A STUDY ON PARTIAL DYNAMIC EQUATION ON TIME SCALES INVOLVING DERIVATIVES OF POLYNOMIALS

PETRO KOLOSOV

ABSTRACT. Let $f_m(x, b)$ be a $2m+1$–degree integer-valued polynomial in $x, b$. Let be a two-dimensional time scale $\Lambda^2 = T_1 \times T_2 = \{t = (x, b): x \in T_1, b \in T_2\}$. Let be $T_1 = T_2$. In this manuscript we derive and discuss the following partial dynamic equation on time scales. For every $t \in T_1$, $x, b \in \Lambda^2$, $m \in \mathbb{N}$

$$(2m+1)\Delta = \frac{\partial f_m(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_m(x, b)}{\Delta b}(t, t),$$

where $\sigma(t) > t$ is forward jump operator. In addition, we discuss various derivative operators in context of partial cases of above equation, we show finite difference, classical derivative, $q$–derivative, $q$–power derivative on behalf of it.

1. Definitions

We now set the following notation, which remains fixed for the remainder of this paper:
• Let be a function $f: \mathbb{T} \rightarrow \mathbb{R}$ and $t \in \mathbb{T}^n$ then $f^\Delta(t)$ is delta time-scale derivative [BP01] of $f$
\[ f^\Delta(t) = \frac{f(\sigma(t)) - f(t)}{\mu(t)}, \]
where $\mu(t) = \sigma(t) - t$, $\mu(t) \neq 0$ and $\sigma(t) > t$ is forward jump operator.
• $\frac{\partial f(t_1, \ldots, t_n)}{\Delta t_i}$, $f^\Delta_{t_i}(t)$ is delta partial derivative of $f: \Lambda^n \rightarrow \mathbb{R}$ on $n$—dimensional time scale $\Lambda^n$ [BG04, AM02, Jac06], defined as a limit
\[ f^\Delta_{t_i}(t) = \lim_{s_i \rightarrow t_i, s_i \neq \sigma(t_i)} \frac{f(t_1, \ldots, t_i-1, \sigma_i(t_i), t_{i+1}, \ldots, t_n) - f(t_1, \ldots, t_i-1, s_i, t_{i+1}, \ldots, t_n)}{\sigma_i(t_i) - s_i}, \]
where $\sigma_i(t_i) > t_i$ and $\sigma_i(t_i) - s_i \neq 0$.
• $\mathbb{Z}$ is an integer time scale such that $\sigma(t) = t + 1$ and $\mu(t) = 1$.
• $\mathbb{R}$ is a real time scale such that $\sigma(t) = t + \Delta t$ and $\mu(t) = \Delta t$, $\Delta t \rightarrow 0$.
• $q^\mathbb{R}$ is a quantum time scale such that $\sigma(t) = qt$ and $\mu(t) = qt - t$, [page 18 [BP01]].
• $\mathbb{R}^q$ is a quantum power time scale such that $\sigma(t) = t^q$ and $\mu(t) = t^q - t$.
• $q^{\mathbb{R}^n}$ is a quantum power time scale such that $\sigma(t) = q^{nt} > t$, $0 < q < 1$, $\mu(t) = q^{nt} - t$ and $n$ is positive odd integer [AMT11].
• $D_q f(x)$, $x \neq 0$, $x \in \mathbb{R}$, $q \in \mathbb{R}$ is $q$—derivative [Jac09, Ern00, Ern08, KC01]
\[ D_q f(x) = \frac{f(qx) - f(x)}{qx - x} \]
• $D_{n,q} f(t)$, $q^{nt} - t \neq 0$ is $q$—power derivative [AMT11]
\[ D_{n,q} f(t) = \frac{f(q^{nt}) - f(t)}{q^{nt} - t}, \]
where $n$ is odd positive integer and $0 < q < 1$.
• $D_q f(x)$, $x^q \neq x$, $x \in \mathbb{R}$, $q \in \mathbb{R}$ is $q$—power derivative
\[ D_q f(x) = \frac{f(x^q) - f(x)}{x^q - x} \]
• $f_m(x, b)$, $x, b \in \mathbb{R}$, $m \in \mathbb{N}$ is $2m + 1$—degree integer-valued polynomial [Kol16]
\[ f_m(x, b) = \sum_{k=0}^{b-1} \sum_{r=0}^{m} A_{m,r} k^r (x - k)^r, \quad (1.1) \]
where $A_{m,r}$, $m \in \mathbb{N}$ is a real coefficient defined recursively
\[ A_{m,r} := \begin{cases} 
(2r + 1) \binom{2r}{r}, & \text{if } r = m, \\
(2r + 1) \binom{2r}{r} \sum_{d=2r+1}^m A_{m,d} \binom{d}{2r+1} (\frac{1}{d-r}) \frac{(-1)^{d-1}}{d-r} B_{2d-2r}, & \text{if } 0 \leq r < m, \\
0, & \text{if } r < 0 \text{ or } r > m,
\end{cases} \]
where $B_t$ are Bernoulli numbers [Wei]. It is assumed that $B_1 = \frac{1}{2}$.
2. Introduction

