PROOF OF THE HRT CONJECTURE FOR ALMOST EVERY (1,3) CONFIGURATION

WENCALI LIU

Abstract. We prove that for almost every (1,3) configuration, there is no linear dependence between the associated time-frequency translates of any \( f \in L^2(\mathbb{R}) \).
Theorem 1.1. The HRT conjecture holds for special $(1,3)$ configurations

\[ \Lambda = \{(0,0), (\alpha, 0), (\beta, 0), (0,1)\} \]

(a) if there exists \( \gamma > 1 \) such that

\[
\liminf_{n \to \infty} n^\gamma \min\{n^{\beta\alpha}, n^{\alpha\beta}\} < \infty,
\]

(b) if at least one of \( \alpha, \beta \) is rational.

It is known that \( \{x \in \mathbb{R} : \text{there exists some } \gamma > 1 \text{ such that } \liminf_{n \to \infty} n^\gamma |nx| < \infty\} \) is a set of zero Lebesgue measure (e.g., [11, Theorem 32]). Thus Theorem 1.1 holds for a measure zero subset of parameters, and it has been an open problem to extend it to other $(1,3)$ configurations.

Our main result is

Theorem 1.2. The HRT conjecture holds for special $(1,3)$ configurations

\[ \Lambda = \{(0,0), (\alpha, 0), (\beta, 0), (0,1)\} \]

(a) if

\[
\liminf_{n \to \infty} n \ln n \min\{n^{\beta\alpha}, n^{\alpha\beta}\} < \infty,
\]

(b) if at least one of \( \alpha, \beta \) is rational.

Remark 1.3. (b) of Theorem 1.2 is the same statement as (b) in Theorem 1.1. We list here for completeness.

It is well known that \( \{x \in \mathbb{R} : \liminf_{n \to \infty} n \ln n |nx| < \infty\} \) is a set of full Lebesgue measure (e.g., [11, Theorem 32]). Then using metaplectic transformations, we have the following theorem

Theorem 1.4. Given any line \( l \) in \( \mathbb{R}^2 \), let \((a_2, b_2)\) and \((a_3, b_3)\) be any two points lying in \( l \). Let \((a_1, b_1)\) be any point not lying in \( l \). Then for almost every point \((a_4, b_4)\) in \( l \), the HRT conjecture holds for the configuration \( \Lambda = \{(a_1, b_1), (a_2, b_2), (a_3, b_3), (a_4, b_4)\} \).

Proof. By metaplectic transformations (see [9] for details), we can assume \( l \) is x-axis, and \((a_1, b_1) = (0,1), (a_2, b_2) = (0,0)\) and \((a_3, b_3) = (\alpha, 0)\). By Theorem 1.2 and the fact that \( \{x \in \mathbb{R} : \liminf_{n \to \infty} n \ln n |nx| < \infty\} \) is a set of full Lebesgue measure, we have for almost every \( \beta \), the HRT conjecture holds for \( \Lambda = \{(0,1), (0,0), (\alpha, 0), (\beta, 0)\} \). We finish the proof. \( \square \)

2. The framework of the proof of Theorem 1.2

If \( \frac{\alpha}{\beta} \) is a rational number, it reduces to the lattice case, which has been proved [12]. Thus we also assume \( \frac{\alpha}{\beta} \) is irrational.

Assume Theorem 1.2 does not hold. Then there exists some function \( f \) satisfying

\[
\lim_{|n| \to \infty} |f(x + n)| = 0 \text{ a.e. } x \in [0,1)
\]

and nonzero \( C_i \in \mathbb{C} \) such that

\[
f(x + 1) = f(x)(C_0 + C_1 e^{2\pi i \alpha x} + C_2 e^{2\pi i \beta x}) \text{ a.e. } x \in \mathbb{R}.
\]

Theorem 1.2 is covered by the known results if \( C_i = 0 \) for some \( i = 0, 1, 2 \).

