \leq \alpha d(x)+(1-\alpha) d(y)-\frac{1}{2} \sigma \alpha(1-\alpha)\|x-y\|^{2} .
$$

Let $\mathcal{G}$ be a function mapping $\mathcal{E}$ to $\mathcal{E}^{*}$. For instance, for the convex minimization problem, the function $\mathcal{G}$ can be a subgradient of the objective function. The generic scheme of dual averaging (DA-scheme) [17] works as below:

Initialization: Set $s_{0}=0 \in \mathcal{E}^{*}$. Choose $\beta_{0}>0$.
Iteration ( $k \geq 0$ ):

1. Compute $g_{k}=\mathcal{G}\left(x_{k}\right)$.
2. Choose $\lambda_{k}>0$. Set $s_{k+1}=s_{k}+\lambda_{k} g_{k}$.
3. Choose $\beta_{k+1} \geq \beta_{k}$. Set $x_{k+1}=\arg \min _{x \in Q}\left\{\left\langle s_{k+1}, x\right\rangle+\beta_{k+1} d(x)\right\}$.

Let

$$
\hat{\beta}_{0}=\hat{\beta}_{1}, \quad \hat{\beta}_{i+1}=\hat{\beta}_{i}+\frac{1}{\hat{\beta}_{i}}, \quad i \geq 1 .
$$

The scheme has two main variants: simple averages where $\lambda_{k}=1$ and $\beta_{k}=\gamma \hat{\beta}_{k}$ with constant $\gamma>0$, and weighted averages where $\lambda_{k}=1 /\left\|g_{k}\right\|_{*}$ and $\beta_{k}=\frac{\hat{\beta}_{k}}{\rho \sqrt{\sigma}}$ with constant $\rho>0$.

There are some other gradient methods for saddle-point problems. In [4, Chambolle and Pock study a first-order primal-dual algorithm for a class of saddle-point problems in two finite-dimensional real vector spaces $\mathcal{E}$ and $\mathcal{V}$ :

$$
\min _{x \in \mathcal{E}} \max _{y \in \mathcal{V}}\langle K x, y\rangle+G(x)-T^{*}(y),
$$

where $K: \mathcal{E} \rightarrow \mathcal{V}$ is a linear operator, and $G$ and $T^{*}$ are proper convex, lower-semicontinuous functions. That algorithm, as well as the classical Arrow-Hurwicz method [1] and its variants for saddle-point problems, is not applicable to our FMO formulation, because in our formulation the function between two spaces is nonlinear. Nemirovski's prox-method [12] reduces the problem of approximating a saddle-point of a $C^{1,1}$ function to that of solving the associated variational inequality by a prox-method. The approach is not applicable to our FMO formulation, because the structure of our FMO formulation is not simple enough and its objective function is not in $C^{1,1}$.

In our approach, the inverse of $A(E)$ in model (2) doesn't need to be calculated, which decreases computational cost per iteration by one magnitude. Solutions of the primal and dual subproblems at each iteration can be written in closed-form. Each iteration takes roughly ( $6 k \cdot n i g \cdot L$ ) $m N$ flops. And the auxiliary storage space is linear in $N$. Furthermore, since the primal subproblem is decoupled into $m$ small problems that can
be solved in parallel. And each small problem can be solved in approximately $\left(10 k^{3}\right)$ flops. Thus, it is possible to work on large-scale problems, compared with second-order methods dealing with the Hessian of 6 m or 21 m variables plus additional constraints on the $m$ matrices. To prove the efficiency of the algorithm, we give iteration complexity bounds of our algorithm, which includes simple dual averaging and weighted dual averaging schemes. The complexity bounds are optimal for the general subgradient methods. Numerical experiments are described at the end of the paper.

The remainder of the paper is organized as follows. In Section 2, we give our saddle-point form of the problem. In Section 3, we show that a solution to our bounded Lagrangian form either solves the original problem or gives an approximate solution of the original problem. In Section 4 we present our algorithm. In Section 5] we give closed-form solutions to the subproblems. In Section 6, we derive complexity bounds of our algorithm. In section 8, we present some computational examples of our algorithm. In Section 7, we describe and analyze a penalized lagrangian approach. In the Appendixes, we give a closed-form solution of a related matrix projection problem and an update scheme for the parameters of the algorithm.

## 2 Saddle-Point Formulation

We first rewrite problem (2) in a saddle-point form. Denote

$$
\begin{equation*}
Q_{k}^{(i)} \stackrel{\text { def }}{=}\left\{U \in S_{k}: \lambda_{\min }(U) \geq r, \rho_{l}^{(i)} \leq\left\langle I_{k}, U\right\rangle \leq \rho_{u}^{(i)}\right\} \tag{3}
\end{equation*}
$$

The second group of constraints in (2) can be represented in max form:

$$
\gamma \geq\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle=\max _{y_{j} \in \mathbb{R}^{N}}\left\{2\left\langle f_{j}, y_{j}\right\rangle-\left\langle A(E) y_{j}, y_{j}\right\rangle\right\}
$$

Assume that problem (2) satisfies some constraint qualifications, such as the Slater condition-there exists $\hat{E}$ such that $\left\langle A(\hat{E})^{-1} f_{j}, f_{j}\right\rangle<\gamma$ for $j=1, \ldots L$. Then a Lagrangian multiplier exists; and we can solve the Lagrangian of problem (2) instead. Thus, problem (2) can be written as follows:

$$
\begin{gathered}
\min _{\substack{E_{i} \in Q_{k}^{(i)} \\
k=1, \ldots, m}} \max _{\substack{y_{j} \in \mathbb{R}^{N}, \lambda_{j} \geq 0 \\
j=1, \ldots, L}}\left\{\sum_{i=1}^{m}\left\langle I_{k}, E_{i}\right\rangle+\sum_{j=1}^{L} \lambda_{j} \cdot\left[2\left\langle f_{j}, y_{j}\right\rangle-\left\langle A(E) y_{j}, y_{j}\right\rangle-\gamma\right]\right\} \\
\lambda_{j} y_{j} \rightarrow x_{j} \\
=\min _{\substack{E_{i} \in Q_{k}^{(i)} \\
k=1, \ldots, m}}\left\{\sum_{i=1}^{m}\left\langle I_{k}, E_{i}\right\rangle+\max \left(0, \max _{\substack{x_{j} \in \mathbb{R}^{N}, \lambda_{j}>0 \\
j=1, \ldots, L}} \sum_{j=1}^{L}\left[2\left\langle f_{j}, x_{j}\right\rangle-\frac{1}{\lambda_{j}}\left\langle A(E) x_{j}, x_{j}\right\rangle-\gamma \lambda_{j}\right]\right)\right\} \\
= \\
\min _{\substack{E_{i} \in Q_{k}^{(i)} \\
k=1, \ldots, m}} \max _{\substack{x_{j} \in \mathbb{R}^{N}, j=1, \ldots, L}}\left\{\sum_{i=1}^{m}\left\langle I_{k}, E_{i}\right\rangle+\sum_{j=1}^{L} 2\left[\left\langle f_{j}, x_{j}\right\rangle-\gamma^{1 / 2}\left\langle A(E) x_{j}, x_{j}\right\rangle^{1 / 2}\right]\right\} .
\end{gathered}
$$

The dimension of the matrix $A(E)$ is large; the first transformation eliminates the need of calculating its inverse, but that results in a nonconcave objective function in $\lambda$ and $y$. The second transformation makes the function concave in $\lambda$ and $x$. In the last step, variable $\lambda$ is eliminated to simplify the formulation.

Denote

$$
F(E, x) \stackrel{\text { def }}{=} \sum_{i=1}^{m}\left\langle I_{k}, E_{i}\right\rangle+\sum_{j=1}^{L} 2\left[\left\langle f_{j}, x_{j}\right\rangle-\gamma^{1 / 2}\left\langle A(E) x_{j}, x_{j}\right\rangle^{1 / 2}\right]
$$

Thus, to solve problem (22), we only need to solve

$$
\begin{equation*}
\min _{\substack{E_{i} \in Q_{k}^{(i)} \\ i=1, \ldots, m}} \max _{\substack{x_{j} \in \mathbb{R}^{N}, j=1, \ldots, L}} F(E, x) . \tag{4}
\end{equation*}
$$

Note that $F(E, x)$ is convex in $E$ and concave in $x \in \mathbb{R}^{L \times N}$.

## 3 Bounded Lagrangian

We apply the primal-dual subgradient method [17] to the saddle-point formulation (4). The convergence of the algorithm requires the iterates be uniformly bounded [17]. We therefore impose a bound on $x$ :

$$
\begin{equation*}
\min _{\substack{E_{i} \in Q_{k}^{(i)} \\ i=1, \ldots, m}} \max _{\substack{\left\|x_{j}\right\| \leq \eta, j=1, \ldots, L}} F(E, x) \tag{5}
\end{equation*}
$$

Next we show that the primal solution of the saddle-point problem (5) is either a solution to the original problem (2) or an approximate solution in the sense that its constraint-violation is bounded by $\eta^{-1}$ and its objective value is smaller than that of the optimal value of (2).

Let $\left(E^{*}, x^{*}\right)$ be a solution to the saddle-point problem (4) ; then for any $\alpha \geq 0,\left(E^{*}, \alpha x^{*}\right)$ is also its solution. We can choose $\alpha^{*}$ small enough; for instance, let $\alpha^{*}=\eta / \max \left\{\left\|x_{j}^{*}\right\|, 1\right\}$, so that $\left(E^{*}, \alpha^{*} x^{*}\right)$ is a solution to the bounded saddle-point form (5).

For any $E \in Q_{k}$, denote the index set of its violated constraints as

$$
W_{E} \stackrel{\text { def }}{=}\left\{1 \leq j \leq L:\left\langle f_{j}, A(E)^{-1} f_{j}\right\rangle>\gamma\right\}
$$

Denote $F(E) \stackrel{\text { def }}{=} \max _{x} F(E, x)$. We have the following results regarding our material design problem.
Lemma 1 Let $(\tilde{E}, \tilde{x})$ be a solution of (5). Let $F^{*}$ be the optimal value of (2).

1. If $\left\|\tilde{x}_{j}\right\|<\eta$ for $j=1, \ldots, L$; then $\tilde{E}$ is a solution to (2).
2. Otherwise, $\tilde{E}$ has the following properties:
(a) $F(\tilde{E}) \leq F^{*}$.
(b) $\sum_{j \in W_{\tilde{E}}}\left(\left\langle f_{j}, A(\tilde{E})^{-1} f_{j}\right\rangle^{1 / 2}-\gamma^{1 / 2}\right) \leq \frac{F^{*}-m \rho_{l}}{2 r \lambda_{\min }\left(B B^{T}\right) \eta}$.

Proof: Item 1 is obvious as the constraints are non-binding.
Next, we prove item 2.
Because

$$
\max _{\substack{\left\|x_{j}\right\| \leq \eta \\ j=1, \ldots, L}} F(E, x) \leq \max _{\substack{x_{j} \in \mathbb{R}^{N}, j=1, \ldots, L}} F(E, x)
$$

we have item (2a). For any fixed $E \in Q$, the point

$$
x_{j}= \begin{cases}\frac{\eta}{\left\|A(E)^{-1} f_{j}\right\|} \|(E)^{-1} f_{j} & j \in W_{E} \\ 0 & j \notin W_{E}\end{cases}
$$

is feasible to

$$
\max _{\substack{\left\|x_{j}\right\| \leq \eta, j=1, \ldots, L}} F(E, x)
$$

with objective value

$$
\begin{equation*}
F_{x}(E) \stackrel{\text { def }}{=}\langle I, E\rangle+2 \sum_{j \in W_{E}}\left(\left\langle f_{j}, A(E)^{-1} f_{j}\right\rangle^{1 / 2}-\gamma^{1 / 2}\right) \frac{\left\langle f_{j}, A(E)^{-1} f_{j}\right\rangle^{1 / 2}}{\left\|A(E)^{-1} f_{j}\right\|} \eta \tag{6}
\end{equation*}
$$

Since

$$
\left\langle f_{j}, A(E)^{-1} f_{j}\right\rangle=\left\langle A(E)^{-1} f_{j}, A(E)\left(A(E)^{-1} f_{j}\right)\right\rangle
$$

we also have

$$
\begin{aligned}
& \frac{\left\langle f_{j}, A(E)^{-1} f_{j}\right\rangle^{1 / 2}}{\left\|A(E)^{-1} f_{j}\right\|} \geq \lambda_{\min } A(E)^{1 / 2} \geq r \lambda_{\min }\left(B B^{T}\right) \\
& \text { and } \\
&\langle I, E\rangle \geq m \rho_{l}
\end{aligned}
$$

Therefore,

$$
F(\tilde{E}, \tilde{x}) \geq m \rho_{l}+2 r \lambda_{\min }\left(B B^{T}\right) \eta \sum_{j \in W_{\tilde{E}}}\left(\left\langle f_{j}, A(\tilde{E})^{-1} f_{j}\right\rangle^{1 / 2}-\gamma^{1 / 2}\right)
$$

By item (2a) of the lemma, we have

$$
F(\tilde{E}, \tilde{x}) \leq F^{*}
$$

Item (2b) then follows.
Note that as $\eta \rightarrow+\infty$, the set of saddle-points of (5) approaches that of the original problem.

## 4 The Algorithm

In this part, we describe how to apply the primal-dual subgradient method [17] to the saddle-point reformulation of model (2). We have developed a parameter update scheme for the algorithm, which is included in the Appendix.

