Sharp Dirac’s Theorem for DP-Critical Graphs

Anton Bernshteyn*  Alexandr Kostochka†

Abstract

Correspondence coloring, or DP-coloring, is a generalization of list coloring introduced recently by Dvořák and Postle [11]. In this paper we establish a version of Dirac’s theorem on the minimum number of edges in critical graphs [9] in the framework of DP-colorings. A corollary of our main result answers a question posed by Kostochka and Stiebitz [15] on classifying list-critical graphs that satisfy Dirac’s bound with equality.

1 Introduction

All graphs considered here are finite, undirected, and simple. We use \( \mathbb{N} \) to denote the set of all nonnegative integers. For \( k \in \mathbb{N} \), let \( [k] := \{1 \ldots , k\} \). For a set \( S \), we use \( \operatorname{Pow}(S) \) to denote the power set of \( S \), i.e., the set of all subsets of \( S \). For a function \( f : A \to B \) and a subset \( S \subseteq A \), we use \( f|_S \) to denote the restriction of \( f \) to \( S \). For a graph \( G \), \( V(G) \) and \( E(G) \) denote the vertex and the edge sets of \( G \), respectively. For a set \( U \subseteq V(G) \), \( G[U] \) is the subgraph of \( G \) induced by \( U \). Let \( G - U := G[V(G) \setminus U] \), and for \( u \in V(G) \), let \( G - u := G - \{u\} \). For two subsets \( U_1, U_2 \subseteq V(G) \), \( E_G(U_1,U_2) \subseteq E(G) \) denotes the set of all edges in \( G \) with one endpoint in \( U_1 \) and the other one in \( U_2 \). For \( u \in V(G) \), \( N_G(u) \subseteq V(G) \) denotes the set of all neighbors of \( u \) and \( \deg_G(u) := |N_G(u)| \) denotes the degree of \( u \) in \( G \). We let \( \Delta(G) := \max_{u \in V(G)} \deg_G(u) \) and \( \delta(G) := \min_{u \in V(G)} \deg_G(u) \) denote the maximum and the minimum degrees of \( G \), respectively. For a subset \( U \subseteq V(G) \), let \( N_G(U) := \bigcup_{u \in U} N_G(u) \) denote the neighborhood of \( U \) in \( G \). A set \( I \subseteq V(G) \) is independent if \( I \cap N_G(I) = \emptyset \), i.e., if \( uv \notin E(G) \) for all \( u, v \in I \). We denote the family of all independent sets in a graph \( G \) by \( \operatorname{Ind}(G) \). The complete graph on \( n \) vertices is denoted by \( K_n \).

1.1 Critical graphs and the theorems of Brooks, Dirac, and Gallai

Recall that a proper coloring of a graph \( G \) is a function \( f : V(G) \to Y \), where \( Y \) is a set, whose elements are referred to as colors, such that \( f(u) \neq f(v) \) for each edge \( uv \in E(G) \). The smallest \( k \in \mathbb{N} \) such that there exists a proper coloring \( f : V(G) \to Y \) with \( |Y| = k \) is called the chromatic number of \( G \) and is denoted by \( \chi(G) \).

For $k \in \mathbb{N}$, a graph $G$ is said to be \textit{$(k + 1)$-vertex-critical} if $\chi(G) = k + 1$ but $\chi(G - u) \leq k$ for all $u \in V(G)$. We will only consider vertex-critical graphs in this paper, so for brevity we will call them simply \textit{critical}. Since every graph $G$ with $\chi(G) > k$ contains a $(k + 1)$-critical subgraph, understanding the structure of critical graphs is crucial for the study of graph coloring. We will only consider critical graphs in this paper, so for brevity we will call them simply \textit{critical}. Since every graph $G$ with $\chi(G) > k$ contains a $(k + 1)$-critical subgraph, understanding the structure of critical graphs is crucial for the study of graph coloring. We will only consider $k \geq 3$, the case $k \leq 2$ being trivial (the only 1-critical graph is $K_1$, the only 2-critical graph is $K_2$, and the only 3-critical graphs are odd cycles).

Let $k \geq 3$ and suppose that $G$ is a $(k + 1)$-critical graph with $n$ vertices and $m$ edges. A classical problem in the study of critical graphs is to understand how small $m$ can be depending on $n$ and $k$. Evidently, $\delta(G) \geq k$; in particular, $2m \geq kn$. Brooks’s Theorem is equivalent to the assertion that the only situation in which $2m = kn$ is when $G \cong K_{k+1}$:

**Theorem 1.1** (Brooks [6, Theorem 14.4]). Let $k \geq 3$ and let $G$ be a $(k + 1)$-critical graph distinct from $K_{k+1}$. Set $n := |V(G)|$ and $m := |E(G)|$. Then

$$2m > kn.$$  

Brooks’s theorem was subsequently sharpened by Dirac, who established a linear in $k$ lower bound on the difference $2m - kn$:

**Theorem 1.2** (Dirac [9, Theorem 15]). Let $k \geq 3$ and let $G$ be a $(k + 1)$-critical graph distinct from $K_{k+1}$. Set $n := |V(G)|$ and $m := |E(G)|$. Then

$$2m \geq kn + k - 2. \quad (1.1)$$

Bound (1.1) is sharp in the sense that for every $k \geq 3$, there exist $(k + 1)$-critical graphs that satisfy $2m = kn + k - 2$. However, for each $k$, there are only finitely many such graphs; in fact, they admit a simple characterization, which we present below.

**Definition 1.3.** Let $k \geq 3$. A graph $G$ is \textit{$k$-Dirac} if its vertex set can be partitioned into three subsets $V_1, V_2, V_3$ such that:

- $|V_1| = k$, $|V_2| = k - 1$, and $|V_3| = 2$;
- the graphs $G[V_1]$ and $G[V_2]$ are complete;
- each vertex in $V_1$ is adjacent to exactly one vertex in $V_3$;
- each vertex in $V_3$ is adjacent to at least one vertex in $V_1$;
- each vertex in $V_2$ is adjacent to both vertices in $V_3$; and
- $G$ has no other edges.

We denote the family of all $k$-Dirac graphs by $\textbf{Dir}_k$.

**Theorem 1.4** (Dirac [10, Theorem, p. 152]). Let $k \geq 3$ and let $G$ be a $(k + 1)$-critical graph distinct from $K_{k+1}$. Set $n := |V(G)|$ and $m := |E(G)|$. Then

$$2m = kn + k - 2 \iff G \in \textbf{Dir}_k.$$  

As $n$ goes to infinity, the gap between Dirac’s lower bound and the sharp bound increases. In fact, Gallai [13] observed that the asymptotic density of large $(k + 1)$-critical graphs distinct from $K_{k+1}$ is strictly greater than $k/2$. However, Gallai’s bound is stronger than (1.1) only for $n$ at least quadratic in $k$.\

2
1.2 List coloring

List coloring was introduced independently by Vizing [19] and Erdős, Rubin, and Taylor [12]. A list assignment for a graph $G$ is a function $L: V(G) \rightarrow \text{Pow}(Y)$, where $Y$ is a set, whose elements, as in the case of ordinary colorings, are referred to as colors. For each $u \in V(G)$, the set $L(u)$ is called the list of $u$ and its elements are said to be available for $u$. If $|L(u)| = k$ for all $u \in V(G)$, then $L$ is called a $k$-list assignment. A proper coloring $f: V(G) \rightarrow Y$ is called an $L$-coloring if $f(u) \in L(u)$ for each $u \in V(G)$. A graph $G$ is said to be $L$-colorable if it has an $L$-coloring. The list-chromatic number $\chi_L(G)$ of $G$ is the smallest $k \in \mathbb{N}$ such that $G$ is $L$-colorable for every $k$-list assignment $L$ for $G$. If $k \in \mathbb{N}$ and $L(u) = [k]$ for all $u \in V(G)$, then $G$ is $L$-colorable if and only if it is $k$-colorable; in this sense, list coloring generalizes ordinary coloring. In particular, $\chi_L(G) \geq \chi(G)$ for all graphs $G$.

A list assignment $L$ for a graph $G$ is called a degree list assignment if $|L(u)| \geq \deg_G(u)$ for all $u \in V(G)$. A fundamental result of Borodin [8] and Erdős–Rubin–Taylor [12], which can be seen as a generalization of Brooks’s theorem to list colorings, provides a complete characterization of all graphs $G$ that are not $L$-colorable with respect to some degree list assignment $L$.

**Definition 1.5.** A Gallai tree is a connected graph in which every block is either a clique or an odd cycle. A Gallai forest is a graph in which every connected component is a Gallai tree.

**Theorem 1.6** (Borodin [8]; Erdős–Rubin–Taylor [12, Theorem, p. 142]). Let $G$ be a connected graph and let $L$ be a degree list assignment for $G$. If $G$ is not $L$-colorable, then $G$ is a Gallai tree; furthermore, $|L(u)| = \deg_G(u)$ for all $u \in V(G)$, and if $u$, $v \in V(G)$ are two adjacent non-cut vertices, then $L(u) = L(v)$.

Theorem 1.6 provides some useful information about the structure of critical graphs:

**Corollary 1.7.** Let $k \geq 3$ and let $G$ be a $(k+1)$-critical graph. Set

$$D := \{u \in V(G) : \deg_G(u) = k\}.$$

Then $G[D]$ is a Gallai forest.

Corollary 1.7 was originally proved by Gallai [13] using a different method. It is crucial for the proof of Gallai’s theorem on the asymptotic average degree of $(k+1)$-critical graphs.

The definition of critical graphs can be naturally extended to list colorings. A graph $G$ is said to be $L$-critical, where $L$ is a list assignment for $G$, if $G$ is not $L$-colorable but for any $u \in V(G)$, the graph $G - u$ is $L|_{V(G-u)}$-colorable. Note that if we set $L(u) := [k]$ for all $u \in V(G)$, then $G$ being $L$-critical is equivalent to it being $(k+1)$-critical. Repeating the argument used to prove Corollary 1.7, we obtain the following more general statement:

**Corollary 1.8** (Kostochka–Stiebitz–Wirth [16, Theorem 5]). Let $k \geq 3$ and let $G$ be a graph. Suppose that $L$ is a $k$-list assignment for $G$ such that $G$ is $L$-critical. Set

$$D := \{u \in V(G) : \deg_G(u) = k\}.$$

Then $G[D]$ is a Gallai forest.
Corollary 1.8 can be used to prove a version of Gallai’s theorem for list-critical graphs, i.e., to show that the average degree of a graph $G$ distinct from $K_{k+1}$ that is $L$-critical for some $k$-list assignment $L$ has average degree strictly greater than $k/2$. On the other hand, list-critical graphs distinct from $K_{k+1}$ do not, in general, admit a nontrivial lower bound on the difference $2m - kn$ that only depends on $k$ (analogous to the one given by Dirac’s Theorem 1.2 for $(k + 1)$-critical graphs). Consider the following example, presented in [15, p. 167]. Fix $k \in \mathbb{N}$ and let $G$ be the graph with vertex set $\{a_0, \ldots, a_k, b_0, \ldots, b_k\}$ of size $2(k + 1)$ and edge set $\{a_ia_j, b_ib_j : i \neq j\} \cup \{a_0b_0\}$. For each $i \in [k]$, let $L(a_i) = L(b_i) := [k]$, and let $L(a_0) = L(b_0) := \{0\} \cup [k - 1]$. Then $G$ is $L$-critical; however, $2|E(G)| - k|V(G)| = 2$.

Nonetheless, Theorem 1.2 can be extended to the list coloring framework if we restrict our attention to graphs that do not contain $K_{k+1}$ as a subgraph:

**Theorem 1.9** (Kostochka–Stiebitz [15, Theorem 2]). Let $k \geq 3$. Let $G$ be a graph and let $L$ be a $k$-list assignment for $G$ such that $G$ is $L$-critical. Suppose that $G$ does not contain a clique of size $k + 1$. Set $n := |V(G)|$ and $m := |E(G)|$. Then

$$2m \geq kn + k - 2.$$ 

Kostochka and Stiebitz [15, Section 4] asked whether the conclusion of Theorem 1.4 also holds for list critical graphs with no $K_{k+1}$ as a subgraph. We answer this question in the affirmative; see Corollary 1.20.