Time-scale calculus is quite graceful generalization and unification of the theory of differential equations. Firstly being introduced by Hilger [Hil88] in his Ph.D thesis in 1988 and thereafter greatly extended by Bohner and Peterson [BP01] in 2001, the calculus on time scales became a sharp tool in the world on differential equations. Various derivative operators like classical derivative $\frac{d}{dx} f(x)$, $q$-derivative $D_q f(x)$, $q$-power derivative $D^n_q f(x)$, finite difference $\Delta f(x)$ etc, may be simply expressed in terms of time-scale derivative over particular time scale $\mathbb{T}$. For instance,

- $f'(x) = f^\Delta(x), \quad x \in \mathbb{T} := \mathbb{R},$
- $\Delta f(x) = f^\Delta(x), \quad x \in \mathbb{T} := \mathbb{Z},$
- $D_{n,q} f(x) = f^\Delta(x), \quad x \in \mathbb{T} := q^n,$
- $D_q f(x) = f^\Delta(x), \quad x \in \mathbb{T} := q,$
- $D_{q} f(x) = f^\Delta(x), \quad x \in \mathbb{T} := \mathbb{R}^q, \ldots$ etc.

In context of Computer Science, namely object oriented programming paradigm, the time scale calculus may be thought as unified interface of derivative operator. Furthermore, the idea of time-scale calculus was slightly extended in [BHT17, BHT16, Cap09, MT09].

3. Main results

Time scale derivative of polynomial $t^{2m+1}$ may be expressed as follows

**Theorem 3.1.** Let $f_m(x, b)$ be a $2m + 1$-degree integer-valued polynomial defined by (1.1). Let be a two-dimensional time scale $\Lambda^2 = \mathbb{T}_1 \times \mathbb{T}_2 := \{t = (x, b) : x \in \mathbb{T}_1, b \in \mathbb{T}_2\}$. Let be $\mathbb{T}_1 = \mathbb{T}_2$. For every $t \in \mathbb{T}_1$, $x, b \in \Lambda^2$, $m \in \mathbb{N}$

$$(t^{2m+1})^\Delta = \frac{\partial f_m(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_m(x, b)}{\Delta b}(t, t),$$

where $\sigma(t) > t$ is forward jump operator.

4. Discussion and examples

To understand the nature of theorem 3.1, let’s discuss an example of some popular time scales, like integer time scale $\mathbb{Z}$, real time scale $\mathbb{R}$, quantum time scale $q^\mathbb{R}$, quantum-power time scale $\mathbb{R}^q$. We use the principle *Divide et Impera*! in order to understand entire behavior of theorem 3.1.

4.1. Time scale $\mathbb{T} = \mathbb{Z} \times \mathbb{Z}$.

**Corollary 4.1.** (Finite difference.) Let be a two-dimensional time scale $\Lambda^2 = \mathbb{Z} \times \mathbb{Z} := \{t = (x, b) : x \in \mathbb{Z}, b \in \mathbb{Z}\}$. For every $t \in \mathbb{Z}$, $x, b \in \Lambda^2 = \mathbb{Z} \times \mathbb{Z}$, $m \in \mathbb{N}$

$$\Delta t^{2m+1} = \frac{\partial f_m(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_m(x, b)}{\Delta b}(t, t),$$

where $\sigma(t) = t + 1$. 
Example 4.2. Let be \( t \in \mathbb{Z}, x, b \in \Lambda^2 = \mathbb{Z} \times \mathbb{Z}, m \in \mathbb{N} \) and let \( m = 1 \), then
\[
\frac{\partial f_1(x, b)}{\Delta x} = 3b + 3b^2
\]
\[
\frac{\partial f_1(x, b)}{\Delta x}(t, \sigma(t)) = 3t + 3t^2
\]
\[
\frac{\partial f_1(x, b)}{\Delta b} = 1 - 6b^2 + 6bx
\]
\[
\frac{\partial f_1(x, b)}{\Delta b}(t, t) = 1
\]