For a matrix $V$, let vector $\lambda(V)$ denote the eigenvalues of $V$; let $\lambda_{\min }(V)$ be the smallest eigenvalue of $V$. The gradient (subgradients) of $F(E, x)$ at $(E, x)$ are: for $i=1, \ldots, m, j=1 \ldots, L$,

$$
\left.\begin{array}{rl}
g_{E_{i}}(E, x)= & I_{k}-\sqrt{\gamma} \sum_{j \in R}\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1 / 2}\left(\sum_{l=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right) \\
& \text { where } R \stackrel{\text { def }}{=}\left\{1 \leq l \leq L:\left\langle A(E) x_{l}, x_{l}\right\rangle>0\right\}
\end{array}\right\} \begin{aligned}
g_{x_{j}}(E, x)= & \begin{cases}2 f_{j}-2 \sqrt{\gamma}\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1 / 2} A(E) x_{j} & \left\langle A(E) x_{j}, x_{j}\right\rangle>0 \\
\left\{2 f_{j}-2 \sqrt{\gamma} A(E) y:\langle A(E) y, y\rangle=1\right\} & \left\langle A(E) x_{j}, x_{j}\right\rangle=0\end{cases}
\end{aligned}
$$

For the primal space, we choose the standard Frobenius norm:

$$
\|E\|_{F}^{2}=\sum_{i=1}^{m}\left\|E_{i}\right\|_{F}^{2}=\operatorname{tr}\left(E^{2}\right), \quad d(E)=\frac{1}{2} \sum_{i=1}^{m}\left\|E_{i}-r I_{k}\right\|_{F}^{2}
$$

For the dual space, we choose the standard Euclidean norm:

$$
\|x\|_{2}^{2}=\sum_{j=1}^{L}\left\|x_{j}\right\|_{2}^{2}=x^{T} x, \quad d(x)=\frac{1}{2} \sum_{j=1}^{L}\left\|x_{j}\right\|_{2}^{2}
$$

Their dual norms are denoted as: $\|\cdot\|_{F, *}=\|\cdot\|_{F},\|\cdot\|_{2, *}=\|\cdot\|_{2}$.
The set $Q_{k}^{(i)}$ for $E_{i}$ is defined in (3) ; and the set $Q_{x}$ for $x_{j}$ is

$$
Q_{x}=\left\{x_{j} \in \mathbb{R}^{N}:\left\|x_{j}\right\| \leq \eta\right\}
$$

Note that $F$ is nonsmooth. The primal-dual subgradient method [17] for saddle-point problems (5) works as follows.

```
Initialization: Set \(s_{0}^{E_{i}}=0(i=1, \ldots, m), s_{0}^{x_{j}}=0(j=1, \ldots, L)\).
    Choose \(\beta_{0}>0,0<\tau<1\).
Iteration \(t=0,1, \ldots\)
1. Compute \(g_{E_{i}}^{(t)}\left(E^{(t)}, x^{(t)}\right), g_{x_{j}}^{(t)}\left(E^{(t)}, x^{(t)}\right)\), for \(i=1, \ldots, m ; j=1, \ldots, L\).
2. Choose \(\alpha_{t}>0\), set
    \(s_{t+1}^{E_{i}}=s_{t}^{E_{i}}+\alpha_{t} g_{E_{i}}^{(t)}(i=1, \ldots, m), \quad s_{t+1}^{x_{j}}=s_{t}^{x_{j}}-\alpha_{t} g_{x_{j}}^{(t)}(j=1, \ldots, L)\).
3. Choose \(\beta_{t+1} \geq \beta_{t}\), set
    \(E^{(t+1)}=\arg \min _{E_{i} \in Q_{k}^{(i)}}\left\{\left\langle s_{t+1}^{E}, E\right\rangle+\beta_{t+1} \tau d_{E}(E)\right\}\),
    \(x^{(t+1)}=\arg \min _{x_{j} \in Q_{x}}\left\{\left\langle s_{t+1}^{x}, x\right\rangle+\beta_{t+1}(1-\tau) d_{x}(x)\right\}\).
    Output: \(\hat{E}^{(t+1)}=\frac{1}{\sum_{l=0}^{t} \alpha_{l}} \sum_{l=0}^{t} \alpha_{l} E^{(l)}\).
```

Details of a parameter update scheme for $\beta_{t}$ is given in the Appendix.
We take

$$
\begin{gathered}
\hat{\beta}_{0}=\hat{\beta}_{1}=1, \quad \hat{\beta}_{t+1}=\hat{\beta}_{t}+\frac{1}{\hat{\beta}_{t}}, t=1, \ldots \\
\beta_{t}=\sigma \hat{\beta}_{t}, t=0, \ldots
\end{gathered}
$$

Based on different choices of $\alpha$, there are two variants of the algorithm:

1. Method of Simple Dual Averages

We let

$$
\alpha_{t}=1, t=0, \ldots
$$

2. Method of Weighted Dual Averages

We let

$$
\alpha_{t}=1 /\left(\frac{\left\|g_{E}^{(t)}\right\|_{F, *}^{2}}{\tau}+\frac{\left\|g_{x}^{(t)}\right\|_{2, *}^{2}}{1-\tau}\right)^{1 / 2}, t=0, \ldots
$$

## 5 Solution to the Subproblem

In this part, we give closed-form solutions to the subproblems at each iteration of our algorithm.
Solution of $x$. The closed-form solution for $x^{(t+1)}$ in Step 3 of the algorithm is derived as below.
By Cauchy-Schwartz-Boniakovsky inequality, for $j=1, \ldots, L$ :

$$
\begin{aligned}
& \left\langle s_{t+1}^{x_{j}}, x_{j}\right\rangle+\beta_{t+1}(1-\tau) d_{x_{j}}\left(x_{j}\right) \\
\geq & -\left\|s_{t+1}^{x_{j}}\right\|_{2, *} \cdot\left\|x_{j}\right\|_{2}+\frac{\beta_{t+1}(1-\tau)}{2}\left\|x_{j}\right\|_{2}^{2} \\
= & \frac{\beta_{t+1}(1-\tau)}{2}\left(\left\|x_{j}\right\|_{2}-\frac{1}{\beta_{t+1}(1-\tau)}\left\|s_{t+1}^{x_{j}}\right\|_{2, *}\right)^{2}-\frac{1}{2 \beta_{t+1}(1-\tau)}\left\|s_{t+1}^{x_{j}}\right\|_{2, *}^{2},
\end{aligned}
$$

with equality iff $x_{j}=-\nu s_{t+1}^{x_{j}}$ for some $\nu \geq 0$. Therefore,

$$
\begin{equation*}
x_{j}^{(t+1)}=-\min \left(\frac{\eta}{\left\|s_{t+1}^{x_{j}}\right\|_{2, *}}, \frac{1}{\beta_{t+1}(1-\tau)}\right) s_{t+1}^{x_{j}} \tag{7}
\end{equation*}
$$

Solution of $E$. For a set $M$, let $|M|$ denote the cardinality of $M$; i.e., the number of elements in $M$. In Step 3 of the algorithm, $E_{i}^{(t+1)}$ can be seen as the projection

$$
\min _{V \in Q_{k}^{(i)}}\left\|V+\frac{1}{\beta_{t+1} \tau} s_{t+1}^{E_{i}}-r I\right\|_{F}^{2}
$$

By Theorem 4 in Appendix: Matrix Projection, we can represent $E^{t+1}$ as follows.
For each $1 \leq i \leq m$, let $U \Lambda U^{T}$ be the eigenvalue decomposition of $s_{t+1}^{E_{i}}$, and $\lambda_{1}, \ldots, \lambda_{k}$ be its eigenvalues. Define the sets

$$
M_{0} \stackrel{\text { def }}{=}\left\{1 \leq l \leq k: \lambda_{l} \geq 0\right\}, \quad \bar{M}_{0} \stackrel{\text { def }}{=}\{1, \ldots, k\} \backslash M_{0} .
$$

Then

$$
\begin{equation*}
E_{i}^{(t+1)}=U \operatorname{diag}(\omega) U^{T} \tag{8}
\end{equation*}
$$

where $\omega$ is determined according to the following three cases.

1. $\beta_{t+1} \tau\left(k r-\rho_{u}^{(i)}\right) \leq \sum_{q \in \bar{M}_{0}} \lambda_{q} \leq \beta_{t+1} \tau\left(k r-\rho_{l}^{(i)}\right)$.

Let

$$
\omega_{l}= \begin{cases}r & l \in M_{0} \\ r-\frac{\lambda_{l}}{\beta_{t+1} \tau} & l \notin M_{0}\end{cases}
$$

2. $\sum_{q \in \bar{M}_{0}} \lambda_{q}<\beta_{t+1} \tau\left(k r-\rho_{u}^{(i)}\right)$.

Then there is a partition $\bar{M}_{0}=P \cup \bar{P}$ :

$$
\begin{aligned}
& P=\left\{l \in \bar{M}_{0}: \lambda_{l}<\frac{\beta_{t+1} \tau\left(\rho_{u}^{(i)}-k r\right)+\sum_{q \in P} \lambda_{q}}{|P|}\right\}, \\
& \bar{P}=\left\{l \in \bar{M}_{0}: \lambda_{l} \geq \frac{\beta_{t+1} \tau\left(\rho_{u}^{(i)}-k r\right)+\sum_{q \in P} \lambda_{q}}{|P|}\right\} .
\end{aligned}
$$

Let

$$
\omega_{l}= \begin{cases}r & l \in \bar{P} \cup M_{0} \\ r-\frac{\lambda_{l}}{\beta_{t+1} \tau}+\frac{\beta_{t+1} \tau\left(\rho_{u}^{(i)}-k r\right)+\sum_{q \in P} \lambda_{q}}{\beta_{t+1} \tau|P|} & l \in P .\end{cases}
$$

3. $\sum_{q \in \bar{M}_{0}} \lambda_{q}>\beta_{t+1} \tau\left(k r-\rho_{l}^{(i)}\right)$.

Then there is a partition $M_{0}=P_{m} \cup \bar{P}_{m}$ :

$$
P_{m}=\left\{l \in M_{0}: \frac{\rho_{l}^{(i)}+\frac{1}{\beta_{t+1^{\tau}}} \sum_{j \in P_{m} \cup \bar{M}_{0}} \lambda_{j}-k r}{\left|P_{m}\right|+\left|M_{0}\right|}>\frac{\lambda_{l}}{\beta_{t+1} \tau}\right\} .
$$

Let

$$
\omega_{l}= \begin{cases}-\frac{\lambda_{l}}{\beta_{t+1} \tau}+\frac{\beta_{t+1} \tau\left(\rho_{l}^{(i)}-\left|\bar{P}_{m}\right| r\right)+\sum_{q \in \bar{M}_{0} \cup P_{m}} \lambda_{q}}{\beta_{t+1} \tau\left(\left|M_{0}\right|+\left|P_{m}\right|\right)}, & l \in \bar{M}_{0} \cup P_{m} \\ r & l \in \bar{P}_{m}\end{cases}
$$

The eigenvalues $\omega$ in case 2 can be obtained by the following algorithm:

## Algorithm projSyml

Step 1 (Initialization) Let $\lambda_{\sigma(1)} \leq \cdots \leq \lambda_{\sigma(p)}<0$ be the $p$ negative eigenvalues of $s_{t+1}^{E_{i}}$.
Let

$$
P=\{\sigma(1)\}, \quad T=\beta_{t+1} \tau\left(\rho_{u}^{(i)}-k r\right)+\lambda_{\sigma(1)}, \quad q=1
$$

Step 2 While $q \lambda_{\sigma(q+1)}<T$, do

$$
P \cup\{\sigma(q+1)\} \rightarrow P, \quad T+\lambda_{\sigma(q+1)} \rightarrow T, \quad q+1 \rightarrow q
$$

Step 3 Let

$$
\omega_{l}= \begin{cases}r & l \notin P \\ r-\frac{\lambda_{l}}{\beta_{t+1} \tau}+\frac{T}{\beta_{t+1} \tau q} & l \in P\end{cases}
$$

Similarly, the eigenvalues in case 3 can be obtained by the following algorithm:

## Algorithm projSymg

Step 1 (Initialization) Let $0<\lambda_{\sigma(1)} \leq \cdots \leq \lambda_{\sigma(u)}$ be the $u$ positive eigenvalues of $s_{t+1}^{E_{i}}$.

- If $u=p$, let

$$
U=\{\sigma(1)\}, \quad T=\beta_{t+1} \tau\left(\rho_{l}^{(i)}-k r\right)+\lambda_{\sigma(1)}, \quad q=1
$$

- If $u<p$, let

$$
U=\bar{M}_{0} \cup\left\{i: \lambda_{i}=0\right\}, \quad T=\beta_{t+1} \tau\left(\rho_{l}^{(i)}-k r\right)+\sum_{j \in \bar{M}_{0}} \lambda_{j}, \quad q=|U|
$$

Step 2 While $q \lambda_{\sigma(q+1)}<T$, do

$$
U \cup\{\sigma(q+1)\} \rightarrow U, \quad T+\lambda_{\sigma(q+1)} \rightarrow T, \quad q+1 \rightarrow q
$$

Step 3 Let

$$
\omega_{l}= \begin{cases}r & l \in M_{0} \backslash U \\ r-\frac{\lambda_{l}}{\beta_{t+1} \tau}+\frac{T}{\beta_{t+1} \tau q} & l \in \bar{M}_{0} \cup U\end{cases}
$$

## 6 Complexity of the Algorithm

To understand the complexity of the algorithm for model (2), in this part we study duality gap and computational cost of each iteration. By [17], it takes $\mathcal{O}\left(\frac{1}{\epsilon^{2}}\right)$ iterations to solve a general convex-concave saddle-point problem to the absolute accuracy $\epsilon$, which is the exact lower complexity bound for such class of algorithm schemes. To give an insight of how the data of FMO model, such as $f, B$, and $\eta$, affect convergence time, we give upper bounds of the duality gap of the iterates generated by our algorithm in terms of the number of iterations and input data in $\S \S 6.1$ In $\S \S 6.2$, we derive computational cost per iteration. From the duality gap and computational cost per iteration given in this section, we can estimate from given data how much computational effort is needed at most to approximate a solution of a problem instance of model (2) based on the method proposed in the paper.

### 6.1 Iteration Bounds

By [7, Chapter 6, Proposition 2.1], for a function $L: \mathcal{A} \times \mathcal{B} \mapsto \mathbb{R}$, assume

- the sets $\mathcal{A}$ and $\mathcal{B}$ are convex, closed, non-empty, and bounded;
- for any fixed $u \in \mathcal{A}, p \mapsto L(u, p)$ is concave and upper semicontinuous;
- for any fixed $p \in \mathcal{A}, u \mapsto L(u, p)$ is convex and upper semicontinuous;
then the function $L$ has at least one saddle-point.
Since $E$ and $x$ are bounded, and $F$ is continuous and finite, by the above results, we conclude that $F$ has a saddle-point and a finite saddle-value. An upper bound on duality gap is given in [17, Theorem 6]. We next represent the duality gap in terms of input data.