### 1.3 DP-colorings and the results of this paper

In this paper we focus on a generalization of list coloring that was recently introduced by Dvořák and Postle [11]; they called it correspondence coloring, and we call it DP-coloring for short. Dvořák and Postle invented DP-coloring in order to prove that every planar graph without cycles of lengths 4 to 8 is 3-list-colorable [11, Theorem 1], thus answering a long-standing question of Borodin [7, Problem 8.1]. In the setting of DP-coloring, not only does each vertex get its own list of available colors, but also the identifications between the colors in the lists can vary from edge to edge.

**Definition 1.10.** Let $G$ be a graph. A **cover** of $G$ is a pair $\mathcal{H} = (L, H)$, consisting of a graph $H$ and a function $L : V(G) \rightarrow \text{Pow}(V(H))$, satisfying the following requirements:

(C1) the sets $\{L(u) : u \in V(G)\}$, form a partition of $V(H)$;

(C2) for every $u \in V(G)$, the graph $H[L(u)]$ is complete;

(C3) if $E_H(L(u), L(v)) \neq \emptyset$, then either $u = v$ or $uv \in E(G)$;

(C4) if $uv \in E(G)$, then $E_H(L(u), L(v))$ is a matching.

A cover $\mathcal{H} = (L, H)$ of $G$ is **$k$-fold** if $|L(u)| = k$ for all $u \in V(G)$.

**Remark 1.11.** The matching $E_H(L(u), L(v))$ in Definition 1.10(C4) does not have to be perfect and, in particular, is allowed to be empty.
Definition 1.12. Let $G$ be a graph and let $\mathcal{H} = (L, H)$ be a cover of $G$. An $\mathcal{H}$-coloring of $G$ is an independent set $I \in \text{Ind}(H)$ of size $|V(G)|$. We say that $G$ is $\mathcal{H}$-colorable if it has an $\mathcal{H}$-coloring.

Remark 1.13. By definition, if $\mathcal{H} = (L, H)$ is a cover of $G$, then $\{L(u) : u \in V(G)\}$ is a partition of $H$ into $|V(G)|$ cliques. Therefore, $I \in \text{Ind}(H)$ is an $\mathcal{H}$-coloring of $G$ if and only if $|I \cap L(u)| = 1$ for all $u \in V(G)$.

Definition 1.14. Let $G$ be a graph. The DP-chromatic number $\chi_{DP}(G)$ of $G$ is the smallest $k \in \mathbb{N}$ such that $G$ is $\mathcal{H}$-colorable for every $k$-fold cover $H$ of $G$.

Example 1.15. Figure 1 shows two distinct 2-fold covers of the 4-cycle $C_4$. Note that $C_4$ is $\mathcal{H}_1$-colorable but not $\mathcal{H}_2$-colorable. In particular, $\chi_{DP}(C_4) \geq 3$. On the other hand, it can be easily seen that $\chi_{DP}(G) \leq \Delta(G) + 1$ for any graph $G$, and so we have $\chi_{DP}(C_4) = 3$. A similar argument demonstrates that $\chi_{DP}(C_n) = 3$ for any cycle $C_n$ of length $n \geq 3$.

Figure 1: Two distinct 2-fold covers of a 4-cycle.

In order to see that DP-colorings indeed generalize list colorings, consider a graph $G$ and a list assignment $L$ for $G$. Let $H$ be the graph with vertex set

$$V(H) := \{(u, c) : u \in V(G) \text{ and } c \in L(u)\},$$

in which two distinct vertices $(u, c)$ and $(v, d)$ are adjacent if and only if

- either $u = v$,
- or else, $uv \in E(G)$ and $c = d$.

For each $u \in V(G)$, set

$$L'(u) := \{(u, c) : c \in L(u)\}.$$

Then $\mathcal{H} := (L', H)$ is a cover of $G$, and there is a natural bijective correspondence between the $L$-colorings and the $\mathcal{H}$-colorings of $G$. Indeed, if $f$ is an $L$-coloring of $G$, then the set

$$I_f := \{(u, f(u)) : u \in V(G)\}$$

is an $\mathcal{H}$-coloring of $G$. Conversely, given an $\mathcal{H}$-coloring $I \in \text{Ind}(H)$ of $G$, $|I \cap L'(u)| = 1$ for all $u \in V(G)$, so one can define an $L$-coloring $f_I$ by the property

$$(u, f_I(u)) \in I \cap L'(u),$$

for all $u \in V(G)$. Therefore, $f_I$ is an $L$-coloring of $G$. Thus we have the following bijection:

$$\begin{align*}
\text{Ind}(L) &\leftrightarrow \text{Ind}(H) \\
\{f : G \to \text{Col}(L)\} &\leftrightarrow \{I : G \to \text{Col}(H)\}
\end{align*}$$

where $\text{Col}(L)$ and $\text{Col}(H)$ denote the sets of $L$-colorings and $H$-colorings, respectively.
for all $u \in V(G)$. This shows that list colorings can be identified with a subclass of DP-colorings. In particular, $\chi_{DP}(G) \geq \chi_l(G)$ for all graphs $G$.

Some upper bounds on list-chromatic numbers hold for DP-chromatic numbers as well. For instance, it is easy to see that $\chi_{DP}(G) \leq d + 1$ for any $d$-degenerate graph $G$. Dvořák and Postle [11] pointed out that for any planar graph $G$, $\chi_{DP}(G) \leq 5$ and, moreover, $\chi_{DP}(G) \leq 3$ if $G$ is a planar graph of girth at least 5 (these statements are extensions of classical results of Thomassen [17, 18] regarding list colorings). On the other hand, there are also some striking differences between DP- and list colorings. For example, even cycles are 2-list-colorable, while their DP-chromatic number is 3 (see Example 1.15). In particular, the orientation theorems of Alon–Tarsi [2] and the Bondy–Boppana–Siegel lemma (see [2]) do not extend to DP-colorings; see [4] for more examples demonstrating the failure of these techniques in the DP-coloring context. Bernshteyn [3, Theorem 1.6] showed that the DP-chromatic number of every graph with average degree $d$ is $\Omega(d/\log d)$, i.e., almost linear in $d$ (recall that due to a celebrated result of Alon [1], the list-chromatic number of such graphs is $\Omega(\log d)$, and this bound is best possible). On the other hand, Johansson’s upper bound [14] on list chromatic numbers of triangle-free graphs also holds for DP-chromatic numbers [3, Theorem 1.7].

A cover $H = (L, H)$ of a graph $G$ is a degree cover if $|L(u)| \geq \deg_G(u)$ for all $u \in V(G)$. Bernshteyn, Kostochka, and Pron [5] established the following generalization of Theorem 1.6:

**Definition 1.16.** A *GDP-tree* is a connected graph in which every block is either a clique or a cycle. A *GDP-forest* is a graph in which every connected component is a GDP-tree.

**Theorem 1.17 ([5, Theorem 9]).** Let $G$ be a connected graph and let $H = (L, H)$ be a degree cover of $G$. If $G$ is not $H$-colorable, then $G$ is a GDP-tree; furthermore, $|L(u)| = \deg_G(u)$ for all $u \in V(G)$, and if $u, v \in V(G)$ are two adjacent non-cut vertices, then $E_H(L(u), L(v))$ is a perfect matching.

Let $G$ be a graph and let $H = (L, H)$ be a cover of $G$. We say that $G$ is $H$-critical if $G$ is not $H$-colorable but for any $u \in V(G)$, there exists $I \in \text{Ind}(H)$ such that $I \cap L(v) \neq \emptyset$ for all $v \neq u$. Theorem 1.17 implies the following:

**Corollary 1.18 ([5]).** Let $k \geq 3$ and let $G$ be a graph. Suppose that $H$ is a $k$-fold cover of $G$ such that $G$ is $H$-critical. Set

$$D := \{u \in V(G) : \deg_G(u) = k\}.$$ 

Then $G[D]$ is a GDP-forest.

Corollary 1.18 implies an extension of Gallai’s theorem to DP-critical graphs [5, Corollary 10].

The main result of this paper is a generalization of Theorem 1.9 to DP-critical graphs. In fact, we establish a sharp version that also generalizes Theorem 1.4:

**Theorem 1.19.** Let $k \geq 3$. Let $G$ be a graph and let $H$ be a $k$-fold cover of $G$ such that $G$ is $H$-critical. Suppose that $G$ does not contain a clique of size $k + 1$. Set $n := |V(G)|$ and $m := |E(G)|$. If $G \notin \text{Dir}_k$, then

$$2m > kn + k - 2.$$
An immediate corollary of Theorem 1.19 is the following version of Theorem 1.4 for list colorings:

**Corollary 1.20.** Let \( k \geq 3 \). Let \( G \) be a graph and let \( L \) be a \( k \)-list assignment for \( G \) such that \( G \) is \( L \)-critical. Suppose that \( G \) does not contain a clique of size \( k + 1 \). Set \( n := |V(G)| \) and \( m := |E(G)| \). If \( G \not\in \text{Dir}_k \), then

\[
2m > kn + k - 2.
\]

Our proof of Theorem 1.19 is, essentially, inductive. As often is the case, having a stronger inductive assumption (due to considering DP-critical and not just list-critical graphs) allows for more flexibility in the proof. In particular, we do not know if our argument can be adapted to give a “DP-free” proof of Corollary 1.20.

2 Proof of Theorem 1.19: first observations

2.1 Set-up and notation

From now on, we fix a counterexample to Theorem 1.19; more precisely, we fix the following data:

- an integer \( k \geq 3 \);
- a graph \( G \) with \( n \) vertices and \( m \) edges such that:
  - \( G \not\in \text{Dir}_k \);
  - \( G \) does not contain a clique of size \( k + 1 \); and
  - \( G \) satisfies the inequality
    \[
    2m \leq kn + k - 2;
    \] (2.1)
- a \( k \)-fold cover \( \mathcal{H} = (L, H) \) of \( G \) such that \( G \) is \( \mathcal{H} \)-critical.

Furthermore, we assume that \( G \) is a counterexample with the fewest vertices.

For brevity, we denote \( V := V(G) \) and \( E := E(G) \). For a subset \( U \subseteq V \), we use \( U^c \) to denote the complement of \( U \) in \( V \), i.e., \( U^c := V \setminus U \). For \( u \in V \) and \( U \subseteq V \), set

\[
\deg(u) := \deg_G(u) \quad \text{and} \quad \deg_U(u) := |U \cap N_G(u)|.
\]

For \( u \in V \), set

\[
\varepsilon(u) := \deg(u) - k,
\]

and for \( U \subseteq V \), define

\[
\varepsilon(U) := \sum_{u \in U} \varepsilon(u).
\]

Note that (2.1) is equivalent to

\[
\varepsilon(V) \leq k - 2.
\] (2.2)
Since $G$ is $\mathcal{H}$-critical, we have $\delta(G) \geq k$, i.e., $\varepsilon(u) \geq 0$ for all $u \in V$. Let

$$D := \{u \in V : \deg(u) = k\} = \{u \in V : \varepsilon(u) = 0\}.$$  

Since $\varepsilon(u) \geq 1$ for every $u \in D^c$, (2.2) yields

$$|D^c| \leq k - 2.$$  

Corollary 1.18 implies that $G[D]$ is a GDP-forest. Furthermore, since $n \geq k + 1$, $D \neq \emptyset$.