Summing up previously obtained partial time-scale derivatives, we get the ordinary finite difference of odd polynomial \( t^{2m+1}, t \in \mathbb{Z}, x, b \in \Lambda^2 = \mathbb{Z} \times \mathbb{Z}, m \in \mathbb{N} \)
\[
\Delta t^3 = \frac{\partial f_1(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_1(x, b)}{\Delta b}(t, t) = 3t^2 + 3t + 1.
\]

Example 4.3. Let be \( t \in \mathbb{Z}, x, b \in \Lambda^2 = \mathbb{Z} \times \mathbb{Z}, m \in \mathbb{N} \) and let \( m = 2 \), then
\[
\frac{\partial f_2(x, b)}{\Delta x} = 5b - 30b^2 + 40b^3 - 15b^4 + 10bx - 30b^2x + 20b^3x
\]
\[
\frac{\partial f_2(x, b)}{\Delta b} = 1 + 30b^4 - 60b^3x + 30b^2x^2
\]
\[
\frac{\partial f_2(x, b)}{\Delta x}(t, \sigma(t)) = 5t + 10t^2 + 10t^3 + 5t^4
\]
\[
\frac{\partial f_2(x, b)}{\Delta b}(t, t) = 1
\]

Summing up previously obtained partial time-scale derivatives, we get time ordinary finite difference of odd polynomial \( t^{2m+1}, t \in \mathbb{Z}, x, b \in \Lambda^2 = \mathbb{Z} \times \mathbb{Z}, m \in \mathbb{N} \)
\[
\Delta t^5 = \frac{\partial f_2(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_2(x, b)}{\Delta b}(t, t) = 1 + 5t + 10t^2 + 10t^3 + 5t^4.
\]

Corollary 4.4. For every \( t \in \mathbb{Z}, x, b \in \Lambda^2 = \mathbb{Z} \times \mathbb{Z}, m \in \mathbb{N} \)
\[
\frac{\partial f_m(x, b)}{\Delta x}(t, \sigma(t)) = \sum_{r=1}^{2m} \binom{2m+1}{r} t^r
\]

Corollary 4.5. For every \( t \in \mathbb{Z}, x, b \in \Lambda^2 = \mathbb{Z} \times \mathbb{Z}, m \in \mathbb{N} \)
\[
\frac{\partial f_m(x, b)}{\Delta b}(t, t) = 1
\]

4.2. Time scale \( T = \mathbb{R} \times \mathbb{R} \).

Corollary 4.6. (Classical derivative.) Let be a two-dimensional time scale \( \Lambda^2 = \mathbb{R} \times \mathbb{R} := \{ t = (x, b): x \in \mathbb{R}, b \in \mathbb{R} \} \). For every \( t \in \mathbb{R}, x, b \in \Lambda^2 = \mathbb{R} \times \mathbb{R}, m \in \mathbb{N} \)
\[
\frac{d}{dt} t^{2m+1} = \frac{\partial f_m(x, b)}{\partial x}(t, \sigma(t)) + \frac{\partial f_m(x, b)}{\partial b}(t, t),
\]
where \( \sigma(t) = t + \Delta t, \Delta t \to 0 \).
Example 4.7. Let be $t \in \mathbb{R}$, $x, b \in \Lambda^2 = \mathbb{R} \times \mathbb{R}$, $m \in \mathbb{N}$ and let $m = 1$, then

$$\frac{\partial f_1(x, b)}{\partial x} = -3b + 3b^2$$
$$\frac{\partial f_1(x, b)}{\partial b} = 6b - 6b^2 - 3x + 6bx$$
$$\frac{\partial f_1(x, b)}{\partial x}(t, \sigma(t)) = -3t + 3t^2$$
$$\frac{\partial f_1(x, b)}{\partial b}(t, t) = 3t$$