Define

$$
\begin{aligned}
\left\|\left(g_{E}, g_{x}\right)\right\|_{*} & \stackrel{\text { def }}{=}\left[\frac{1}{\tau}\left\|g_{E}\right\|_{F, *}^{2}+\frac{1}{1-\tau}\left\|g_{x}\right\|_{2, *}^{2}\right]^{1 / 2} \\
\|(E, x)\| & \stackrel{\text { def }}{=}\left[\tau\|E\|_{F}^{2}+(1-\tau)\|x\|_{2}^{2}\right]^{1 / 2}
\end{aligned}
$$

For a matrix $V$, denote $\|V\|_{2}^{2} \stackrel{\text { def }}{=} \lambda_{\max }\left(V^{T} V\right)$.
Since

$$
\left(\begin{array}{cccc}
\rho_{u}-(k-1) r & & & \\
& r & & \\
& & \ddots & \\
& & & r
\end{array}\right) \in \quad \arg \max _{E_{i} \in Q_{k}^{(i)}} d_{E}\left(E_{i}\right)
$$

we have

$$
\begin{equation*}
D_{E} \stackrel{\text { def }}{=} \frac{1}{2} \max _{E_{i} \in Q_{k}^{(i)}}\|E-r I\|_{F}^{2} \leq \frac{1}{2} m\left(\rho_{u}-k r\right)^{2} \tag{9}
\end{equation*}
$$

Furthermore, by our algorithm scheme,

$$
\begin{equation*}
D_{x} \stackrel{\text { def }}{=} \max _{x \in Q_{x}} \frac{1}{2}\|x\|_{2}^{2} \leq \frac{L}{2} \eta^{2} \tag{10}
\end{equation*}
$$

Define

$$
\begin{aligned}
\kappa_{t} & \stackrel{\text { def }}{=} \frac{1}{\sum_{l=0}^{t} \alpha_{l}} \max _{E_{i} \in Q_{k}^{(i)}}\left\{\sum_{l=0}^{t} \alpha_{l}\left\langle g_{E}\left(E^{(l)}, x^{(l)}\right), E^{(l)}-E\right\rangle\right\} \\
v_{t} & \stackrel{\text { def }}{=} \frac{1}{\sum_{l=0}^{t} \alpha_{l}} \max _{x_{j} \in \mathbb{R}^{N}}\left\{\sum_{l=0}^{t} \alpha_{l}\left\langle g_{x}\left(E^{(l)}, x^{(l)}\right), x-x^{(l)}\right\rangle:\left\|x_{j}\right\|_{2} \leq \eta\right\} .
\end{aligned}
$$

By Cauchy-Schwartz-Boniakovsky inequality, it is easy to verify that

$$
v_{t}=\frac{1}{\sum_{l=0}^{t} \alpha_{l}}\left(\sum_{j=1}^{L} \eta\left\|s_{t+1}^{x_{j}}\right\|_{2, *}-\sum_{l=0}^{t} \alpha_{l}\left\langle g_{x}\left(E^{(l)}, x^{(l)}\right), x^{(l)}\right\rangle\right)
$$

which is attained at

$$
x_{j}= \begin{cases}\frac{\eta}{\left\|s_{t+1}^{x_{j}}\right\|_{2, *}} s_{t+1}^{x_{j}} & s_{t+1}^{x_{j}} \neq 0 \\ 0 & \text { otherwise }\end{cases}
$$

Now let us give a bound for $\kappa_{t}$. Let $\kappa_{t}=\frac{1}{\sum_{l=1}^{t} \alpha_{l}} \sum_{i=1}^{m} \kappa_{i}^{t}$, where

$$
\kappa_{i}^{t} \stackrel{\text { def }}{=} \max _{E_{i} \in Q_{k}^{(i)}}\left\{\sum_{l=0}^{t} \alpha_{l}\left\langle g_{E_{i}}\left(E^{(l)}, x^{(l)}\right), E_{i}^{(l)}-E_{i}\right\rangle\right\}
$$

By Hoffman-Wielandt theorem,

$$
\begin{aligned}
\kappa_{i}^{t}= & \sum_{l=0}^{t} \alpha_{l}\left\langle g_{E_{i}}\left(E^{(l)}, x^{(l)}\right), E_{i}^{l}\right\rangle-\min _{E_{i} \in Q_{k}^{(i)}}\left\langle s_{t+1}^{E_{i}}, E_{i}\right\rangle \\
= & \sum_{l=0}^{t} \alpha_{l}\left\langle g_{E_{i}}\left(E^{(l)}, x^{(l)}\right), E_{i}^{l}\right\rangle \\
& - \begin{cases}{\left[\rho_{l}-k r\right]_{+} \lambda_{\min }\left(s_{t+1}^{E_{i}}\right)+r \operatorname{tr}\left(s_{t+1}^{E_{i}}\right)} & \lambda_{\min }\left(s_{t+1}^{E_{i}}\right)>0, \\
\left(\rho_{u}-k r\right) \lambda_{\min }\left(s_{t+1}^{E_{i}}\right)+r \operatorname{tr}\left(s_{t+1}^{E_{i}}\right) & \lambda_{\min }\left(s_{t+1}^{E_{i}}\right) \leq 0\end{cases}
\end{aligned}
$$

Define

$$
\delta_{t} \stackrel{\text { def }}{=} \max _{E_{i} \in Q_{k}^{(i)}, x \in Q_{x}}\left\{\sum_{l=0}^{t} \alpha_{l}\left\langle\left(g_{E}^{(l)}, g_{x}^{(l)}\right),\left(E^{(l)}, x^{(l)}\right)-(E, x)\right\rangle: d(x) \leq \tau D_{E}+(1-\tau) D_{x}\right\}
$$

By [17, Theorem 6], $\kappa_{t}+v_{t}$ is a bound of the duality gap; i.e.

$$
\begin{equation*}
0 \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i}^{(i)} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \leq \kappa_{t}+v_{t} \leq \frac{1}{\sum_{l=0}^{t} \alpha_{l}} \delta_{t} \tag{11}
\end{equation*}
$$

Next, we bound the above duality gap by input data. To this end, we first bound the partial derivatives $g_{E}$ and $g_{x}$.

Denote

$$
B_{i} \stackrel{\text { def }}{=}\left[\begin{array}{c}
B_{i, 1}  \tag{12}\\
\vdots \\
B_{i, n i g}
\end{array}\right], \quad B \stackrel{\text { def }}{=}\left[\begin{array}{c}
B_{1} \\
\vdots \\
B_{m}
\end{array}\right]
$$

Lemma 2 The partial derivative of $F(E, x)$ in $E$ can be bounded by $\|x\|_{2}$ as follows:

$$
\left\|g_{E}(E, x)\right\|_{F, *}^{2} \leq m k+L^{2} \frac{\gamma}{r}\|B\|_{2}^{2} \eta^{2} \stackrel{\text { def }}{=} L_{E}^{2}
$$

Proof: We have

$$
\begin{align*}
\left\langle A(E) x_{j}, x_{j}\right\rangle & =\sum_{i=1}^{m} \sum_{l=1}^{n i g}\left\langle E_{i} B_{i, l} x_{j}, B_{i, l} x_{j}\right\rangle \\
& \geq \sum_{i=1}^{m} \lambda_{\min }\left(E_{i}\right) \sum_{l=1}^{n i g}\left\langle B_{i, l} x_{j}, B_{i, l} x_{j}\right\rangle  \tag{13}\\
& \geq r \sum_{i=1}^{m} \sum_{l=1}^{n i g}\left\langle B_{i, l} x_{j}, B_{i, l} x_{j}\right\rangle,
\end{align*}
$$

where the last inequality is from the definition of the set $Q_{k}^{(i)}$.
Since for two matrices $A$ and $B$ of proper dimensions, $\operatorname{tr}(A B)=\operatorname{tr}(B A)$, we have

$$
\begin{align*}
\left\|\sum_{l=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right\|_{F} & \leq \sum_{l=1}^{n i g}\left\|B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right\|_{F} \\
& =\sum_{l=1}^{n i g}\left[\operatorname{tr}\left(B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right)\right]^{1 / 2}  \tag{14}\\
& =\sum_{l=1}^{n i g}\left[\left(x_{j}^{T} B_{i, l}^{T} B_{i, l} x_{j}\right)^{2}\right]^{1 / 2} \\
& =\sum_{l=1}^{n i g}\left\langle B_{i, l} x_{j}, B_{i, l} x_{j}\right\rangle
\end{align*}
$$

Therefore,

$$
\begin{aligned}
\left\|\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1 / 2}\left(\sum_{l=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right)\right\|_{F} & \leq \frac{1}{\sqrt{r}}\left[\sum_{l=1}^{n i g}\left\langle B_{i, l} x_{j}, B_{i, l} x_{j}\right\rangle\right]^{1 / 2} \\
& \leq \frac{1}{\sqrt{r}} \lambda_{\max }\left(\sum_{l=1}^{n i g} B_{i, l}^{T} B_{i, l}\right)^{1 / 2}\left\|x_{j}\right\|_{2}
\end{aligned}
$$

Note that

$$
\lim _{x_{j} \rightarrow 0}\left\|\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1 / 2}\left(\sum_{l=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right)\right\|_{F}=0 .
$$

We also have

$$
\sum_{i=1}^{m} \sum_{l=1}^{n i g} B_{i, l}^{T} B_{i, l}=B^{T} B, \quad \quad \lambda_{\max }\left(\sum_{i=1}^{m} \sum_{l=1}^{n i g} B_{i, l}^{T} B_{i, l}\right)^{1 / 2}=\|B\|_{2}
$$

Hence, $g_{E}(E, x)$ is bounded as below:

$$
\begin{align*}
& \left\|g_{E}(E, x)\right\|_{F, *}^{2} \leq\|I\|_{F}^{2}+\gamma \sum_{i=1}^{m}\left\|\sum_{j \in R}\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1 / 2}\left(\sum_{i=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right)\right\|_{F}^{2} \\
& \leq\|I\|_{F}^{2}+L \gamma \sum_{i=1}^{m} \sum_{j \in R}\left\|\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1 / 2}\left(\sum_{i=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right)\right\|_{F}^{2} \\
& =m k+L \gamma \sum_{j \in R}\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1} \sum_{i=1}^{m}\left\|\sum_{i=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right\|_{F}^{2} \\
& \stackrel{\sqrt{144}}{\leq} m k+L \gamma \sum_{j \in R}\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1} \sum_{i=1}^{m}\left(\sum_{l=1}^{n i g}\left\langle B_{i, l} x_{j}, B_{i, l} x_{j}\right\rangle\right)^{2}  \tag{15}\\
& \leq m k+L \gamma \sum_{j \in R}\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1}\left(\sum_{i=1}^{m} \sum_{l=1}^{n i g}\left\langle B_{i, l} x_{j}, B_{i, l} x_{j}\right\rangle\right)^{2} \\
& \stackrel{\text { (13) }}{\leq} m k+L \frac{\gamma}{r} \sum_{j \in R} \sum_{i=1}^{m} \sum_{l=1}^{n i g}\left\langle B_{i, l} x_{j}, B_{i, l} x_{j}\right\rangle \\
& \stackrel{\text { (122) }}{\leq} m k+L^{2} \frac{\gamma}{r}\|B\|_{2}^{2} \eta^{2} \text {. }
\end{align*}
$$

Next, we give a bound on the norm of $g_{x}(E, x)$.
Let $\tilde{E}_{i}$ be the block diagonal matrix of $n i g$ same diagonal blocks $E_{i}$. Let $\tilde{E}$ be the block diagonal matrix with diagonal blocks $\tilde{E}_{i},(i=1, \ldots, m)$ :

$$
\tilde{E}_{i} \stackrel{\text { def }}{=}\left[\begin{array}{ccc}
E_{i} & & \\
& \ddots & \\
& & E_{i}
\end{array}\right], \quad \tilde{E} \stackrel{\text { def }}{=}\left[\begin{array}{ccc}
\tilde{E}_{1} & & \\
& \ddots & \\
& & \tilde{E}_{m}
\end{array}\right]
$$

Then

$$
A(E)=B^{T} \tilde{E} B
$$

Lemma 3 The partial derivative of $F(E, x)$ in $x$ can be bounded as follows:

$$
\left\|g_{x}(E, x)\right\|_{2, *} \leq 2\|f\|_{2}+2 \sqrt{\gamma L\left(\rho_{u}-k r+r\right)}\|B\|_{2} \stackrel{\text { def }}{=} L_{x}
$$

Proof: For a vector $z$ of proper dimension, we have

$$
\|A(E) z\|_{2} \quad \leq\|A(E)\|_{2}^{1 / 2}\langle A(E) z, z\rangle^{1 / 2}
$$

And for two matrices $A$ and $B$ of proper dimension, it holds that $\lambda_{\max }(A B) \leq \lambda_{\max }(A) \lambda_{\max }(B)$, and $\lambda_{\text {max }}(A B)=\lambda_{\text {max }}(B A)$.

In addition, by the definition of $Q_{k}^{(i)}$, we have

$$
\lambda_{\max }(\tilde{E})=\lambda_{\max }(E) \leq \rho_{u}-(k-1) r
$$

Therefore, $\|A(E)\|_{2}$ can be bounded as below:

$$
\|A(E)\|_{2}^{1 / 2} \leq\|\tilde{E}\|_{2}^{1 / 2}\left\|B^{T} B\right\|_{2}^{1 / 2} \leq \sqrt{\rho_{u}-(k-1) r}\|B\|_{2}
$$

Hence

$$
\begin{align*}
\left\|g_{x}(E, x)\right\|_{2, *} & \leq 2\|f\|_{2}+2 \sqrt{\gamma}\left(\sum_{j \in R}\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1}\left\langle A(E) x_{j}, A(E) x_{j}\right\rangle\right. \\
& \left.+\sum_{j \notin R}\langle A(E) y, A(E) y\rangle\right)^{1 / 2}  \tag{16}\\
& \leq 2\|f\|_{2}+2 \sqrt{\gamma L\left(\rho_{u}-k r+r\right)}\|B\|_{2}
\end{align*}
$$

Next, we give bounds on the duality gaps.
By [17, Lemma 3], we have

$$
\begin{equation*}
\sqrt{2 t-1} \leq \hat{\beta}_{t} \leq \frac{1}{1+\sqrt{3}}+\sqrt{2 t-1}, \quad t \geq 1 \tag{17}
\end{equation*}
$$

Theorem 1 If the iterates are generated by the method of Simple Dual Average, the duality gap is bounded as

$$
\begin{align*}
0 & \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \\
& \leq \frac{0.37+\sqrt{2 t+1}}{t+1}\left[\sqrt{\left(m k+\frac{\gamma}{r} L^{2}\|B\|_{2}^{2} \eta^{2}\right) m}\left(\rho_{u}-k r\right)\right.  \tag{18}\\
& \left.+2\left(\|f\|_{2}+\sqrt{\gamma L\left(\rho_{u}-k r+r\right)}\|B\|_{2}\right) \sqrt{L} \eta\right]
\end{align*}
$$

Proof: Since partial subdifferentials of $f$ are uniformly bounded:

$$
\left\|g_{E}\right\|_{F, *} \leq L_{E}, \quad\left\|g_{x}\right\|_{2, *} \leq L_{x}, \quad \forall(E, x) \in Q_{k} \times Q_{x}
$$

when we choose

$$
\begin{aligned}
\frac{1}{\tau} & =1+\frac{L_{x}}{L_{E}} \sqrt{\frac{D_{E}}{D_{x}}} \\
\sigma & =\sqrt{\frac{\tau L_{E}^{2}+(1-\tau) L_{x}^{2}}{2 \tau D_{E}+2(1-\tau) D_{x}}}
\end{aligned}
$$

by [17, (4.6)], we have

$$
\begin{equation*}
\frac{1}{\sum_{l=0}^{t} \alpha_{l}} \delta_{t} \leq \frac{\hat{\beta}_{t+1}}{t+1} \sqrt{2}\left(L_{E} \sqrt{D_{E}}+L_{x} \sqrt{D_{x}}\right) \tag{19}
\end{equation*}
$$

Therefore, by (15), (16), (11), (17), (9), (10), we get

$$
\begin{aligned}
0 & \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \\
& \leq \frac{0.37+\sqrt{2 t+1}}{t+1}\left[\sqrt{\left(m k+\frac{\gamma}{r} L^{2}\|B\|_{2}^{2} \eta^{2}\right) m}\left(\rho_{u}-k r\right)\right. \\
& \left.+2\left(\|f\|_{2}+\sqrt{\gamma L\left(\rho_{u}-k r+r\right)}\|B\|_{2}\right) \sqrt{L} \eta\right]
\end{aligned}
$$