From now on, we refer to the vertices of $H$ as colors and to the independent sets in $H$ as colorings. For $I, I' \in \text{Ind}(H)$, we say that $I'$ extends $I$ if $I' \supseteq I$. For $I \in \text{Ind}(H)$, let

$$\text{dom}(I) := \{u \in V : I \cap L(u) \neq \emptyset\}.$$  

Since $G$ is $\mathcal{H}$-critical, there is no coloring $I$ with $\text{dom}(I) = V$; but for every proper subset $U \subset V$, there exists a coloring $I$ with $\text{dom}(I) = U$.

For $I \in \text{Ind}(H)$ and $u \in (\text{dom}(I))^c$, let

$$L_I(u) := L(u) \setminus N_H(I).$$  

In other words, $L_I(u)$ is the set of all colors available for $u$ in a coloring extending $I$.

For $u \in V$ and $U \subseteq V$, let

$$\varphi_U(u) := \deg_{U}(u) - \varepsilon(u).$$  

In particular, if $u \in D$, then $\varphi_U(u) = \deg_{U}(u)$. Note that

$$\varphi_U(u) = \deg_{U}(u) - (\deg(u) - k) = k - (\deg(u) - \deg_{U}(u)) = k - \deg_{U^c}(u).$$  

Therefore, if $I$ is a coloring such that $\text{dom}(I) = U^c$, then for all $u \in U$,

$$|L_I(u)| \geq \varphi_U(u).$$  

(2.3)

2.2 A property of GDP-forests

The following simple general property of GDP-forests will be quite useful:

**Proposition 2.1.** Let $F$ be a nonempty GDP-forest of maximum degree at most $k$ not containing a clique of size $k + 1$. Then

$$\sum_{u \in V(F)} (k - \deg_{F}(u)) \geq k,$$  

(2.4)

with equality only if $F \cong K_1$ or $F \cong K_k$.

**Proof.** It suffices to establish the proposition for the case when $F$ is connected, i.e., a GDP-tree. If $F$ is 2-connected, i.e., a clique or a cycle, then the statement follows via a simple calculation. It remains to notice that adding a leaf block to a GDP-tree of maximum degree at most $k$ cannot decrease the quantity on the left-hand side of (2.4).
Corollary 2.2. Let $U \subseteq D$ be the vertex set of a connected component of $G[D]$. Then

$$|E_G(U, D^c)| \geq k,$$

with equality only if $G[U] \cong K_k$.

Proof. We have

$$|E_G(U, D^c)| = \sum_{u \in U} \deg_{D^c}(u) = \sum_{u \in U} \deg_{U^c}(u) = \sum_{u \in U} (k - \deg_U(u)).$$

By Proposition 2.1 applied to $G[U]$, the latter quantity is at least $k$, with equality only if $G[U] \cong K_1$ or $G[U] \cong K_k$. It remains to notice that $G[U] \not\cong K_1$, since $\deg(u) = k$ for each $u \in U$, while $|D^c| \leq k - 2$. ■

2.3 Enhanced vertices

The following definition will play a crucial role in our argument:

Definition 2.3. Let $I$ be a coloring and let $U := (\operatorname{dom}(I))^c$. A vertex $u \in U \cap D$ is enhanced by $I$, or $I$ enhances $u$, if $|L_I(u)| > \deg_U(u)$.

Remark 2.4. Note that, in the context of Definition 2.3, we always have $|L_I(u)| \geq \deg_U(u)$.

The importance of Definition 2.3 stems from the following lemma:

Lemma 2.5. Let $I$ be a coloring and let $U := (\operatorname{dom}(I))^c$.

(i) Suppose that $I'$ is a coloring extending $I$. Let $u \in (\operatorname{dom}(I'))^c \cap D$. If $u$ is enhanced by $I$, then it is also enhanced by $I'$.

(ii) Let $U' \subseteq U \cap D$ be a subset such that the graph $G[U']$ is connected. Suppose that $U'$ contains a vertex enhanced by $I$. Then $I$ can be extended to a coloring $I'$ with $\operatorname{dom}(I') = U^c \cup U'$.

(iii) Suppose that $I$ enhances at least one vertex in each component of $G[U \cap D]$. Then $I$ cannot be extended to a coloring $I'$ with $\operatorname{dom}(I') \supseteq D^c$.

Proof. Since (i) is an immediate corollary of the definition and (ii) follows from Theorem 1.17, it only remains to prove (iii). To that end, suppose, under the assumptions of (iii), that $I'$ is a coloring extending $I$ with $\operatorname{dom}(I') \supseteq D^c$. Reducing $I'$ if necessary, we may arrange that $\operatorname{dom}(I') = U^c \cup D^c$. Then, by (i), $I'$ enhances at least one vertex in each component of $G[U \cap D]$. Applying (ii) to each connected component of $G[U \cap D]$, we can extend $I'$ to a coloring of the entire graph $G$; a contradiction. ■

The next lemma gives a convenient sufficient condition under which a given coloring can be extended so that the resulting coloring enhances a particular vertex:

Lemma 2.6. Let $I$ be a coloring and let $U := (\operatorname{dom}(I))^c$. Let $u \in U \cap D$ and suppose that $A \subseteq U \cap N_G(u)$ is an independent set in $G$. Moreover, suppose that

$$\min\{\varphi_U(v) : v \in A\} > 0 \quad \text{and} \quad \sum_{v \in A} \varphi_U(v) > \deg_G(u).$$

Then there is a coloring $I'$ with $\operatorname{dom}(I') = U^c \cup A$ that extends $I$ and enhances $u$. 

9
Proof. Since $A \in \text{Ind}(G)$ and for all $v \in A$, $\varphi_V(v) > 0$ (and hence, by (2.3), $|L_I(v)| > 0$), any coloring $I'$ with $\text{dom}(I') \subseteq U^c \cup A$ can be extended to a coloring with domain $U^c \cup A$. Therefore, it suffices to find a coloring that extends $I$ and enhances $u$ and whose domain is contained in $U^c \cup A$.

If $u$ is enhanced by $I$ itself, then we are done, so assume that $|L_I(u)| = \deg_{U}(u)$. If for some $v \in A$, there is $x \in L_I(v)$ with no neighbor in $L_I(u)$, then $u$ is enhanced by $I \cup \{x\}$, and we are done again. Thus, we may assume that for every $v \in A$, the matching $E_H(L_I(v), L_I(u))$ saturates $L_I(v)$. For each $v \in A$ and $x \in L_I(v)$, let $f(x)$ denote the neighbor of $x$ in $L_I(u)$. Since $\sum_{v \in A} \varphi_U(v) > \deg_{U}(u)$, and hence, by (2.3), $\sum_{v \in A} |L_I(v)| > |L_I(u)|$, there exist distinct vertices $v, w \in A$ and colors $x \in L_I(v), y \in L_I(w)$ such that $f(x) = f(y)$. Then $u$ is enhanced by the coloring $I \cup \{x, y\}$, and the proof is complete. $\blacksquare$

**Corollary 2.7.** Suppose that $u, u_1, u_2 \in D$ are distinct vertices such that $uu_1, uu_2 \in E$, while $u_1u_2 \not\in E$. Then the graph $G[D] - u_1 - u_2$ is disconnected.

**Proof.** Note that, since $u, u_1, u_2 \in D$, we have

$$\varphi_V(u_1) = \varphi_V(u_2) = k \quad \text{and} \quad \deg(u) = k,$$

so, by Lemma 2.6, there exist $x_1 \in L(u_1)$ and $x_2 \in L(u_2)$ such that $u$ is enhanced by the coloring $\{x_1, x_2\}$. Since for all $v \in D^c$,

$$|L(x_1, x_2)(v)| \geq |L(v)| - |\{x_1, x_2\}| = k - 2 \geq |D^c|,$$

we can extend $\{x_1, x_2\}$ to a coloring $I$ with $\text{dom}(I) = \{u_1, u_2\} \cup D^c$. Due to Lemma 2.5(iii), at least one connected component of the graph $G[D] - u_1 - u_2$ contains no vertices enhanced by $I$. Since, by Lemma 2.5(i), $I$ enhances $u$, $G[D] - u_1 - u_2$ is disconnected, as desired. $\blacksquare$

We will often apply Lemma 2.6 in the form of the following corollary:

**Corollary 2.8.** Suppose that $v \in D$ and let $v_1, v_2 \in D^c \cap N_G(v)$ be distinct vertices such that $v_1v_2 \not\in E$. Let $U \subseteq D$ be any set such that $u \in U$ and the graph $G[U]$ is connected. Then

$$\text{either} \quad \min\{\varphi_U(v_1), \varphi_U(v_2)\} \leq 0,$$

$$\text{or} \quad \varphi_U(v_1) + \varphi_U(v_2) \leq \deg_{U}(u) + 2.$$

**Proof.** Notice that

$$\varphi_{U \cup \{v_1, v_2\}}(v_i) = \varphi_U(v_i) \quad \text{for each } i \in \{1, 2\}, \quad \text{and} \quad \deg_{U \cup \{v_1, v_2\}}(u) = \deg_{U}(u) + 2.$$

Therefore, if the claim fails, then we can first fix any coloring $I$ with $\text{dom}(I) = (U \cup \{v_1, v_2\})^c$, and then apply Lemma 2.6 to extend it to a coloring $I'$ with $\text{dom}(I') = U^c$ that enhances $u$. Since $G[U]$ is connected, such a coloring cannot exist by Lemma 2.5(iii). $\blacksquare$

The following observation can be viewed as an analog of Lemma 2.5(ii) for edges instead of vertices:

**Lemma 2.9.** Let $I$ be a coloring and let $U := (\text{dom}(I))^c$. Let $U' \subseteq U \cap D$ be a subset such that the graph $G[U']$ is connected and let $u_1, u_2 \in U'$ be adjacent non-cut vertices in $G[U']$. Suppose that the matching $E_H(L_I(u_1), L_I(u_2))$ is not perfect. Then $I$ can be extended to a coloring $I'$ with $\text{dom}(I') = U^c \cup U'$.

**Proof.** Follows from Theorem 1.17.
2.4 Vertices of small degree

In this subsection we establish some structural properties that $G$ must possess if the minimum degree of the graph $G[D]$ is “small” (namely at most 2).

Lemma 2.10. (i) The minimum degree of $G[D]$ is at least 2.

(ii) If there is a vertex $u \in D$ such that $\deg_D(u) = 2$, then $|D^c| = k - 2$, $u$ is adjacent to every vertex in $D^c$, and $\varepsilon(v) = 1$ for all $v \in D^c$.

(iii) If the graph $G[D]$ has a connected component with at least 3 vertices of degree 2, then $G[D^c]$ is a disjoint union of cliques.

(iv) If the graph $G[D]$ has a connected component with at least 4 vertices of degree 2, then $G[D^c] \cong K_{k-2}$.

Proof. (i) For each $u \in D$, we have

$$k - 2 \geq |D^c| \geq \deg_{D^c}(u) = k - \deg_D(u),$$

so $\deg_D(u) \geq 2$.

(ii) If $u \in D$ and $\deg_D(u) = 2$, then $u$ has exactly $k - 2$ neighbors in $D^c$. Thus,

$$\varepsilon(D^c) = |D^c| = k - 2,$$

which implies all the statements in (ii).

(iii) Let $U \subseteq D$ be the vertex set of a connected component of $G[D]$ such that $G[U]$ contains at least 3 vertices of degree 2. Suppose, towards a contradiction, that $G[D^c]$ is not a disjoint union of cliques, i.e., there exist distinct vertices $v_0, v_1, v_2 \in D^c$ such that $v_0v_1, v_0v_2 \in E$, while $v_1v_2 \not\in E$. By (ii), each vertex in $D^c$ is adjacent to every vertex of degree 2 in $G[D]$, $|D^c| = k - 2$, and $\varepsilon(v) = 1$ for all $v \in D^c$. Thus,

$$\varphi_{U \cup \{v_0, v_1, v_2\}}(v_i) = \deg_{U \cup \{v_0, v_1, v_2\}}(v_i) - \varepsilon(v_i) \geq (3 + 1) - 1 = 3$$

for each $i \in \{1, 2\}$.