Summing up previously obtained partial time-scale derivatives, we get classical derivative of odd polynomial $t^{2m+1}$, $t \in \mathbb{R}$, $x \in \Lambda^2 = \mathbb{R} \times \mathbb{R}$, $m \in \mathbb{N}$

$$\frac{d}{dt}t^2 = \frac{\partial f_1(x, b)}{\partial x}(t, \sigma(t)) + \frac{\partial f_1(x, b)}{\partial b}(t, t) = 3t^2.$$

Example 4.8. Let be $t \in \mathbb{R}$, $x, b \in \Lambda^2 = \mathbb{R} \times \mathbb{R}$, $m \in \mathbb{N}$ and let $m = 2$, then

$$\frac{\partial f_2(x, b)}{\partial x} = -15b^2 + 30b^3 - 15b^4 + 10bx - 30b^2x + 20b^3x,$$
$$\frac{\partial f_2(x, b)}{\partial b} = 30b^2 - 60b^3 + 30b^4 - 30bx + 90b^2x - 60b^3x + 5x^2 - 30bx^2 + 30b^2x^2$$
$$\frac{\partial f_2(x, b)}{\partial x}(t, \sigma(t)) = -5t^2 + 5t^4$$
$$\frac{\partial f_2(x, b)}{\partial b}(t, t) = 5t^2$$

Summing up previously obtained partial time-scale derivatives, we get classical derivative of an odd polynomial $t^{2m+1}$, $t \in \mathbb{R}$, $x \in \Lambda^2 = \mathbb{R} \times \mathbb{R}$, $m \in \mathbb{N}$

$$\frac{d}{dt}t^2 = \frac{\partial f_2(x, b)}{\partial x}(t, \sigma(t)) + \frac{\partial f_2(x, b)}{\partial b}(t, t) = 5t^4.$$

4.3. Time scale $\mathbb{T} = q^{\mathbb{R}} \times q^{\mathbb{R}}$.

Corollary 4.9. (Q-derivative [Jac09].) Let be a two-dimensional time scale $\Lambda^2 = q^{\mathbb{R}} \times q^{\mathbb{R}} := \{t = (x, b): x \in q^{\mathbb{R}}, b \in q^{\mathbb{R}}\}$. For every $t \in q^{\mathbb{R}}$, $x, b \in \Lambda^2 = q^{\mathbb{R}} \times q^{\mathbb{R}}$, $m \in \mathbb{N}$

$$D_q t^{2m+1} = \frac{\partial f_m(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_m(x, b)}{\Delta b}(t, t),$$

where $\sigma(t) = qt$, $q > 1$.

Example 4.10. Let be $t \in q^{\mathbb{R}}$, $x, b \in \Lambda^2 = q^{\mathbb{R}} \times q^{\mathbb{R}}$, $m \in \mathbb{N}$ and let $m = 1$, then

$$\frac{\partial f_1(x, b)}{\Delta x} = -3b + 3b^2$$
$$\frac{\partial f_1(x, b)}{\Delta b} = 3b - 2b^2 + 3bq - 2b^2q^2 - 2b^2 - 3x + 3bx + 3bqx$$
$$\frac{\partial f_1(x, b)}{\Delta x}(t, \sigma(t)) = -3qt + 3q^2t^2$$
$$\frac{\partial f_1(x, b)}{\Delta b}(t, t) = 3qt + t^2 + qt^2 - 2q^2t^2$$
Summing up previously obtained partial time-scale derivatives, we get $q$–derivative of odd polynomial $t^{2m+1}$, $t \in \mathbb{R}^q$, $x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q$, $m \in \mathbb{N}$

$$D_q t^3 = \frac{\partial f_1(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_1(x, b)}{\Delta b}(t, t) = t^2 + qt^2 + q^2 t^2.$$