Theorem 2 If the iterates are generated by the method of Weighted Dual Average, the duality gap is bounded
by

$$
\begin{align*}
0 & \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \\
& \leq \min \left\{\frac { 0 . 3 7 + \sqrt { 2 t + 1 } } { t + 1 } \left[\sqrt{m^{2} k+L^{2} m \frac{\gamma}{r}\|B\|_{2}^{2} \eta^{2}}\left(\rho_{u}-k r\right)+2 \sqrt{L} \eta\|f\|_{2}\right.\right.  \tag{20}\\
& \left.+2 \sqrt{\gamma\left(\rho_{u}-k r+r\right)}\|B\|_{2} L \eta\right], \frac{(4 \sqrt{2}+2) \hat{\beta}_{t+1} \sqrt{d\left(E^{*}, x^{*}\right)}}{t+1}\left[m k+8(3+\sqrt{2}) \frac{\gamma}{r} L\|B\|_{2}^{2} d\left(E^{*}, x^{*}\right)\right. \\
& \left.\left.+4\left(\|f\|_{2}+\sqrt{\gamma L\left(\rho_{u}-k r+r\right)}\|B\|_{2}\right)^{2}\right]^{1 / 2}\right\}
\end{align*}
$$

## Proof:

1. Bound 1

Let $\left(E^{*}, x^{*}\right)$ be an optimal solution. Since

$$
\begin{equation*}
d(E, x)=\frac{\tau}{2}\|E-r I\|_{F}^{2}+\frac{1-\tau}{2}\|x\|_{2}^{2} \tag{21}
\end{equation*}
$$

we get

$$
\sqrt{d(E, x)} \leq \sqrt{d\left(E^{*}, x^{*}\right)}+\frac{1}{\sqrt{2}}\left\|(E, x)-\left(E^{*}, x^{*}\right)\right\|
$$

In addition, [17, Theorem 3] states that

$$
\left\|(E, x)-\left(E^{*}, x^{*}\right)\right\|^{2} \leq 2 d\left(E^{*}, x^{*}\right)+\frac{1}{\sigma^{2}}
$$

Therefore,

$$
\begin{aligned}
D_{E, x} & \stackrel{\text { def }}{=} \max _{E_{i} \in Q_{k}^{(i)}, x \in Q_{x}} d(E, x) \leq\left(\sqrt{d\left(E^{*}, x^{*}\right)}+\sqrt{d\left(E^{*}, x^{*}\right)+\frac{1}{2 \sigma^{2}}}\right)^{2} \\
& =2 d\left(E^{*}, x^{*}\right)+\frac{1}{2 \sigma^{2}}+2 \sqrt{d\left(E^{*}, x^{*}\right)^{2}+d\left(E^{*}, x^{*}\right) \frac{1}{2 \sigma^{2}}} \\
& \leq 4 d\left(E^{*}, x^{*}\right)+\frac{1}{2 \sigma^{2}}+\sqrt{2 d\left(E^{*}, x^{*}\right)} \frac{1}{\sigma}
\end{aligned}
$$

By [17. Theorem 3], we further have

$$
\delta_{t} \leq \hat{\beta}_{t+1}\left(D_{E, x} \sigma+\frac{1}{2 \sigma}\right) \leq \hat{\beta}_{t+1}\left[4 d\left(E^{*}, x^{*}\right) \sigma+\frac{1}{\sigma}+\sqrt{2 d\left(E^{*}, x^{*}\right)}\right]
$$

Minimizing the above last term in $\sigma$, we obtain that at $\sigma=1 /\left(2 \sqrt{d\left(E^{*}, x^{*}\right.}\right)$,

$$
\begin{align*}
\delta_{t} & \leq \hat{\beta}_{t+1}(4+\sqrt{2}) \sqrt{d\left(E^{*}, x^{*}\right)}  \tag{22}\\
D_{E, x} & \leq 2(3+\sqrt{2}) d\left(E^{*}, x^{*}\right) \tag{23}
\end{align*}
$$

Let $\tau=\frac{1}{2}$. By (21), (15) and (23), we have

$$
\begin{equation*}
L_{E}^{2}=\max _{E_{i} \in Q_{k}^{(i)}, x \in Q_{x}}\left\|g_{E}(E, x)\right\|_{F, *}^{2} \leq m k+8(3+\sqrt{2}) \frac{\gamma}{r} L\|B\|_{2}^{2} d\left(E^{*}, x^{*}\right) \tag{24}
\end{equation*}
$$

Therefore,

$$
\begin{array}{rll}
\frac{1}{\sum_{l=1}^{t} \alpha_{l}} & \leq & \frac{1}{t+1} \sqrt{2 L_{E}^{2}+2 L_{x}^{2}} \\
& \stackrel{(16),(24)}{\leq} & \frac{1}{t+1}\left[2 m k+16(3+\sqrt{2}) \frac{\gamma}{r} L\|B\|_{2}^{2} d\left(E^{*}, x^{*}\right)\right. \\
& \left.+\quad 2\left(2\|f\|_{2}+2 \sqrt{\gamma L\left(\rho_{u}-k r+r\right)}\|B\|_{2}\right)^{2}\right]^{1 / 2}
\end{array}
$$

Along with (11) and (22), we obtain the duality gap

$$
\begin{aligned}
0 & \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \\
& \leq \frac{(4 \sqrt{2}+2) \hat{\beta}_{t+1} \sqrt{d\left(E^{*}, x^{*}\right)}}{t+1}\left[m k+8(3+\sqrt{2}) \frac{\gamma}{r} L\|B\|_{2}^{2} d\left(E^{*}, x^{*}\right)\right. \\
& \left.+4\left(\|f\|_{2}+\sqrt{\gamma L\left(\rho_{u}-k r+r\right)}\|B\|_{2}\right)^{2}\right]^{1 / 2}
\end{aligned}
$$

2. Bound 2

Since

$$
\alpha_{l} \geq \frac{1}{\sqrt{L_{E}^{2} / \tau+L_{x}^{2} /(1-\tau)}}
$$

by [17. Theorem 3], we have

$$
\begin{aligned}
0 & \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \leq \frac{\delta_{t}}{\sum_{l=0}^{t} \alpha_{l}} \\
& \leq \frac{\hat{\beta}_{t+1}}{t+1}\left[\sigma\left(\tau D_{E}+(1-\tau) D_{x}\right)+\frac{1}{2 \sigma}\right] \sqrt{L_{E}^{2} / \tau+L_{x}^{2} /(1-\tau)} .
\end{aligned}
$$

We choose

$$
\sigma=\frac{1}{\sqrt{2 \tau D_{E}+2(1-\tau) D_{x}}}, \quad \tau=\frac{\sqrt{D_{x}} L_{E}}{\sqrt{D_{E} L_{x}+\sqrt{D_{x}} L_{E}}} .
$$

Then

$$
\begin{aligned}
0 & \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \\
& \leq \frac{\sqrt{2} \hat{\beta}_{t+1}}{t+1}\left(L_{E} \sqrt{D_{E}}+L_{x} \sqrt{D_{x}}\right) .
\end{aligned}
$$

From (17), (15), (16), (9), and (10), we have

$$
\begin{aligned}
0 & \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \\
& \leq \frac{0.37+\sqrt{2 t+1}}{t+1}\left[\sqrt{m^{2} k+L^{2} m \frac{\gamma}{r}\|B\|_{2}^{2} \eta^{2}}\left(\rho_{u}-k r\right)+2 \sqrt{L} \eta\|f\|_{2}\right. \\
& \left.+2 \sqrt{\gamma\left(\rho_{u}-k r+r\right)}\|B\|_{2} L \eta\right] .
\end{aligned}
$$

### 6.2 Computational Cost of Each Iteration

The costs of each iteration of our algorithm have two components: that from calculating the subgradients and that from solving the subproblems.

1. Cost of updating $s^{E}$ and $s^{x}$.

$$
\begin{aligned}
0 & \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \\
& \leq \frac{(4 \sqrt{2}+2) \hat{\beta}_{t+1} \sqrt{d\left(E^{*}, x^{*}\right)}}{t+1}\left[m k+8(3+\sqrt{2}) \frac{\gamma}{r} L\|B\|_{2}^{2} d\left(E^{*}, x^{*}\right)\right. \\
& \left.+4\left(\|f\|_{2}+\sqrt{\gamma L\left(\rho_{u}-k r+r\right)}\|B\|_{2}\right)^{2}\right]^{1 / 2}
\end{aligned}
$$

We don't keep $g_{E}$ and $g_{x}$ in memory, but update $s_{t+1}^{E}$ and $s_{t+1}^{x}$ directly. Since $g_{E}$ and $g_{x}$ share some same components, we compute $\sum_{l=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}$ and $A(E) x_{j}$ in the same loop. To balance the demands between memory and speed, we compute $s_{t+1}^{E}$ and $s_{t+1}^{x}$ as follows:

```
do j = 1 ... L
    if }j\in
        0}->
        \alphat\sqrt{}{\gamma}<A(E)\mp@subsup{x}{j}{},\mp@subsup{x}{j}{}\mp@subsup{\rangle}{}{-1/2}->\mp@subsup{u}{j}{}
        do i = 1 ...m
            \sum n== nig}\mp@subsup{B}{i,l}{}\mp@subsup{x}{j}{}\mp@subsup{x}{j}{T}\mp@subsup{B}{i,l}{T}->
            w}+\mp@subsup{A}{i}{}(E)\mp@subsup{x}{j}{}->
            s}\mp@subsup{}{\mp@subsup{E}{i}{}}{}-\mp@subsup{u}{j}{}q->\mp@subsup{s}{}{\mp@subsup{E}{i}{}}\quad(k(k+1) flops
        end i
    else
```

```
    end if
    s}\mp@subsup{x}{}{\mp@subsup{x}{j}{}}+2(\mp@subsup{\alpha}{t}{}\mp@subsup{f}{j}{}-\mp@subsup{u}{j}{}w)->\mp@subsup{s}{}{\mp@subsup{x}{j}{}}\quad(5N flops
end do j
s}\mp@subsup{}{}{E}+\mp@subsup{\alpha}{t}{}\mp@subsup{I}{k}{}->\mp@subsup{s}{}{E}\quad(mk flops
```

The inner products $\left\langle A(E) x_{j}, x_{j}\right\rangle$ are computed as follows:

```
0 ->u
do i = 1 ... m
    do l = 1 ... nig
        Bi,l}\mp@subsup{x}{j}{}->v\quad(2kN flops
```

```
        u+\mp@subsup{v}{}{T}p->u (2k flops)
    end do l
end do i
output s
```

In the algorithm, we keep the value $\sqrt{\gamma}$ in memory. Therefore, the arithmetic costs of calculating $\alpha_{t} \sqrt{\gamma}\left\langle A(E) x_{j}, x_{j}\right\rangle^{-1 / 2}$ for $j=1, \ldots, L$ are $\left(2 L \cdot m \cdot n i g \cdot\left[k N+k^{2}+k\right]+4 L\right)$ flops. The total length of auxiliary vectors $v, p$ and $u_{j}$ is $(N+k+L)$. After computing the $u_{j}$ 's, memory for $v$ and $p$ can be released.

We compute $\left(\sum_{l=1}^{n i g} B_{i, l} x_{j} x_{j}^{T} B_{i, l}^{T}\right)$ for $g_{E}$ and $A(E) x_{j}$ for $g_{x}$ in the same loop; i.e., the update of $q$ and $w$ in loop $i$ of the above algorithm is done as follows:

```
q }->
do l = 1 ... nig
    Bi,l}\mp@subsup{x}{j}{}->
    q+v\mp@subsup{v}{}{T}}
    Eiv 倝 v
    w+ B
end do l
```

The above 1 loop takes a total of $\operatorname{nig}\left(4 k N+3 k^{2}+k\right)$ flops. And it is executed at most $L m$ times. The total length of the auxiliary vectors $v, q$ and $w$ is $\left(k+\frac{k(k+1)}{2}+N\right)$.
Adding all together, we get that the total number of flops used in updating $s^{E}$ and $s^{x}$ is at most $(6 k L \cdot n i g) m N+\left[\left(5 k^{2}+3 k\right) L \cdot n i g+\left(k^{2}+k\right) L+k\right] m+(5 L) N+4 L$. And at most $\left(\frac{1}{2} k^{2}+\frac{3}{2} k+N+L\right)$ auxiliary storage space units are used.
2. Cost of solving the subproblems.

For $t=0, \ldots$, from the closed-from solution (7) given in $\S$, we obtain that it takes $L(3 N+7)$ flops to compute $x^{(t+1)}$. The value of $\beta_{t+1} \tau$ is stored for calculating $E^{(t+1)}$ later.
Now we consider the worst-case complexity of computing $E^{(t+1)}$. By the representation of $E^{(t+1)}$, it is obvious that the most computation is needed when

$$
\lambda<0, \quad \sum_{i=1}^{k} \lambda_{i}<\beta_{t+1} \tau\left(k r-\rho_{u}\right)
$$

Comparing $\sum_{q \in \bar{M}_{0}} \lambda_{q}$ with $\beta_{t+1} \tau\left(k r-\rho_{u}\right)$ and $\beta_{t+1} \tau\left(k r-\rho_{l}\right)$ takes $(2 k+7)$ flops and 3 auxiliary storage space units, since we can keep $k r$ as an intermediate result. Similarly to the analysis in $\S \S 1.2$ of Appendix: Matrix Projection, we can obtain the complexity of Algorithm projSyml as follows: Step 1 takes at most $k(k-1)$ comparisons and exchanges. Because we have already calculated $\beta_{t+1} \tau\left(k r-\rho_{u}\right), 2$ additions and subtractions are needed to obtain $T$. Step 2 takes at most $3(k-1)$ flops. Step 3 takes at most $(2+3 k)$ steps. Therefore, a total of at most $\left(k^{2}+7 k+8\right)$ flops are needed to obtain $\omega$. And $(k+4)$ auxiliary space units are needed to store the sorted index set, $T, \beta_{t+1} \tau, \beta_{t+1} \tau\left(k r-\rho_{u}\right), q$, since we overwrite the memory storing $\beta_{t+1} \tau\left(k r-\rho_{l}\right)$ by $T$.
Eigenvalue decomposition of $s_{t+1}^{E_{i}}$ takes about $9 k^{3}$ flops and $k^{2}+2 k+1$ auxiliary storage space units. Computing $U \operatorname{diag}(\omega) U^{T}$ takes about $\left(k^{2}(k+1)+k^{2}\right)$ flops. Therefore, at most $m\left(10 k^{3}+3 k^{2}+7 k+8\right)$ flops and $\left(k^{2}+2 k+1\right)$ auxiliary storage space units are needed to obtain $E^{(t+1)}$.

For problem (2), $k$ equals to 3 or $6 ; L$ and $n i g$ are much smaller than $m$ or $N$. After omitting small-order terms, we then conclude that about $(6 k L \cdot n i g) m N$ flops are needed for each iteration of our algorithm. And the auxiliary storage space units are about $N$.

On the other hand, to evaluate $\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle$ presented in the original formula (2), we need to first form the matrix $A(E)$, which requires $m \cdot n i g \cdot\left[2 k^{2} N+\left(k+\frac{1}{2}\right) N(N+1)\right]$ flops: computing $E_{i} B_{i, l}$ takes $2 k^{2} N$ flops; calculating $B_{i, l}^{T} E_{i} B_{i, l}$ for $k N(N+1)$ flops; adding the $m \cdot n i g$ matrices $B_{i, l}^{T} E_{i} B_{i, l}$ together requires $\frac{1}{2} m \cdot \operatorname{nig} N(N+1)$ flops. An auxiliary vector of size $\frac{N(N+1)}{2}$ is needed to store $A(E)$. We then compute the Cholesky factorization of $A(E)=C C^{T}$, which takes $\frac{N^{3}}{3}$ flops. Next we compute $z_{j}=C^{-T}\left(C^{-1} x_{j}\right)$ (for $j=1, \ldots, L)$, which needs $2 L N^{2}$ flops. Finally, the inner products $\left\langle z_{j}, x_{j}\right\rangle$ takes $2 L N$ flops to compute. Therefore, a total of $m \cdot n i g \cdot\left[2 k^{2} N+\left(k+\frac{1}{2}\right) N(N+1)\right]+\frac{N^{3}}{3}+2 L\left(N^{2}+N\right)$ flops and an auxiliary vector of size $\frac{N(N+1)}{2}$ are required to compute $\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle$ (for $j=1, \ldots, L$ ). After omitting small-order terms, we conclude that about $\frac{1}{3} N^{3}$ flops and $\frac{1}{2} N^{2}$ auxiliary storage space units are needed to obtain $\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle$.