Fix any vertex $u \in U$ such that $\deg_U(u) = 2$. Then

$$\deg_{U \cup \{v_0, v_1, v_2\}}(u) = 2 + 3 = 5.$$

Therefore, by Lemma 2.6, there exists a coloring $I$ with domain

$$\dom(I) = (U \cup \{v_0, v_1, v_2\})^c \cup \{v_1, v_2\} = (U \cup \{v_0\})^c$$

that enhances $u$. By (2.3),

$$|L_I(v_0)| \geq \varphi_U(v_0) = \deg_U(v_0) - \varepsilon(v_0) \geq 3 - 1 = 2 > 0,$$

so $I$ can be extended to a coloring $I'$ with $\dom(I') = U^c$. This contradicts Lemma 2.5(iii).

(iv) If $U \subseteq D$ is the vertex set of a connected component of $G[D]$ with at least 4 vertices of degree 2 and $v_1, v_2 \in D^c$ are distinct nonadjacent vertices, then we have

$$\varphi_U(v_i) = \deg_U(v_i) - \varepsilon(v_i) \geq 4 - 1 = 3$$

for each $i \in \{1, 2\}$,

so for every vertex $u \in U$ with $\deg_U(u) = 2$, we have

$$\varphi_U(v_1) + \varphi_U(v_2) \geq 3 + 3 > 4 = \deg_U(u) + 2,$$

a contradiction to Corollary 2.8. \qed
2.5 Terminal sets

We start this section by introducing some definitions and notation that will be used throughout the rest of the proof.

Definition 2.11. A terminal set is a subset \( B \subseteq D \) such that \( G[B] \) is a leaf block in a connected component of \( G[D] \). For a terminal set \( B \), \( C_B \supseteq B \) denotes the vertex set of the connected component of \( G[D] \) that contains \( B \). A vertex \( u \in D \) is terminal if it belongs to some terminal set \( B \) and is not a cut-vertex in \( G[C_B] \).

By definition, a terminal set contains at most one non-terminal vertex. Since \( G[D] \) is a GDP-forest, if \( B \) is a terminal set, then \( G[B] \) is either a cycle or a clique. By Lemma 2.10(i), the cardinality of a terminal set is at least 3.

Definition 2.12. A terminal set \( B \) is dense if \( G[B] \) is not a cycle; otherwise, \( B \) is sparse.

By definition, the cardinality of a dense terminal set is at least 4.

Our proof hinges on the following key fact:

Lemma 2.13. There exists a dense terminal set.

Before proving Lemma 2.13, we need the following simple observation:

Proposition 2.14. Let \( W_4 \) denote the 4-wheel. Then \( \chi_{DP}(W_4) = 3 \).

Proof. Let \( \mathcal{F} = (M, F) \) be a 3-fold cover of \( W_4 \) and suppose that \( W_4 \) is not \( \mathcal{F} \)-colorable. Let \( v \in V(W_4) \) denote the center of \( W_4 \) and let \( U := V(W_4) \setminus \{v\} \) (so \( W_4[U] \) is a 4-cycle). Define a function \( f : V(F) \to M(v) \) by

\[
    f(x) = y : \Longleftrightarrow (x = y) \text{ or } (x \not\in M(v) \text{ and } xy \in E(F)).
\]

Since \( \deg_{W_4}(u) = 3 \) for all \( u \in U \), Theorem 1.17 implies that \( f \) is well-defined. Since \( W_4 \) is 3-colorable (in the sense of ordinary graph coloring), there exist an edge \( u_1u_2 \in E(W_4) \) and a pair of colors \( x_1 \in M(u_1), x_2 \in M(u_2) \) such that \( x_1x_2 \in E(F) \) and \( f(x_1) \neq f(x_2) \). Note that \( u_1 \neq v \) since otherwise \( f(x_1) = x_1 = f(x_2) \) by definition. Similarly, \( u_2 \neq v \), so \( \{u_1, u_2\} \subset U \). Let \( y := f(x_2) \). Then \( x_1 \) has no neighbor in \( M(u_2) \setminus N_F(y) \), and hence \( \{y\} \) can be extended to an \( \mathcal{F} \)-coloring of \( W_4 \); a contradiction.

Proof of Lemma 2.13. Suppose that every terminal set is sparse. Since every terminal set induces a cycle, each component of \( G[D] \) contains at least 3 vertices of degree 2, and a component of \( G[D] \) with exactly 3 vertices of degree 2 must be isomorphic to a triangle. By Lemma 2.10(ii), each vertex in \( D^c \) is adjacent to every vertex of degree 2 in \( G[D] \), \( |D^c| = k - 2 \), and \( \varepsilon(v) = 1 \) for all \( v \in D^c \). Furthermore, by Lemma 2.10(iii)(iv), \( G[D^c] \) is a disjoint union of cliques and, unless every component of \( G[D] \) is isomorphic to a triangle, \( G[D^c] \cong K_{k-2} \).

Claim 2.14.1. \( G[D^c] \cong K_{k-2} \).

Proof. Assume, towards a contradiction, that \( G[D^c] \cong K_{k-2} \). Then every vertex in \( D^c \) has exactly \( (k + 1) - (k - 3) = 4 \) neighbors in \( D \). Therefore, the number of vertices of degree 2 in \( G[D] \) is at most 4. Since every component of \( G[D] \) contains at least 3 vertices of degree 2, the
graph $G[D]$ is connected. Since $|D| \geq 4$, $G[D]$ is not a triangle. Thus, it contains precisely 4 terminal vertices of degree 2; i.e., it either is a 4-cycle, or contains exactly two leaf blocks, both of which are triangles.

**Case 1:** $G[D]$ is a 4-cycle. We will show that in this case $G$ is $\mathcal{H}$-colorable. Choose any vertex $v \in D^c$ and let $W := G[\{v\} \cup D]$. Note that $W$ is a 4-wheel. Fix an arbitrary coloring $I \in \text{Ind}(H)$ with $\text{dom}(I) = (\{v\} \cup D)^c$. For all $u \in \{v\} \cup D$, we have $|L_I(u)| \geq k - (k-3) = 3$, so by Proposition 2.14, $I$ can be extended to an $\mathcal{H}$-coloring of the entire graph $G$.

**Case 2:** $G[D]$ contains exactly two leaf blocks, both of which are triangles. Since each vertex in $D^c$ has only 4 neighbors in $D$, every non-terminal vertex in $D$ has degree $k$ in $G[D]$. Notice that every vertex of degree $k$ in $G[D]$ is a cut-vertex. Indeed, if a vertex $u \in D$ is not a cut-vertex in $G[D]$, then the degree of any cut-vertex in the same block as $u$ strictly exceeds the degree of $u$ (since the blocks of the GDP-tree $G[D]$ are regular graphs). Thus, either the two terminal triangles share a cut-vertex (and, in particular, $k = 4$), or else, their cut-vertices are joined by an edge (and $k = 3$). The former option contradicts Corollary 2.7; the latter one implies $G \in \text{Dir}_3$.

By Claim 2.14.1, $G[D^c]$ is a disjoint union of at least 2 cliques. In particular, every connected component of $G[D]$ is isomorphic to a triangle. Suppose that $G[D]$ has $\ell$ connected components (so $|D| = 3\ell$). If a vertex $v \in D^c$ belongs to a component of $G[D^c]$ of size $r$, then its degree in $G$ is precisely ($r-1) + 3\ell$. On the other hand, $\deg(v) = k + 1$. Thus, $k + 1 = (r - 1) + 3\ell$, i.e., $r = k - 3\ell + 2$. In particular, $|D^c| = k - 2$ is divisible by $k - 3\ell + 2$, so $\ell \geq 2$.

**Case 1:** The set $D^c$ is not independent, i.e., $k - 3\ell + 2 \geq 2$. Let $T_1, T_2 \subset D$ (resp. $C_1, C_2 \subset D^c$) be the vertex sets of any two distinct connected components of $G[D]$ (resp. $G[D^c]$). For each $i \in \{1, 2\}$, fix a vertex $u_i \in T_i$ and a pair of distinct vertices $v_{1i}, v_{2i} \in C_i$. Set $U := T_1 \cup T_2 \cup \{v_{11}, v_{12}, v_{21}, v_{22}\}$ and let $I \in \text{Ind}(H)$ be such that $\text{dom}(I) = U^c$. Note that $\varphi_U(v_{11}) = \varphi_U(v_{21}) = 7 - 1 = 6$,

while

$$\deg_U(u_1) = 6,$$

so, by Lemma 2.6, there exist $x_{11} \in L_I(v_{11})$ and $x_{21} \in L_I(v_{21})$ such that

$$I' := I \cup \{x_{11}, x_{21}\}$$

is a coloring that enhances $u_1$. Now, upon setting $U' := U \setminus \{v_{11}, v_{21}\}$, we obtain

$$\varphi_{U'}(v_{12}) = \varphi_{U'}(v_{22}) = 6 - 1 = 5,$$

while

$$\deg_{U'}(u_2) = 4,$$

so, by Lemma 2.6 again, we can choose $x_{12} \in L_{I'}(v_{12})$ and $x_{22} \in L_{I'}(v_{22})$ so that

$$I'' := I' \cup \{x_{12}, x_{22}\}$$

is a coloring that enhances both $u_1$ and $u_2$. However, the existence of such $I''$ contradicts Lemma 2.5(iii).
Case 2: The set \( D^c \) is independent, i.e., \( k - 3\ell + 2 = 1 \). In other words, we have \( k = 3\ell - 1 \). Since \( \ell \geq 2 \), we get \( k \geq 6 - 1 = 5 \), so \( |D^c| = k - 2 \geq 3 \). Let \( v_1, v_2, v_3 \in D^c \) be any three distinct vertices in \( D^c \) and let \( T \subset D \) be the vertex set of any connected component of \( G[D] \). Fix a vertex \( u \in T \), set \( U := T \cup \{v_1, v_2, v_3\} \), and let \( I \in \text{Ind}(H) \) be such that \( \text{dom}(I) = U^c \). Note that
\[
\varphi_U(v_1) = \varphi_U(v_2) = \varphi_U(v_3) = 3 - 1 = 2,
\]
while
\[
\deg_U(u) = 5.
\]
Therefore, by Lemma 2.6, we can choose \( x_1 \in L_I(v_1), x_2 \in L_I(v_2), \) and \( x_3 \in L_I(v_3) \) so that
\[
I' := I \cup \{x_1, x_2, x_3\}
\]
enhances \( u \). This observation contradicts Lemma 2.5(iii) and finishes the proof. \( \blacksquare \)

3 Dense terminal sets and their neighborhoods

3.1 Outline of the proof

Lemma 2.13 asserts that at least one terminal set is dense. In this section we explore the structural consequences of this assertion and eventually arrive at a contradiction.

Definition 3.1. Let \( B \) be a terminal set. Let \( S_B \) denote the set of all vertices in \( B^c \) that are adjacent to every vertex in \( B \) and let \( T_B := N_G(B) \setminus (B \cup S_B) \).

By definition, \( S_B \subseteq D^c \); however, if \( B \neq C_B \), then \( T_B \cap D \neq \emptyset \).

The following statement will be used several times throughout the rest of the argument:

Lemma 3.2. Let \( B \) be a dense terminal set and let \( v \in T_B \). Then \( v \) has at least \( k - 1 \) neighbors outside of \( B \). If, moreover, there exist terminal vertices \( u_0, u_1 \in B \) such that \( u_0v \notin E, u_1v \in E \), then \( v \) has at least \( k - 1 \) neighbors outside of \( C_B \).