Let

\[
P(x) = C_0 + C_1 e^{2\pi i \alpha x} + C_2 e^{2\pi i \beta x}.
\]
For \( n > 0 \), define
\[
P_n(x) = \prod_{j=0}^{n} P(x + j),
\]
\[
P_{-n}(x) = \prod_{j=-n}^{-1} P(x + j).
\]
Notice that \( P(x + n) \) is an almost periodic function. Thus for almost every \( x \in [0, 1) \),
\[
P(x + n) \neq 0 \text{ for any } n \in \mathbb{Z}.
\]
Iterating (4) \( n \) times on both sides (positive and negative), we have for \( n > 0 \),
\[
f(x + n) = P_n(x) f(x) \text{ a.e. } x \in [0, 1),
\]
and
\[
f(x - n) = P_{-n}(x)^{-1} f(x) \text{ a.e. } x \in [0, 1).
\]
This implies that the value of function \( f \) on \( \mathbb{R} \) can be determined uniquely by its value on \( [0, 1) \) and function \( P(x) \).

By Egoroff’s theorem and conditions (3), (5) and (6), there exists some positive Lebesgue measure set \( S \subset [0, 1) \) and \( d > 0 \), such that
\[
\lim_{|n| \to \infty} f(x + n) = 0 \text{ uniformly for } x \in S,
\]
\[
d < |f(x)| < d^{-1} \text{ for all } x \in S,
\]
\[
f(x + n) = P_n(x) f(x) \text{ for all } x \in S,
\]
and
\[
f(x - n) = P_{-n}(x)^{-1} f(x) \text{ for all } x \in S.
\]
Demeter constructed a sequence \( \{n_k\} \subset \mathbb{Z}^+ \), such that
\[
|P_{n_k}(x_k)P_{-n_k}(x'_k)^{-1}| \geq C
\]
for some \( x_k, x'_k \in S \). This contradicts (7), (8), (9) and (10).

In order to complete the construction of (11), growth condition (11) was necessary in [5]. In the present paper, we follow the approach of [5]. The novelty of our work is in the subtler Diophantine analysis. This allows to make the restriction weak enough to obtain the result for a full Lebesgue measure set of parameters, and significantly simplifies the proof.

The rest of the paper is organized as follows. In §3, we will give some basic facts. In §4, we give the proof of Theorem 1.2.

3. Preliminaries

We start with some basic notations. Denote by \( [x], \{x\}, \|x\| \) the integer part, the fractional part and the distance to the nearest integer of \( x \). Let \( \langle x \rangle \) be the unique number in \([-1/2, 1/2)\) such that \( x - \langle x \rangle \) is an integer. For a measurable set \( A \subset \mathbb{R} \), denote by \( |A| \) its Lebesgue measure.

For any irrational number \( \alpha \in \mathbb{R} \), we define
\[
a_0 = [\alpha], \alpha_0 = \alpha,
\]
and inductively for \( k > 0 \),
\[
a_k = [\alpha_{k-1}^{-1}], \alpha_k = \alpha_{k-1}^{-1} - a_k.
\]
We define
\[ p_0 = a_0, \quad q_0 = 1, \]
\[ p_1 = a_0a_1 + 1, \quad q_1 = a_1, \]
and inductively,
\[ p_k = a_k p_{k-1} + p_{k-2}, \quad q_k = a_k q_{k-1} + q_{k-2}. \]
(13)

Recall that \{q_n\}_{n \in \mathbb{N}} is the sequence of denominators of best approximations of irrational number \( \alpha \), since it satisfies
\[ \forall 1 \leq k < q_{n+1}, \|k\alpha\| \geq \|q_n\alpha\|. \]
(14)

Moreover, we also have the following estimate,
\[ \frac{1}{2q_{n+1}} \leq \|q_n\alpha\| \leq \frac{1}{q_n}. \]
(15)

**Lemma 3.1.** Let \( k_1 < k_2 < k_3 < \cdots < k_m \) be a monotone integer sequence such that \( k_m - k_1 < q_n \). Suppose for some \( x \in \mathbb{R} \)
\[ \min_{j=1,2,\ldots,m} \|k_j\alpha - x\| \geq \frac{1}{4q_n}. \]
(16)

Then
\[ \sum_{j=1,2,\ldots,m} \frac{1}{\|k_j\alpha - x\|} \leq Cq_n \ln q_n. \]