For every $t \in \mathbb{R}^q$, $x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q$, $m \in \mathbb{N}$ the following polynomial identity holds as $q$ tends to zero

$$\lim_{q \to 0} \frac{\partial f_1(x, b)}{\Delta b}(t, t) = t^2$$

However, it would be generalized as follows

**Corollary 4.11.** For every $t \in \mathbb{R}^q$, $x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q$, $m \in \mathbb{N}$

$$\lim_{q \to 0} \frac{\partial f_m(x, b)}{\Delta b}(t, t) = t^{2m}.$$

**Example 4.12.** Let be $t \in \mathbb{R}^q$, $x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q$, $m \in \mathbb{N}$ and let $m = 2$, then

$$\frac{\partial f_2(x, b)}{\Delta x} = -15b^2 + 30b^3 - 15b^4 + 5bx - 15b^2x + 10b^3x + 5bqx - 15b^2qx + 10b^3qx$$

$$\frac{\partial f_2(x, b)}{\Delta b} = 10b^2 - 15b^3 + 6b^4 + 10b^2q - 15b^3q + 6b^4q + 10b^2q^2 - 15b^3q^2 + 6b^4q^2 - 15b^3q^3$$

$$+ 6b^4q^3 + 6b^4q^4 - 15bx + 30b^2x - 15b^3x - 15bqx + 30b^2qx - 15b^3qx + 30b^2q^2x$$

$$- 15b^3q^2x - 15b^3q^3x + 5x^2 - 15bx^2 + 10b^2x^2 - 15bqx^2 + 10b^2qx^2 + 10b^2q^2x^2$$

$$\frac{\partial f_2(x, b)}{\Delta x}(t, \sigma(t)) = 5qt^2 - 10q^2t^2 - 15q^2t^3 + 15q^3t^3 + 10q^4t^4 - 5q^4t^4$$

$$\frac{\partial f_2(x, b)}{\Delta b}(t, t) = -5qt^2 + 10q^2t^2 + 15q^2t^3 - 15q^3t^3 + t^4 + qt^4 + q^2t^4 - 9q^4t^4 + 6q^4t^4$$

Summing up previously obtained partial time-scale derivatives, we get the $q$–derivative of odd polynomial $t^{2m+1}$, $t \in \mathbb{R}^q$, $x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q$, $m \in \mathbb{N}$

$$D_q t^5 = \frac{\partial f_2(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_2(x, b)}{\Delta b}(t, t) = t^4 + qt^4 + q^2t^4 + q^3t^4 + q^4t^4.$$

**4.4. Time scale $T = \mathbb{R}^q \times \mathbb{R}^q$.**

**Corollary 4.13.** ($Q$-power derivative [AMT11].) Let be a two-dimensional time scale $\Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q := \{t = (x, b): \ b \in \mathbb{R}^q, \ x \in \mathbb{R}^q\}$. For every $t \in \mathbb{R}^q$, $x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q$, $m \in \mathbb{N}$

$$D_q t^{2m+1} = \frac{\partial f_m(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_m(x, b)}{\Delta b}(t, t),$$

where $\sigma(t) = t^q$, $q > 1$. 
Example 4.14. Let be \( t \in \mathbb{R}^q \), \( x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q \), \( m \in \mathbb{N} \) and let \( m = 1 \), then
\[
\begin{align*}
\frac{\partial f_1(x, b)}{\Delta x} &= 3b + 3b^2 \\
\frac{\partial f_1(x, b)}{\Delta b} &= 3b - 2b^2 + 3b^q - 2b^{1+q} - 3x + 3bx + 3b^q x
\end{align*}
\]
Summing up previously obtained partial time-scale derivatives, we get \( q \)-power derivative of odd polynomial \( t^{2m+1} \), \( t \in \mathbb{R}^q \), \( x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q \), \( m \in \mathbb{N} \)
\[
D_q t^3 = \frac{\partial f_1(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_1(x, b)}{\Delta b}(t, t) = t^2 + t^2q + t^{1+q}.
\]