In summary, the number of flops and auxiliary storage space units per iteration of our algorithm are both one order smaller than that for evaluating $\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle$. Furthermore, if the matrices $B_{i, l}$ are sparse, computational work per iteration and auxiliary storage space requirement of our algorithm will be even smaller.

## 7 Penalized Lagrangian

Because $\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle$ is convex in $E$, and the function $\left(\left[\sqrt{a}-\gamma^{1 / 2}\right]_{+}\right)^{2}$ is convex and increasing in $a$, we conclude that $\left(\left[\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle^{1 / 2}-\gamma^{1 / 2}\right]_{+}\right)^{2}$ is convex in $E$; see, for instance [9, Proposition 2.1.8]. To have a faster rate of convergence to feasibility, we add to the objective of (2) a convex penalty function for the compliance constraint:

$$
\sum_{j=1}^{L} \nu\left(\left[\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle^{1 / 2}-\gamma^{1 / 2}\right]_{+}\right)^{2}
$$

where $\nu>0$ is the penalty parameter.
Then the Lagrangian becomes

$$
p(E, x) \stackrel{\text { def }}{=} F(E, x)+\sum_{j=1}^{L} \nu\left(\left[\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle^{1 / 2}-\gamma^{1 / 2}\right]_{+}\right)^{2}
$$

which is convex in $E$ and concave in $x$. And a solution to

$$
\min _{\substack{E_{i} \in Q_{k}^{(i)} \\ k=1, \ldots, m}} \max _{\substack{x_{j} \in \mathbb{R}^{N}, j=1, \ldots, L}} p(E, x)
$$

approximate that of model (2).
The gradient of $p(E, x)$ at $(E, x)$ is

$$
\begin{aligned}
\nabla_{E_{i}} p(E, x)= & g_{E_{i}}(E, x)-\sum_{j \in W_{E}} \nu\left[1-\gamma^{1 / 2} /\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle^{1 / 2}\right]_{+} \\
& \cdot\left(\sum_{l=1}^{n i g} B_{i, l} A(E)^{-1} f_{j} f_{j}^{T} A(E)^{-1} B_{i, l}^{T}\right) \quad i=1, \ldots, m \\
\nabla_{x_{j}} p(E, x)= & g_{x_{j}}(E, x) \quad j=1, \ldots, L
\end{aligned}
$$

Similar to Lemma [1 we have the following results about the bounded version of penalized Lagrangian method.

Lemma $4 \operatorname{Let}(\tilde{E}, \tilde{x})$ be a solution to

$$
\begin{equation*}
\min _{\substack{E_{i} \in Q_{k}^{(i)} \\ i=1, \ldots, m}} \max _{\substack{\left\|x_{j}\right\| \leq \eta, j=1, \ldots, L}} p(E, x) \tag{25}
\end{equation*}
$$

Let $f^{*}$ be the optimal value of (21).

1. If $\left\|\tilde{x}_{j}\right\|<\eta$ for $j=1, \ldots, L$; then $\tilde{E}$ is a solution to the original problem.
2. Otherwise, $\tilde{E}$ has the following properties:
(a) $F(\tilde{E}) \leq F^{*}$.
(b) $\sum_{j \in W_{\tilde{E}}}\left(\left\langle f_{j}, A(\tilde{E})^{-1} f_{j}\right\rangle^{1 / 2}-\gamma^{1 / 2}\right) \leq$
$1 /\left[\sqrt{\frac{\nu}{\left(f^{*}-m \rho_{l}\right) \mid W_{\hat{E}}}+\frac{r^{2} \lambda_{\min }^{2}\left(B B^{T}\right) \eta^{2}}{\left(f^{*}-m \rho_{l}\right)^{2}}}+\frac{r \lambda_{\min }\left(B B^{T}\right) \eta}{f^{*}-m \rho_{l}}\right]$.
Proof: Proof for Item 1 is the same as that for Lemma 1t Item 2 can be proved similarly as Lemma 1] Below, we briefly give the proof.

For any fixed $E \in Q$, the point

$$
x_{j}= \begin{cases}\frac{\eta}{\left\|A(E)^{-1} f_{j}\right\|} A(E)^{-1} f_{j} & j \in W_{E} \\ 0 & j \notin W_{E}\end{cases}
$$

is feasible to

$$
\max _{\substack{\left\|x_{j}\right\| \leq \eta, j=1, \ldots, L}} p(E, x)
$$

with objective value

$$
p_{x}(E) \stackrel{\text { def }}{=}\langle I, E\rangle+\sum_{j \in W_{E}} \nu w_{j}^{2}(E)+2 \frac{\left\langle f_{j}, A(E)^{-1} f_{j}\right\rangle^{1 / 2}}{\left\|A(E)^{-1} f_{j}\right\|} \eta w_{j}(E)
$$

where

$$
w_{j}(E) \stackrel{\text { def }}{=}\left\langle f_{j}, A(\tilde{E})^{-1} f_{j}\right\rangle^{1 / 2}-\gamma^{1 / 2}, \quad j \in W_{E}
$$

Therefore,

$$
F^{*}-m \rho_{l} \geq \sum_{j \in W_{\tilde{E}}} \nu w_{j}^{2}(\hat{E})+2 r \lambda_{\min }\left(B B^{T}\right) \eta w_{j}(\hat{E})
$$

from which we obtain

$$
\begin{gathered}
F^{*}-m \rho_{l}+\left|W_{\hat{E}}\right| r^{2} \lambda_{\min }^{2}\left(B B^{T}\right) \eta^{2} / \nu \geq \sum_{j \in W_{\tilde{E}}} \nu\left[w_{j}(\hat{E})+r \lambda_{\min }\left(B B^{T}\right) \eta / \nu\right]^{2} \\
\geq \frac{\nu}{\left|W_{\hat{E}}\right|}\left[\sum_{j \in W_{\tilde{E}}} w_{j}(\hat{E})+\left|W_{\hat{E}}\right| r \lambda_{\min }\left(B B^{T}\right) \eta / \nu\right]^{2}
\end{gathered}
$$

Hence,

$$
\sum_{j \in W_{\tilde{E}}} w_{j}(\hat{E}) \leq 1 /\left[\sqrt{\frac{\nu}{\left(f^{*}-m \rho_{l}\right)\left|W_{\hat{E}}\right|}+\frac{r^{2} \lambda_{\min }^{2}\left(B B^{T}\right) \eta^{2}}{\left(f^{*}-m \rho_{l}\right)^{2}}}+\frac{r \lambda_{\min }\left(B B^{T}\right) \eta}{F^{*}-m \rho_{l}}\right] .
$$

Observe that as $\eta \rightarrow+\infty$ and $\nu \rightarrow+\infty$, the set of saddle-points of (25) approaches that of (22).
We can apply the preceding algorithm to obtain a saddle-point of $p(E, x)$ as well. And its subproblems have closed-form solutions.

Bounds on duality gaps To estimate the duality gap of each iteration, We first bound $\nabla_{E} p(E, x)$ as follows

$$
\begin{aligned}
\left\|\nabla_{E} p(E, x)\right\|_{F, *} & \leq L_{E}+\nu\left[\sum_{i=1}^{m} \operatorname{tr}\left(\sum_{j=1}^{L} \sum_{l=1}^{n i g} B_{i, l} A(E)^{-1} f_{j} f_{j}^{T} A(E)^{-1} B_{i, l}^{T}\right)^{2}\right]^{1 / 2} \\
& \leq L_{E}+\nu \operatorname{tr}\left(\sum_{i=1}^{m} \sum_{j=1}^{L} \sum_{l=1}^{n i g} B_{i, l} A(E)^{-1} f_{j} f_{j}^{T} A(E)^{-1} B_{i, l}^{T}\right)^{2} \\
& =L_{E}+\nu \sum_{j=1}^{L} \sum_{i=1}^{m} \sum_{l=1}^{n i g} f_{j}^{T} A(E)^{-1} B_{i, l}^{T} B_{i, l} A(E)^{-1} f_{j} \\
\lambda_{\min }(E)=r & L_{E}+\nu / r \sum_{j=1}^{L} f_{j}^{T} A(E)^{-1} f_{j} \\
& \leq \quad L_{E}+\frac{\nu}{r^{2} \lambda_{\min }\left(B^{T} B\right)} \sum_{j=1}^{L}\left\|f_{j}\right\|_{2}^{2}
\end{aligned}
$$

where the last inequality is from

$$
\lambda_{\min }(A(E)) \geq \lambda_{\min }(E) \lambda_{\min }\left(B^{T} B\right)=r \lambda_{\min }\left(B^{T} B\right)
$$

By (9), (19), (18), and (20) in 96 we obtain that the duality gaps of the iterates are bounded as follows: for $t=0, \ldots$,

$$
0 \leq \max _{x_{j} \in Q_{x}} F\left(\hat{E}^{(t+1)}, x\right)-\min _{E_{i} \in Q_{k}^{(i)}} F\left(E, \hat{x}^{(t+1)}\right) \leq g a p+\frac{0.37+\sqrt{2 t+1}}{t+1} \frac{\sqrt{m}\left(\rho_{u}-k r\right) \nu}{r^{2} \lambda_{\min }\left(B^{T} B\right)} \sum_{j=1}^{L}\left\|f_{j}\right\|_{2}^{2}
$$

Cost of each iteration. Compared with (5), extra computation is needed to calculate $\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle$ for $j=1, \ldots, L$ in order to solve (25), which is $\mathcal{O}\left(N^{3}\right)$ flops; see the analysis at the end of $\mathbb{4} 6$. Therefore, the total cost of each iteration for solving (25) is $\mathcal{O}\left(N^{3}\right)$ flops and $\mathcal{O}\left(N^{2}\right)$ memory space units.

## 8 Numerical Examples

Below, we present some computational examples which are done in the MATLAB environment on a windows PC. For each run, the starting point is as follows: We choose $E_{0}$ to be the identity matrix with trace equals to the upper bound of trace. For $j=1, \ldots, L$, we let $x_{j}$ be a vector with the same element and $\left\|x_{j}\right\|_{2}=\eta$.

Figure 1 shows how the objective value and the violation of constraints vary with the number of iterations. The problem instance is tc18_s1 from the academic test library of the Plato project (ww.plato-n.org) with $m=128, N=298, L=1$, nig $=4$.

The figure shows that during the first few iterations the objective value decreases but the constraint violation increases rapidly, where constraint violation is measured by $\sum_{j=1}^{L} \min \left[\left(\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle-\gamma\right), 0\right]$. With iterations moving on, the constraint violation decreases with the objective value.

Figure 1: An Example From the Academic Test Library

In Table 1 and Table 2 we present further numerical results on problems in the academic test library of the Plato project (wWW.plato-n.org). In the tables, columns 'cpu' give the total CPU times in seconds; columns 'obj' give the final objective values; column 'obj0' gives the initial objective values; column 'const' indicates whether the constraints are satisfied or not for the final solutions: ' f ' means feasible. We compare formulas (5) and (25) on some infeasible problems, because constraints of these problems are difficult. The results are presented in Table 2, For each instance, we run 5000 gradient iterations. In Table 2, columns 'const' give the sum of the values of the violation of constraints; i.e. $\sum_{j=1}^{L} \min \left[\left(\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle-\gamma\right), 0\right]$. Columns 'obj- 0 ' and 'const- 0 ' give objective values and the sum of values of the violation of constraints for the initial solutions. Columns 'obj-p' and 'const-p' give objective values and the sum of the values of the violation of constraints of the final solutions obtained by model (25). Columns 'obj' and 'const' give objective values and the sum of the values of the violation of constraints of the final solutions obtained by model (5).

From the results in Table 2, we see that the penalized Lagrangian can produce a better solution for infeasible problems, although it may not be the case for feasible problems. The penalty term forces iterates to move to the feasible region. On the other hand, because each iteration is much cheaper without calculating $\left\langle A(E)^{-1} f_{j}, f_{j}\right\rangle$, the penalized Lagrangian takes longer to solve a problem instance of FMO. The larger the dimension of the problem, the less time model (5) used compared with model (25).

## Appendix: Matrix Projection

Let $\mathcal{H}^{n}$ denote the space of $n \times n$ Hermitian matrices. We take the standard inner product on the space of complex square matrices of order $n$ (or linear operators between Hilbert spaces of same dimension): $\forall U, V \in$ $\mathbb{C}^{n \times n}$,

$$
\langle U, V\rangle=\operatorname{tr}\left(U V^{*}\right),
$$

where $V^{*}$ is the conjugate transpose of $V$. Let $\|\cdot\|_{F}$ denote the corresponding Frobenius norm. In this part, we give a closed-form solution to the following projection problem:

$$
\begin{array}{rc}
\min _{Z \in \mathcal{H}^{n}} & \|Z-U\|_{F} \\
\text { s.t. } & c_{l} \leq \operatorname{tr}(Z) \leq c_{u}  \tag{26}\\
& \lambda_{\text {min }}(Z) \geq r,
\end{array}
$$

where $U$ is a square complex matrix of order $n$.
To this end, we first consider a least squares problem with nonnegativity constraint and a two sided inequality.

### 1.1 Least squares with a two-sided inequality and non-negative variables

Least squares problems have been studied intensively; however, we cannot find any reference for the problem discussed in this section elsewhere. In this part, we first give an analytical solution of the problem; then we present an algorithm with total number of operations being a quadratic term in the dimension of problem variable.

Given $A \in \mathbb{R}^{n \times n}$ be diagonal, $b \in \mathbb{R}^{n}, w \in \mathbb{R}^{n}, r \in \mathbb{R}^{n}, c_{l} \in \mathbb{R} \cup\{-\infty\}, c_{u} \in \mathbb{R} \cup\{+\infty\}$ with $c_{l} \leq c_{u}$. Let $\|\cdot\|_{2}$ denote the norm induced by the inner product $\langle\cdot, \cdot\rangle$. In this part, we give an analytical solution for the following least squares problem:

$$
\begin{array}{cc}
\min _{z \in \mathbb{R}^{n}} & \|A z-b\|_{2}^{2} \\
\text { s.t. } & c_{l} \leq\langle w, z\rangle \leq c_{u}  \tag{27}\\
& z \geq r .
\end{array}
$$

Note that our problem includes the one-side inequality case when $c_{l}=-\infty$ or $c_{u}=+\infty$, the lower bounded variable case when $c_{l}=-\infty$ and $c_{u}=+\infty$, one equality case when $c_{l}=c_{u}$. Our problem also includes the case when not all variables are bounded, since we can replace an unconstrained variable $z_{i} \in \mathbb{R}$ by $z_{i}=z_{i}^{+}-z_{i}^{-}$ with $z_{i}^{+} \geq 0, z_{i}^{-} \geq 0$.