Proof. Let \( u_0, u_1 \in B \) be such that \( u_0v \notin E \) and \( u_1v \in E \). If one of \( u_0, u_1 \) is not terminal, then set \( U := B \); otherwise, set \( U := C_B \). Our goal is to show that \( v \) has at least \( k - 1 \) neighbors outside of \( U \). Assume, towards a contradiction, that \( \deg_{U^c}(v) \leq k - 2 \). Let \( I \in \text{Ind}(H) \) be such that \( \text{dom}(I) = (U \cup \{v\})^c \). By (2.3), we have
\[
|L_I(v)| \geq \varphi_U(v) \geq k - (k - 2) = 2,
\]
so let \( x_1, x_2 \) be any two distinct elements of \( L_I(v) \). Since \( u_0v \notin E \), we have
\[
L_{I \cup \{x_1\}}(u_0) = L_{I \cup \{x_2\}}(u_0) = L_I(u_0),
\]
so, by Lemma 2.9, the matching \( E_H(L_I(u_0), L_{I \cup \{x_i\}}(u_1)) \) is perfect for each \( i \in \{1, 2\} \). This implies that the unique vertex in \( L_I(u_1) \) that has no neighbor in \( L_I(u_0) \) is adjacent to both \( x_1 \) and \( x_2 \), which is impossible. \( \blacksquare \)
The rest of the proof of Theorem 1.19 proceeds as follows. Consider a dense terminal set \( B \). Roughly speaking, Lemma 3.2 asserts that the vertices in \( T_B \) must have “many” neighbors outside of \( B \). Since the degrees of the vertices in \( D^c \) cannot be too big, the vertices in \( T_B \) should only have “very few” neighbors in \( B \). This implies that “most” edges between \( B \) and \( D^c \) actually connect \( B \) with \( S_B \). This intuition guides the proof of Corollary 3.7, which asserts that \( G[B \cup S_B] \) is a clique of size \( k \) (however, the proof of Lemma 3.6, the main step towards Corollary 3.7, is somewhat lengthy and technical).

The fact that \( G \) is a minimum counterexample to Theorem 1.19 is only used once during the course of the proof, namely in establishing Lemma 3.11, which claims that for a dense terminal set \( B \), the graph \( G[T_B] \) is a clique. The proof of Lemma 3.11 is also the only time when it is important to work in the more general setting of DP-colorings rather than just with list colorings. The proof proceeds by assuming, towards a contradiction, that there exist two nonadjacent vertices \( v_1, v_2 \in T_B \), and letting \( G^* \) be the graph obtained from \( G \) by removing \( B \) and adding an edge between \( v_1 \) and \( v_2 \). Since \( G^* \) has fewer vertices than \( G \), it cannot contain a counterexample to Theorem 1.19 as a subgraph. This fact can be used to eventually arrive at a contradiction. En route to that goal we study the properties of a certain cover \( \mathcal{H}^* \) of \( G^* \), and that cover is not necessarily induced by a list assignment, even if \( \mathcal{H} \) is.

With Lemma 3.11 at hand, we can pin down the structure of \( G[S_B \cup T_B] \) very precisely, which is done in Lemmas 3.13 and 3.14 and in Corollary 3.15. The restrictiveness of these results precludes having “too many” dense terminal sets; this is made precise by Lemma 3.16, which asserts that at least one terminal set is sparse. However, due to Lemma 2.10, having a sparse terminal set leads to its own restrictions on the structure of \( G[D^c] \), which finally yield a contradiction that finishes the proof of Theorem 1.19.

### 3.2 The set \( S_B \) is large

In this section we prove that for any dense terminal set \( B \), \(|S_B| \geq k - |B| \) (see Lemma 3.5).

**Lemma 3.3.** Let \( B \) be a dense terminal set. If \(|S_B| \leq k - |B| - 1 \), then the following statements hold:

1. \(|S_B| = k - |B| - 1\);
2. \( D^c = S_B \cup (T_B \cap D^c) \);
3. \(|D^c| = |S_B| + |T_B \cap D^c| = k - 2 \), and thus \( \varepsilon(v) = 1 \) for every \( v \in D^c \);
4. every vertex in \( T_B \cap D^c \) has exactly \( k - 1 \) neighbors outside of \( B \); and
5. \( B \neq C_B \), and the cut vertex \( u_0 \in B \) of \( G[C_B] \) has no neighbors in \( T_B \cap D^c \).

**Proof.** Let \( S := S_B \) and let \( T := T_B \cap D^c \). Set \( b := |B|, \ s := |S|, \) and \( t := |T| \). Suppose that \( s \leq k - b - 1 \). Since each terminal vertex in \( B \) has exactly \( k - (b - 1) - s \) neighbors in \( T \), the number of edges between \( B \) and \( T \) is at least \((b - 1)(k - (b - 1) - s)\). Also, by Lemma 3.2, each vertex in \( T \) has at least \( k - 1 \) neighbors in \( B^c \). Hence,

\[
\varepsilon(D^c) \geq \varepsilon(S) + \varepsilon(T) \\
\geq s + (b - 1)(k - (b - 1) - s) + (k - 1)t - kt \\
= s + (b - 1)(k - (b - 1) - s) - t.
\]
Note that \( s + t \leq |D^c| \leq k - 2 \), so \( t \leq k - 2 - s \). Therefore,

\[
s + (b - 1)(k - (b - 1) - s) - t \geq 2s + (b - 1)(k - (b - 1) - s) - k + 2.
\]

Since \( b \geq 4 \), the last expression is decreasing in \( s \), and hence

\[
2s + (b - 1)(k - (b - 1) - s) - k + 2 \\
\geq 2(k - b - 1) + (b - 1)(k - (b - 1) - (k - b - 1)) - k + 2 \\
= k - 2.
\]

On the other hand, \( \varepsilon(D^c) \leq k - 2 \). This implies that none of the above inequalities can be strict, yielding (i)–(v).

\[ \square \]

**Lemma 3.4.** Let \( B \) be a dense terminal set. Suppose that \( v_1, v_2 \in S_B \) are distinct vertices such that \( v_1v_2 \notin E \). Then the following statements hold:

(i) \( |D^c| = k - |B| + 1 \);

(ii) \( \varepsilon(v_1) + \varepsilon(v_2) = |B| - 1 \); and

(iii) \( \varepsilon(v) = 1 \) for every \( v \in D^c \setminus \{v_1, v_2\} \).

**Proof.** Let \( b := |B| \). Each terminal vertex \( u \in B \) has exactly \( k - b + 1 \) neighbors in \( D^c \); in particular, \( |D^c| \geq k - b + 1 \). By Corollary 2.8, we have

\[
either \min\{\varphi_B(v_1), \varphi_B(v_2)\} \leq 0, & \text{or } \varphi_B(v_1) + \varphi_B(v_2) \leq b + 1.
\]

In the case when \( \varphi_B(v_i) \leq 0 \) for some \( i \in \{1, 2\} \), we have \( \varepsilon(v_i) = b - \varphi_B(v_i) \geq b \), so

\[
\varepsilon(v_1) + \varepsilon(v_2) \geq b. \quad (3.1)
\]

In the other case, i.e., when \( \varphi_B(v_1) + \varphi_B(v_2) \leq b + 1 \), we get

\[
\varepsilon(v_1) + \varepsilon(v_2) = (b - \varphi_B(v_1)) + (b - \varphi_B(v_2)) \geq b - 1.
\]

Hence

\[
\varepsilon(D^c) \geq \varepsilon(v_1) + \varepsilon(v_2) + |D^c \setminus \{v_1, v_2\}| \geq (b - 1) + (k - b - 1) = k - 2. \quad (3.2)
\]

Since \( \varepsilon(D^c) \leq k - 2 \), (3.1) does not hold and none of the inequalities in (3.2) can be strict, yielding (i)–(iii).

\[ \square \]

**Lemma 3.5.** Let \( B \) be a dense terminal set. Then \( |S_B| \geq k - |B| \).

**Proof.** Let \( S := S_B \) and let \( T := T_B \cap D^c \). Set \( b := |B| \), \( s := |S| \), and \( t := |T| \). Suppose that \( s \leq k - b - 1 \). Then, by Lemma 3.3(i), \( s = k - b - 1 \). We claim that \( G[S] \) is a clique. Indeed, otherwise, by Lemma 3.4(i), \( |D^c| = k - b + 1 \); on the other hand, by Lemma 3.3(iii), \( |D^c| = k - 2 \), so we get \( k - 2 = k - b + 1 \), i.e., \( b = 3 \), which contradicts the fact that \( B \) is dense.
By Lemma 3.3(iii), the degree of every vertex in \( D^c \) is exactly \( k + 1 \). Since each vertex in \( S \) has \( b \) neighbors in \( B \) and \( s - 1 = k - b - 2 \) neighbors in \( S \), it has exactly \((k+1) - b - (k-b-2) = 3\) neighbors in \((B \cup S)^c\).

By Lemma 3.3(v), \( B \neq C_B \). Let \( u_0 \) denote the cut vertex in \( B \) and let \( B' \) be any terminal subset of \( C_B \) distinct from \( B \). Set \( b' := |B'| \).

By Lemma 3.3(ii), \( t = |D^c| - s = (k-2) - (k-b-1) = b-1 \geq 3 \); in particular, \( T \neq \emptyset \). Due to Lemma 3.3(iv)(v), every vertex in \( T \) has exactly \( k-1 \) neighbors in \( B^c \) and is not adjacent to \( u_0 \). Together with Lemma 3.3(iii), this implies that each vertex in \( T \) has exactly \((k+1) - (k-1) = 2\) neighbors in \( B \setminus \{u_0\} \). We have \( |B \setminus \{u_0\}| = b-1 \geq 3 \), so, by Lemma 3.2, every vertex in \( T \) has \( k-1 \) neighbors outside of \( C_B \). Therefore, there are no edges between \( T \) and \( C_B \setminus B \); in particular, there are no edges connecting \( T \) to the terminal vertices in \( B' \).

Consider any terminal vertex \( u \in B' \). Since \( T \neq \emptyset \) and no edges connect \( u \) and \( T \), \( \deg_{B'}(u) > 2 \); therefore, \( B' \) is a dense terminal set. By Lemma 3.3(ii), \( D^c = S \cup T \), so \( u \) has exactly \( k - b' + 1 \) neighbors in \( S \). Thus, \( k - b - 1 = s \geq k - b' + 1 \), i.e., \( b' \geq b + 2 \geq 6 \). Let \( v \) be any neighbor of \( u \) in \( S \). Since \( v \) has only 3 neighbors in \( (B \cup S)^c \) and \( b' > 4 \), there exists another terminal vertex \( v' \in B' \) such that \( u'v \notin E \). By Lemma 3.2, \( v \) has at least \( k-1 \) neighbors outside of \( C_{B'} = C_B \). Of those, \( s - 1 \) belong to \( S \); since \( v \) has only 3 neighbors outside of \( B \cup S \) and is adjacent to \( u \), it has at most \((s - 1) = 2 \) neighbors in \((C_B \cup S)^c \). Hence, \( k - 1 \leq (s - 1) + 2 = (k - b - 2) + 2 = k - b \), i.e., \( b \leq 1 \), which is impossible. 

3.3 The graph \( G[S_B] \)

**Lemma 3.6.** Let \( B \) be a dense terminal set. Then \( G[S_B] \) is a clique.

**Proof.** Let \( S := S_B \) and suppose that \( G[S] \) is not a clique, i.e., there exist distinct \( v_1, v_2 \in S \) such that \( v_1v_2 \notin E \). Without loss of generality, we may assume that \( \deg(v_1) \geq \deg(v_2) \). We will proceed via a series of claims, establishing a precise structure of \( G[D^c] \), which will eventually lead to a contradiction. For the rest of the proof, we set \( b := |B| \) and \( s := |S| \).

Recall that, by Lemma 3.4, we have the following:

(i) \(|D^c| = k - b + 1|\);

(ii) \( \varepsilon(v_1) + \varepsilon(v_2) = b - 1 \); and

(iii) \( \varepsilon(v) = 1 \) for every \( v \in D^c \setminus \{v_1, v_2\} \).