Example 4.15. Let be \( t \in \mathbb{R}^q \), \( x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q \), \( m \in \mathbb{N} \) and let \( m = 2 \), then
\[
\begin{align*}
\frac{\partial f_2(x, b)}{\Delta x} &= -15b^2 + 30b^3 - 15b^4 + 5bx - 15b^2x + 10b^3x + 5bx^q - 15b^2x^q + 10b^3x^q \\
\frac{\partial f_2(x, b)}{\Delta b} &= 10b^2 - 15b^3 + 6b^4 + 10b^2q - 15b^3q + 6b^4q + 10b^{1+q} - 15b^{2+q} + 6b^{3+q} \\
&\quad - 15b^{1+2q} + 6b^{2+2q} + 6b^{1+3q} - 15b^x + 30b^2x - 15b^3x - 15b^3x + 30b^2x \\
&\quad - 15b^3q x + 30b^{1+q} - 15b^{2+q} + 15b^{1+2q} + 5x^2 - 15bx^2 + 10b^2x^2 \\
&\quad - 15b^q x^2 + 10b^2q x^2 + 10b^1q x^2
\end{align*}
\]
\[
\frac{\partial f_2(x, b)}{\Delta x}(t, \sigma(t)) = -10t^2q + 15t^3q - 5t^4q + 5t^{1+q} - 15t^{1+2q} + 10t^{1+3q}
\]
\[
\frac{\partial f_2(x, b)}{\Delta b}(t, t) = t^4 + 10t^2q - 15t^{3q} + 6t^4q - 5t^{1+q} + t^3q + 15t^{1+2q} + t^{2+2q} - 9t^{1+3q}
\]
Summing up previously obtained partial time-scale derivatives, we get \( q \)-power derivative of odd polynomial \( t^{2m+1} \), \( t \in \mathbb{R}^q \), \( x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q \), \( m \in \mathbb{N} \)
\[
D_q t^5 = \frac{\partial f_2(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_2(x, b)}{\Delta b}(t, t) = t^4 + t^{3q} + t^{2+2q} + t^{1+3q}.
\]

Another polynomial identity, that is exponential sum holds

Corollary 4.16. For every \( t \in \mathbb{R}^q \), \( x, b \in \Lambda^2 = \mathbb{R}^q \times \mathbb{R}^q \), \( t \in \mathbb{R} \), \( m \in \mathbb{N} \)
\[
\lim_{q \to 0} \frac{\partial f_m(x, b)}{\Delta b}(t, t) = \sum_{k=0}^{2m} t^k
\]

4.5. **Time scale** \( \mathbb{T} = q^{\mathbb{R}^n} \times q^{\mathbb{R}^n} \). In this subsection we discuss a pure quantum power time scale \( q^{\mathbb{R}^n} \) provided by Aldwoah, Malinowska and Torres in [AMT11], among with the \( q \)-power derivative operator \( D_{n,q}f(t) \) defined by
\[
D_{n,q}f(t) = \frac{f(q^nt) - f(t)}{q^nt - t},
\]
where \( n \) is odd positive integer and \( 0 < q < 1 \).
Corollary 4.17. (Quantum power derivative [AMT11].) Let be a two-dimensional time scale \( \Lambda^2 = q^R \times q^R := \{ t = (x, b): b \in q^R, x \in q^R \} \). For every \( t \in q^R, x, b \in \Lambda^2 = q^R \times q^R, m \in \mathbb{N} \)
\[
D_{n,q}t^{2m+1} = \frac{\partial f_m(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_m(x, b)}{\Delta b}(t, t),
\]
where \( \sigma(t) = qt^n, \sigma(t) > t \).

Example 4.18. Let be \( t \in q^R, x, b \in \Lambda^2 = q^R \times q^R, m \in \mathbb{N} \) and let \( m = 1 \), then
\[
\begin{align*}
\frac{\partial f_1(x, b)}{\Delta x} &= -3b + 3b^2 \\
\frac{\partial f_1(x, b)}{\Delta b} &= 3b - 2b^2 + 3b^2q - 2b^{1+j}q - 2b^{2}q^2 - 3x + 3bx + 3b^2qx \\
\frac{\partial f_1(x, b)}{\Delta x}(t, \sigma(t)) &= -3qt^j + 3q^2t^{2j} \\
\frac{\partial f_1(x, b)}{\Delta b}(t, t) &= t^2 + 3qt^j - 2q^2t^{2j} + qt^{1+j}
\end{align*}
\]
Summing up previously obtained partial time-scale derivatives, we get q--power derivative of odd polynomial \( t^{2m+1}, t \in q^R, x, b \in \Lambda^2 = q^R \times q^R, m \in \mathbb{N} \)
\[
D_{n,q}t^3 = \frac{\partial f_1(x, b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_1(x, b)}{\Delta b}(t, t) = t^2 + q^2t^{2j} + qt^{1+j}.
\]