### 1.1.1 Problem Reduction

To solve problem (27), we first show that we only need to consider the case with $A$ being identity and $w_{i} \neq 0$ for $i=1, \ldots, n$.

If there exists ( $\exists$ ) $a_{i i}=0, w_{i}=0$, we let

$$
z_{i}^{*}=r_{i} .
$$

If $\exists a_{i i}=0, w_{i}>0$, we let

$$
z_{i}^{*}=\max \left\{\left[c_{l}-\sum_{\left(1 \leq j \leq n: a_{j j} \neq 0\right.} w_{j} \max \left\{b_{j} / a_{j j}, r_{j}\right\}\right]_{+} / w_{i}, r_{i}\right\} .
$$

If $\exists a_{i i}=0, w_{i}<0$, we let

$$
z_{i}^{*}=\max \left\{-\left[\sum_{\left(1 \leq j \leq n: a_{j j} \neq 0\right)} w_{j} \max \left\{b_{j} / a_{j j}, r_{j}\right\}-c_{u}\right]_{+} / w_{i}, r_{i}\right\} .
$$

We also replace $c_{u}$ and $c_{l}$ by

$$
c_{u}-w_{i} z_{i}^{*}, \quad c_{l}-w_{i} z_{i}^{*} .
$$

If $\exists a_{i i}<0$, we replace $a_{i i}$ with $-a_{i i}$ and $b_{i}$ with $-b_{i}$.
Hence after simplification, we can assume that $A$ is a positive diagonal matrix in the text below. And our least squares problem is equivalent to

$$
\begin{array}{cc}
\min _{z \in \mathbb{R}^{n}} & \|z-b+A r\|_{2}^{2} \\
\text { s.t. } & c_{l}-\langle w, r\rangle \leq\left\langle A^{-1} w, z\right\rangle \leq c_{u}-\langle w, r\rangle \\
z \geq 0
\end{array}
$$

Therefore, for notation simplicity, we only need to consider problem (27) in the following form:

$$
\begin{array}{cc}
\min _{z \in \mathbb{R}^{n}} & \|z-b\|_{2}^{2} \\
\text { s.t. } & c_{l} \leq\langle w, z\rangle \leq c_{u}  \tag{28}\\
& z \geq 0
\end{array}
$$

If $w_{i}=0$ for some $i \in\{1, \ldots, n\}$ in problem (28); then the corresponding solution of $z_{i}$ must be $\left[b_{i}\right]_{+}$. After determining the solutions for these elements, we thereafter assume $w_{i} \neq 0$ for $i=1, \ldots, n$.

### 1.1.2 Analytical Solution

In this part, we deduce the analytical solution for our least squares problem.
Theorem 3 The solution to (28) is

$$
z^{*}=\left[b-\frac{\left[\langle\tilde{w}, \tilde{b}\rangle-c_{u}\right]_{+}}{\|\tilde{w}\|_{2}^{2}} w+\frac{\left[c_{l}-\langle\tilde{w}, \tilde{b}\rangle\right]_{+}}{\|\tilde{w}\|_{2}^{2}} w\right]_{+}
$$

where $\tilde{w}$ and $\tilde{b}$ denote the subvectors of $w$ and $b$ with indices in the set

$$
S=\left\{1 \leq i \leq n: b_{i}>\frac{\left[\langle\tilde{w}, \tilde{b}\rangle-c_{u}\right]_{+}}{\|\tilde{w}\|_{2}^{2}} w_{i}-\frac{\left[c_{l}-\langle\tilde{w}, \tilde{b}\rangle\right]_{+}}{\|\tilde{w}\|_{2}^{2}} w_{i}\right\}
$$

Proof: Because the constraints of problem eq:SLS are linear, Lagrange multipliers exist. Let's write down the Lagrangian function:

$$
L(z, \lambda)=\|z-b\|_{2}^{2}+\lambda_{l}\left(c_{l}-\langle w, z\rangle\right)+\lambda_{u}\left(\langle w, z\rangle-c_{u}\right), \quad\left(z \geq 0, \lambda_{l} \geq 0, \lambda_{u} \geq 0\right)
$$

The solutions to problem (28) can be obtained by solving the following problem:

$$
\max _{\lambda_{l} \geq 0, \lambda_{u} \geq 0} \min _{z \geq 0} L(z, \lambda)
$$

Note that

$$
L(z, \lambda)=\left\|z-b+\frac{\lambda_{u}-\lambda_{l}}{2} w\right\|_{2}^{2}-\left(\frac{\lambda_{u}-\lambda_{l}}{2}\right)^{2}\|w\|_{2}^{2}+\left(\lambda_{u}-\lambda_{l}\right)\langle w, b\rangle+\lambda_{l} c_{l}-\lambda_{u} c_{u}
$$

from which we conclude that the solution to the Lagrangian dual $\min _{z \geq 0} L(z, \lambda)$ is

$$
z^{*}=\left[b-\frac{\lambda_{u}-\lambda_{l}}{2} w\right]_{+}
$$

We next determine the optimal values for $\lambda_{u}$ and $\lambda_{l}$.
We first consider $\lambda_{l}$.
Let $S$ denote the index set

$$
S \stackrel{\text { def }}{=}\left\{1 \leq i \leq n: b_{i}>\frac{\lambda_{u}-\lambda_{l}}{2} w_{i}\right\}
$$

Let $\tilde{w}$ and $\tilde{b}$ denote the subvectors of $w$ and $b$ with indices in $S$. Let $\bar{b}$ denote the subvector of $b$ with indices not in $S$. We then have

$$
\left.\begin{array}{rl}
L\left(z^{*}, \lambda\right)= & -\left(\frac{\lambda_{u}-\lambda_{l}}{2}\right)^{2}\|\tilde{w}\|_{2}^{2}+\left(\lambda_{u}-\lambda_{l}\right)\langle\tilde{w}, \tilde{b}\rangle+\lambda_{l} c_{l}-\lambda_{u} c_{u}+\|\bar{b}\|_{2}^{2} \\
= & -\left(\frac{\|\tilde{w}\|_{2}}{2} \lambda_{l}-\frac{\|\tilde{w}\|_{2}^{2}}{2} \lambda_{u}-\langle\tilde{w}, \tilde{b}\rangle+c_{l}\right. \\
\|\tilde{w}\|_{2}
\end{array}\right)^{2}+\left(\frac{\|\tilde{w}\|_{2}^{2}}{2} \lambda_{u}-\langle\tilde{w}, \tilde{b}\rangle+c_{l}\right)^{2}\|\tilde{w}\|_{2} \quad\left(\tilde{b} \|_{2}^{2}-\frac{\|\tilde{w}\|_{2}^{2}}{4} \lambda_{u}^{2}+\lambda_{u}\langle\tilde{w}, \tilde{b}\rangle-\lambda_{u} c_{u} .\right.
$$

Hence a solution of $\lambda_{l}$ for $\max _{\lambda \geq 0} L\left(z^{*}, \lambda\right)$ must be in the form

$$
\lambda_{l}^{*}=\left[\lambda_{u}-\frac{2}{\|\tilde{w}\|_{2}^{2}}\left(\langle\tilde{w}, \tilde{b}\rangle-c_{l}\right)\right]_{+}
$$

To determine the solution of $\lambda_{u}$, we consider different cases.
Case 1. For $\lambda_{u}<\frac{2}{\|\tilde{w}\|_{2}^{2}}\left(\langle\tilde{w}, \tilde{b}\rangle-c_{l}\right)$, the representation of $\lambda_{l}^{*}$ is reduced to

$$
\lambda_{l}^{*}=0
$$

Since $\lambda_{u} \geq 0$, we have

$$
\langle\tilde{w}, \tilde{b}\rangle>c_{l} .
$$

And

$$
\begin{aligned}
L\left(z^{*}, \lambda_{l}^{*}, \lambda_{u}^{*}\right) & =-\frac{\|\tilde{w}\|_{2}^{2}}{4} \lambda_{u}^{2}+\langle\tilde{w}, \tilde{b}\rangle \lambda_{u}-c_{u} \lambda_{u}+\|\bar{b}\|_{2}^{2} \\
& =-\left(\frac{\|\tilde{w}\|_{2}}{2} \lambda_{u}-\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}}{\|\tilde{w}\|_{2}}\right)^{2}+\|\bar{b}\|_{2}^{2}+\left(\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}}{\|\tilde{w}\|_{2}}\right)^{2} .
\end{aligned}
$$

Therefore, for this case, the solution to $\max _{\lambda \geq 0} L\left(z^{*}, \lambda\right)$ is

$$
\lambda_{u}^{*}=\frac{2}{\|\tilde{w}\|_{2}^{2}}\left[\langle\tilde{w}, \tilde{b}\rangle-c_{u}\right]_{+}
$$

Case 1.a. When $c_{l}<\langle\tilde{w}, \tilde{b}\rangle<c_{u}$, we have

$$
\lambda_{u}^{*}=0, \quad z^{*}=[b]_{+}
$$

Case 1.b. When $\langle\tilde{w}, \tilde{b}\rangle \geq c_{u}$, we have

$$
\begin{aligned}
\lambda_{u}^{*} & =\frac{2}{\|\tilde{w}\|_{2}^{2}}\left(\langle\tilde{w}, \tilde{b}\rangle-c_{u}\right) \\
z^{*} & =\left[b-\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}}{\|\tilde{w}\|_{2}^{2}} w\right]_{+} \\
\left\langle w, z^{*}\right\rangle & =c_{u} .
\end{aligned}
$$

Case 2. For $\lambda_{u} \geq \frac{2}{\|\tilde{w}\|_{2}^{2}}\left(\langle\tilde{w}, \tilde{b}\rangle-c_{l}\right)$, we have

$$
\lambda_{l}^{*}=\lambda_{u}-\frac{2}{\|\tilde{w}\|_{2}^{2}}\left(\langle\tilde{w}, \tilde{b}\rangle-c_{l}\right)
$$

And

$$
L\left(z^{*}, \lambda_{l}^{*}, \lambda_{u}\right)=\left(c_{l}-c_{u}\right) \lambda_{u}+\left(\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{l}}{\|\tilde{w}\|_{2}}\right)^{2}+\|\bar{b}\|_{2}^{2}
$$

Therefore, in this case, the solution to $\max _{\lambda \geq 0} L\left(z^{*}, \lambda\right)$ is

$$
\begin{aligned}
\lambda_{u}^{*} & =0 \\
\lambda_{l}^{*} & =2 \frac{c_{l}-\langle\tilde{w}, \tilde{b}\rangle}{\|\tilde{w}\|_{2}^{2}} \\
z^{*} & =\left[b+\frac{c_{l}-\langle\tilde{w}, \tilde{b}\rangle}{\|\tilde{w}\|_{2}^{2}} w\right]_{+} \\
\left\langle w, z^{*}\right\rangle & =c_{l} .
\end{aligned}
$$

Because $\lambda_{l}^{*} \geq 0$, this case implies

$$
\langle\tilde{w}, \tilde{b}\rangle \leq c_{l}
$$

Combining Case 1 and Case 2, we obtain

$$
z^{*}=\left[b-\frac{\left[\langle\tilde{w}, \tilde{b}\rangle-c_{u}\right]_{+}}{\|\tilde{w}\|_{2}^{2}} w+\frac{\left[c_{l}-\langle\tilde{w}, \tilde{b}\rangle\right]_{+}}{\|\tilde{w}\|_{2}^{2}} w\right]_{+}
$$

where $\tilde{w}$ denote the subvector of $w$ with indices in the set

$$
S=\left\{1 \leq i \leq n: b_{i}>\frac{\left[\langle\tilde{w}, \tilde{b}\rangle-c_{u}\right]_{+}}{\|\tilde{w}\|_{2}^{2}} w_{i}-\frac{\left[c_{l}-\langle\tilde{w}, \tilde{b}\rangle\right]_{+}}{\|\tilde{w}\|_{2}^{2}} w_{i}\right\}
$$

Remark 1 In our deduction, it is obvious that for $c_{l}=-\infty$, we have $\lambda_{l}^{*}=0$; for $c_{u}=+\infty$, we have $\lambda_{u}^{*}=0$.

### 1.1.3 Algorithm

From the discussion in the previous section, we know that to find the optimal solution $z^{*}$ of our least squares problem, we only need to determine the set $S$. In this part, we describe how to find the set $S$ for our solution.

Properties of $S$ based on Lagrange multipliers We first give some simple observations which will be used later on.

Proposition 1 Let $r_{1} \in \mathbb{R}, r_{3} \in \mathbb{R}, r_{2}>0, r_{4}>0$. Then

$$
\begin{aligned}
& \frac{r_{1}}{r_{2}}>\frac{r_{3}}{r_{4}} \Leftrightarrow \frac{r_{1}}{r_{2}}>\frac{r_{3}+r_{1}}{r_{4}+r_{2}} \\
& \frac{r_{1}}{r_{2}}<\frac{r_{3}}{r_{4}} \Leftrightarrow \frac{r_{1}}{r_{2}}<\frac{r_{3}+r_{1}}{r_{4}+r_{2}}
\end{aligned}
$$

We next give some properties of the set $S$ based on Lagrange multipliers. Observe that $\lambda_{l}^{*}$ and $\lambda_{u}^{*}$ cannot be both positive at the same time. We organize our analysis based on scenarios depending on the signs of the Lagrange multipliers.

Case 1. $\lambda_{u}^{*}>0$.
By the deduction above and Lagrange multiplier properties, we have the corresponding relations:

$$
\begin{aligned}
\langle w, z\rangle & =c_{u} \\
\langle\tilde{w}, \tilde{b}\rangle & >c_{u} \\
\lambda_{u}^{*} & =2 \frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}}{\|\tilde{w}\|_{2}^{2}} .
\end{aligned}
$$

We next consider which indices are in the set $S$.

1. $S_{1} \stackrel{\text { def }}{=}\left\{i: w_{i}>0, b_{i} \geq 0\right\}$ :

Lemma 5 Suppose $\frac{b_{j}}{w_{j}} \geq \frac{b_{i}}{w_{i}}$. If $i \in S$; then $j \in S$ as well.
Proof: Assume $j \notin S$. Since $i \in S$, we have

$$
\frac{b_{j} w_{j}}{w_{j}^{2}} \geq \frac{b_{i} w_{i}}{w_{i}^{2}}>\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}}{\|\tilde{w}\|_{2}^{2}}
$$

By Proposition 1, we have

$$
\frac{b_{j} w_{j}}{w_{j}^{2}}>\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}+b_{j} w_{j}}{\|\tilde{w}\|_{2}^{2}+w_{j}^{2}}
$$

Therefore, $j \in S$.
2. $S_{2} \stackrel{\text { def }}{=}\left\{i: w_{i}>0, b_{i}<0\right\}$ :

By the definition of $S$, we have $S_{2} \nsubseteq S$.
3. $S_{3} \stackrel{\text { def }}{=}\left\{i: w_{i}<0, b_{i} \geq 0\right\}$ :

It is obvious $S_{3} \subseteq S$.
4. $S_{4} \stackrel{\text { def }}{=}\left\{i: w_{i}<0, b_{i}<0\right\}$ :

Lemma 6 Suppose $\frac{b_{j}}{w_{j}} \leq \frac{b_{i}}{w_{i}}$. If $i \in S$; then $j \in S$ as well.
Proof: Assume $j \notin S$. Since $i \in S$, we have

$$
\frac{b_{j} w_{j}}{w_{j}^{2}} \leq \frac{b_{i} w_{i}}{w_{i}^{2}}<\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}}{\|\tilde{w}\|_{2}^{2}}
$$

By Proposition 1, we have

$$
\frac{b_{j} w_{j}}{w_{j}^{2}}<\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}+b_{j} w_{j}}{\|\tilde{w}\|_{2}^{2}+w_{j}^{2}}
$$

Therefore, $j \in S$.