**Proof.** Recall that \( \langle x \rangle \) is the unique number in \([-1/2, 1/2)\) such that \( x - \langle x \rangle \) is an integer. Thus \( \|x\| = |\langle x \rangle| \). In order to prove the Lemma, it suffices to show that
\[ \sum_{j=1,2,\ldots,m} \frac{1}{|k_j\alpha - x|} \leq Cq_n \ln q_n. \]
(17)

Let \( S^+ = \{ j : j = 1, 2, \ldots, m, \langle k_j\alpha - x \rangle > 0 \} \). Let \( j_0^+ \) be such that \( j_0^+ \in S^+ \), and
\[ \langle k_{j_0^+}\alpha - x \rangle = \min_{j \in S^+} \langle k_j\alpha - x \rangle. \]
(18)

By (14) and (15), one has for \( i \neq j \) and \( i, j \in S^+ \),
\[ |\langle k_i\alpha - x \rangle - \langle k_j\alpha - x \rangle| = ||(k_i\alpha - x) - (k_j\alpha - x)|| \geq \frac{1}{2q_n}. \]

It implies the gap between any two points \( \langle k_i\alpha - x \rangle \) and \( \langle k_j\alpha - x \rangle \) with \( i, j \in S^+ \) is larger than \( \frac{1}{2q_n} \). See the following figure.

\[
\begin{array}{cccc}
\langle k_{j_0^+} - \alpha \rangle & \langle k_{j_1} - \alpha \rangle & \langle k_{j_2} - \alpha \rangle \\
0 & \geq \frac{1}{2q_n} & \geq \frac{1}{2q_n} & \geq \frac{1}{2q_n} & \geq \frac{1}{2q_n} & \geq \frac{1}{2q_n}
\end{array}
\]

It easy to see that the upper bound of \( \sum_{j \in S^+} \frac{1}{\|k_j\alpha - x\|} \) is achieved if all the gaps are exactly \( \frac{1}{2q_n} \). In this case, the gap between the \( i \)th closest points of \( \langle k_j\alpha - x \rangle \) with \( j \in S^+ \) to \( \langle k_{j_0^+}\alpha - x \rangle \)
is exactly $\frac{1}{2q_n}$. Thus by (16), we have
\[
\sum_{j \in S^+} \frac{1}{\|k_j \alpha - x\|} = \frac{1}{\|k_j^0 \alpha - x\|} + \sum_{j \in S^+, j \neq j_0^+} \frac{1}{\|k_j \alpha - x\|}
\]
\[
= \frac{1}{\langle k_{j_0} \alpha - x \rangle} + \sum_{j \in S^+, j \neq j_0^+} \frac{1}{\langle k_j \alpha - x \rangle}
\]
\[
\leq 4q_n + \sum_{1 \leq j \leq q_n} \frac{2q_n}{j}
\]
\[
\leq Cq_n \ln q_n.
\]
(19)

Similarly, letting $S^- = \{ j : j = 1, 2, \ldots, m, \langle k_j \alpha - x \rangle < 0 \}$, one has
\[
\sum_{j \in S^-} \frac{1}{\|k_j \alpha - x\|} \leq Cq_n \ln q_n.
\]
(20)

By (19) and (20), we finish the proof. □

Now we give two lemmas which can be found in [5].

Lemma 3.2. ([5, Lemma 2.1]) Let $C_0, C_1, C_2 \in \mathbb{C} \setminus \{0\}$. The polynomial $p(x, y) = C_0 + C_1 e^{2\pi ix} + C_2 e^{2\pi iy}$ has at most two real zeros $(\gamma_1^{(j)}, \gamma_2^{(j)}) \in [0, 1)^2$, $j \in \{1, 2\}$ and there exists $t = t(C_0, C_1, C_2) \in \mathbb{R} \setminus \{0\}$ such that
\[
|p(x, y)| \geq C(C_0, C_1, C_2) \min_{j=1,2} (\|x - \gamma_1^j + t(y - \gamma_2^j)\| + \|x - \gamma_1^j\|^2 + \|y - \gamma_2^j\|^2),
\]
(21)

for each $x, y \in \mathbb{R}$.