**Claim 3.6.1.** \( D^c = S \) and \( B = C_B \).

**Proof.** Suppose, towards a contradiction, that there is a vertex \( v \in D^c \setminus S \). Since, by Lemma 3.4(i), \(|D^c| = k - b + 1|\), each terminal vertex in \( B \) is adjacent to every vertex in \( D^c \). Therefore, \( \deg_B(v) = b - 1 \) and, due to Lemma 3.2, \( \deg_{B'}(v) \geq k - 1 \). Then

\[
\varepsilon(v) = \deg(v) - k \geq (b - 1) + (k - 1) - k = b - 2 > 1;
\]

a contradiction to Lemma 3.4(iii).

Since \(|S| = |D^c| = k - b + 1|\), every vertex in \( B \) has \((b - 1) + (k - b + 1) = k \) neighbors in \( B \cup S \), so there are no edges between \( B \) and \( D \setminus B \); therefore, \( B = C_B \).

**Claim 3.6.2.** The graph \( G[D] \) has no vertices of degree 2.
Claim 3.6.3. \( s \geq 3, \text{ i.e., } b \leq k - 2. \)

Proof. Suppose, towards a contradiction, that \( s = 2, \text{ i.e., } S = \{v_1, v_2\}. \) We will argue that in this case \( G \in \text{Dir}_k. \) Since, by Lemma 3.4(i), \( s = k - b + 1, \) we have \( b = k - 1. \) In particular, since \( b \geq 4, \) we have \( k \geq 5. \) By Lemma 3.4(ii), \( \varepsilon(S) = b - 1 = k - 2, \) so there are exactly \((k - 2) + 2k - 2(k - 1) = k\) edges between \( S \) and \( D \setminus B. \) Let \( U \) be any connected component of \( G[D] \) distinct from \( B. \) By Corollary 2.2, the number of edges between \( U \) and \( S \) is at least \( k, \) with equality only if \( G[U] \cong K_k; \) therefore, \( D \setminus B = U, \) and we indeed have \( G[U] \cong K_k. \) Then every vertex in \( U \) has exactly one neighbor in \( S \) and each vertex in \( S \) has at least two neighbors in \( U \) (for its degree is at least \( k + 1 \)), yielding \( G \in \text{Dir}_k, \) as desired. \( \dashv \)

Claim 3.6.4. \( G[S \setminus \{v_1\}] \) is a clique.

Proof. Suppose that for some distinct \( w_1, w_2 \in S \setminus \{v_1\}, \) we have \( w_1w_2 \not\in E. \) Applying Lemma 3.4(iii) with \( w_1 \) and \( w_2 \) in place of \( v_1 \) and \( v_2, \) we obtain \( \varepsilon(v_1) = 1. \) Since, by our choice, \( \deg(v_1) \geq \deg(v_2), \) and thus \( \varepsilon(v_1) \geq \varepsilon(v_2), \) we get \( \varepsilon(v_2) = 1 \) as well. But then \( 2 = \varepsilon(v_1) + \varepsilon(v_2) = b - 1, \) i.e., \( b = 3; \) a contradiction. \( \dashv \)

Claim 3.6.5. \( \deg_S(v_1) = 0. \)

Proof. Suppose that \( v \in S \setminus \{v_1, v_2\} \) is adjacent to \( v_1. \) Note that by Claim 3.6.4, \( v \) is also adjacent to \( v_2. \) Let \( U := B \cup \{v_1, v_2\} \) and let \( u \) be any vertex in \( B. \) Note that
\[
\deg_U(u) = (b - 1) + 3 = b + 2.
\]
On the other hand, since \( \varepsilon(v_1) + \varepsilon(v_2) = b - 1, \) for each \( i \in \{1, 2\}, \) we have \( \varepsilon(v_i) \leq b - 2, \) so
\[
\varphi_U(v_i) = (b + 1) - \varepsilon(v_i) \geq (b + 1) - (b - 2) = 3 > 0;
\]
moreover,
\[
\varphi_U(v_1) + \varphi_U(v_2) = 2(b + 1) - (b - 1) = b + 3 > b + 2.
\]
Therefore, by Lemma 2.6, for any \( I \in \text{Ind}(H) \) with \( \text{dom}(I) = U^c, \) we can find \( x_1 \in L_I(v_1) \) and \( x_2 \in L_I(v_2) \) such that \( u \) is enhanced by \( I' := I \cup \{x_1, x_2\}. \) Note that
\[
|L_{I'}(v)| \geq \varphi_B(v) = b - 1 > 0,
\]
so \( I' \) can be extended to a coloring with domain \( B^c, \) which contradicts Lemma 2.5(iii). \( \dashv \)

Claim 3.6.6. \( \varepsilon(v_1) = b - 2 \) and \( \varepsilon(v) = 1 \) for all \( v \in S \setminus \{v_1\}. \)

Proof. Consider any \( v \in S \setminus \{v_1\}. \) By Claim 3.6.3, we can choose some \( v' \in S \setminus \{v_1, v\}. \) Due to Claim 3.6.5, \( v_1v' \not\in E, \) so we can apply Lemma 3.4(iii) with \( v' \) in place of \( v_2 \) to obtain \( \varepsilon(v) = 1. \) In particular, \( \varepsilon(v_1) = 1, \) so \( \varepsilon(v_1) = (b - 1) - \varepsilon(v_2) = b - 2. \) \( \dashv \)

Claim 3.6.7. Every terminal set distinct from \( B \) induces a clique of size \( k. \)
Proof. Suppose that $B'$ is a terminal set distinct from $B$ and $b' := |B'| \leq k-1$. By Claim 3.6.2, $B'$ is dense. Thus, by Lemma 3.5, $|S_{B'}| \geq k - b'$, i.e., $S$ contains at least $k - b'$ vertices that are adjacent to every vertex in $B'$. Consider $v \in S \setminus \{v_1\}$. By definition, $v$ has $b$ neighbors in $B$; due to Claim 3.6.4, $v$ also has $s - 2 = (k - b + 1) - 2 = k - b - 1$ neighbors in $S$. On the other hand, by Claim 3.6.6, deg$(v) = k + 1$. Therefore,
\[
\text{deg}_{D \setminus B}(v) = (k + 1) - b - (k - b - 1) = 2.
\]
In particular, $v$ cannot be adjacent to all the vertices in $B'$. Thus, $S_{B'} = \{v_1\}$ and $|B'| = k - 1$. But
\[
\text{deg}_{D \setminus B}(v_1) = \varepsilon(v_1) + k - \text{deg}_B(v_1) - \text{deg}_S(v_1) = (b - 2) + k - b - 0 = k - 2 < k - 1;
\]
a contradiction. \halmos

Claim 3.6.8. There are exactly two terminal sets distinct from $B$.

Proof. Suppose $D \setminus B$ contains $\ell$ terminal sets. By Claim 3.6.7, the number of edges between $S$ and the terminal vertices of any terminal set $B'$ distinct from $B$ is at least $k - 1$ and at most $k$. On the other hand, the number of edges between $S$ and $D \setminus B$ is exactly $(k - 2) + 2(k - b) = 3k - 2b - 2$. Therefore,
\[
\ell(k - 1) \leq 3k - 2b - 2 \leq \ell k,
\]
so $1 \leq \ell \leq 2$. However, if $\ell = 1$, then $3k - 2b - 2 \leq k$, so $b \geq k - 1$, which contradicts Claim 3.6.3. Thus, $\ell = 2$, as desired. \halmos

Now we are ready to finish the argument. Let $B_1$ and $B_2$ denote the only two terminal sets in $D \setminus B$, which, by Claim 3.6.7, induce cliques of size $k$. We have $D \setminus B = C_{B_1} \cup C_{B_2}$. Notice that $v_1$ is adjacent to at least one terminal vertex in $B_1 \cup B_2$. Indeed, there are at least $2(k - 1)$ edges between $S$ and the terminal vertices in $B_1 \cup B_2$, while each vertex in $S \setminus \{v_1\}$ has 2 neighbors in $D \setminus B$, providing in total only $2(k - b)$ edges.

Without loss of generality, assume that $v_1$ is adjacent to at least one terminal vertex in $B_1$. Since $v_1$ has only $k - 2$ neighbors in $D \setminus B$, Lemma 3.2 implies that $v_1$ has at least $k - 1$ neighbors outside of $C_{B_1}$. Since $v_1$ has only $b \leq k - 2$ neighbors outside of $C_{B_1} \cup C_{B_2}$, we see that $C_{B_1} \neq C_{B_2}$ and $v_1$ has a neighbor in $C_{B_2}$. Since $B_1$ and $B_2$ are the unique terminal sets in $C_{B_1}$ and $C_{B_2}$ respectively, we have $B_1 = C_{B_1}$ and $B_2 = C_{B_2}$. Therefore, $v_1$ is also adjacent to at least one terminal vertex in $B_2$ and, hence, has at least $k - 1$ neighbors outside of $B_2$.

Notice that $2k = |E_G(B_1 \cup B_2, S)| = 3k - 2b - 2$, i.e., $k = 2b + 2$. Let $d_i := \text{deg}_{B_i}(v_1)$. Then for each $i \in \{1, 2\}$, $d_i \geq k - 1 - b$. Since
\[
b + d_1 + d_2 = \text{deg}(v_1) = k + b - 2,
\]
we obtain that $k + b - 2 \geq b + 2(k - 1 - b)$, i.e., $2b \geq k$, contradicting $k = 2b + 2$. \hfill \blacksquare

Corollary 3.7. Let $B$ be a dense terminal set. Then $G[B \cup S_B]$ is a clique of size $k$.

Proof. By Lemma 3.5, $|B \cup S_B| \geq k$; on the other hand, by Lemma 3.6, $G[B \cup S_B]$ is a clique, so $|B \cup S_B| \leq k$. \hfill \blacksquare
Corollary 3.8. There does not exist a subset $U \subseteq V$ of size $k+1$ such that $G[U]$ is a complete graph minus an edge with the two nonadjacent vertices in $D^c$.

Proof. Suppose, towards a contradiction, that $U$ is such a set and let $v_1, v_2 \in U \cap D^c$ be the two nonadjacent vertices in $U$. Set $B := U \cap D$. Note that $|B| \geq |U| - |D^c| \geq (k+1) - (k-2) = 3$.

So, using that $|B| = 3$, there are no edges between $B$ and $U$. In particular, $B = C_B$. If $|B| \geq 4$, then $B$ is a dense set and $U = B \cup S_B$, which is impossible due to Corollary 3.7. Therefore, $|B| = 3$. Thus, $|U \setminus B| = (k + 1) - 3 = k - 2$, so $D^c = U \setminus B$. By Lemma 2.10(iii), $G[D^c]$ is a disjoint union of cliques. On the other hand, $G[D^c]$ is a complete graph minus the edge $v_1v_2$. The only possibility then is that $|D^c| = 2$, i.e., $k = 4$. Each vertex in $D^c$ is of degree 5 and, therefore, has exactly 2 neighbors in $D \setminus B$. By Lemma 2.13, there exists a dense terminal set $B' \subseteq D \setminus B$. Since $k = 4$, we must have $|B'| = 4$, so there are 4 edges between $B'$ and $D^c$. This implies that $D \setminus B = B'$ and each vertex in $D^c$ has exactly 2 neighbors in $B'$. But then $G \in \text{Dir}_4$. ■

3.4 The graph $G[T_B]$

In this section we show that if $B$ is a dense terminal set, then $G[T_B]$ is a clique. However, in order for some of our arguments to go through, we need to establish some of the results for the more general case when $B$ is a terminal set such that $G[B \cup S_B]$ is a clique of size $k$ (i.e., $G[B]$ can also be isomorphic to a triangle).

Lemma 3.9. Let $B$ be a terminal set such that $G[B \cup S_B]$ is a clique of size $k$. Then every vertex in $S_B$ has at most $|B| - 1$ neighbors outside of $B \cup S_B$.