Case 2. $\quad \lambda_{l}^{*}>0$.
For this case, we have

$$
\begin{aligned}
\left\langle w, z^{*}\right\rangle & =c_{l} \\
\langle\tilde{w}, \tilde{b}\rangle & <c_{l} \\
\lambda_{l}^{*} & =2 \frac{c_{l}-\langle\tilde{w}, \tilde{b}\rangle}{\|\tilde{w}\|_{2}^{2}} .
\end{aligned}
$$

We now determine which indices are in the set $S$.

1. $S_{1} \stackrel{\text { def }}{=}\left\{i: w_{i}>0, b_{i} \geq 0\right\}$ :

By the definition of $S$, we have $S_{1} \subseteq S$.
2. $S_{2} \stackrel{\text { def }}{=}\left\{i: w_{i}>0, b_{i}<0\right\}$ :

Similar to the case for $\lambda_{u}^{*}>0$, we have:
Suppose $\frac{b_{j}}{w_{j}} \geq \frac{b_{i}}{w_{i}}$. If $i \in S$; then $j \in S$ as well.
3. $S_{3} \stackrel{\text { def }}{=}\left\{i: w_{i}<0, b_{i} \geq 0\right\}$ :

Similar to the case for $\lambda_{u}^{*}>0$, we have:
Suppose $\frac{b_{j}}{w_{j}} \leq \frac{b_{i}}{w_{i}}$. If $i \in S$; then $j \in S$ as well.
4. $S_{4} \stackrel{\text { def }}{=}\left\{i: w_{i}<0, b_{i}<0\right\}$ :

By the definition of $S$, we have $S_{4} \nsubseteq S$.
Case 3. $\quad \lambda_{l}^{*}=\lambda_{u}^{*}=0$.
For this case, we have

$$
Z^{*}=[b]_{+} .
$$

Determine the signs of Lagrange multipliers We next show that whether the Lagrange multiplier is positive or not can be determined by $\left\langle w,[b]_{+}\right\rangle$.

Lemma 7 The Lagrange multiplier $\lambda_{l}^{*}$ satisfies the following condition:

$$
\lambda_{l}^{*} \begin{cases}=0 & \left\langle w,[b]_{+}\right\rangle \geq c_{l} \\ >0 & \left\langle w,[b]_{+}\right\rangle<c_{l}\end{cases}
$$

Proof: We first use contradiction to prove the result for the case $\left\langle w,[b]_{+}\right\rangle \geq c_{l}$. Assume $\lambda_{l}^{*}>0$. By the properties for $\lambda_{l}^{*}>0$, we have $c_{l}>\langle\tilde{w}, \tilde{b}\rangle$ and $S_{1} \subseteq S$. Since $\left\langle w,[b]_{+}\right\rangle \geq c_{l}$, we must have $S_{2} \cap S \neq \emptyset$.

Let $l \in S_{2} \cap S$ such that $\frac{b_{l}}{w_{l}} \cdot \frac{w_{j}}{b_{j}} \geq 1\left(\forall j \in S_{2} \cap S\right)$. We would have

$$
\begin{aligned}
\sum_{j \in S_{2} \cap S} \frac{b_{l}}{w_{l}} w_{j}^{2}=\sum_{j \in S_{2} \cap S}\left(\frac{b_{l}}{w_{l}} \cdot \frac{w_{j}}{b_{j}}\right) w_{j} b_{j} & \leq \sum_{j \in S_{2} \cap S} w_{j} b_{j} \\
0 & \leq \sum_{j \in S \backslash S_{2}} w_{j} b_{j}-c_{l}=\left\langle w,[b]_{+}\right\rangle-c_{l}
\end{aligned}
$$

Adding the above two inequalities together, we would have

$$
-\frac{b_{l}}{w_{l}} \geq \frac{c_{l}-\sum_{j \in S} w_{j} b_{j}}{\sum_{j \in S_{2} \cap S} w_{j}^{2}} \geq \frac{1}{2} \lambda_{l}^{*}
$$

contradicting to $l \in S$.
We next consider the case $\left\langle w,[b]_{+}\right\rangle<c_{l}$.
By the assumption, we have

$$
\begin{aligned}
c_{l}-\left\langle w,[b]_{+}\right\rangle=c_{l}- & \sum_{i \in S \cap\left(S_{1} \cup S_{3}\right)} w_{j} b_{j}
\end{aligned}>0 .
$$

Adding the above two inequalities together, we have

$$
\lambda_{l}^{*}>0
$$

Similarly, we have the results for $\lambda_{u}^{*}$.

Lemma 8 The Lagrange multiplier $\lambda_{u}^{*}$ satisfies the following condition:

$$
\lambda_{u}^{*} \begin{cases}=0 & \left\langle w,[b]_{+}\right\rangle \leq c_{u} \\ >0 & \left\langle w,[b]_{+}\right\rangle>c_{u}\end{cases}
$$

For the case $\lambda_{u}^{*}>0$, deleting any index from the set $S_{1} \cap S$ decreases the value $\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{u}}{\|\tilde{w}\|_{2}^{2}}$, and deleting any index from the set $S_{4} \cap S$ increases that value. Similarly, for the case $\lambda_{l}^{*}>0$, deleting any index from the set $S_{2} \cap S$ decreases the value $\frac{\langle\tilde{w}, \tilde{b}\rangle-c_{l}}{\|\tilde{w}\|_{2}^{2}}$, and deleting any index from the set $S_{3} \cap S$ increases that value.

The discussion above proves that our algorithm below finds an optimal solution of the problem (27).
Algorithm Reduce problem (27) to the form (28) and solve problem (28):
Let $n_{i}$ be the cardinality of the index set $S_{i},(i=1, \ldots, 4)$. We first compute $\left\langle w,[b]_{+}\right\rangle$.

- If $\left\langle w,[b]_{+}\right\rangle \in\left[c_{l}, c_{u}\right]$, we let

$$
z^{*}=[b]_{+} .
$$

- If $\left\langle w,[b]_{+}\right\rangle>c_{u}$, we do the following.

1. Re-order the elements in $S_{1}$ so that

$$
b_{\sigma(1)} / w_{\sigma(1)} \geq b_{\sigma(2)} / w_{\sigma(2)} \geq \cdots b_{\sigma\left(n_{1}\right)} / w_{\sigma\left(n_{1}\right)}
$$

Re-order the elements in $S_{4}$ so that

$$
b_{\tau(1)} / w_{\tau(1)} \leq b_{\tau(2)} / w_{\tau(2)} \leq \cdots b_{\tau\left(n_{1}\right)} / w_{\tau\left(n_{4}\right)}
$$

2. Let

$$
S=S_{3}, \quad T=\sum_{i \in S_{3}} w_{i} b_{i}-c_{u}, \quad v=\sum_{i \in S_{3}} w_{i}^{2}, \quad j=1, \quad l=1
$$

3. Repeat the following two while loops till stable.

While $v \frac{b_{\sigma(j)}}{w_{\sigma(j)}}>T$ and $j \leq n_{1}$, do

$$
S \cup\{\sigma(j)\} \rightarrow S, \quad T+w_{\sigma(j)} b_{\sigma(j)} \rightarrow T, \quad v+w_{\sigma(j)}^{2} \rightarrow v, \quad j+1 \rightarrow j
$$

While $v \frac{b_{\tau(l)}}{w_{\tau(l)}}<T$ and $l \leq n_{4}$, do

$$
S \cup\{\tau(l)\} \rightarrow S, \quad T+w_{\tau(l)} b_{\tau(l)} \rightarrow T, \quad v+w_{\tau(l)}^{2} \rightarrow v, \quad l+1 \rightarrow l
$$

4. Let

$$
z_{i}^{*}= \begin{cases}0 & i \in \bar{S} \\ b_{i}-\frac{T}{v} w_{i} & i \in S\end{cases}
$$

- If $\left\langle w,[b]_{+}\right\rangle<c_{l}$, we do the following.

1. Re-order the elements in $S_{2}$ so that

$$
b_{\sigma(1)} / w_{\sigma(1)} \geq b_{\sigma(2)} / w_{\sigma(2)} \geq \cdots b_{\sigma\left(n_{2}\right)} / w_{\sigma\left(n_{2}\right)}
$$

Re-order the elements in $S_{3}$ so that

$$
b_{\tau(1)} / w_{\tau(1)} \leq b_{\tau(2)} / w_{\tau(2)} \leq \cdots b_{\tau\left(n_{3}\right)} / w_{\tau\left(n_{3}\right)}
$$

2. Let

$$
S=S_{1}, \quad T=\sum_{i \in S_{1}} w_{i} b_{i}-c_{l}, \quad v=\sum_{i \in S_{1}} w_{i}^{2}, \quad j=1, \quad l=1 .
$$

3. Repeat the following two while loops till stable.
(a) While $v \frac{b_{\sigma(j)}}{w_{\sigma(j)}}>T$ and $j \leq n_{2}$, let

$$
S \cup\{\sigma(j)\} \rightarrow S, \quad T+w_{\sigma(j)} b_{\sigma(j)} \rightarrow T, \quad v+w_{\sigma(j)}^{2} \rightarrow v, \quad j+1 \rightarrow j
$$

(b) While $v \frac{b_{\tau(l)}}{w_{\tau(l)}}<T$ and $l \leq n_{3}$, let

$$
S \cup\{\tau(l)\} \rightarrow S, \quad T+w_{\tau(l)} b_{\tau(l)} \rightarrow T, \quad v+w_{\tau(l)}^{2} \rightarrow v, \quad l+1 \rightarrow l
$$

4. Let

$$
z_{i}^{*}= \begin{cases}0 & i \in \bar{S} \\ b_{i}-\frac{T}{v} w_{i} & i \in S\end{cases}
$$

Lemma 9 After reducing problem (27) to problem (28), the algorithm above stops at an optimal solution to (28) with at most $n^{2}+14 n+1$ arithmetic operations and $2 n+3$ auxiliary storage space units. If all $w_{i}=1$, the above algorithm needs at most $n^{2}+7 n+1$ arithmetic operations and $n+2$ auxiliary storage space units.

Proof: Determining the signs of $b_{i}$ and computing $\left\langle w,[b]_{+}\right\rangle$takes $3 n-1$ flops. Further dividing the index set into $S_{1}, \ldots, S_{4}$ takes another $n$ flops. Comparing $\left\langle w,[b]_{+}\right\rangle$with $c_{l}$ and $c_{u}$ takes 2 operations. Computing $b_{i} / w_{i}(i=1, \ldots, n)$ takes $n$ flops. Bubble sorting the elements in the sets $S_{1}, \ldots, S_{4}$ takes at most $n(n-1)$ operations. Two auxiliary vectors of size $n$ are required to store $b_{j} / w_{j}$ for $(j=1, \ldots, n)$ and the sorted index set. The number of flops needed for Step 2 and Step 3 is at most $7 n$. We also need three auxiliary space units to store $j, v$ and $T$. Step 4 takes at most $3 n$ flops. Since we overwrite $b$ by $z$, we don't need an additional vector for $z$. Therefore, at most a total of $n^{2}+14 n+1$ operations and $2 n+3$ auxiliary storage space units are required for our algorithm. If all $w_{i}=1$, we don't need to divide and multiply the intermediate results by $w_{j}$. The index sets $S_{3}$ and $S_{4}$ are not needed. And $b_{j} / w_{j}$ doesn't need to be stored. As well, we don't need to keep and compute $v$, since its value equals to $j$. Therefore, the total number of operations is reduced to at most $n^{2}+7 n+1$.

### 1.2 Symmetric Matrix Projection with Lower Bounds and a Two-Sided Linear Constraint

Theorem 4 For given $U \in \mathbb{C}^{n}$, and $c_{l}, c_{u}, r \in \mathbb{R}$ with $c_{u} \geq \max \left\{n r, c_{l}\right\}$, the solution $\hat{Z}$ to the projection problem (26) is the following.

Let $Q \Lambda Q^{*}$ be the eigenvalue decomposition of $\frac{U+U^{*}}{2}$. Let $\lambda$ denote the diagonal entries of $\Lambda$.
Denote

$$
S_{0} \stackrel{\text { def }}{=}\left\{1 \leq j \leq n: \lambda_{j} \leq r\right\}, \quad \bar{S}_{0} \stackrel{\text { def }}{=}\{1, \ldots, n\} \backslash S_{0}
$$

1. Assume $c_{l} \leq \sum_{i \in \bar{S}_{0}} \lambda_{i}+\left|S_{0}\right| r \leq c_{u}$.

Then we let

$$
\hat{\omega}_{i}=\lambda_{i} \quad i \in \bar{S}_{0}, \quad \hat{\omega}_{i}=r \quad i \in S_{0}
$$

2. Assume $\sum_{i \in \bar{S}_{0}} \lambda_{i}+\left|S_{0}\right| r>c_{u}$.

Then there is a partition of $\bar{S}_{0}$ as $\bar{S}_{0}=S \cup \bar{S}$ :

$$
\begin{aligned}
& S \quad \stackrel{\text { def }}{=}\left\{i \in \bar{S}_{0}: \lambda_{i}>\frac{\sum_{j \in S} \lambda_{j}+n r-c_{u}}{|S|}\right\} \\
& \bar{S} \stackrel{\text { def }}{=}\left\{i \in \bar{S}_{0}: \lambda_{i} \leq \frac{\sum_{j \in S} \lambda_{j}+n r-c_{u}}{|S|}\right\} .
\end{aligned}
$$

And we let

$$
\hat{\omega}_{i}= \begin{cases}r & i \in \bar{S} \cup S_{0} \\ \lambda_{i}-\frac{\sum_{j \in S} \lambda_{j}+n r-c_{u}}{|S|}+r & i \in S\end{cases}
$$

3. Assume $\sum_{i \in \bar{S}_{0}} \lambda_{i}+\left|S_{0}\right| r<c_{l}$.

Then there is a partition of $S_{0}$ as $S_{0}=S_{l} \cup \bar{S}_{l}$ where

$$
S_{l}=\left\{i \in S_{0}: \frac{c_{l}-\sum_{j \in S_{l} \cup \bar{S}_{0}} \lambda_{j}-n r}{\left|S_{0}\right|+\left|S_{l}\right|}>-\lambda_{i}\right\} .
$$

We let

$$
\hat{\omega}_{i}= \begin{cases}\lambda_{i}+\frac{c_{l}-\sum_{j \in \bar{S}_{0} \cup S_{S} \lambda_{j}-\left|\bar{S}_{l}\right| r}^{\left|S_{0}\right|+\left|S_{l}\right|}}{} & i \in \bar{S}_{0} \cup S_{l} \\ r & i \in \bar{S}_{l} .\end{cases}
$$

Let $\hat{\Omega}$ be the diagonal matrix with diagonal entries $\hat{\omega}$. Then $\hat{Z}=Q \hat{\Omega} Q^{*}$ is the unique solution to (26).
If $U \in \mathcal{S}^{n}, \hat{Z}$ can be obtained in $\left(10 n^{3}+3 n^{2}+9 n+5\right)$ flops with an auxiliary storage vector of size $\left(n^{2}+3 n+4\right)$.