Remark 3.3. In (21), we assume $p(x, y)$ has two zeros. If $p(x, y)$ has one or no zeros, we can proceed with our proof by replacing (21) with
\[
|p(x, y)| \geq C(C_0, C_1, C_2) (\|x - \gamma_1 + t(y - \gamma_2)\| + \|x - \gamma_1\|^2 + \|y - \gamma_2\|^2),
\]
or
\[
|p(x, y)| \geq C(C_0, C_1, C_2).
\]

Lemma 3.4. ([5, Lemma 4.1]) Let $x_1, x_2, \ldots, x_N$ be $N$ not necessarily distinct real numbers. Then for each $N \in \mathbb{Z}^+$ and each $\delta > 0$, there exists a set $E_{N, \delta} \subset [0, 1)$ with $|E_{N, \delta}| \leq \delta$, such that
\[
\sum_{n=1}^N \frac{1}{\|x - x_n\|} \leq C(\delta) N \log N,
\]
(22)

and
\[
\sum_{n=1}^N \frac{1}{\|x - x_n\|^2} \leq C(\delta) N^2,
\]
(23)

for each $x \in [0, 1) \setminus E_{N, \delta}$.
4. Proof of Theorems 1.2

In this section, \( q_k, p_k, a_k \) are always the coefficients of the continued fraction expansion of \( \frac{\alpha}{\beta} \) as given in (12) and (13). Then condition (2) holds iff
\[
\limsup_k \frac{a_k}{\ln q_k} > 0,
\]
and also iff
\[
\limsup_k \frac{q_{k+1}}{q_k \ln q_k} > 0.
\]

Lemma 4.1. Suppose \( \frac{\alpha}{\beta} \) is irrational and satisfies condition (2). Then for any \( s \in (0, 1) \), there exists a sequence \( N_k \) such that

(i)
\[
N_k = m_n q_n, \quad m_n \leq C(s),
\]

(ii)
\[
\| N_k \frac{\alpha}{\beta} \| \leq \frac{C(s)}{N_k \ln N_k},
\]

and

(iii)
\[
\{ \frac{N_k}{\beta} \} \leq s.
\]

Proof. By (24), there exists a sequence \( n_k \) such that \( a_{n_k} \geq c \ln q_{n_k} \). For any \( s \in (0, 1) \), let \( m_{n_k} \in \mathbb{Z}^+ \) be such that \( 1 \leq m_{n_k} \leq 1/s + 1 \) and \( N_k = m_{n_k} q_{n_k} \) satisfies (iii) (this can be done by the pigeonhole principle). It is easy to check that \( N_k \) satisfies condition (ii) by the fact \( a_{n_k} \geq c \ln q_{n_k} \).

Lemma 4.2. Let \( C_0, C_1, C_2 \in \mathbb{C} \setminus \{0\} \) and \( \alpha, \beta \) be such that \( \frac{\alpha}{\beta} \) is irrational. Let \( Q_k \) be a sequence such that \( \gamma q_{n_k} \leq Q_k \leq \hat{\gamma} q_{n_k} \), where \( q_n \) is the continued fraction expansion of \( \frac{\alpha}{\beta} \) and \( \gamma, \hat{\gamma} \) are constants. Define
\[
P(x) = C_0 + C_1 e^{2\pi i \alpha x} + C_2 e^{2\pi i \beta x}.
\]
Then for each \( \delta > 0 \), there exists a set \( E_{Q_k, \delta} \subset [0, 1) \) such that
\[
|E_{Q_k, \delta}| < \delta
\]
and
\[
\sum_{n=0}^{Q_k-1} \frac{1}{|P(x+n)|} \leq C(\gamma, \hat{\gamma}, \delta, C_0, C_1, C_2, \alpha, \beta) Q_k \ln Q_k
\]
for each \( x \in [0, 1) \setminus E_{Q_k, \delta} \).

Proof. In order to make the proof simpler, we will use \( C \) for constants depending on \( \gamma, \hat{\gamma}, \delta, C_0, C_1, C_2, \alpha, \beta \).