Another polynomial identity, that is exponential sum holds

Corollary 4.19. For every \( t \in q^R, x, b \in \Lambda^2 = q^R \times q^R, t \in \mathbb{R}, m \in \mathbb{N} \)
\[
\lim_{j \to 0} \lim_{q \to 1} \frac{\partial f_m(x, b)}{\Delta b}(t, t) = \sum_{k=0}^{2m} t^k
\]
An identity in even polynomials holds too

Corollary 4.20. For every \( t \in q^R, x, b \in \Lambda^2 = q^R \times q^R, t \in \mathbb{R}, m \in \mathbb{N} \)
\[
\lim_{j \to 0} \lim_{q \to 0} \frac{\partial f_m(x, b)}{\Delta b}(t, t) = t^{2m}
\]

Example 4.21. Let be \( t \in q^R, x, b \in \Lambda^2 = q^R \times q^R, m \in \mathbb{N} \) and let \( m = 2 \), then
\[
\begin{align*}
\frac{\partial f_2(x, b)}{\Delta x} &= -15b^2 + 30b^3 - 15b^4 + 5bx - 15b^2x + 10b^3x - 15b^2q^2x - 10b^3q^3x \\
\frac{\partial f_2(x, b)}{\Delta b} &= 10b^2 - 15b^3 + 6b^4 + 10b^{1+j}q - 15b^{2+j}q + 6b^{3+j}q + 10b^{2+j}q^2 - 15b^{1+2j}q^2 \\
&+ 6b^{2+2j}q^2 - 15b^{3+j}q^3 + 6b^{1+3j}q^3 + 6b^{1+2j}q^4 - 15bx + 30b^2x - 15b^3x - 15b^2q^2x \\
&+ 30b^{1+j}qx - 15b^{2+j}qx + 30b^{2+j}q^2x - 15b^{1+2j}q^2x - 15b^{3+j}q^3x + 5x^2 - 15bx^2 \\
&+ 10b^{2}x^2 - 15b^{1+j}qx^2 + 10b^{1+j}q^2x^2 + 10b^{2+j}q^2x^2
\end{align*}
\]
\[
\begin{align*}
\frac{\partial f_2(x, b)}{\Delta x}(t, \sigma(t)) &= -10q^2t^{2j} + 15q^3t^{3j} - 5q^4t^{4j} + 5qt^{1+j} - 15q^2t^{1+2j} + 10q^3t^{1+3j} \\
\frac{\partial f_2(x, b)}{\Delta b}(t, t) &= t^4 + 10q^2t^{2j} - 15q^3t^{3j} + 6q^4t^{4j} - 5qt^{1+j} + qt^{3+j} + 15q^2t^{1+2j} + q^2t^{2+2j} - 9q^3t^{1+3j}
\end{align*}
\]
Summing up previously obtained partial time-scale derivatives, we $q$–power derivative of odd polynomial $t^{2m+1}$, $t \in q^\mathbb{R}$, $x, b \in \Lambda^2 = \mathbb{R}^2 \times q^\mathbb{R}$, $m \in \mathbb{N}$

\[
D_{n,q}x^5 = \frac{\partial f_1(x,b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_1(x,b)}{\Delta b}(t, t) = t^4 + q^4t^{4j} + qt^{3+j} + q^3t^{2+2j} + q^3t^{1+3j}.
\]

5. Proof of main theorem

By [Lemma 3.1 [Kol16]], for every $x \in \mathbb{R}$, $m \in \mathbb{N}$ it is true that

\[f_m(x, x) = x^{2m+1}\]

Proof of theorem 3.1. Let be $x, b \in \Lambda^2 = \mathbb{T}_1 \times \mathbb{T}_2 := \{ t = (x, b): x \in \mathbb{T}_1, b \in \mathbb{T}_2 \}$. Let be $\mathbb{T}_1 = \mathbb{T}_2$, then

\[(x^{2m+1})^\Delta = \lim_{b \to x} \lim_{t \to x} \frac{f_m(\sigma(x), \sigma(b)) - f_m(t, b)}{\sigma(x) - t}, \tag{5.2}\]

where $\sigma(x) > x$ is forward jump operator. However, equation (5.2) is not a timescale derivative of $f_m(x, b)$ over $x$ how it might seem because of denominator $\sigma(x) - t$. Parameter $b$ of $f_m(x, b)$ is implicitly incremented as well. Let’s try to express nominator of (5.2) in terms of partial derivative $\frac{\partial f_m(x,b)}{\Delta b}$ on timescales. Let be the following equation

\[f_m(x, \sigma(b)) - f_m(x, b) = f_m(x, b)^\Delta \cdot \Delta b\]