Proof. Set $S := S_B$. Let $v \in S$ and suppose that $v$ has $d$ neighbors outside of $B \cup S$. Then

$$
\varepsilon(v) = \deg_{B \cup S}(v) + \deg_{(B \cup S)^c}(v) - k = (k - 1) + d - k = d - 1,
$$

so, using that $|S| = k - |B|$, we obtain

$$
k - 2 \geq \varepsilon(D^c) = \varepsilon(S) + \varepsilon(D^c \setminus S) \geq (d - 1) + (k - |B| - 1) + |D^c \setminus S|,
$$

i.e., $d \leq |B| - |D^c \setminus S|$. It remains to notice that $D^c \setminus S \neq \emptyset$, since each terminal vertex in $B$ has a neighbor in $D^c \setminus S$. ■

Lemma 3.10. Let $B$ be a terminal set such that $G[B \cup S_B]$ is a clique of size $k$. Let $I$ be a coloring with $\text{dom}(I) = (B \cup S_B)^c$. Then for any $u \in B$, $|L_I(u)| = k - 1$, and for any two distinct $u_1, u_2 \in B$, the matching $E_H(L_I(u_1), L_I(u_2))$ is perfect.

Proof. Set $S := S_B$. By Lemma 3.9, $|L_I(v)| \geq k - |B| + 1$ for all $v \in S$. Since $|S| = k - |B|$, $I$ can be extended to a coloring $I'$ with $\text{dom}(I') = B^c$. Therefore, due to Lemma 2.5(iii) and since $G[B]$ is connected, $I$ does not enhance any $u \in B$, i.e., $|L_I(u)| = k - 1$, as claimed. Now, let $u_1, u_2$ be two distinct vertices in $B$ and suppose, towards a contradiction, that $x \in L_I(u_1)$ has no neighbor in $L_I(u_2)$. For each $v \in S$, let $L'(v) := L_I(v) \setminus N_H(x)$. Then $|L'(v)| \geq k - |B| = |S|$ for all $v \in S$, so there is $I' \in \text{Ind}(H)$ with $\text{dom}(I') = S$ such that $I' \subseteq \bigcup_{v \in S} L'(v)$. Then $I \cup I'$ is a coloring with domain $B^c$; moreover, $x \in L_{I \cup I'}(u_1)$, which implies that the matching $E_H(L_{I \cup I'}(u_1), L_{I \cup I'}(u_2))$ is not perfect. Due to Lemma 2.9, $I \cup I'$ can be extended to an $\mathcal{H}$-coloring of $G$; a contradiction. ■

20
Lemma 3.11. Let $B$ be a terminal set such that $G[B \cup S_B]$ is a clique of size $k$. Then $G[T_B]$ is a clique of size at least 2.

Proof. Set $S := S_B$ and $T := T_B$. First, observe that $|T| \geq 2$: Each vertex in $B$ has a (unique) neighbor in $T$; thus, if $|T| = 1$, then the only vertex in $T$ has to be adjacent to all the vertices in $B$, which contradicts the way $T$ is defined.

Now suppose that $v_1, v_2 \in T$ are two distinct nonadjacent vertices. For each $i \in \{1, 2\}$, choose a neighbor $u_i \in B$ of $v_i$. Since every vertex in $B$ has only one neighbor outside of $B \cup S$, $u_1v_2, u_2v_1 \notin E$. Note that, by Lemma 3.10, there are at least $k - 1$ edges between $L(u_1)$ and $L(u_2)$. Let $H'$ be the graph obtained from $H$ by adding, if necessary, a single edge between $L(u_1)$ and $L(u_2)$ that completes a perfect matching between those two sets. Let $H^*$ be the graph obtained from $H$ by adding a matching $M$ between $L(v_1)$ and $L(v_2)$ in which $x_1 \in L(v_1)$ is adjacent to $x_2 \in L(v_2)$ if and only if there exist $y_1 \in L(u_1), y_2 \in L(u_2)$ such that $x_1y_1y_2x_2$ is a path in $H'$. Observe that $H^* := (L, H^*)$ is a cover of the graph $G^*$ obtained from $G$ by adding the edge $v_1v_2$.

Claim 3.11.1. There is no independent set $I \in \text{Ind}(H^*)$ with $\text{dom}(I) = (B \cup S)^c$.

Proof. Assume, towards a contradiction, that $I \in \text{Ind}(H^*)$ is such that $\text{dom}(I) = (B \cup S)^c$. Since, in particular, $I \in \text{Ind}(H)$, Lemma 3.10 guarantees that the edges of $H$ between $L_I(u_1)$ and $L_I(u_2)$ form a perfect matching of size $k - 1$. For each $i \in \{1, 2\}$, let $y_i$ be the unique element of $L(u_i) \setminus L_I(u_i)$. Then $y_1y_2$ is an edge in $H'$. However, since $y_i \notin L_I(u_i)$, the unique element of $I \cap L(v_i)$, which we denote by $x_i$, is adjacent to $y_i$ in $H$. Therefore, $x_1y_1y_2x_2$ is a path in $H'$, so $x_1x_2$ is an edge in $H^*$. This contradicts the independence of $I$ in $H^*$.

Let $W \subseteq (B \cup S)^c$ be an inclusion-minimal subset for which there is no $I \in \text{Ind}(H^*)$ with $\text{dom}(I) = W$. Since $G$ is $\mathcal{H}$-critical, $G^*[W]$ is not a subgraph of $G$, so $\{v_1, v_2\} \subseteq W$. Since for all $v \in W$, $\deg(v) \geq \deg_{G^*[W]}(v)$, we have

$$\varepsilon(W) \geq \sum_{v \in W} (\deg_{G^*[W]}(v) - k).$$

In particular,

$$\sum_{v \in W} (\deg_{G^*[W]}(v) - k) \leq k - 2.$$

By the minimality of $G$, either $G^*[W] \in \text{Dir}_k$, or else, $G^*[W]$ contains a clique of size $k + 1$.

If $G^*[W] \in \text{Dir}_k$, then

$$\sum_{v \in W} (\deg_{G^*[W]}(v) - k) = k - 2.$$ 

Therefore, $D^c \subseteq W$ and $\deg(v) = \deg_{G^*[W]}(v)$ for all $v \in W$. The latter condition implies that the only vertices in $W$ that are adjacent to a vertex in $B$ are $v_1$ and $v_2$; moreover, the only neighbor of $v_1$ in $B$ is $u_1$ and the only neighbor of $v_2$ in $B$ is $u_2$. Since $D^c \subseteq W$, this implies $S = \emptyset$ and $T \cap D^c \subseteq \{v_1, v_2\}$. Therefore, $|B| = k - |S| = k$. Each terminal vertex in $B$ has a neighbor in $T \cap D^c$, so the set of all terminal vertices in $B$ is a subset of $\{u_1, u_2\}$. Since $k \geq 3$, this implies $k = |B| = 3$ and $u_1, u_2$ are indeed the terminal vertices in $B$. But then every vertex in $D^c$ is adjacent both to $u_1$ and to $u_2$, contradicting the fact that $v_1$ and $v_2$ each have only one neighbor among $u_1, u_2$. 

21
Thus, $G^*[W]$ contains a clique of size $k + 1$. Since $G$ does not contain such a clique, there exists a set $U \subseteq (B \cup S \cup \{v_1, v_2\})^c$ of size $k - 1$ such that the graph $G[U \cup \{v_1, v_2\}]$ is isomorphic to $K_{k+1}$ minus the edge $v_1v_2$. Note that $U \not\subseteq D^c$, since $|D^c| \leq k - 2$. Thus, the set $B' := U \cap D$ is nonempty. Let $S' := U \setminus B'$. Each vertex in $B'$ has $k$ neighbors in $U \cup \{v_1, v_2\}$, so there are no edges between $B'$ and $(U \cup \{v_1, v_2\})^c$. Due to Corollary 3.8, $\{v_1, v_2\} \not\subseteq D^c$, so we can assume, without loss of generality, that $v_2 \in D$ and let $B^* := B' \cup \{v_2\}$. Then $G[B \cup B^*]$ is a connected component of $G[D]$, with $u_2v_2$ being a unique edge between terminal sets $B$ and $B^*$. Note that $S' = S_{B^*}$ and $G[B^* \cup S']$ is a clique of size $k$. Moreover, $v_1u_2 \not\in E$ and $\{v_1, u_2\} \subseteq T_{B^*}$. Thus, we can apply the above reasoning to $B^*$ in place of $B$ and $v_1, u_2$ in place of $v_1, v_2$. As a result, we see that $G[B \cup S \cup \{v_1\}]$ is isomorphic to $K_{k+1}$ minus the edge $v_1u_2$. Therefore,

$$\varepsilon(v_1) \geq \deg_{B \cup S}(v_1) + \deg_{B^* \cup S'}(v_1) - k = (k - 1) + (k - 1) - k = k - 2.$$ 

Thus, $D^c = \{v_1\}$, $S = S' = \emptyset$, and $|B| = |B^*| = k$. This implies that $G \in \text{Dir}_k$. \hfill \blacksquare

**Corollary 3.12.** Let $B$ be a dense terminal set. Then $G[T_B]$ is a clique of size at least 2.

**Proof.** Follows from Corollary 3.7 and Lemma 3.11. \hfill \blacksquare

### 3.5 The graph $G[S_B \cup T_B]$

**Lemma 3.13.** Let $B$ be a dense terminal set. Then:

(i) $|T_B| = 2$;

(ii) $D^c = S_B \cup (T_B \cap D^c)$;

(iii) each vertex in $T_B$ has exactly $k - 1$ neighbors outside of $B$; and

(iv) $\varepsilon(v) = 1$ for all $v \in S_B$.

**Proof.** Let $S := S_B$ and $T := T_B$. By Corollaries 3.7 and 3.12, $G[S \cup B]$ is a clique of size $k$ and $G[T]$ is a clique of size at least 2.

Suppose that (i) does not hold, i.e., $|T| \geq 3$. Recall that, by Lemma 3.2, each vertex in $T$ has at least $k - 1$ neighbors outside of $B$. If $T$ contains at most one vertex with exactly $k - 1$ neighbors outside of $B$, then

$$\varepsilon(S) + \varepsilon(T) \geq |S| + \sum_{v \in T} \deg(v) - k|T| \geq (k - |B|) + (|B| + k|T| - 1) - k|T| = k - 1;$$

a contradiction. Thus, there exist two distinct vertices $v_1, v_2 \in T$ such that

$$\deg_{B^c}(v_1) = \deg_{B^c}(v_2) = k - 1.$$ 

Since $|T| \geq 3$ and every vertex in $B$ has exactly one neighbor in $T$, there exists a vertex $u_0 \in B$ such that $u_0v_1, u_0v_2 \not\in E$. Also, we can choose a vertex $v_1 \in B$ with $u_1v_1 \in E$; note that $u_1v_2 \not\in E$. Let $I \in \text{Ind}(H)$ be such that $\text{dom}(I) = (B \cup \{v_1, v_2\})^c$. Then

$$\varphi_{B \cup \{v_1, v_2\}}(v_1) = \varphi_{B \cup \{v_1, v_2\}}(v_2) = k - (k - 2) = 2.$$ 

22
(Here we use that \( v_1 \) and \( v_2 \) are adjacent to each other.) Let \( x_1, x_2 \) be any two distinct elements of \( L_I(v_1) \) and choose \( y_1, y_2 \in L_I(v_2) \) so that \( x_1y_1, x_2y_2 \not\in E(H) \). Since

\[
L_{I \cup \{x_1, y_1\}}(u_0) = L_{I \cup \{x_2, y_2\}}(u_0) = L_I(u_0),
\]

and for each \( i \in \{1, 2\} \),

\[
L_{I \cup \{x_i, y_i\}}(u_1) = L_{I \cup \{x_i\}}(u_1),
\]

Lemma 2.9 implies that for each \( i \in \{1, 2\} \), the matching \( E_B(L_I(u_0), L_{I \cup \{x_i\}}(u_1)) \) is perfect. But then the unique vertex in \( L_I(u_1) \) that has no neighbor in \( L_I(u_0) \) is adjacent to both \( x_1 \) and \( x_2 \), which is impossible. This contradiction proves (i).