Let \( (\gamma_1, \gamma_2) \) be a zero of the polynomial \( p(x, y) = C_0 + C_1 e^{2\pi i x} + C_2 e^{2\pi i y} \), and let \( t \) be the real number given by Lemma 3.2. Define
\[
A_n(x) := \| \alpha(x+n) - \gamma_1 + t(\beta(x+n) - \gamma_2) \| + \| \alpha(x+n) - \gamma_1 \|^2 + \| \beta(x+n) - \gamma_2 \|^2.
\]
By Lemma 3.2 it suffices to find a set with \( |E_{Q_k, \delta}| < \delta \), such that
\[
\sum_{n=0}^{Q_k-1} \frac{1}{A_n(x)} \leq C Q_k \ln Q_k,
\]
for each \( x \in [0, 1) \setminus E_{Q_k, \delta} \).

We distinguish between two cases.

**Case 1: \( \alpha + t\beta \neq 0 \)**

In this case, one has

\[
\|\alpha(x+n) - \gamma_1 + t(\beta(x+n) - \gamma_2)\| = \|\alpha + t\beta) x + (\alpha + t\beta)n - \gamma_1 - t\gamma_2 - t[\beta(x+n) - \gamma_2] + mt\|
\]

where \( m = -1 \) if \( \{\beta(x+n) - \gamma_2\} > 1/2 \) and \( m = 0 \) otherwise. We remind that \( [\beta(x+n) - \gamma_2] \)

is the integer part of \( \beta(x+n) - \gamma_2 \).

Note that the set

\[
S := \{(\alpha + t\beta)n - \gamma_1 - t\gamma_2 - t[\beta(x+n) - \gamma_2] + mt : x \in [0, 1), 0 \leq n \leq Q_k - 1, m \in \{0, -1\}\}
\]

has \( O(Q_k) \) elements. By (22) there exists some \( E_{Q_k, \delta}^1 \) with \( |E_{Q_k, \delta}^1| < \delta/2 \) such that

\[
\sum_{y \in S} \frac{1}{\|(\alpha + t\beta)x + y\|} \leq CQ_k \ln Q_k
\]

for each \( x \in [0, 1) \setminus E_{Q_k, \delta}^1 \). This implies (28).

**Case 2: \( \alpha + t\beta = 0 \)**

In this case, one has

\[
\|\alpha(x+n) - \gamma_1 + t(\beta(x+n) - \gamma_2)\| = \|\gamma_1 - t\gamma_2 + mt + \frac{\alpha}{\beta}[\beta(x+n) - \gamma_2]||
\]

where \( m \) is as before. Let \( \xi \) be either \( \gamma_1 + t\gamma_2 \) or \( \gamma_1 + t\gamma_2 + t \), depending on whether \( m = 0 \) or \(-1\). From Lemma 3.1 we have that for each \( x \in [0, 1) \)

\[
\sum_{n=0}^{Q_k-1} \frac{1}{\|\beta n - \xi\|} \leq \sum_{n=0}^{Q_k-1} \frac{1}{\|\beta n - \xi\|} \leq CQ_k \ln Q_k
\]

(29)

Let \( S(\xi) \) (not depending on \( x \)) be the set of those \( 0 \leq n \leq Q_k - 1 \) such that \( \|\beta n - \xi\| \leq \frac{1}{4\|\beta\|} \) for some \( x \in [0, 1) \). It is easy to see that \( \#S(\xi) \leq C \) by (14) and (15). For \( n \in S(\xi) \), we will use an alternative estimate

\[
A_n(x) \geq \|\alpha(x+n) - \gamma_1\|^2.
\]

By (23), there exists some set \( E_{Q_k, \delta}^2 \subset [0, 1) \) such that \( |E_{Q_k, \delta}^2| \leq \frac{\delta}{2} \) and

\[
\sum_{n=0}^{Q_k-1} \frac{1}{\|\beta n - \xi\|} \leq \sum_{n=0}^{Q_k-1} \frac{1}{\|\beta n - \xi\|} \leq C(\delta),
\]

(30)

for each \( x \in [0, 1) \setminus E_{Q_k, \delta}^2 \). Thus in this case, (28) follows from (29) and (30). Putting two cases together, we finish the proof.

\[\square\]