Let $t \to x$ in (5.2). Then nominator of (5.2) equals to

\[f_m(\sigma(x), \sigma(b)) - f_m(x, b) = f_m(x, \sigma(b)) - f_m(x, b) + A\]

where $A$ is yet implicit term. Let’s now collapse the terms $f_m(x, b)$ from both sides of above equation, such that

\[f_m(\sigma(x), \sigma(b)) = f_m(x, \sigma(b)) + A\]

Therefore,

\[A = f_m(\sigma(x), \sigma(b)) - f_m(x, b) = f_m(x, b)^\Delta (x, \sigma(b)) \cdot \Delta x\]

Now, let’s express the nominator of (5.2) as follows

\[f_m(\sigma(x), \sigma(b)) - f_m(x, b) = f_m(x, b)^\Delta (x, \sigma(b)) \cdot \Delta x + f_m(x, b)^\Delta (x, b) \cdot \Delta b\]

\[f_m(\sigma(b)) - f_m(x, b) = f_m(x, b)^\Delta (x, \sigma(b)) \cdot (\sigma(x) - x) + f_m(x, b)^\Delta (x, b) \cdot (\sigma(b) - b)\]

We can collapse the terms $(\sigma(x) - x)$, $(\sigma(b) - b)$ in above expressions, as $b \to x$. Therefore,

\[f_m(\sigma(x), \sigma(x)) - f_m(x, x) = f_m(x, b)^\Delta (x, \sigma(x)) + f_m(x, b)^\Delta (x, x)\]

Finally, by the identity (5.1) we can express timescale derivative of $x^{2m+1}$, $x \in \Lambda^2 = \mathbb{T}_1 \times \mathbb{T}_2$, $m \in \mathbb{N}$ as

\[(x^{2m+1})^\Delta(x_0) = \frac{\partial f_m(x,b)}{\Delta x}(x_0, \sigma(x_0)) + \frac{\partial f_m(x,b)}{\Delta b}(x_0, x_0)\]

Which may be simplified for $t \in \mathbb{T}_1$, $x \in \Lambda^2 = \mathbb{T}_1 \times \mathbb{T}_2$, $m \in \mathbb{N}$

\[(t^{2m+1})^\Delta = \frac{\partial f_m(x,b)}{\Delta x}(t, \sigma(t)) + \frac{\partial f_m(x,b)}{\Delta b}(t, t)\]
A STUDY ON PARTIAL DYN. EQ. ON TIME SCALES INVOLV. DERIVATIVES OF POLYNOMIALS

This completes the proof. □

6. Mathematica scripts

To fulfill our study, we attach here a link to the set of Mathematica programs, designed to verify the results of current manuscript. To reach these programs follow the link [Kol20].

7. Conclusion and future research

In this manuscript we have discussed partial time scale differential equation involving derivatives of polynomials in context of time scale \( \Lambda^2 = T_1 \times T_2 \) where \( T_1 = T_2 \). Future research can be conducted to study the case \( T_1 \neq T_2 \), which makes the theorem 3.1 to be generalised

\[
\frac{\partial f_m(x, b)}{\Delta x} + \frac{\partial f_m(x, b)}{\Delta b} = \alpha_m(x, b)(x^{2m+1})^\Delta,
\]

where \( \alpha_m(x, b) \) is arbitrary differentiable function. Also, it is worth to discuss the theorem 3.1 in context of high order derivatives on time scales. We have established a few power identities, and shown the theorem 3.1 for different 2-dimensional time scales \( \Lambda^2 \) like integer time scale \( \mathbb{Z} \times \mathbb{Z} \), real time scale \( \mathbb{R} \times \mathbb{R} \), quantum time scale \( q^\mathbb{R} \times q^\mathbb{R} \) and quantum power time scale \( \mathbb{R}^q \times \mathbb{R}^q \).