In view of (i), we now have

\[
\varepsilon(D^c) \geq \varepsilon(S) + \varepsilon(T) \geq (k - |B|) + (|B| + 2(k - 1)) - 2k = k - 2,
\]

so none of the inequalities in (3.3) can be strict. This yields (ii), (iii), and (iv). \( \square \)

**Lemma 3.14.** Let \( B \) be a dense terminal set. Then \( B = C_B \).

**Proof.** Suppose, towards a contradiction, that \( B \neq C_B \). Then \( T_B \cap D \neq \emptyset \). On the other hand, every terminal vertex in \( B \) has a neighbor in \( T_B \cap D^c \), so we also have \( T_B \cap D^c \neq \emptyset \). By Lemma 3.13(i), \( |T_B| = 2 \), so \( T_B =: \{v, u\} \), where \( v \in D^c \) and \( u \in D \), with \( v \) adjacent to all the terminal vertices in \( B \). By Lemma 3.13(ii), \( D^c = S_B \cup \{v\} \). By Corollary 3.7, \( G[B \cup S_B] \cong K_k \); in particular, \( |S_B| = k - |B| \). Therefore,

\[
|D^c| = k - |B| + 1.
\]

Let \( B' \) be any other terminal set such that \( C_{B'} = C_B \). Note that \( B' \) is dense, since, otherwise, by Lemma 2.10(ii), \( |D^c| = k - 2 \), contradicting (3.4). Therefore, the above reasoning can be applied to \( B' \) in place of \( B \). In particular, \( T_{B'} =: \{v', u'\} \), where \( v' \in D^c \) and \( u' \in D \), with \( v' \) adjacent to all the terminal vertices in \( B' \). Moreover, \( D^c = S_B \cup \{v\} = S_{B'} \cup \{v'\} \). Consider any vertex \( w \in D^c \). If \( w \in S_{B'} \), then, by definition, \( w \) is adjacent to every vertex in \( B' \). If, on the other hand, \( w = v' \), then \( w \) is adjacent to all the terminal vertices in \( B' \). In either case, \( w \) has at least \( |B'| - 1 \) neighbors in \( B' \). However, if \( w \in S_B \), then due to Lemma 3.13(iv), \( w \) has exactly \( (k + 1) - (k - 1) = 2 \) neighbors outside of \( B \cup S_B \). This implies that \( S_B = \emptyset \), and similarly \( S_{B'} = \emptyset \). Thus, \( v = v' \) and \( |B| = |B'| = k \). Then \( v \) is adjacent to \( k - 1 \) terminal vertices in \( B' \) and to \( u \), contradicting Lemma 3.13(iii). \( \square \)

**Corollary 3.15.** Let \( B \) be a dense terminal set. Then \( D^c = S_B \cup T_B \).

**Proof.** Follows immediately by Lemma 3.14 and Lemma 3.13(ii). \( \square \)

### 3.6 Finishing the proof of Theorem 1.19

**Lemma 3.16.** There exists a sparse terminal set.

**Proof.** Suppose, towards a contradiction, that every terminal set is dense. Lemma 3.14 implies that in such case every connected component of \( G[D] \) is a clique of size at least 4. Moreover, due to Corollary 3.15, Corollary 3.7, and Lemma 3.13(i), the size of every connected component
of $G[D]$ is precisely $k - |D^c| + 2 =: b$. Note that due to Lemma 3.13(iii), the graph $G[D]$ is disconnected.

Let $B_1$ and $B_2$ be the vertex sets of any two distinct connected components of $G[D]$. Lemma 3.13(iv) implies that $S_{B_1} \cap S_{B_2} = \emptyset$, since every vertex in $S_{B_1}$ has only 2 neighbors outside of $B_1 \cup S_{B_1}$. Since, by Corollary 3.15,

$$D^c = S_{B_1} \cup T_{B_1} = S_{B_2} \cup T_{B_2},$$

it follows that $S_{B_1} \subseteq T_{B_2}$ and $S_{B_2} \subseteq T_{B_1}$. Therefore, $|S_{B_1}| \leq |T_{B_2}|$, i.e., $k - b \leq 2$, which implies

$$b \in \{k - 2, k - 1, k\}.$$

Now it remains to consider the three possibilities.

**Case 1:** $b = k - 2$. Let $B$ be the vertex set of any connected component of $G[D]$. Set $T_B := \{v_1, v_2\}$ and let $v_1, v_2 \in B$ be such that $u_1v_1, u_2v_2 \in E$. Choose any $x \in L(v_1)$. Note that $|L(x)(v_2)| \geq 2$, so we can choose $y \in L(x)(v_2)$ in such a way that $E_H(L(x,y)(u_1), L(x,y)(u_2))$ is not a perfect matching. For all $u \in D \setminus B$, we have $|L_{xy}(u)| \geq k - 2$ and the size of every connected component of $G[D \setminus B]$ is $k - 2$. Therefore, there exists a coloring $I$ with $\text{dom}(I) = D \setminus B$ such that $I \cup \{x, y\} \in \text{Ind}(H)$. But then

$$\text{dom}(I \cup \{x, y\}) = (B \cup S_B)^c,$$

and the matching $E_H(L_{u_1(x,y)}(u_1), L_{u_2(x,y)}(u_1))$ is not perfect, contradicting Lemma 3.10.

**Case 2:** $b = k - 1$. Let $B_1$ and $B_2$ be the vertex sets of any two distinct connected components of $G[D]$. Let $v$ be the unique vertex in $S_{B_1}$. Then $v \in T_{B_2}$ (recall that $S_{B_1} \cap S_{B_2} = \emptyset$), so, by Lemma 3.13(iii), $v$ has exactly $k - 1$ neighbors outside of $B_2$. By Corollary 3.12, one of the neighbors of $v$ is the other vertex in $T_{B_2}$. Therefore, $v$ can have at most $k - 2$ neighbors in $B_1$; a contradiction with the choice of $v$.

**Case 3:** $b = k$. In this case, $G[D^c] \cong K_2$ and every vertex in $D$ has exactly one neighbor in $D^c$, so there are exactly $k$ edges between $D^c$ and every connected component of $G[D]$. On the other hand, if $B$ is the vertex set of a connected component of $G[D]$, then, by Lemma 3.13(iii), there are exactly $2(k - 2) < 2k$ edges between $D^c$ and $D \setminus B$. Thus, the graph $G[D \setminus B]$ is connected. Moreover, $k \geq 4$, for $2 \cdot (3 - 2) = 2 < 3$. Let $B' := D \setminus B$ (so $G[B']$ is a clique of size $k$). Set $D^c := \{v_1, v_2\}$ an let $u_1, u_2 \in B$, $u_1', u_2' \in B'$ be such that $u_1v_1, u_2v_2, u_1'v_1, u_2'v_2 \in E$. Choose any $x \in L(v_1)$. Note that $|L_{x}(v_2)| \geq 3$. There is at most one element $y \in L_{x}(v_2)$ such that $E_H(L_{x,y}(u_1), L_{x,y}(u_2))$ is a perfect matching; similarly for $u_1'$ and $u_2'$. Therefore, there exists $z \in L_{x}(v_2)$ such that neither $E_H(L_{x,z}(u_1), L_{x,z}(u_2))$ nor $E_H(L_{x,z}(u_1'), L_{x,z}(u_2'))$ are perfect matchings. Thus, by Lemma 2.9, $\{x, z\}$ can be extended to an $\mathcal{F}$-coloring of $G$; a contradiction.

Now we are ready to finish the proof of Theorem 1.19. Let $B$ be a dense terminal set (which exists by Lemma 2.13) and let $B'$ be a sparse terminal set (which exists by Lemma 3.16). By Lemma 3.14, $B = C_B$ and every terminal set in $C_{B'}$ is sparse. In particular, $G[C_{B'}]$ contains at least 3 vertices of degree 2. Thus, by Lemma 2.10(ii), every vertex in $D^c$ has at least 3 neighbors in $C_{B'}$. On the other hand, by Lemma 3.13(iv), a vertex in $S_B$ has only 2 neighbors in $(B \cup S_B)^c$. Therefore, $S_B = \emptyset$. Due to Corollary 3.15, we obtain $D^c = T_B$; thus, by Corollary 3.12 and Lemma 3.13(i), $G[D^c] \cong K_2$. On the other hand, by Lemma 2.10(ii), $|D^c| = k - 2$, so $k = 4$. But each vertex in $T_B$ has at least 4 neighbors outside of $B$ (1 in $T_B$ by Corollary 3.12 and 3 in $C_{B'}$ by Lemma 2.10(ii)), which contradicts Lemma 3.13(iii).
4 Concluding remarks

In [5], the notion of DP-coloring was naturally extended to multigraphs (with no loops). The only difference from the graph case is that if distinct vertices \( u, v \in V(G) \) are connected by \( t \) edges in \( G \), then the set \( E_H(L(u), L(v)) \) is a union of \( t \) matchings (not necessarily perfect and possibly empty). Bounding the difference \( 2|E(G)| - k|V(G)| \) for DP-critical multigraphs \( G \) appears to be a challenging problem.

**Definition 4.1.** For \( k \geq 3 \), a \( k \)-brick is a \( k \)-regular multigraph whose underlying simple graph is either a clique or a cycle and in which the multiplicities of all edges are the same.

Note that for a \( k \)-brick \( G \), \( 2|E(G)| = k|V(G)| \). In [5], it is shown that \( k \)-bricks are the only \( k \)-DP-critical multigraphs with this property.

Theorem 1.19 fails for multigraphs, as the following example demonstrates. Fix an integer \( k \in \mathbb{N} \) divisible by 3 and let \( G \) be the multigraph with vertex set \([3]\) such that \(|E_G(1,2)| = \frac{k}{3}\) and \(|E_G(2,3)| = \frac{2k}{3}\), so we have \( 2|E(G)| - k|V(G)| = \frac{k}{3} \). Let \( H \) be the graph with vertex set \([3] \times [3] \times [k/3]\) in which two distinct vertices \((i_1,j_1,a_1)\) and \((i_2,j_2,a_2)\) are adjacent if and only if one of the following three (mutually exclusive) situations occurs:

1. \( \{i_1,i_2\} = [2] \) and \( j_1 = j_2 \); 
2. \( \{i_1,i_2\} \neq [2] \) and \( j_1 \neq j_2 \); or 
3. \( (i_1,j_1) = (i_2,j_2) \).

For each \( i \in [3] \), let \( L(i) := \{i\} \times [3] \times [k/3] \). Then \( \mathcal{H} := (L,H) \) is a \( k \)-fold cover of \( G \). We claim that \( G \) is not \( \mathcal{H} \)-colorable. Indeed, suppose that \( I \in \text{Ind}(H) \) is an \( \mathcal{H} \)-coloring of \( G \) and for each \( i \in [3] \), let \( I \cap L(i) = \{ (i,j_i,a_i) \} \). By the definition of \( H \), we have \( j_1 \neq j_2 \), while also \( j_1 = j_3 = j_2 \), which is a contradiction. It is also easy to check that \( G \) is \( \mathcal{H} \)-critical and that it does not contain any \( k \)-brick as a subgraph.

In light of the above example, we propose the following problem:

**Problem 4.2.** Let \( k \geq 3 \). Let \( G \) be a multigraph and let \( \mathcal{H} \) be a \( k \)-fold cover of \( G \) such that \( G \) is \( \mathcal{H} \)-critical. Suppose that \( G \) does not contain any \( k \)-brick as a subgraph. What is the minimum possible value of the difference \( 2|E(G)| - k|V(G)| \), as a function of \( k \)?

**Acknowledgement.** The authors are very grateful to the anonymous referee for the valuable comments and suggestions.