**Theorem 4.3.** Under the conditions of Lemma 4.2, let \( N_k \) be a sequence such that (i), (ii) and (iii) in Lemma 4.1 hold. Define \( P_k := \frac{N_k}{\beta} \) for \( \beta > 0 \) and \( P_k := -\frac{N_k}{\beta} \) for \( \beta < 0 \). Given
δ > 0, there exists $E_{k,δ} \subset [0,1)$ with $|E_{k,δ}| \leq δ$ such that for each $x, y$ satisfying $x \in [0,1) \setminus E_{k,δ}$ and $x = y + P_k$, we have

$$|\prod_{n=0}^{[P_k]-1} P(y+n)| \leq C(\delta, s, C_0, C_1, C_2, α, β) |\prod_{n=0}^{[P_k]-1} P(x+n)|.$$  

**Proof.** We write $C$ for $C(\delta, s, C_0, C_1, C_2, α, β)$ again. Without loss of generality, we only consider the case $β > 0$.

By (30) we have

$$|e^{2πix} - e^{2πiy}| = |e^{2πiN_k'y} - 1| \leq \frac{C}{P_k \ln P_k}$$

and

$$|e^{2πiβx} - e^{2πiβy}| = 0.$$

Thus, for each $n \in \mathbb{Z}^+$, one has

$$|P(y+n)| \leq |P(x+n)| + \frac{C}{P_k \ln P_k}.\]$$

By the fact $1 + x \leq e^x$ for $x > 0$, we get

$$|P(y+n)| \leq |P(x+n)| e^{\frac{C}{P_k \ln P_k} \sum_{n=0}^{[P_k]-1} \frac{1}{|P_k+n|}}.$$

and thus

$$\prod_{n=0}^{[P_k]-1} P(y+n) \leq |\prod_{n=0}^{[P_k]-1} P(x+n)| e^{\frac{C}{P_k \ln P_k} \sum_{n=0}^{[P_k]-1} \frac{1}{|P_k+n|}}.$$

Now Theorem 4.3 follows from Lemma 4.2. \qed

**Proof of Theorem 1.2.** Suppose Theorem 1.2 is not true. As argued in Section 2, there exist some function $f$, a positive Lebesgue measure set $S \subset [0,1)$ and $d > 0$ such that (7), (8), (9) and (10) hold. By the continuity of Lebesgue measure, there exists $ε = ε(S) > 0$ such that

$$|S \cup \{[P_k] + S\}| \leq \frac{101}{100} |S|,$$

for $\{P_k\}$ is $ε$. Let $δ = \frac{|S|}{100}$. Then $(S \setminus E_{k,δ}) \cap ([P_k] + S) \neq ∅$. Let $s = ε$. Applying Theorem 4.3 with $s$ and $δ$, we have

$$(31)\ |\prod_{n=0}^{[P_k]-1} P(y+n)| \leq C|\prod_{n=0}^{[P_k]-1} P(x+n)|,$$

for each $x \in [0,1) \setminus E_{k,δ}$ and $x = y + P_k$.

Now we can choose $x_k \in S \setminus E_{k,δ}$ such that $x_k - [P_k] \in S$. Let $y_k = x_k' - [P_k] = x_k - P_k$.

Then

$$(32)\ |\prod_{n=0}^{[P_k]-1} P(y_k+n)| = \prod_{n=1}^{[P_k]} P(x_k' - n).$$

By (31) and (32), we get

$$|\prod_{n=1}^{[P_k]} P(x_k' - n)| \leq C|\prod_{n=0}^{[P_k]-1} P(x_k + n)|.$$
Applying (9) and (10) with \( x_k, x'_k \in S \), one has

\[
(33) \quad f(x_k + [P_k]) = f(x_k) \prod_{n=0}^{[P_k]-1} P(x_k + n),
\]

and

\[
(34) \quad f(x'_k - [P_k]) = f(x'_k) \left( \prod_{n=1}^{[P_k]} P(x'_k - n) \right)^{-1}.
\]

By (8), (33) and (34), we obtain that

\[
|f(x_k + [P_k])f(x'_k - [P_k])| \geq \frac{d^2}{C}.
\]

This is contradicted by (7), if we let \( k \to \infty \).

\[\square\]

ACKNOWLEDGMENTS

I would like to thank Svetlana Jitomirskaya for introducing to me the HRT conjecture and inspiring discussions on this subject. The author was supported by the AMS-Simons Travel Grant 2016-2018 and NSF DMS-1700314. This research was also partially supported by NSF DMS-1401204.