Proof: Since $Z \in \mathcal{H}^{n}$, we have

$$
\begin{aligned}
\|Z-U\|_{F}^{2} & =\frac{1}{2}\left(\|Z-U\|_{F}^{2}+\left\|Z-U^{*}\right\|_{F}^{2}\right) \\
& =\operatorname{tr}\left(Z^{2}\right)+\operatorname{tr}\left(U U^{*}\right)-\operatorname{tr}\left(Z U+Z U^{*}\right) \\
& =\operatorname{tr}\left(Z-\frac{U+U^{*}}{2}\right)^{2}+\frac{1}{2} \operatorname{tr}\left(U U^{*}\right)-\frac{1}{4} \operatorname{tr}\left(U^{2}\right)-\frac{1}{4} \operatorname{tr}\left(U^{* 2}\right) .
\end{aligned}
$$

Therefore, the solution to (26) is the same as the solution to the following problem:

$$
\begin{array}{rc}
\min _{Z \in \mathcal{H}^{n}} & \left\|Z-\frac{U+U^{*}}{2}\right\|_{F}^{2} \\
\text { s.t. } & c_{l} \leq \operatorname{tr}(Z) \leq c_{u} \\
& \lambda_{\text {min }}(Z) \geq r .
\end{array}
$$

Let $\hat{F}$ be the optimal value of the above problem.
By Theorem 3 in the Appendix, $\hat{\omega}$ in the statement of the theorem is the solution to

$$
\begin{array}{ll}
\min _{\omega \geq r} & \|\omega-\lambda\|_{2} \\
\text { s.t. } & c_{l} \leq \sum_{i=1}^{n} \omega_{i} \leq c_{u} .
\end{array}
$$

The Hoffman-Wielandt theorem [10] states that for two Hermitian matrices $V$ and $W$, let $\lambda_{1}(V), \ldots, \lambda_{n}(V)$ and $\lambda_{1}(W), \ldots, \lambda_{n}(W)$ be the eigenvalues of $V$ and $W$ in non-increasing order. Then there is a permutation $\sigma(i)(i=1, \ldots, n)$ such that

$$
\sum_{i=1}^{n}\left[\lambda_{\sigma(i)}(W)-\lambda_{i}(V)\right]^{2}=\|W-V\|_{F}^{2} .
$$

And it is obvious from Theorem 3 in the Appendix that $\hat{\omega}$ is in the same order as $\lambda$; i.e. if $\lambda$ is arranged in non-increasing order, $\hat{\omega}$ is also in non-increasing order. Therefore,

$$
\hat{F} \geq\|\hat{\omega}-\lambda\|_{2}^{2}
$$

Since $\hat{Z}$ and $\frac{U+U^{*}}{2}$ are unitary similar, we have

$$
\left\|\hat{Z}-\frac{U+U^{*}}{2}\right\|_{F}^{2}=\|\hat{\omega}-\lambda\|_{F}^{2} .
$$

Hence $\hat{Z}$ is the solution to (26).
Now we consider the complexity and memory requirement of getting the solution $\hat{Z}$ when $U$ is real symmetric.

The eigenvalue decomposition of $U$ by the symmetric QR algorithm takes roughly $9 n^{3}$ flops. Since we can overwrite $U, n^{2}$ space units are needed to store the orthogonal matrix $Q$ and about $2 n+1$ auxiliary space units are needed to store intermediate results. The algorithm in $\S \$ 1.1 .3$ of the Appendix can be used to compute $\hat{\omega}$. Since all the $r_{i}$ are identical, variable transformations from $c_{l}$ and $c_{u}$ to $\tilde{c}_{l}$ and $\tilde{c}_{u}$ takes 4 flops, instead of
$2 n$ flops for $r_{i}$ 's being heterogenous. Therefore, calculating $\hat{\omega}$ takes at most $\left(n^{2}+9 n+5\right)$ flops and $3 n+4$ auxiliary storage space units. Computing $Q \hat{\Omega} Q^{*}$ takes $\left(n^{2}(n+1)+n^{2}\right)$ flops. Since the auxiliary vector for storing the intermediate results of the eigenvalue decomposition of $U$ can be over-written, the total length of the auxiliary vectors is $\left(n^{2}+3 n+4\right)$. And the total number of flops is $\left(10 n^{3}+3 n^{2}+9 n+5\right)$ for $U \in \mathcal{S}^{n}$.

If $n \leq 3$, the characteristic polynomial of $\frac{U+U^{*}}{2}$ is of order no more than 3 ; therefore, its eigenvalues can be obtained analytically. Its eigenvectors can then be obtained by solutions to its eigen-systems.

## Appendix: Updating the Parameters

As is stated earlier, by [17, Theorem 1], the duality gap of the $t$ th iteration generated by the primal-dual algorithm is bounded by

$$
\begin{equation*}
\frac{1}{\sum_{l=0}^{t} \alpha_{t}} \delta_{t}, \quad \text { with } \quad \delta_{t} \leq \beta_{t+1} D+\frac{1}{2} \sum_{l=0}^{t} \frac{\alpha_{l}^{2}}{\beta_{l}}\left\|g_{l}\right\|_{*}^{2} . \tag{29}
\end{equation*}
$$

In our algorithm, $\left\|g_{l}\right\|_{*}=\left\|\left[\left(g_{E}\right)_{l},\left(g_{x}\right)_{l}\right]\right\|_{*}, D=\tau D_{E}+(1-\tau) D_{x}$.
For $t=1, \ldots$, let :

$$
\begin{equation*}
\hat{\beta}_{0}=\hat{\beta}_{1}=1, \quad \hat{\beta}_{t+1}=\hat{\beta}_{t}+\frac{1}{\hat{\beta}_{t}} \tag{30}
\end{equation*}
$$

And

$$
\beta_{t}=\sigma \hat{\beta}_{t}
$$

## Simple Dual Averages

$$
\alpha_{t}=1
$$

Assume $\left\|g_{t}\right\|_{*} \leq L$ for $t=1, \ldots$; then by [17, Theorem 2], we have

$$
\delta_{t} \leq \hat{\beta}_{t+1}\left(D \sigma+\frac{1}{2 \sigma} L^{2}\right), \quad \sum_{l=0}^{t} \alpha_{l}=t+1
$$

## Weighted Dual Averages

$$
\alpha_{t}=\frac{1}{\left\|g_{t}\right\|_{*}}
$$

Assume $\left\|g_{t}\right\|_{*} \leq L$ for $t=1, \ldots$; then by [17, Theorem 3], we have

$$
\delta_{t} \leq \hat{\beta}_{t+1}\left(D \sigma+\frac{1}{2 \sigma}\right), \quad \sum_{l=0}^{t} \alpha_{l} \geq \frac{t+1}{L}
$$

The above results show that the convergence rate of the algorithm depends on the choice of $\sigma$. It is not possible to determine the optimal $\sigma$ without the knowledge of $D$ or $L$. In this part, we show how to dynamically update the parameter $\sigma_{t}$ in the algorithm to obtain the best convergence rate.

Choosing $\beta_{t}$ : Let $\sigma_{0}>0$ be the smallest possible value for $\sigma$. Let $w>0$ be the number of steps for each test in updating $\sigma$.

1. Choose $w>0, \sigma_{0}>0$.
2. Let

$$
v=0, \quad \sigma=\sigma_{0}
$$

For $t=0, \ldots w$, let

$$
\beta_{t}=\sigma_{0} \hat{\beta}_{t} .
$$

3. Repeat the following until convergence rate starts to decrease.

- Let

$$
v=v+1, \quad \sigma=2 * \sigma
$$

- For $t=v w+1 \ldots(v+1) w$, let

$$
\beta_{t}=\sigma \hat{\beta}_{t}
$$

4. Let

$$
v=v-1, \quad \sigma=\sigma / 2
$$

For $t=(v+2) w+1, \ldots$, let

$$
\beta_{t}=\sigma \hat{\beta}_{t}
$$

Theorem 5 The total number of test steps for the above procedure of determining $\sigma$ is finite. And the total number of iterations of the algorithm including the above procedure is at most $5 / 3$ of the algorithm without the procedure but using optimal parameters plus a term in the order of $\mathcal{O}\left(\frac{1}{\epsilon}\right)$.
Proof: Assume that at iteration $t$ we have obtained the $\sigma$ from the above procedure. Denote $v=v_{t}$. Suppose $\left\|g_{l}\right\|_{*} \leq L(l=0, \ldots, t)$. Since there is one backtrack period with $w$ steps before landing at the current $\sigma$, from the above procedure, we have $\sigma=2^{v_{t}} \cdot \sigma_{0}$ and $\beta_{t}=\sigma \hat{\beta}_{t}$.

To prove the theorem, we need to bound $\delta_{t}$.
We first consider the method of simple dual averages. By (29),

$$
\begin{aligned}
& \delta_{t(s)} \leq \sigma_{0} 2^{v_{t}} \hat{\beta}_{t+1} D+\sum_{v=0}^{v_{t}+1} \frac{L^{2}}{\sigma_{0} 2^{v+1}} \sum_{l=v \cdot w+1}^{(v+1) w} \frac{1}{\hat{\beta}_{l}}+\sum_{l=\left(v_{t}+2\right) w+1}^{t} \frac{L^{2}}{2^{v_{t}+1} \sigma_{0} \hat{\beta}_{l}} \\
&= \sigma_{0} 2^{v_{t}} \hat{\beta}_{t+1} D+\frac{L^{2}}{\sigma_{0} 2^{v_{t}+1}} \sum_{l=0}^{t} \frac{1}{\hat{\beta}_{l}}+\frac{L^{2}}{\sigma_{0} 2^{v_{t}+1}} \sum_{v=1}^{v_{t}-1} \sum_{l=0}^{v \cdot w} \frac{1}{\hat{\beta}_{l}}-\frac{L^{2}}{\sigma_{0} 2^{v_{t}+2}} \sum_{l=\left(v_{t}+1\right) w+1}^{\left(v_{t}+2\right) w} \frac{1}{\hat{\beta}_{l}} \\
& \stackrel{(30)}{=} \hat{\beta}_{t+1}\left(\sigma_{0} 2^{v_{t}} D+\frac{1}{\sigma_{0} 2^{v_{t}+1}} L^{2}\right)+\frac{L^{2}}{\sigma_{0} 2^{v}+1} \\
& \sum_{v=1}^{v_{t}-1} \hat{\beta}_{v \cdot w+1} \\
&+\frac{L^{2}}{\sigma_{0} 2^{v_{t}+2}}\left[\hat{\beta}_{\left(v_{t}+1\right) w+1}-\hat{\beta}_{\left(v_{t}+2\right) w+1}\right] .
\end{aligned}
$$

To further estimate the bound, we use [17, Lemma 3]:

$$
\hat{\beta}_{t} \leq \frac{1}{1+\sqrt{3}}+\sqrt{2 t-1}, \quad t \geq 1
$$

From the above result, we have

$$
\begin{aligned}
\sum_{v=1}^{v_{t}-1} \hat{\beta}_{v \cdot w+1} & \leq \frac{v_{t}-1}{1+\sqrt{3}}+\sum_{v=1}^{v_{t}-1} \sqrt{2 v w+1} \\
& \leq \frac{v_{t}-1}{1+\sqrt{3}}+\sqrt{\frac{1}{v_{t}-1} \sum_{v=1}^{v_{t}-1}(2 v w+1)} \\
& =\frac{v_{t}-1}{1+\sqrt{3}}+\sqrt{v_{t} w+1} \\
& \leq 2^{v_{t}} \sqrt{w / 2} .
\end{aligned}
$$

The optimal value of $\sigma$ is $\sigma^{*}=\frac{L}{\sqrt{2 D}}$. The total number of iterations decreases with $\sigma$ for $\sigma<\sigma^{*}$ and increases with $\sigma$ for $\sigma>\sigma^{*}$. Therefore, we have

$$
\begin{aligned}
v_{t} & \leq \frac{1}{2}+\log _{2} \frac{L}{\sigma_{0} \sqrt{D}} \\
\frac{\sigma^{*}}{2} \leq \sigma & \leq 2 \sigma^{*} .
\end{aligned}
$$

From the above inequalities, we obtain that the total number of test steps for the method of simple dual averages to obtain an optimal $\sigma$ is no more than $\left\lceil\frac{5}{2}+\log _{2} \frac{L}{\sigma_{0} \sqrt{D}}\right\rceil w$. And $\left(D \sigma+\frac{1}{2 \sigma} L^{2}\right) /\left(D \sigma^{*}+\frac{1}{2 \sigma^{*}} L^{2}\right) \leq 5 / 3$. Therefore, the total number of iterations of our procedure for the method of simple dual averages is at most $5 / 3$ of that with optimal parameter plus $\mathcal{O}\left(\frac{\sqrt{w} L^{2}}{2 \sqrt{2} \sigma_{0} \epsilon}\right)$.

Similarly, for the method of weighted dual averages, we have

$$
\delta_{t(d)} \leq \hat{\beta}_{t+1}\left(\sigma_{0} 2^{v_{t}} D+\frac{1}{\sigma_{0} 2^{v_{t}+1}}\right)+\frac{\sqrt{w}}{\sigma_{0} 2 \sqrt{2}}
$$

The optimal value of $\sigma$ is $\sigma^{*}=\frac{1}{\sqrt{2 D}}$. Therefore, we obtain

$$
\begin{aligned}
v_{t} & \leq \frac{1}{2}-\log _{2} \sigma_{0} \sqrt{D} \\
\frac{\sigma^{*}}{2} \leq \sigma & \leq 2 \sigma^{*}
\end{aligned}
$$

Since

$$
\sum_{l=0}^{t} \geq \frac{t+1}{L}
$$

we conclude that the total number of test steps for the method of weighted dual averages to obtain an optimal $\sigma$ is no more than $\left\lceil\frac{5}{2}-\log _{2} \sigma_{0} \sqrt{D}\right\rceil w$. And $\left(D \sigma+\frac{1}{2 \sigma}\right) /\left(D \sigma^{*}+\frac{1}{2 \sigma^{*}}\right) \leq 5 / 3$. Therefore, the total number of iterations of our procedure for the method of weighted dual averages is at most $5 / 3$ of that by the original algorithm with optimal parameter plus $\mathcal{O}\left(\frac{\sqrt{w} L}{2 \sqrt{2} \sigma_{0} \epsilon}\right)$.

The worst case complexity bound of the original algorithm is $\mathcal{O}\left(\frac{1}{\epsilon^{2}}\right)$ 17. Since our procedure adds a term of $\mathcal{O}\left(\frac{1}{\epsilon}\right)$, the complexity remains at $\mathcal{O}\left(\frac{1}{\epsilon^{2}}\right)$.
